Abstract

The multi-indexed Jacobi polynomials are the main part of the eigenfunctions of exactly solvable quantum mechanical systems obtained by certain deformations of the Pöschl–Teller potential (Odake–Sasaki). By fine-tuning the parameter(s) of the Pöschl–Teller potential, we obtain several families of explicit and global solutions of certain second-order Fuchsian differential equations with an apparent singularity of characteristic exponents \(-2\) and \(-1\). They form orthogonal polynomials over \(x \in (-1, 1)\) with weight functions of the form \((1 - x)^{\alpha}(1 + x)^{\beta}/\{(ax + b)^2q(x)^2\}\), in which \(q(x)\) is a polynomial in \(x\).

1. Introduction

The theory of Fuchsian differential equations is essentially a local theory [1, 2]. Exactly solvable quantum mechanics, on the other hand, has recently provided infinitely many examples of global solutions, called the multi-indexed Jacobi polynomials [3]\textsuperscript{4}, of second-order Fuchsian equations with \(3 + \ell \ (\ell \geq 1)\) regular singularities. The first three regular singularities correspond to those for the Jacobi polynomials and the extra \(\ell\) singularities are all apparent and their characteristic exponents are generically all \(-1\). At this point a naive and deep question is: ‘\textit{is it possible to construct global, i.e. rational solutions having higher \((\rho = -2, -3, \ldots)\) characteristic exponents at apparent singularities?’ In a sense, this could be regarded as a problem of the confluence of apparent singularities. In a previous paper [4], a related question was asked in connection with the multi-indexed Laguerre polynomials [3, 5] and a partial positive answer was obtained. Namely several examples of second-order differential equations with one irregular singularity at \(\infty\) and two or more regular singularities

\textsuperscript{4} For the bibliography of various exceptional orthogonal polynomials, see the references therein.
at finite locations were constructed together with solutions having a characteristic exponent $-2$ at one of the regular singularities, through fine-tuning of the parameter of the multi-indexed Laguerre polynomials.

In this paper, we provide a partial positive answer to the above question within the framework of the multi-indexed Jacobi polynomials. As recapitulated in section 2, the multi-indexed Jacobi polynomials are obtained as the main part of the eigenfunctions of a quantum system with the Pöschl–Teller (PT) potential [6, 7], deformed by Darboux–Crum transformations [8–10] in terms of the polynomial solutions called the virtual state solutions. The ‘confluence of apparent singularities’ is achieved through fine-tuning of the two parameters $(g, h)$ of the Jacobi polynomial to a curve $g = g(h)$ or $h = h(g)$ in such a way that the seed solutions have a cubic zero. In other words, these curves are the roots of the discriminants of the polynomial part of the candidate seed solutions, see (2.23). Here, we show several examples of such Fuchsian equations (with a $\rho = -2$) together with their global solutions. We also restrict the parameter ranges such that the extra singularities do not appear in the physical region.

Therefore, the fine-tuned multi-indexed Jacobi polynomials form orthogonal polynomials over $\rho = -2$ with the weight function of the form $(1 - x)^\alpha (1 + x)^\beta /[((ax + b)^2 q(x)^2)]$, in which $q(x)$ is a polynomial in $x$. The denominator does not vanish in $(-1, 1)$. Most of the explicit examples in section 4 have four regular singularities at 0, 1, $t$ and $\infty$, for which Heun’s equation is the canonical form:

$$
\frac{d^2y}{dz^2} + \left( \frac{\gamma}{z} + \frac{\delta}{z-1} + \frac{\epsilon}{z-t} \right) \frac{dy}{dz} + \frac{\alpha \beta z - q}{z(z-1)(z-t)} y = 0,
$$

with the condition $\gamma + \delta + \epsilon = \alpha + \beta + 1$ (Fuchs’ relation). As is well known $(0, 1 - \gamma)$, $(0, 1 - \delta)$ and $(0, 1 - \epsilon)$ are the exponents at 0, 1 and $t$, respectively, and $(\alpha, \beta)$ are those at $\infty$. The parameter $q$ is called the accessory parameter. Heun’s differential equation appears in several systems in physics [11, 12]; in particular, its special cases appear as the differential equations for the exceptional Jacobi polynomials of type $X_1$, and some of their properties were studied in [13]. By the change of the independent variable $\eta = 1 - 2z$, the equations satisfied by the polynomials in all the examples of section 4, (4.11), (4.12), (A.4), (A.8), (A.14), (A.20), can be cast into the above canonical form (1.1).

This paper is organized as follows. In section 2, the essence of the multi-indexed Jacobi polynomials is recapitulated. Starting with the general Schrödinger equation with Darboux–Crum transformations in section 2.1, the details of the PT potential and the eigenpolynomials as well as the virtual state solutions are introduced in section 2.2 and the explicit forms of the multi-indexed Jacobi polynomials are explained in section 2.3. A résumé of the method for the confluence of apparent singularities is given here. The method to realize the higher degrees of apparent singularities is explained in section 3. Section 4 is the main body of the paper. In section 4.1, eight distinct seed functions are chosen among the Wronskians of two and three virtual state solutions of lower degrees. Their parameters are fine-tuned so that a cubic zero is realized. They are divided into four groups, I, II, III and IV. Groups I and II (III and IV) have the same form of potentials (4.2) (respectively (4.4)) and thus the same form of differential equations (4.9) and (4.11) (respectively (4.10) and (4.12)) when expressed in the shifted parameters $\bar{g}$ and $\bar{h}$ (2.28). Within the same group, the potential and the differential equations of one member can be obtained from the others by a simple shift of the parameter, e.g. $\bar{h} \to \bar{h} - 2$, etc. In section 4.2, the aspects of Heun’s equation are discussed in some detail. The limit to the multi-indexed Laguerre systems is discussed in section 4.3. Several other interesting cases are commented on in section 5. The final section is for a summary and comments. A summary table of the contents of section 4 and the appendix is provided here for reference purposes. The appendix provides the explicit forms of the fine-tuned multi-indexed
polynomials, the differential equations for the rational as well as the polynomial solutions and the orthonormality relations for groups I, II, III and IV, together with the Laguerre limits of IV.

2. Multi-indexed Jacobi polynomials

Here, we recapitulate the essence of the multi-indexed Jacobi polynomials as derived in [3]. The main ingredients are (i) the Jacobi polynomials as the main part of the eigenfunctions of the exactly solvable quantum system, the PT potential, (ii) the virtual state solutions and (iii) the Darboux–Crum transformations.

2.1. Darboux–Crum transformations

We start with the Darboux–Crum transformation, which applies to any one-dimensional Schrödinger equation. Let

\[ \mathcal{H} = -\frac{d^2}{dx^2} + U(x), \]  

be a Hamiltonian and \( U(x) \) be a potential defined in a complex domain. To define the Darboux–Crum transformation, we pick up distinct seed solutions \( \{ \phi_j(x), \tilde{E}_j \} \) \((j = 1, \ldots, M)\) of the original Schrödinger equation. Namely

\[ \mathcal{H}\phi_j(x) = \tilde{E}_j \phi_j(x), \quad \tilde{E}_j \in \mathbb{C}, \quad j = 1, \ldots, M, \]  

and the functions \( \phi_j(x) \) need not be square-integrable. Let

\[ \mathcal{H}^{(M)}\psi(x) = \mathcal{E}\psi(x), \]  

(2.3)

\[ \mathcal{H}^{(M)} = -\frac{d^2}{dx^2} + U^{(M)}(x), \quad U^{(M)}(x) \overset{\text{def}}{=} U(x) - 2 \frac{d^2 \log W[\phi_1, \ldots, \phi_M](x)}{dx^2}, \]  

(2.4)

be the \( M \)th deformed Schrödinger equation, where \( W[f_1, \ldots, f_N](x) \) is a Wronskian

\[ W[f_1, \ldots, f_N](x) \overset{\text{def}}{=} \text{Det} \left( \frac{d^{k-1} f_j(x)}{dx^{k-1}} \right)_{1 \leq i, j \leq N}. \]  

(2.5)

Then we have

**Proposition 2.1** [9, 10]. Let \( \psi(x) \) be a solution of the original Schrödinger equation

\[ \mathcal{H}\psi(x) = \mathcal{E}\psi(x). \]  

(2.6)

Then, the function

\[ \psi^{(M)}(x) \overset{\text{def}}{=} \frac{W[\psi_1, \ldots, \psi_M, \psi](x)}{W[\psi_1, \ldots, \psi_M](x)}, \]  

(2.7)

satisfies the \( M \)th deformed Schrödinger equation (2.3) with the same energy:

\[ \mathcal{H}^{(M)}\psi^{(M)}(x) = \mathcal{E}\psi^{(M)}(x). \]  

(2.8)

In the \( M \)th deformed potential (2.4), the zeros of the Wronskian \( W[\phi_1, \ldots, \phi_M](x) \) are the extra singularities.

