Abstract

Perovskite solar cells were fabricated and characterized. X-ray diffraction analysis and transmission electron microscopy were used for investigation of the devices. The structure analysis by them showed structural transformation of the crystal structure of the perovskite, which indicated that a cubic-tetragonal crystal system depended on the annealing condition. The photovoltaic properties of the cells also depended on the structures. Metal doping and halogen doping to the perovskite and TiO$_2$ were also investigated. The results showed an increase in the efficiencies of the devices, due to the structural change of the perovskite compound layers.

Keywords: perovskite, solar cell, doping, structure, CH$_3$NH$_3$PbI$_3$, Sb, Cl, TiO$_2$, Nb, Ge, Cs

1. Introduction

Various organic-inorganic hybrid solar cells with perovskite-type pigments have been broadly studied recently [1–4]. Organic solar cells with a CH$_3$NH$_3$PbI$_3$ compound that has a perovskite structure have high conversion efficiencies [5–7]. Since achieving a photoconversion efficiency of 15% [8], higher efficiencies have been reported for various device structures and processes [9–11], and the photoconversion efficiency increased up to ca. 20% [12–18]. The solar cell properties depend on the crystal structures of the perovskite phase, electron transport layers, hole transport layers (HTLs), nanoporous layers, and fabrication process. Especially, the energy band gaps and carrier transport of the perovskite compounds are dependent on the crystal structures [19], and further analyses of the structures and properties are imperative.
In this article, fabrication and characterization of perovskite-type solar cells are reviewed and summarized. Various perovskite compounds, such as CH$_3$NH$_3$PbI$_3$, [HC(NH$_2$)$_2$]PbI$_3$, and CsSnI$_3$, are expected for solar cell materials. Since these perovskite-type materials often have nanostructures in the solar cell devices, information on the crystal structures, fabrication, and characterization would be useful for fabrication of the perovskite-type crystals. Transmission electron microscopy, electron diffraction, and high-resolution electron microscopy are powerful tools for structure analysis of solar cells [20] and perovskite-type structures in atomic scale [21–23].

The crystals of CH$_3$NH$_3$PbX$_3$ (X = Cl, Br, or I) have perovskite structures and provide structural transitions upon heating [24–26]. The crystal structures of cubic, tetragonal, and orthorhombic CH$_3$NH$_3$PbI$_3$ are shown in Figure 1(a)–(c), respectively. Space group is Pm-3m, and the lattice constant $a = 6.391$ Å at 330 K for cubic CH$_3$NH$_3$PbI$_3$ [27]. Hydrogen positions in the orthorhombic CH$_3$NH$_3$PbI$_3$ were also determined at 4 K by neutron diffraction [28], as shown in Figure 1(d). Although the crystals of perovskite CH$_3$NH$_3$PbX$_3$ provide a cubic system as the high-temperature phase, the CH$_3$NH$_3^+$ ions are polar and have a symmetry of C$_3v$. This results in formation of cubic phase with disordering [27]. Besides the CH$_3$NH$_3^+$ ions, disordering of the halogen ions is also observed in the cubic perovskite phase, as indicated in Figure 1(a). Site occupancies of I were 1/4, and those of C and N were 1/12, respectively. The CH$_3$NH$_3$ ion occupies 12 equivalent orientations of the C$_2$ axis, and hydrogen atoms have two kinds of configurations on the C$_2$ axis. Therefore, the total degree of freedom is 24 [26].

![Figure 1](image-url). Structure models of CH$_3$NH$_3$PbI$_3$ with (a) cubic, (b) tetragonal and (c) orthorhombic structures, and (d) orthorhombic CH$_3$NH$_3$PbI$_3$ with hydrogen positions.
In addition to the CH₃NH₃PbI₃ (MAPbI₃), [HC(NH₂)₂]PbI₃ (formamidinium lead iodide, FAPbI₃) provided high conversion efficiencies [17, 18]. Structure parameters, including hydrogen positions, were also determined at 298 K by neutron diffraction [29], and the structure model with the lattice constant \( a = 6.3620 \text{ Å} \) is shown in Figure 2(a).

![Figure 2](Image)

**Figure 2.** Structure models of (a) [HC(NH₂)₂]PbI₃, (b) CsSnI₃, and (c) CsGeI₃ with cubic structures.

CH₃NH₃ ions can be substituted by other elements such as Cs. The structure models of CsSnI₃ and CsGeI₃ for high-temperature phase are shown in Figure 2(b) and (c), respectively [30–32]. Space group is \( Pm-3m \) (\( Z = 1 \)), and \( a = 6.219 \text{ Å} \) at 446 K for CsSnI₃, \( a = 6.05 \text{ Å} \) at 573 K for CsGeI₃, respectively. Solar cells with F-doped CsSnI₂.₉₅F₀.₀₅ provided a photoconversion efficiency of 8.5\% [6].

2. Basic device structures

A typical fabrication process of the TiO₂/CH₃NH₃PbI₃ photovoltaic devices is described here [8, 33, 34]. Fluorine-doped tin oxide (FTO) substrates were washed in an ultrasonic cleaner using methanol and acetone, and then dried in N₂ gas. Precursor solution of 0.30 M TiOₓ was prepared from titanium diisopropoxide bis(acetyl acetonate) with 1-butanol, and the TiOₓ precursor solution was spin-coated on the FTO substrate at 3000 rpm and annealed at 125°C for 5 min. This process was carried out twice, and the FTO substrate was annealed at 500°C for 30 min to form the compact TiO₂ layer as an electron transport layer. After that, TiO₂ paste was coated on the substrate by a spin-coating method at 5000 rpm to form a mesoporous structure. For the mesoporous TiO₂ layer, TiO₂ paste was arranged with TiO₂ powder with poly(ethylene glycol) in ultrapure water. The solution was stirred with triton X-100 and acetylacetone for 30 min. The prepared cells were heated at 120°C, and annealed at 500°C for 30 min in air. Designed for the preparation of pigment with a perovskite structure, a solution of CH₃NH₃I and PbI₂ with a mole ratio of 1:1 in \( \gamma \)-butyrolactone was mixed at 60°C. The mixture solution of CH₃NH₃I and PbI₂ was then poured into the TiO₂ mesopores by spin-coating, and annealed at 100°C. After that, the hole transport layer (HTL) was prepared by the spin coating. For preparation of the HTL, a solution of spiro-OMeTAD in chlorobenzene was mixed with a solution of lithium bis(trifluoromethylsulfonyl) imide (Li-TFSI) in acetonitrile for 12 h. The former solution with 4-tert-butylpyridine was mixed with the Li-TFSI solution at 70°C. Finally, gold (Au) metal contacts were evaporated as top electrodes of the cell. Layered structures of
the present photovoltaic cells were represented as FTO/TiO$_2$/CH$_3$NH$_3$PbI$_3$/Spiro-OMeTAD/Au, as shown in Figure 3.

![Figure 3](image-url)  
Figure 3. Schematic illustration for the fabrication of CH$_3$NH$_3$PbI$_3$ photovoltaic cells.

The typical $J$–$V$ characteristics of the TiO$_2$/CH$_3$NH$_3$PbI$_3$/spiro-OMeTAD photovoltaic cells under illumination are shown in Figure 4(a), which indicates an annealing effect of the CH$_3$NH$_3$PbI$_3$ layer. The as-deposited CH$_3$NH$_3$PbI$_3$ cell provided a conversion efficiency of 2.83%. The CH$_3$NH$_3$PbI$_3$ cell annealed at 100°C for 15 min provided better photovoltaic properties compared with the as-deposited one, as shown in Figure 4(a). The highest efficiency was obtained for the annealed CH$_3$NH$_3$PbI$_3$ cell, which provided a power conversion efficiency of 5.16%, a fill factor of 0.486, a short-circuit current density of 12.9 mA cm$^{-2}$, and an open-
circuit voltage of 0.827 V [35]. **Figure 4(b)** shows results of multiple spin-coating of CH₃NH₃PbI₃, which will be described later.

XRD patterns of CH₃NH₃PbI₃ thin films on the glass substrate are shown in **Figure 5(a)**. The diffraction reflections could be indexed with tetragonal and cubic structures for as-deposited and annealed films, respectively. Though the as-deposited film showed a single phase of the perovskite structure, broader diffraction reflections owing to a PbI₂ phase appeared after annealing, as shown in **Figure 5(a)**. **Figure 5(b) and (c)** is enlarged XRD patterns at 2θ of ~14° and ~28°, respectively. Split diffraction reflections of 002–110 and 004–220 for the as-deposited sample changed into diffraction reflections of 100 and 200 after annealing, which indicate the

![XRD patterns of CH₃NH₃PbI₃ thin films before and after annealing.](image)

**Figure 5.** (a) XRD patterns of CH₃NH₃PbI₃ thin films before and after annealing. Enlarged XRD patterns at 2θ of (b) ~14° and (c) ~28°.
structural transformation from the tetragonal to cubic system. The CH$_3$NH$_3$PbI$_3$ crystals have perovskite structures and provide structural transitions from a tetragonal to a cubic system upon heating at ~330 K, as shown in the structure models of Figure 1(a) and (b). For the high-temperature phase, unit cell volume of the cubic system is 261 Å$^3$, which is bigger compared with that of the tetragonal system (246 Å$^3$), as shown in Table 1 [35]. This might be because of both thermal expansion of the unit cell and atomic disordering of iodine in the cubic structure. As the temperature decreases, the tetragonal structure is transformed to the orthorhombic structure because of ordering of CH$_3$NH$_3$ ions in the unit cell [37].