3
2.2. Pöschl–Teller potential

The Jacobi polynomials constitute the main part of the eigenfunctions of a quantum system with the PT potential:

\[
\mathcal{H} = -\frac{d^2}{dx^2} + U(x; g, h), \quad U(x; g, h) = \frac{g(g-1)}{\sin^2 x} + \frac{h(h-1)}{\cos^2 x} - (g + h)^2,
\]  

\( g > 0, \quad h > 0, \quad x \in \left(0, \frac{\pi}{2}\right). \) 

(2.9)

It has regular singularities at \( x = 0 \) and \( x = \pi / 2 \) modulo \( \pi \), and the characteristic exponents at \( x = 0 \) (resp. \( x = \pi / 2 \)) are \( \rho = g, 1-g \) (resp. \( \rho = h, 1-h \)). The Hamiltonian is self-adjoint and the eigenfunctions and the eigenenergies are given by

\[
\phi_n(x; g, h) = (\sin x)^\frac{g}{2}(\cos x)^\frac{h}{2} P_n^{(g-1/2, h-1/2)}(\eta(x)), \quad \eta(x) \overset{\text{def}}{=} \cos(2x),
\]

(2.11)

\[
\mathcal{E}_n(g, h) = 4n(n + g + h), \quad n = 0, 1, 2, \ldots,
\]

(2.12)

where \( P_n^{(\alpha, \beta)}(\eta) \) is the Jacobi polynomial in the variable \( \eta \) defined by

\[
P_n^{(\alpha, \beta)}(\eta) = \frac{(\alpha + 1)_n}{n!} \sum_{k=0}^n \frac{(-n)_k (n + \alpha + \beta + 1)_k}{k! (\alpha + 1)_k} \left( \frac{1 - \eta}{2} \right)^k.
\]

(2.13)

The eigenpolynomial solutions form a complete set of orthogonal polynomials over \((0, \pi/2)\) under a suitable restriction of the parameters \( g, h \):

\[
(\phi_n, \phi_m) \overset{\text{def}}{=} \int_0^{\pi/2} \phi_n(x; g, h)\phi_m(x; g, h) \, dx = h_n(g, h)\delta_{nm},
\]

(2.14)

\[
h_n(g, h) \overset{\text{def}}{=} \frac{\Gamma(n + g + \frac{1}{2}) \Gamma(n + h + \frac{1}{2})}{2^{n+1} n! (2n + g + h) \Gamma(n + g + h)}.
\]

(2.15)

Another ingredient is the virtual state solutions, which are three types of seed polynomial solutions of the Schrödinger equation (2.9) indexed by \( \nu \in \mathbb{Z}_{\geq 0} \), which all have real energies:

\[
\tilde{\phi}^I_X(x; g, h) \overset{\text{def}}{=} (\sin x)^{1-g}(\cos x)^{1-h} P_x^{(1/2, 1/2-h)}(\eta(x)),
\]

\[
\tilde{\mathcal{E}}^I_X(g, h) = -4(g + \nu + 1/2)(h - \nu - 1/2);
\]

(2.16)

\[
\tilde{\phi}^{II}_X(x; g, h) \overset{\text{def}}{=} (\sin x)^{1-\nu}(\cos x)^{1-h} P_x^{(1/2-h, 1/2)}(\eta(x)),
\]

\[
\tilde{\mathcal{E}}^{II}_X(g, h) = -4(g - \nu - 1/2)(h + \nu + 1/2);
\]

(2.17)

\[
\tilde{\phi}^{III}_X(x; g, h) \overset{\text{def}}{=} (\sin x)^{1-\nu}(\cos x)^{1-h} P_x^{(1/2-h, 1/2)}(\eta(x)),
\]

\[
\tilde{\mathcal{E}}^{III}_X(g, h) = -4(\nu + 1)(g + h - 1 - \nu) = \mathcal{E}_{-(\nu+1)}(g, h).
\]

(2.18)

Note that the seed solutions of type I and II are used to construct generic multi-indexed Jacobi polynomials in [3]. The third type III is now employed to produce a wider class of polynomials, to be called tentatively non-generic multi-indexed Jacobi polynomials (for the non-generic multi-indexed Laguerre polynomials, see [4]). Because of the type III virtual solutions, the absence of singularities in \( \eta \in (-1, 1) \) is no longer guaranteed. One salient feature of the non-generic multi-indexed polynomials is the existence of the additional modes...
at \( n < 0 \). When \( \phi_{\text{III}}^n \) is used as a seed solution, an additional mode at \( n = -(v + 1) \) is created. The degree of the polynomial \( \phi_1^v(x) \) (resp. \( \phi_{\text{III}}^v(x) \)) is equal to \( v \) under the condition \( g - h + k \neq 0 \) (resp. \( g - h - k \neq 0, g + h + 1 - k \neq 0 \)) for \( k = v + 1, v + 2, \ldots, 2v \).

In the rest of this section, we assume that the parameters are general and satisfy these conditions, unless otherwise stated. In section 3 and after, fine-tuning of the parameters will be used extensively and the above conditions will not be assumed any longer.

2.3. Explicit forms of the multi-indexed Jacobi polynomials

We define a wider class of multi-indexed Jacobi polynomials by applying the Darboux–Crum transformation with three types of seed solutions to the quantum system with the PT potential in (2.9). Let \( \phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N} \) \((t_1, \ldots, t_N \in \{I, II, III\}, v_1, \ldots, v_N \in \mathbb{Z}_{>0})\) be distinct seed solutions. Let us denote the number of type I seed solutions in the set \( \{\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}\} \) by \( M \geq 0 \), that of type II by \( N \geq 0 \) and that of type III by \( L \geq 0 \). Then, \( N \) \( \text{def} \equiv M + N + L \) is the total number of the used seed solutions. It follows from proposition 2.1 that the function

\[
\phi_n^{(N)}(x) \defeq \frac{W[\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}, \phi_n]}{W[\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}]}(x)
\]

is an eigenfunction of the deformed Hamiltonian

\[
\mathcal{H}^{(N)} = -\frac{d^2}{dx^2} + U(x; g, h) - 2 \frac{d}{dx} \log W[\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}](x)
\]

with the same eigenvalue \( \xi_n = 4n(n + g + h) \), provided that the deformed potential is non-singular. Let us express the numerator and the denominator of \( \phi_n^{(N)}(x) \) as

\[
W[\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}, \phi_n](x) \defeq (1 - \eta)^N (1 + \eta)^L Q_n(\eta), \quad Q_n(\pm 1) \neq 0,
\]

\[
W[\phi_{\text{I}}^{v_1}, \ldots, \phi_{\text{III}}^{v_N}](x) \defeq (1 - \eta)^N (1 + \eta)^L D(\eta), \quad D(\pm 1) \neq 0,
\]

in which \( Q_n(\eta) \) and \( D(\eta) \) are polynomials in \( \eta \).

Proposition 2.2. The exponents are given by

\[
\Lambda \defeq \frac{1}{4}(J + 1)(2g + J), \quad \Sigma \defeq \frac{1}{4}(K + 1)(2h + K),
\]

\[
\Lambda' \defeq \frac{1}{4}J(2g + J - 1), \quad \Sigma' \defeq \frac{1}{4}K(2h + K - 1),
\]

with \( J \defeq M - N - L, \quad K \defeq -M + N + L \).

The deformed potential is given by

\[
U^{(N)}(x) \defeq \frac{\tilde{g}(\tilde{g} - 1)}{1 - \eta} + \frac{2\tilde{h}(\tilde{h} - 1)}{1 + \eta} - (\tilde{g} + \tilde{h} + 2L)^2
\]

\[
+ 8 \left[ (1 - \eta^2) \frac{D'(\eta)^2 - D(\eta)D''(\eta)}{D(\eta)^2} + \eta \frac{D'(\eta)}{D(\eta)} \right],
\]

\[
\tilde{g} \defeq g + M + N - L, \quad \tilde{h} \defeq h - M + N - L, \quad \tilde{g} + \tilde{h} + 2L = g + h,
\]

\[
\tilde{g} \defeq g + M + N - L, \quad \tilde{h} \defeq h - M + N - L, \quad \tilde{g} + \tilde{h} + 2L = g + h,
\]
and the eigenfunctions have a simple form

\[ \phi_n^{(N)}(x) = (1 - \eta)^{\ell/2}(1 + \eta)^{\ell/2} \frac{Q_n(\eta)}{\mathcal{D}(\eta)}, \quad \deg(Q_n) = \ell + n + L, \quad \deg(\mathcal{D}) = \ell, \]

(2.29)

\[ \ell \equiv \sum_{j=1}^{M+N+L} v_j \frac{M(M-1)}{2} - \frac{N(N-1)}{2} - \frac{L(L-1)}{2} + MN \geq 0. \]

(2.30)

For general values of \( g \) and \( h \), the two polynomials \( Q_n(\eta) \) and \( \mathcal{D}(\eta) \) are relatively prime and the polynomials \( \{ Q_n(\eta) = Q_n(\eta; g, h) \} \) are called the multi-indexed Jacobi polynomials.

With a slight change of notation, these formulas are generalization of those in [3] with the inclusion of the type III seed solutions. For example, formulas (2.28), (2.29) and (2.30) correspond to (26), (25) and (30) of [3], respectively.

The regularity of the solutions and/or the positivity of the resulting weight functions etc must be verified in each specific case for the chosen parameter values. This is in good contrast with the generic multi-indexed Laguerre and Jacobi polynomials in [3], in which the conditions for the parameters are given (equations (23) and (24) of [3]).