| Samples          | Crystal system | Lattice constants (Å) | V (Å$^3$) | Z | V/Z (Å$^3$) |
|------------------|----------------|-----------------------|-----------|---|-------------|
| As-deposited     | Tetragonal     | $a = 8.8620$          | 993.10    | 4 | 248.27      |
|                  |                | $c = 12.6453$         |           |   |             |
| Annealed         | Cubic          | $a = 6.2724$          | 246.78    | 1 | 246.78      |
| Ref. [36] (220 K)| Tetragonal     | $a = 8.800$           | 982.33    | 4 | 245.6       |

| Ref. [27] (330 K)| Cubic          | $a = 6.391$           | 261.0     | 1 | 261.0       |

V: unit cell volume; Z: number of chemical units in the unit cell.

Table 1. Measured and reported structural parameters of CH$_3$NH$_3$PbI$_3$.

The XRD results in Figure 5 indicated phase transformation of the CH$_3$NH$_3$PbI$_3$ perovskite structure from the tetragonal to the cubic system by partial separation of PbI$_2$ from the CH$_3$NH$_3$PbI$_3$ phase at elevated temperatures, which would be related to the decrease of the unit cell volume of the perovskite structure from 248.3 to 246.8 Å$^3$, as shown in Table 1. Besides the iodine atoms, Pb atoms may be deficient, and the occupancy of the Pb sites might be smaller than 1. It should be noted that the structural transition of the CH$_3$NH$_3$PbI$_3$ from the tetragonal to cubic system here would be attributed to the formation of PbI$_2$ by decomposition of the CH$_3$NH$_3$PbI$_3$ phase, which is different from the ordinary tetragonal-cubic transition at 330 K [24, 25].

Figure 6(a) and (b) is the TEM image and the electron diffraction pattern of TiO$_2$/CH$_3$NH$_3$PbI$_3$, respectively [35]. The TEM image shows TiO$_2$ nanoparticles with sizes of ~50 nm, and the polycrystalline CH$_3$NH$_3$PbI$_3$ phase shows dark contrast, which is due to Pb having the largest atomic number in the present materials.

The electron diffraction pattern of Figure 6(b) shows the Debye-Scherrer rings from the nanocrystalline TiO$_2$ particles, which can be indexed with the 101, 004, and 200 reflections of anatase-type TiO$_2$. Thickness of the mesoporous TiO$_2$ layer was found to be ~300 nm from atomic force microscopy measurements. Along with the Debye–Scherrer rings of TiO$_2$, diffraction reflections agreeing with the CH$_3$NH$_3$PbI$_3$ structure [6] were observed and indexed, as shown in Figure 6(b). Other diffraction spots, except for the Debye-Scherrer rings of TiO$_2$, are also from the CH$_3$NH$_3$PbI$_3$ nanoparticles. A structure model and its calculated electron diffraction pattern of a cubic CH$_3$NH$_3$PbI$_3$ phase projected along the [210] direction are shown.
in Figure 6(c) and (d), respectively. The calculated electron diffraction pattern agrees well with the observed pattern of Figure 6(b).

**Figure 6.** (a) TEM image and (b) electron diffraction pattern of TiO$_2$/CH$_3$NH$_3$PbI$_3$. “P” indicates CH$_3$NH$_3$PbI$_3$ perovskite phase. (c) Structure model and (d) its calculated electron diffraction pattern of cubic CH$_3$NH$_3$PbI$_3$ projected along the [210] direction.