When there is no singularity in \( \eta \in (-1, 1) \), the norm of the \( N \)th transformed solution \( \phi_n^{(N)}(x) \) of the \( n \)th the eigenfunction \( \phi_n(x) \) is related that of the original \( \phi_n(x) \):

\[ (\phi_n^{(N)}, \phi_n^{(N)}) = \prod_{j=1}^{M} (\xi_j - \bar{\xi}_j^1) \cdot \prod_{j=1}^{N} (\xi_j - \bar{\xi}_j^2) \cdot \prod_{j=1}^{L} (\xi_j - \bar{\xi}_j^3) \cdot (\phi_n, \phi_n), \]

(2.31)

where \( \bar{\xi}_j \) is the energy of the \( \ell \)th seed solution.

Here is a résumé of the method for the confluence of apparent singularities. Based on the general Darboux transformation formulas (2.3)–(2.7), the multi-indexed Jacobi polynomials \( Q_n(\eta) \) (2.29) are derived from the eigenfunctions of the PT potential (2.9) by using the three types of virtual state wavefunctions (2.16)–(2.18). A high degree of apparent singularity is realized when the denominator polynomial \( \mathcal{D}(\eta) \) (2.29) determined by (2.23) has a multiple zero (3.1). As explained in the following section, a multiple zero is achieved through fine-tuning of the parameters of the original Jacobi polynomials (2.13) at the zeros of the discriminant of the denominator polynomial \( \mathcal{D}(\eta) \) (2.29).

3. Higher degree of apparent singularities

We are going to investigate the relationship between the zero of the Wronskian and the singularity of the deformed Schrödinger equation.

Let us start with a general Schrödinger equation (2.1) with an unspecified potential \( U(x) \). Suppose \( x_0 \), a regular point of the original potential \( U(x) \), is a zero of the Wronskian \( W[\varphi_1, \ldots, \varphi_N](x) \) (2.4) with multiplicity \( m \), i.e.

\[ W[\varphi_1, \ldots, \varphi_N](x) = c_0(x - x_0)^m + O(x - x_0)^{m+1}, \quad m \in \mathbb{Z}_{>0}. \]

(3.1)

Then, it is a singularity of the potential of the deformed Hamiltonian \( H^{(N)} \) such that

\[ x \approx x_0, \quad U^{(N)}(x) = U(x_0) + \frac{2m}{(x - x_0)^2} + \text{regular terms}. \]

(3.2)

The point \( x_0 \) is an apparent singularity of the deformed Schrödinger equation, because the monodromy is preserved by Darboux transformations. The characteristic exponents at the apparent singularity \( x_0 \) are determined by

\[ \rho(\rho - 1) - 2m = 0, \]

(3.3)
and the difference of the exponents is an integer because of the apparentness of the singularity. Combining it with that \( m \in \mathbb{Z}_{>0} \), the admitted values are

\[
m = l(l + 1)/2, \quad \rho = -l, \quad l + 1, \quad (l \in \mathbb{Z}_{>0}).
\]  

(3.4)

Hence, the degrees of zeros of the Wronskian are restricted to \( m = 1, 3, 6, 10, \ldots \). In the case \( m = 1 \), the exponents are \(-1\) and \(2\), and the higher exponents of the singularity are realized only in the cases \( m = 3, 6, 10, \ldots \).

Next we investigate the condition that the Schrödinger equation of the deformed PT potential (2.27) has an extra singularity in \( \eta \) with higher exponents on a curve \( g = g(h) \) (or equivalently, \( h = h(g) \)) in the two-dimensional parameter plane \((g, h)\). This means that the polynomial \( D(\eta; g(h), h) \) has a multiple zero except for \( \eta = \pm 1 \). Hence, a necessary condition for the curve \( g = g(h) \) is that the discriminant of the polynomial \( D(\eta; g(h), h) \) in the variable \( \eta \) vanishes. It is not sufficient because the multiple zeros of \( D(\eta; g(h), h) \) may be realized at \( \eta = \pm 1 \) or the coefficient of the leading term of \( D(\eta; g(h), h) \) may be zero. If the polynomial \( D(\eta; g(h), h) \) has a multiple zero at \( \eta = \eta_0(h) \), then the degrees of the zeros are restricted to \( m = 3, 6, 10, \ldots \). By fine-tuning the parameters on the curve \( g = g(h) \), the confluence of some apparent singularities is achieved. The fine-tuning has another effect. At the multiple zeros, the numerator polynomial \( Q(\eta) \) and the denominator polynomial \( D(\eta) \) are no longer relatively prime. While the denominator \( D(\eta) \) has an \( m = l(l + 1)/2 \) zero, the numerator polynomial \( Q(\eta) \) has an \((l(l + 1)/2 - l = l(l - 1)/2)\) zero:

\[
D(\eta; g(h), h) = (\eta - \eta_0(h))^{l(l-1)/2} w(\eta; g(h), h), \quad w(\eta; g(h), h) = (\eta - \eta_0(h))^l \times q(\eta), \quad \text{deg}(q) = \ell - l,
\]  

(3.5)

(3.6)

(3.7)

The function \( \phi_{\ell}^{(N)}(x) = (1 - \eta)^{3(l)/2} (1 + \eta)^{5(l)/2} \mathcal{P}_n(\eta; g(h), h) / w(\eta; g(h), h) \) defined by (2.29) satisfies the deformed Schrödinger equation and the exponents are \(-l\) and \(l + 1\). If \( l = 2 \), then the denominator Wronskian has a triple zero, and the degree 1 polynomial is cancelled by that of the numerator. It should be stressed that the normalization of the polynomials \( \{\mathcal{P}_n\} \) is uniquely determined by that of \( w(\eta; g(h), h) \).

Hereafter, for simplicity of presentation, we simply write \( \mathcal{P}_n(\eta; g, h) \), etc when the curve \( g = g(h) \) (or \( h = h(g) \)) is pre-specified.

### 4. Four groups of new Jacobi systems

Now we present several concrete examples of interesting systems exhibiting apparent singularities with the characteristic exponent \( \rho = -2 \). We shall be interested in new quantum systems generated by the Darboux transformation using the following eight sets of seed functions:

\[
[\phi_1^+; \phi_1^\text{III}], \quad [\phi_1^+; \phi_1^\text{II}], \quad [\phi_1^+; \phi_2^\text{I}], \quad [\phi_1^+; \phi_1^\text{II}], \quad [\phi_1^+; \phi_1^\text{III}], \quad [\phi_1^+; \phi_2^\text{II}], \quad [\phi_1^+; \phi_1^\text{II}], \quad [\phi_1^+; \phi_1^\text{III}].
\]

The four sets in the second row are obtained by replacing in the first row the type I seed functions by the type II ones. Systems generated by other choices of the set of seed functions can be studied accordingly by the method described in the main text.
4.1. The four groups of Jacobi systems

We look for the situation where the polynomial part of the Wronskian of the set of seed functions, \(D(\eta)\), contains a cubic zero outside of the physical domain \(x \in (0, \pi/2)\) (or \(\eta \in (-1, 1)\)). It turns out that such a situation exists for the eight cases above when \(g = g(h)\) is a linear fractional function. Note that it is equally well to consider \(h = h(g)\) as a function of \(g\) in each case. But taking \(g\) as a function of \(h\) allows us to consider the \(h \to \pm \infty\) limit, which will take the PT potential to the radial oscillator considered in [4].

It is discovered that these eight cases fall into four groups of two members each, such that one member of a group can be obtained from the other by a shift in the value of \(h\), which is determined by the universal formula for \(\bar{g}\) and \(\bar{h}\) derived in section 2.3. This is because the main part of the denominator polynomial \(D(\eta; g(h), h)\), which has a cubic zero, is the same for the two members when expressed in terms of \(\bar{h}\). Moreover, the polynomial up to a multiplicative constant is identical for groups I and II and it has the same form for groups III and IV, with only the value of a parameter \(\gamma\) being different. This means that the deformed potential \(U^{(\gamma)}(x)\) is identical for groups I and II, and it has the same form in groups III and IV, when expressed in terms of \(\bar{g}\) and \(\bar{h}\).

- **Group I:** (a) \([\bar{\phi}_1, \bar{\phi}_1^{(\text{III})}]\), \(g = \frac{3(h-3)}{4(h+1)}\), \(\bar{g} = g\), \(\bar{h} = h - 2\);
- **Group I:** (b) \([\bar{\phi}_1^{(\text{II})}, \bar{\phi}_2^{(\text{III})}]\), \(g = \frac{3(h-1)}{4(h+3)}\), \(\bar{g} = g - 3\), \(\bar{h} = h + 1\).
  For both cases, \(\bar{g} = \frac{3(h-1)}{4(h+1)}, \bar{g} + \bar{h} = g + h, (L = 1)\).

- **Group II:** (a) \([\bar{\phi}_1, \bar{\phi}_1^{(\text{IV})}]\), \(g = \frac{4(h-3)}{4(h-3)}\), \(\bar{g} = g\), \(\bar{h} = h - 2\);
- **Group II:** (b) \([\bar{\phi}_1^{(\text{II})}, \bar{\phi}_2^{(\text{IV})}]\), \(g = \frac{4(h-3)}{4(h-3)}\), \(\bar{g} = g - 2\), \(\bar{h} = h\).
  For both cases, \(\bar{g} = \frac{4(h-3)}{4(h-3)}, \bar{g} + \bar{h} = g + h, (L = 1)\).

For groups I and II: \(D_{\text{II}}(\eta; g, h) = (2\bar{h}\eta - 2\eta - 2\bar{h} - 1)^3 \times \text{constant}, (4.1)\)

\[
U^{(\gamma)}_{\text{II}}(x) = \frac{2\bar{g}(\bar{g} - 1)}{1 - \eta} + \frac{2\bar{h}(\bar{h} - 1)}{1 + \eta} - (\bar{g} + \bar{h} + 2)^2
- 8 \left[ \frac{3(2\bar{h} + 1)}{2\bar{h} - 2\eta - 2h - 1} + \frac{9(4\bar{h} - 1)}{(2\eta - 2\bar{h} - 2 - 1)^2} \right], (4.2)
\]

- **Group III:** (a) \([\bar{\phi}_1^{(\text{II})}, \bar{\phi}_1^{(\text{IV})}]\), \(g = \frac{9(h-1)}{4(h-1)}\), \(\bar{g} = g - 2\), \(\bar{h} = h\);
- **Group III:** (b) \([\bar{\phi}_1^{(\text{II})}, \bar{\phi}_2^{(\text{IV})}]\), \(g = \frac{3(h-3)}{4(h+3)}\), \(\bar{g} = g + 1\), \(\bar{h} = h - 3\).
  For both cases, \(\bar{g} = \frac{3(h-3)}{4(h+3)}, \bar{g} + \bar{h} = g + h, (L = 1)\).

- **Group IV:** (a) \([\bar{\phi}_1, \bar{\phi}_1^{(\text{IV})}]\), \(g = \frac{4(h-3)}{4(h-3)}\), \(\bar{g} = g - 3\), \(\bar{h} = h - 1\);
- **Group IV:** (b) \([\bar{\phi}_1^{(\text{II})}, \bar{\phi}_2^{(\text{IV})}]\), \(g = \frac{4(h-3)}{4(h-3)}\), \(\bar{g} = g - 1\), \(\bar{h} = h - 3\).
  For both cases, \(\bar{g} = \frac{4(h-3)}{4(h-3)}, \bar{g} + \bar{h} = g + h, (L = 2)\).

For groups III and IV: \(D_{\text{III,IV}}(\eta; g, h) = (2\bar{h}\eta - 2\eta + 3)^3 \times \text{constant}, (4.3)\)

\[
U^{(\gamma)}_{\text{III,IV}}(x) = \frac{2\bar{g}(\bar{g} - 1)}{1 - \eta} + \frac{2\bar{h}(\bar{h} - 1)}{1 + \eta} - (\bar{g} + \bar{h} + \gamma)^2
- 8 \left[ \frac{3(2\bar{h} - 3)}{2\eta - 2\bar{h} + 3} - \frac{9(4\bar{h} - 3)}{(2\eta - 2\bar{h} + 3)^2} \right], (4.4)
\]

\(\gamma = 2\) (for group III), 4 (for group IV). (4.5)
The normalization of the (fine-tuned) multi-indexed polynomials \( \{P_n(\eta)\} \) is fixed by
\[
\phi_{\text{I}}^{(N)}(x) = (1 - \eta)\tilde{g}(h)^{1/2}(1 + \eta)^{\tilde{h}(h)^{1/2}}P_n(\eta; g(h), h)/w(\eta; g(h), h),
\]
for groups I and II,
\[
w(\eta) = w_1(\eta; \tilde{g}, \tilde{h}) \defeq (2\tilde{h}\eta - 2\eta - 2\tilde{h} - 1)^2,
\]
for groups III and IV.

For these to be non-singular in the physical domain \( \eta \in (-1, 1) \), one must restrict
\[
\tilde{h} > \frac{1}{4} \quad \text{and} \quad \tilde{h} \neq 1: I, \quad \tilde{h} < \frac{3}{4} \quad \text{and} \quad \tilde{h} \neq 0: III, IV.
\]
The conditions \( \tilde{h} \neq 0 \) are also needed, otherwise the denominator in each case will be a constant, which is not the case we want to consider here. The square integrability of the eigenfunctions requires
\[
\tilde{g} > -\frac{1}{2}, \quad \tilde{h} > -\frac{1}{2},
\]
In the appendix, we list the possible range of \( h \) for each specific case.

We note here that \( \tilde{g}_I = 1 - \tilde{g}_U \) and \( \tilde{g}_{III} = 1 - \tilde{g}_{IV} \). This explains why the potentials in \( \eta \) are the same for groups I and II, and for III and IV. By equating \( \tilde{h} \) for the two cases in the same group, one obtains a transformation between the two systems. Hence, by setting \( h \to h + 3 \) in the potential, the eigenvalues, the eigenfunctions, etc in case I(a) (with \( g \) expressed in terms of \( h \)), one obtains the corresponding formulas for case I(b). Similarly, setting \( h \to h + 2, \ h \to h - 3 \) and \( h \to h - 2 \) maps cases II(a) to II(b), III(a) to III(b) and IV(a) to IV(b), respectively. These are the required shiftings mentioned above.

Here are the Fuchsian differential equations for the rational functions \( y_n(\eta) \defeq P_n(\eta)/w(\eta), n = 0, 1, \ldots \) with a \( \rho = -2 \) apparent singularity. They are obtained by rewriting the Schrödinger equation with the potential \( U^{(N)}(x) \) (4.2), (4.4):
\[
(1 - \eta^2)y''_n(\eta) + \left( \tilde{h} - \tilde{g} - (\tilde{g} + \tilde{h} + 1)\eta \right)y'_n(\eta) + \left\{ (n + 1)(n + \tilde{g} + \tilde{h} + 1) + \frac{6(2\tilde{h} + 1)}{2\tilde{h}\eta - 2\eta - 2\tilde{h} - 1} + \frac{18(4\tilde{h} - 1)}{(2\tilde{h}\eta - 2\eta - 2\tilde{h} - 1)^2} \right\} y_n(\eta) = 0,
\]
for groups I and II, and
\[
(1 - \eta^2)y''_n(\eta) + \left( \tilde{h} - \tilde{g} - (\tilde{g} + \tilde{h} + 1)\eta \right)y'_n(\eta) + \left\{ (n + \frac{\nu}{2})(n + \tilde{g} + \tilde{h} + \frac{\nu}{2}) + \frac{6(2\tilde{h} - 3)}{2\tilde{h}\eta - 2\eta + 3} - \frac{18(4\tilde{h} - 3)}{(2\tilde{h}\eta - 2\eta + 3)^2} \right\} y_n(\eta) = 0,
\]
for groups III and IV. In these equations, \( \tilde{g} = \tilde{g}(\tilde{h}) \) should be replaced by its respective value for each group as given before. These are second-order differential equations with regular singularities at \( \eta = \pm 1, \infty \) and \( \eta = (2h + 1)/(2(\tilde{h} - 1)) \) (for groups I and II), or \( 1 - 3/2h \) (for groups III, IV) with conditions (4.7).

The polynomials \( P_n \) satisfy
\[
\begin{align*}
&\{-1 + 2n + n^2 - 2\tilde{h}^2(3 + n)(\eta - 1) - 6\tilde{h} + 4n\eta + 2n^2\eta \\}\ + \hat{h}[-1 + n(5 - 2n) - 2n^2(\eta - 1) + 12\eta] + \tilde{g}[5 + n + 6\eta + 2n\eta - 2\tilde{h}(1 + n(\eta - 1) + 3\eta)]P_n(\eta) + \{ -8 + 2\tilde{h}^2(\eta - 1)^2 - \eta + 6n^2 \\} \tilde{g}(\eta) \ + \{-1 + 2\tilde{h}(\eta - 1) - 2n)(\eta + 1) - \tilde{h}(\eta - 1)(8n + 9)\} P_n(\eta) \\
&\quad + (-1 + 2\tilde{h}(\eta - 1) - 2n)(\eta - 1)P_n'(\eta) = 0,
\end{align*}
\]
for groups I and II, and
\[
- [3(\gamma + 2n)^2 + 2\tilde{h}[3(\gamma + 2n) - 16\gamma + (\gamma + 2n)^2(\eta - 1)] + 4\tilde{h}^2(4 + \gamma + 2n)(\eta - 1)]
\]
\[+ 2\tilde{g}[3(\gamma + 2n) + 2\tilde{h}(4\eta + 1) + (\gamma + 2n)(\eta - 1)))]P_n(\eta)
\]
\[+ 4[(2\tilde{h}^2(\eta - 1)^2 + 3\eta + \tilde{g}[3 + 2\tilde{h}(\eta - 1)](\eta + 1)
\]
\[- \tilde{h}(6\eta + 5)(\eta - 1)]P_n'(\eta) + [3 + 2\tilde{h}(\eta - 1))(\eta - 1)^2]P_n''(\eta) = 0,
\]
(4.12)
for groups III and IV.

The appendix presents the essential data for these new polynomials for one case from each group. The other member can be obtained by the shifting mentioned in the last section. Examples II(b) and III(a) were discussed in [14] from a different point of view.

4.2. Heun’s systems

All the examples in the previous subsection have four regular singularities, three at finite locations and one at \(\infty\). Thus, they belong to Heun’s systems with one apparent singularity of characteristic exponent \(\rho = -2\). Let us discuss Heun’s properties by taking the example, group I(a) with \(g = 3(h - 3)/(4h - 9)\). The \(\mathcal{D}(\eta)\) polynomial (4.1) in terms of \(h = h + 2\) reads

\[
\mathcal{D}(\eta; g, h) = (2(h - 3)\eta - 2h + 3)^3 \times \text{constant}.
\]

By the change of the independent variable \(\eta = 1 - 2z\), the equation for the two-indexed Jacobi polynomial \(f_n = P_n(\eta; 3(h - 3)/(4h - 9), h)\) is rewritten into Heun’s differential equation (1.1):

\[
\frac{d^2 f_n}{dz^2} + \left(\frac{g + 1/2}{z} + \frac{h - 3/2}{z - 1} - \frac{4}{z + \frac{3}{4(h - 3)}}\right) \frac{df_n}{dz} + \frac{(n + g + h - 3)z - 3(4h - 9)n^2 + 3(4h^2 - 6h - 9)n + 2h(10h - 27)}{4(h - 3)(4h - 9)} f_n = 0,
\]

\[n = 0, 1, \ldots \ldots \]
(4.13)

The exponents at \(z = 0, 1\) and the position of the extra singularity are specialized by the parameter \(h\), and the exponents at \(z = \infty\) (i.e. \(-n - 3\) and \(n + g + h - 3\)) depend on the discrete parameter \(n\). The accessory parameter \((q\) in equation (1.1)) is specialized so that the extra singularity is apparent and the equation has a polynomial solution. As shown in appendix A.1, the equation has an extra solution for \(\alpha = -2\), (A.2).

It is interesting to note that the accessory parameter \(q\) in (4.13) has a very special dependence on \(\alpha, \beta\) (the exponents at \(\infty\)) and the location \(t\) of the extra singularity:

\[
\frac{3(4h - 9)n^2 + 3(4h^2 - 6h - 9)n + 2h(10h - 27)}{4(h - 3)(4h - 9)} \equiv q = \alpha \beta t + q_r,
\]

\[\alpha \equiv -(n + 3), \quad \beta \equiv n + g + h - 3, \quad t \equiv -\frac{3}{4(h - 3)}, \quad q_r \equiv -\frac{2h - 9}{2(h - 3)}.
\]

Here, the reduced accessory parameter \(q_r\) does not depend on \(n\). This simplifies (4.13) to

\[
\frac{d^2 f_n}{dz^2} + \left(\frac{g + 1/2}{z} + \frac{h - 3/2}{z - 1} - \frac{4}{z - t}\right) \frac{df_n}{dz} + \left(\frac{\alpha \beta}{z(z - 1)} - \frac{q_r}{z(z - 1)(z - t)}\right) f_n = 0.
\]

\[n = 0, 1, \ldots \ldots \]
(4.13)
For all the examples in section 4.1, we have

\[ q = \alpha \beta t + q_r, \quad q_r : \text{does not depend on } n, \quad (4.14) \]

and the following proposition.

**Proposition 4.1.** The polynomial solutions of the eight examples in section 4.1 can be written in the following special form of Heun’s equation with n-independent \( q_r \):

\[
\frac{d^2 f_n}{dz^2} + \left( \frac{\gamma}{z} + \frac{\delta}{z-1} - \frac{4}{z-t} \right) \frac{df_n}{dz} + \left( \frac{\alpha \beta}{z(z-1)} - \frac{q_r}{z(z-1)(z-t)} \right) f_n = 0, \quad (4.15)
\]

\[
q_r = \begin{cases} 
(2 + \tilde{\gamma} + \tilde{h} - 4\tilde{g})/(2(h - 1)) & \text{groups I and II,} \\
(-6 + \tilde{g}(3 - 4\tilde{h}) + 7\tilde{h})/2\tilde{h} & \text{groups III and IV,}
\end{cases} \quad \gamma + \delta = \alpha + \beta + 5. \quad (4.16)
\]

This can be verified in each case. The above relation (4.14) can be rephrased that the pole residues of the extra singularities are \( n \)-independent. This is also the case for the \( X \) Jacobi polynomials which have \( \rho = -1 \). See (3.11)–(3.12) in [15]. The same statement applies to the generic multi-indexed Jacobi polynomials, (4.6)–(4.7) in [3].

Another example is the case \([\phi^1_n, \phi^2_n] \) with \( g = 1 - \tilde{h} \). The denominator polynomial is simply

\[ D(\eta; 1 - h, h) = \eta^3 \times \text{constant}. \]

The degree of the two-indexed Jacobi polynomial \( P_n(\eta; 1 - h, h) \) is \( n + 2 \), and the function \((1 - \eta)^{-1} -(1 + \eta)^{-1} P_n(\eta; 1 - h, h)/\eta^2 \) is a solution of the deformed Schrödinger equation. In this case, however, the extra singularity at \( \eta = 0 \) is located in the physical domain, and it destroys the self-adjointness of the Hamiltonian as well as the quantum mechanical interpretation. From a viewpoint of mathematics, this case is out of the Sturm–Liouville theory, but it satisfies a second-order differential equation. Namely the two-indexed Jacobi polynomial \( f_n = P_n(\eta; 1 - h, h) \) satisfies

\[
\frac{d^2 f_n}{d\eta^2} + \left( -h + 3/2 \eta - 3/2 \eta + 4 \eta \right) \frac{df_n}{d\eta} + \frac{(n-2)(n-1)\eta + 4h - 2}{\eta(\eta-1)(\eta+1)} f_n = 0,
\]

and it also satisfies Heun’s differential equation by setting \( \eta = 1 - 2z \).

Similar phenomena happen in the cases \([\phi^1_n, \phi^2_n], g = 1 - h \) and \([\phi^3_n, \phi^4_n], g = h \).

Note that the Darboux–Crum transformation was already applied to Heun’s equation in [16]. However, the motivation and the results in this paper are different from those in [16].

### 4.3. Limits to Laguerre systems

We now discuss the relations of these Jacobi systems with the Laguerre systems presented in [4]. It is well known that by a simple limiting procedure, one can obtain the (deformed)-radial oscillator potential from the (deformed) trigonometric PT potential [17]. For this one makes use of the limit formulas of the base polynomials

\[
\lim_{\beta \to \infty} P_n^{(\alpha, \pm\beta)}(1 - 2x\beta^{-1}) = L_n^{(\alpha)}(\pm x). \quad (4.17)
\]

By taking the limit of infinite coupling \( h \to \infty \) with the rescaling of the coordinate:

\[
x = \frac{x^L}{\sqrt{h}}, \quad 0 < x < \frac{\pi}{2} \Leftrightarrow 0 < x^L < \frac{\pi}{2} \sqrt{h}, \quad (4.18)
\]
we have, with \( \eta(x) = \cos(2x) \) and \( \eta^L(x^L) = x^L \), the relation
\[
\eta(x) = 1 - \frac{2\eta^L}{h} + O(h^{-2}).
\] (4.19)
Taking the limit \( h \to \pm \infty \) (or equivalently, \( \tilde{h} \to \pm \infty \)), where the upper (lower) sign applies to groups I and II (III and IV), we have
\[
\lim_{h \to \pm \infty} h^{-1} \xi_n^L(g, h) = \xi_n^L(g) = 4n,
\] (4.20)
and
\[
\lim_{\tilde{h} \to \pm \infty} \left[ \frac{U^{(N)}(x)}{\tilde{h}} \right] = \eta^L - \frac{3}{16\eta^L} + \frac{48}{4\eta^L + 3} + \frac{288}{(4\eta^L + 3)^2} - 2\left( \tilde{\eta} + \gamma + \frac{1}{2} \right),
\] (4.21)
with \( \gamma = 2 \) for groups I to III, and \( \gamma = 4 \) for group IV. These are the potentials of the Laguerre systems presented in [4], where \( \tilde{\eta} = \tilde{\xi}(\tilde{h}) \) takes on the respective value for each group at the limits \( \tilde{h} \to \pm \infty \), namely
\[
\tilde{\eta} \to \frac{1}{4} \text{ (II, III)}, \quad \frac{3}{4} \text{ (I, IV)}.
\] (4.22)
Group I corresponds to the case (A), II to (B) and III to (D) in [4].

Equations (4.9) and (4.10) for \( y(\eta) \) reduce to
\[
y\eta'' + \left( \tilde{\eta} + \frac{1}{2} - \eta \right) y' + \left( n + \frac{\gamma}{2} - \frac{12(4\eta + 3)}{(3 + 4\eta)^2} \right) y = 0, \quad n = 0, 1, \ldots ,
\] (4.23)
for groups I and II (upper sign and \( \gamma = 2 \)) and groups III and IV (lower sign and \( \gamma = 2 \) and 4, respectively). This corresponds to equation (3.40), (3.49) and (3.55) in [4].

In the same limit, the polynomial \( P_n \) reduces to the corresponding polynomial \( L_n \), which satisfies, from the limits of (4.11) and (4.12) for \( y(\eta) \):
\[
4\eta(4\eta + 3) L_n''(\eta) - 2\left( -3 - 6\tilde{\eta} + 34\eta - 8\tilde{\xi} + 8\eta^2 \right) L_n'(\eta)
+ 4\left( 11 - 8\tilde{\xi} + 3n + 4(3 + n)\eta \right) L_n(\eta) = 0
\] (4.24)
for groups I and II, and
\[
4\eta(4\eta - 3) L_n''(\eta) - 2\left( 3 - 2\tilde{\eta}(4\eta - 3) + 22\eta + 8\eta^2 \right) L_n'(\eta)
+ \left( 32 - 32\tilde{\xi} - 6\gamma - 12n + 8(4 + \gamma + 2n)\eta \right) L_n(\eta) = 0
\] (4.25)
for groups III (\( \gamma = 2 \)) and IV (\( \gamma = 4 \)). These correspond to equation (3.41), (3.50) and (3.56) in [4].

The above results indicate that the systems described in groups I, II and III (the potential, eigenfunctions, eigenvalues, etc) reduce to the cases (A), (B) and (D) Laguerre systems given in [4], respectively (for details of the Laguerre systems, see [4]). Group IV corresponds to a new Laguerre system. Since this is not discussed in [4], we shall give some details of this case in the appendix.

Specifically, the forms of \( U^{(N)}(x) \) in (4.2) and (4.4) imply that the eigenfunctions have the form:
\[
\psi^L_n(x; \eta, g, h) = \frac{(1 - \eta)\tilde{\xi}^2(1 + \eta)^{\tilde{h}/2}}{w_1(\eta; \tilde{h})} P_n(\eta; g, h), \quad i = 1, 2.
\] (4.26)
Under the above limiting process, the prefactor of \( P_n(\eta; g, h) \) (times the factor \( h^{-\tilde{h}/2} \)) tends to
\[
\eta^{L-1/2} e^{-\tilde{\xi}^2/(4\eta^L + 3)^2}.
\] (4.27)
with \( \tilde{\xi} = 3/4 \) for groups I and IV, and \( \tilde{\xi} = 1/4 \) for groups II and III. The polynomial part \( h^{-m} P_n(\eta; g, h) \) \((m = 2 \) for groups I, II and III, and \( m = 3 \) for group IV) approaches to
\[
L^A_{\tilde{h}}, \text{ B, D, New}(\eta^L; \tilde{g}),
\] (4.28)
with \( \tilde{g} = 3/4, 1/4, 9/4 \) and 13/4, respectively.
5. Other examples of higher degrees of apparent singularities

5.1. The case \([\hat{\phi}_1^1, \hat{\phi}_2^1]\) and related cases

In the case \([\hat{\phi}_1^1, \hat{\phi}_2^1]\), the Wronskian is written as \(W[\hat{\phi}_1^1, \hat{\phi}_2^1](x) = (1 - \eta)^{3/2}dD(\eta)\), where \(D(\eta)\) is a polynomial of degree 4. The discriminant of the polynomial \(D(\eta)\) is written as

\[
-256(2h + 1)(2h - 3)^2(2g - 3)(2g - 11)^3(2g - 5)^4 \times (g + h - 4)(g - h - 3)(2gh^2 - 2gh - 3g - 5h^2 + 5h + 12)^2.
\]

We set \(g = (5h^2 - 5h - 12)/(2h^2 - 2h - 3)\), which is a root of \(2gh^2 - 2gh - 3g - 5h^2 + 5h + 12 = 0\).

Then, the polynomial \(D(\eta)\) is written as

\[
\{(h + 2)(h - 3)\eta - (h^2 - h + 3)\}(h(h - 1)\eta - (h^2 - h - 3))^3,
\]

and the potential is

\[
\frac{(g + h - 2)(g - 3)}{1 - \eta} + \frac{2h(h - 1)}{\eta + 1} - (g + h)^2 \left( \frac{24h(h - 1)(h^2 - h - 3)\eta - h(h - 1)}{(h(h - 1)\eta - (h^2 - h - 3)^2} + \frac{8(h + 2)(h - 3)(h^2 - h + 3)\eta - (h + 2)(h - 3)}{(h + 2)(h - 3)\eta - (h^2 - h + 3)^2} \right).
\]

Note that \(\eta = 1 - 3/((h(h - 1))\eta - (h^2 - h - 3))\) is an apparent singularity of exponent \(-2\) and \(\eta = 1 + 9/((h + 2)(h - 3))\) is that of exponent \(-1\).

The four cases \([\hat{\phi}_1^1, \hat{\phi}_2^1], [\hat{\phi}_1^1, \hat{\phi}_2^1, \hat{\phi}_3^1], [\hat{\phi}_1^1, \hat{\phi}_2^1, \hat{\phi}_3^1, \hat{\phi}_4^1]\) and \([\hat{\phi}_1^1, \hat{\phi}_2^1, \hat{\phi}_3^1, \hat{\phi}_4^1, \hat{\phi}_5^1]\) can be treated similarly to groups I and II in section 4 and the four cases \([\hat{\phi}_2^1, \hat{\phi}_2^1], [\hat{\phi}_1^1, \hat{\phi}_2^1, \hat{\phi}_3^1], [\hat{\phi}_2^1, \hat{\phi}_3^1, \hat{\phi}_4^1, \hat{\phi}_5^1]\) correspond to groups III and IV.

5.2. The case \([\hat{\phi}_1^1, \hat{\phi}_2^1]\) and related cases

In the case \([\hat{\phi}_1^1, \hat{\phi}_2^1]\), the Wronskian \(W[\hat{\phi}_1^1, \hat{\phi}_2^1](x) = D(\eta)\) is a polynomial of degree 4. The discriminant of the polynomial \(D(\eta)\) is written as

\[
-1024(2h + 1)(2h - 3)(2h + 3)^2(2g + 1)(2g - 3)(2g - 5)^2(g - h - 3)(g - h - 1)^3 \times (4g^2h - 4gh^2 - 30g^2 - 56gh - 26h^2 + 69g + 43h - 12)^2.
\]

The equation \(4g^2h - 4gh^2 - 30g^2 - 56gh - 26h^2 + 69g + 43h - 12 = 0\) is quadratic in both \(g\) and \(h\). We find some lower lying rational solutions, \((g, h) = (131/2, 25/2), (115/2, 16), (113/2, 41/2)\). For these points in the parameter plane, the polynomial \(D(\eta)\) is proportional to

\[
(13 + 7\eta)(5\eta + 7)^3, \quad (45\eta + 107)(3\eta + 5)^3, \quad (\eta + 3)(\eta + 2)^3,
\]

respectively. The potential for the \((g, h) = (113/2, 41/2)\) case is

\[
\frac{113 \cdot 111}{2(1 - \eta)} + \frac{41 \cdot 39}{2(1 + \eta)} - \left( \frac{113}{2} + \frac{41}{2} \right)^2 + \frac{24(2h + 1)(\eta + 2)}{(\eta + 2)^2} + \frac{8(3\eta + 1)}{(\eta + 3)^2}.
\]

Note that \(\eta = -2\) is an apparent singularity of exponent \(-2, \eta = -3\) is that of exponent \(-1\), and they are outside of \([-1, 1]\). The corresponding (fine-tuned) multi-indexed polynomials, \(\{P_n(\eta)\}\), satisfy

\[
- (1 - \eta^2)(\eta + 2)(\eta + 3) \frac{d^2P_n(\eta)}{d\eta^2} + 2(n + 77 + 32\eta)(\eta + 2)(\eta + 3)P_n(\eta) = 0.
\]
and the solutions are
\[
P_n(\eta) = -82[(9(1517 + 1952\eta + 825\eta^2 + 114\eta^3) + n(n + 77)(2 + \eta)^2(3 + \eta)]P_n^{56,20}(\eta) \\
+(1 - \eta^2)(2 + \eta)(11 + 4\eta)\partial_n P_n^{56,20}(\eta)).
\] (5.6)
They satisfy the orthonormality relations
\[
\int_{-1}^{1} \frac{(1 - \eta)^{56}(1 + \eta)^{20}}{(\eta + 2)^4(\eta + 3)^2} P_n(\eta)P_m(\eta)\,d\eta = H_\delta_{nm},
\] (5.7)
\[
H_n \overset{\text{def}}{=} 2^5(n(n + 77) + 1102)(n(n + 77) + 1242)(n + 1)_{20}(n + 57)_{20} \\
(2n + 77).
\] (5.8)
The other parameter choices \((g, h) = (131/2, 25/2), (115/2, 16)\) show equally interesting characteristics. The cases \([\phi_1, \phi_1], [\phi_1, \phi_3], [\phi_1, \phi_1], [\phi_1, \phi_1], [\phi_1, \phi_3]\) have similar features.

6. Summary and comments

Several families of infinitely many rational solutions are constructed of certain second-order Fuchsian differential equations having four or more regular singularities. All the extra singularities are apparent and their characteristic exponents are \(-2\) or \(-1\). They are obtained by fine-tuning the parameters of multi-indexed Jacobi polynomials [3]. In other words, these Fuchsian equations are derived from the Schrödinger equation with the PT potential through Darboux–Crum transformations with the seed solutions having a cubic zero. The fine-tuning of the parameters \((g, h)\) is realized as a curve \(\bar{g} = g(h)\) (or \(h = h(g)\)) obtained from a particular root of the discriminant of the seed solutions corresponding to a cubic zero. These families of infinite solutions constitute orthogonal polynomials over \((-1, 1)\) with the weight function of the form \((1 - x)^\rho(1 + x)^\delta/((ax + b)^2 q(x)^2)\), in which \(q(x)\) is a polynomial in \(x\). Being the special cases of the multi-indexed Jacobi polynomials, these polynomials have ‘gaps’ in the degrees and they do not satisfy the three-term recurrence relations. The eight examples presented in section 4 are divided into four groups, each consisting of two members. Reflecting the structure of the theory, the orthogonal polynomials of one member of the group can be obtained from those of the others by a simple shift of the parameters. Examples II(b) and III(a) were discussed in [14] from a different point of view. Properties of Heun’s equations with an apparent singularity are discussed in some detail for two explicit examples. By the standard limiting procedures leading from the Jacobi to the Laguerre polynomials, these special cases of multi-indexed Jacobi polynomials are shown to reduce to the special cases of multi-indexed Laguerre polynomials. Three of them had been explicitly constructed in [4].

It is a good challenge to construct solutions with higher degrees \((\rho = -3, -4)\) of apparent singularities within the multi-indexed Jacobi polynomials. In the preparation of this paper, we tried in vain some combinations of lower degree virtual state solutions. With increasing complexity in dealing with higher degrees of virtual state solutions, some new ideas might be needed.

Table 1 summarizes the contents of section 4 and the appendix. The first column denotes the seed functions for the four groups introduced in section 4. For example, I_2 III_1 means \(W[\phi_1, \phi_1](x)\). The second column shows the fine-tuning curve \(g = g(h)\), which are linear fractional functions. The third and fourth columns are the shifted parameters \(\bar{g}\) and \(\bar{h}\). The fifth column gives the equation numbers of the common forms of the denominator polynomial \(D(\eta)\) and the deformed potential \(U(\sqrt{\eta})\). The sixth column gives the equation numbers of the common forms of the differential equations for the rational eigenfunction \(y_n = \frac{P_n}{w}\) (4.6) and the multi-indexed polynomial \(\bar{P}_n\). Here, \(w\) is the reduced denominator polynomial (3.5).
Table 1. Summary table

| Seeds      | \( g(h) \) | \( \bar{g} \) | \( \bar{h} \) | \( D \) and pot. | Equation \( P_n \) | Add. | Equation \( P_n \) | Ort. |
|------------|-------------|-------------|-------------|-----------------|-----------------|------|-----------------|------|
| I \(_1\) \text{III}_1 | \( \frac{3(h - 3)}{4h - 9} \) | \( g \) | \( h - 2 \) | (4.1) and \( y_n \) | (4.9) | (A.1) | (A.2) and (A.4) | (A.5) |
| II \(_1\) \text{II}_2 \text{III}_1 | \( \frac{3(5h + 3)}{4h + 3} \) | \( g - 3 \) | \( h + 1 \) | (4.2) | \( P_n \) : (4.11) | (A.3) | |
| II \(_1\) \text{III}_1 | \( \frac{h}{4h - 9} \) | \( g \) | \( h - 2 \) | (4.1) and \( y_n \) | (4.9) | (A.6) | (A.7) | (A.8) (A.9) |
| II \(_1\) \text{III}_2 | \( \frac{9h}{4h - 1} \) | \( g - 2 \) | \( h \) | (4.2) | \( P_n \) : (4.11) | (A.3) | |
| II \(_1\) \text{III}_1 | \( \frac{4h - 3}{9(h - 1)} \) | \( g - 2 \) | \( h \) | (4.3) and \( y_n \) | (4.10) | (A.11) | (A.12) and (A.14) | (A.15) |
| I \(_1\) \text{II}_2 \text{III}_1 | \( \frac{3(h - 3)}{4h - 15} \) | \( g + 1 \) | \( h - 3 \) | (4.4) | \( P_n \) : (4.12) | (A.13) | |
| II \(_1\) \text{III}_1 \text{II}_2 | \( \frac{4h - 7}{3(5h - 8)} \) | \( g - 3 \) | \( h - 1 \) | (4.3) and \( y_n \) | (4.10) | (A.16) | (A.17) - (A.19) | (A.20) (A.21) |
| I \(_1\) \text{III}_1 \text{II}_3 | \( \frac{7h - 24}{4h - 15} \) | \( g - 1 \) | \( h - 3 \) | (4.4) | \( P_n \) : (4.12) | |

The seventh to tenth columns give the equation numbers of the explicit forms of the multi-indexed polynomial \( P_n \), the additional modes, the differential equations of the multi-indexed polynomial \( P_n \) and the orthogonality relations, respectively, for the upper member of each group.

Appendix. Basic data for four cases in section 4

A.1. Case I(a)

- \( g = \frac{\eta(h-3)}{h-\eta}, \tilde{g} = g, \tilde{h} = h - 2 \)
- Explicit form of wavefunctions:

\[
\psi_n^{(I)}(\eta; h) = \frac{(1 - \eta)^{\frac{3}{2}}(1 + \eta)^{\frac{h-3}{2}}}{(2h - 6\eta - 2h + 3)^2} P_n^{(I)}(\eta; h), \quad n = 0, 1, 2, \ldots
\]

\[
P_n^{(I)}(\eta; h) = \left(1053 - 612h + 96h^2 - 248h^3 + 176h^4 - 32h^5 - 162n + 108hn + 144h^2n\right.
\]

\[
- 144h^3n + 32h^4n - 162n^2 + 288hn^2 - 168h^2n^2 + 32h^3n^2
\]

\[
+ (1944 - 1026h - 1740h^2 + 1976h^3 - 736h^4 + 486n - 108hn
\]

\[- 432h^2n + 240h^3n - 32h^4n + 486n^2 - 648hn^2 + 264h^2n^2 - 32h^3n^2)\eta
\]

\[
+ (1458 - 4914h + 6132h^2 - 3520h^3 + 944h^4 - 96h^5 - 216hn
\]

\[- 72h^2n + 144h^3n - 32h^4n - 216hn^2 + 168h^2n^2 - 32h^3n^2)\eta^2
\]

\[
+ (-1620 + 4248h - 4020h^2 + 1792h^3 - 384h^4 + 32h^5 - 648n + 504h^2n
\]

\[- 240h^3n + 32h^4n - 648n^2 + 720hn^2 - 264h^2n^2 + 32h^3n^2)\eta^3 \right) \times P_{n}^{(\nu-1/2, h-1/2)}(\eta) + (-9 + 4h)(-1 + \eta^2)(3 - 2h - 6\eta + 2h\eta)
\]

\[
\times (27 - 4h^2 + 54\eta - 30hn + 4h^2\eta) \delta_{\eta} P_{n}^{\nu-1/2, h-1/2}(\eta). \quad (A.1)
\]

From (4.7), one has \( h > 9/4 \) and \( h \neq 3 \). The square integrability (4.8) requires a stronger condition \( h > 27/10 \).
- Additional mode corresponds to \( n = -2 \) with

\[
P_{-2}^{(I)}(\eta; h) = 27 - 4h^2 + 2(h - 3)(2h - 9)\eta. \quad (A.2)
\]

\[
\mathcal{E}_{-2}^{(I)} = -8(9 - 14h + 4h^2)/(4h - 9) = \mathcal{E}_{-2}^{\text{III}} \left( \frac{3(h - 3)}{4h - 9}, h \right). \quad (A.3)
\]
• Orthonormality relations:

\[
\int_{-1}^{1} d\eta \frac{(1 - \eta)^{n-1/2}(1 + \eta)^{h-5/2}}{(2h\eta - 6\eta - 2h + 3)^4} P_n^{(a)}(\eta; h) P_m^{(a)}(\eta; h) = \delta_{nm}, \quad n, m = -2, 0, 1, 2, \ldots,
\]

\[h_n^{(a)} = 2^{y_n+h-1}(4h - 9)^2(h_n - c_n^{(1)}(\varepsilon_n - \tilde{c}_n^{(1)})h_n), \quad n \neq -2.
\]  

(A.4)

A.2. Case II(a)

• Explicit form of wavefunctions:

\[
\psi_n^{II(a)}(\eta; h) = \frac{(1 - \eta)^{n/2}(1 + \eta)^{h-1/2}}{(2h\eta - 6\eta - 2h + 3)^2} P_n^{II(a)}(\eta; g), \quad n = 0, 1, 2, \ldots,
\]

\[P_n^{II(a)}(\eta; h) = (1458 - 918h - 144h^3 + 160h^4 - 32h^5 - 44h^6 + 264h^2n - 160h^3n
+ 32h^4n - 162h^2n^2 + 288hn^2 - 168h^2n^2 + 32hn^2 + (2187 - 2106h
- 936h^3 + 1776h^3 - 720h^4 + 96h^5 + 323hn - 600h^2n + 256h^3n
- 32h^4n + 486hn^2 - 648h^2n^2 - 32h^4n^2)\eta
+ (-3888h + 6120h^2 - 3624h^3 + 960h^4 - 96h^5 - 192h^6 + 160h^7n
- 32h^4n - 216hn^2 + 168h^2n^2 - 32h^4n^2)\eta^2 + (-2916 + 6048h
- 4932h^2 + 1992h^3 - 400h^4 + 32h^5 - 576hn + 672h^2n - 256h^3n
+ 32h^4n - 648hn^2 + 720hn^2 - 264h^2n^2 + 32hn^3)\eta^3)P_n^{(g-1/2,h-1/2)}(\eta)
+ (-9 + 4h)(-1 + \eta^2)(3 - 2h - 6\eta + 2hn)
\times (27 - 4h^2 + 54\eta - 30hn + 4h^2\eta)\delta_n P_n^{(g-1/2,h-1/2)}(\eta).
\]  

(A.6)

From (4.7), one has \( h > 9/4 \) and \( h \neq 3 \). The square integrability (4.8) is satisfied.

• An additional mode corresponds to \( n = -3 \) with

\[ P_{-3}^{II(a)} = 1, \quad \psi_{-3}^{II(a)} = -\frac{12(27 - 20h + 4h^2)}{-9 + 4h} = \tilde{c}_2^{III} \left( \frac{h}{(4h - 9)}, h \right).
\]  

(A.7)

• Equation satisfied by \( P_n^{II(a)}(\eta; h) \):

\[
(-9 + 4h)(3 - 2h + 2(-3 + h)n)(1 - \eta^2)y_n^{(a)}(\eta)
- ((135 - 198h + 96h^2 - 16h^3)\eta
+ (-3 + h)(-9 - 20h + 12h^2 + (45 - 28h + 4h^2)(2\eta^2 - 1)))y_n^{(a)}(\eta)
+ (3 + n)(27 - 20h + 4h^2 - 9n + 4hn)(3 - 2h - 6\eta + 2hn)y_n^{(a)}(\eta) = 0.
\]  

(A.8)
A.3. Case III(a)

- Explicit form of wavefunctions:

\[
\psi_n^{III(a)}(\eta; h) = \frac{1 - \eta^2}{\sqrt{2h\eta - 2h + 3}} P_n^{III(a)}(\eta; h), \quad n = 0, 1, 2, \ldots.
\]  

\[
P_n^{III(a)}(\eta; h) = (405 - 648h + 72h^2 + 72h^3 + 80h^4 + 32h^5 - 486n + 1620nh - 1728h^2n
\]
\[
+ 432h^3n + 288hn^2 - 128h^2n - 162n + 648hn^2 - 936hn^2 + 576hn^2
\]
\[
- 128h^4n + (810 - 1566h + 612h^2 + 408h^3 - 192h^4 + 96h^5 + 864n)
\]
\[
- 2268hn + 3456h^2n - 1584h^3n - 480h^4n + 384h^5n + 162n^2 + 64hn^2
\]
\[
+ 1656hn^2 - 1344hn^2 + 384hn^2 + (270h + 36h^2 - 528h^3 + 144h^4
\]
\[
+ 96h^2 + 648hn - 1944hn^2 + 1584hn^2 + 96h^4n - 384h^5n + 216hn^2
\]
\[
- 792h^2n + 960h^3n - 384h^4n^2)\eta^2 + (36h^2 + 48h^3 - 32h^4 - 32h^5
\]
\[
+ 216hn^2 - 432h^2n + 96hn^2 + 128h^2n + 72hn^2 - 192hn^2 + 128hn^2)\eta^3
\]
\[
\times P_n^{IV(n, 1/2, 1/2)}(\eta) - 3(3 - 2h + 2h\eta)\eta)
\]
\[
\times (3 - 4h^2 - 2h\eta + 4h^2)\eta \delta_n P_n^{IV(n, 1/2, 1/2)}(\eta).
\]  

(A.11)

From (4.7), one has \( h < 3/4 \) and \( h \neq 0 \). The square integrability (4.8) requires \(-1/2 < h\).

- Additional mode corresponds to \( n = -2 \) with

\[
P_{-2}^{III(a)}(\eta; h) = 3 - 4h^2 + 2h(-1 + 2h)^2\eta.
\]  

(A.12)

\[
\mathcal{E}_{-2}^{III(a)} = -8(-3 - 2h + 4h^2)/(3 + 4h) = \mathcal{E}_1^{III(a)}(3(h - 1)/(4h - 9), h).
\]  

(A.13)

- Equation satisfied by \( P_n^{III(a)} \):

\[
(-3 + 4h^2)(3 - 2h + 2h\eta)(1 - \eta^2)^2\eta^\nu(\eta)
\]
\[
+ (9 + 2h^2 - 12h^3 + 2(9 - 6h - 8h^2 + 8h^3)\eta - 2h(3 - 7h + 2h^2)
\]
\[
\times (2\eta^2 - 1)\eta^\nu(\eta) + (-8h^5(3 + n) - 8h^2(-3 + n^2) - 9(2 + 3n + n^2)
\]
\[
+ 6h(1 + 6n + 3n^2) + 2h(3 + n)(4h^2 - 3n + h(-6 + 4n))\eta)\eta\nu(\eta) = 0.
\]  

(A.14)

- Orthonormality relations:

\[
\int_{-1}^{1} d\eta (1 - \eta)^{3/2}(1 + \eta)h^{-1/2} P_n^{III(a)}(\eta; h) P_m^{III(a)}(\eta; h) = h_n^{III(a)} \delta_{nm}, \quad n, m = -2, 0, 1, 2, \ldots
\]
\[
h_n^{III(a)} \equiv 2^{3h-1} (4h - 3)^4 \left( \mathcal{E}_n - \mathcal{E}_2^{III} \right) \left( \mathcal{E}_n - \mathcal{E}_1^{III} \right) h_n, \quad n \neq -2.
\]  

(A.15)
A.4. Case IV(a)

- \( g = \frac{1}{4} (5h - 8), \) \( \bar{g} = g - 3, \) \( \bar{h} = h - 1. \)

- Explicit form of wavefunctions:

\[
\psi_n^{IV(a)}(\eta; h) = \frac{(1 - \eta) \bar{g}^{\frac{1}{2}} (1 + \eta) \bar{g}^{\frac{1}{2}}}{(2\eta - 2\eta - 2h + 5)^2} \mathcal{P}_n^{IV(a)}(\eta; g), \quad n = 0, 1, 2, \ldots .
\]

\[
\mathcal{P}_n^{IV(a)}(\eta; h) = (133407 - 291870h + 189396h^2 + 30456h^3 - 98352h^4 + 51552h^5 - 12096h^6
+ 185640h - 460616hn + 440564h^3n - 191368h^4n + 24144h^5n + 10356h^6n
- 4352h^7n + 541452n^2 - 147238hn^2 + 165212h^2n^2 - 98712h^3n^2 + 33568h^4n^2
- 6272h^5n^2 + 512h^6n^2 + 128h^7(9 + 4n) + [-194400 + 574560h - 581760h^2

- 249\eta^2 + 59\eta^3) + 2n(-953 + 2373\eta - 1896\eta^2 + 476n^2)]
- 2h[28n^2(-85 + 174\eta - 111\eta^2 + 22\eta^3) + 8n(-895 + 1863\eta - 1212\eta^2
+ 244\eta^3) + 3(-1447 + 3859\eta - 2144\eta^2 + 488n^3)]\eta \delta_n^{IV(1/2,1/2,1/2)}(\eta).

(A.16)

From (4.7), one has \( h < 7/4 \) and \( h \neq 1 \). The square integrability (4.8) requires a stronger condition \( 1/2 < h < 13/10 \).

- There are two additional modes corresponding to \( n = -3 \) and \( n = -2 \):

(i) \( n = -3 \). With

\[
P_{-3}^{IV(a)} = (2h - 5)\eta - 2h + 2, \quad \xi_{-3}^{IV(a)} = \frac{-12(-3 + 2h)(1 + 2h)}{4h - 7} = \xi_2^{III}\left(\frac{3(5h - 8)}{(4h - 7)}, h\right).
\]

(A.17)
Here, we have adopted orthonormality relations:

\[
\left( L_n \right) (\eta) \left( L_m \right) (\eta) = \delta_{nm} (\eta) \delta_{mn}, n, m = -3, -2, 0, 1, 2, \ldots,
\]

\[
h_n^{IV(a)} \overset{\text{def}}{=} 2^{s+h-3} (4h-7)^{\frac{s}{2}} \left( E_n - \tilde{c}_1^{\text{II}} \right) \left( E_n - \tilde{c}_1^{\text{III}} \right) \left( E_n - \tilde{c}_2^{\text{III}} \right) \tilde{h}_n, n \neq -3, -2.
\]

**Laguerre limit.** In the \( h \rightarrow -\infty \) limit as described before, the polynomial \( P_{n}^{IV(a)}(\eta; h) \) \((n = 0, 1, 2, \ldots)\) tends to

\[
\mathcal{L}_n^{\text{New}}(\eta) = \{5265 + (-5616 - 2592\eta)\eta + (11232 + 5184\eta)\eta^2 \}
\]

\[
+ (-6912 - 3072\eta)\eta^3 + (2304 + 1024\eta)\eta^4) L_{n}^{(13/4)}(\eta)
\]

\[
+ \{1620\eta - 4(252 + 144\eta)\eta^2 - 4(-816 - 384\eta)\eta^3
\]

\[
- 4(576 + 256\eta)\eta^4) \delta_n L_{n}^{(13/4)}(\eta).
\]

Here, we have adopted \( \eta \) instead of \( \eta^\dagger \) for the simplicity of presentation. The two additional modes approach to

\[
P_{-3}^{IV(a)} \rightarrow -(4\eta + 3),
\]

\[
P_{-2}^{IV(a)} \rightarrow 4(16\eta^2 + 24\eta + 45).
\]

They satisfy the equation

\[
4\eta(4\eta - 3)\mathcal{L}_n^{\text{New}}(\eta)'' - (4\eta + 3)(4\eta + 5)\mathcal{L}_n^{\text{New}}(\eta)'
\]

\[
+ 4(4n\eta + 16\eta - 3n - 4)\mathcal{L}_n^{\text{New}}(\eta) = 0, n = -3, -2, 0, 1, 2, \ldots
\]