**Figure 7(a)** is a high-resolution TEM image of the CH$_3$NH$_3$PbI$_3$ taken along the a-axis [33]. The images of thinner parts of the crystals indicate the direct projection of the crystal structure [21, 22]. The darkness and the size of the dark spots corresponding to Pb positions could be directly identified, and atomic positions of iodine (I) in the crystal indicate weak contrast, as compared with the projected atomic structure model of CH$_3$NH$_3$PbI$_3$ along the [100] direction in **Figure 7(b)**. NH$_3$ and CH$_3$ molecules cannot be represented as dark spots in the image, which is due to the smaller atomic number of N and C. **Figure 7(c)** is a high-resolution image of the surface of a TiO$_2$ nanoparticle, which indicates {101} lattice fringes. The $J$–$V$ characteristics of the TiO$_2$/CH$_3$NH$_3$PbI$_3$/spiro-OMeTAD photovoltaic cells prepared by multiple spin-coating of CH$_3$NH$_3$PbI$_3$ are shown in **Figure 4(b)**. **Figure 4(b)** indicates the effect of spin-coating times of CH$_3$NH$_3$PbI$_3$ on the photovoltaic properties. The highest efficiency of 6.96% was achieved for the cell coated for four times, which provided a $J_{SC}$ of 16.5 mA cm$^{-2}$, a $V_{OC}$ of 0.848 V, and $FF$ of 0.496. More spin-coating reduced the efficiencies of the
cells. Although 2-step deposition [8] (spin-coating PbI₂ and dipping in the CH₃NH₃I solution) was also performed in air, the efficiency was lower compared with that by multiple spin-coating, as observed in Figure 4(b). It is believed that the CH₃NH₃PbI₃ phase was embedded inside pores of the mesoporous TiO₂ layer during one- or two-time spin-coating. After the inside pores of the mesoporous TiO₂ were completely filled with the perovskite compound, only the perovskite layer might be formed on the mesoporous TiO₂ layer by four-time spin-coating, which would result in the highest efficiency.

![Figure 7](image)

**Figure 7.** (a) High-resolution TEM image and (b) structure model of CH₃NH₃PbI₃. (c) Lattice image of TiO₂.

The IPCE spectrum of the photovoltaic cell with the TiO₂/CH₃NH₃PbI₃/spiro-OMeTAD structure exhibits photoconversion efficiencies between 300 and 800 nm, which nearly agrees with the measured energy gaps of 1.51 eV [37] for the CH₃NH₃PbI₃ compound. This indicates that excitons might be effectively generated in the perovskite compound layers upon light illumination.

An energy level diagram of TiO₂/CH₃NH₃PbI₃ photovoltaic cells is summarized as shown in Figure 8(a). The electronic charge generation is caused by light irradiation from the FTO substrate side. The TiO₂ layer receives the electrons from the CH₃NH₃PbI₃ crystal, and the electrons are carried to the FTO. On the other hand, the holes are carried to the Au electrode through the HTL of spiro-OMeTAD. For these processes, the devices were produced in air,
which would induce the reduction of device stability. Perovskite compounds with higher crystal quality would be produced in future works.

![Figure 8](image.jpg)

Figure 8. (a) IPCE spectrum and (b) energy level diagram of TiO$_2$/CH$_3$NH$_3$PbI$_3$ cell. (c) Model of interfacial structure.

From the TEM results, size distributions of TiO$_2$ nanoparticles were observed, indicating a microcrystalline structure, as shown in Figure 6(b), and there seems to be no special crystallographic relation at the interface. The interface between the TiO$_2$ and CH$_3$NH$_3$PbI$_3$ phases would not be perfectly connected over the large area. The cell prepared by four-time spin-coating provided the highest efficiency, which would have an interfacial microstructure as shown in Figure 8(b). The layer thickness of the CH$_3$NH$_3$PbI$_3$ phase was too thick for the cells prepared by 10-time spin-coating, which resulted in an increase in the inner electronic resistance and decrease in the efficiency.

As a summary, the structure analysis of TiO$_2$/CH$_3$NH$_3$PbI$_3$ indicated phase transformation of the perovskite structure from the tetragonal to the cubic system by partial separation of PbI$_2$ from the CH$_3$NH$_3$PbI$_3$ compound upon annealing, which was presumed by decrease of the unit cell volume of the perovskite structure and resulted in the enhancement of photovoltaic properties of the devices. Effects of the multiple spin-coating were also investigated, which improved the efficiency when the four-time spin-coating was carried out. The improvement of the devices might attribute to the complete coverage and optimal thickness of the perovskite layer on the porous TiO$_2$. Additionally, the lattice constants and crystallite sizes of the CH$_3$NH$_3$PbI$_3$ increased and decreased, respectively, which indicates the microstructural difference of the perovskite phase between the inside of and above the porous TiO$_2$.

3. Enlargement of cell

Enlargement of the cell area is especially mandatory to enable the use of perovskite devices such as actual commercial solar cell panels [38]. The photovoltaic properties of perovskite-type solar cells with a substrate size of 70 mm × 70 mm were investigated [39].
The photovoltaic devices consisted of a CH$_3$NH$_3$PbI$_3$ compound layer, TiO$_2$ electron transport layers, and spiro-OMeTAD hole-transport layer, prepared by a simple spin-coating technique. The effect of the distance from the center of the cell on conversion efficiency was investigated based on light-induced $J$–$V$ curves and IPCE measurements. A photograph of a perovskite solar cell measuring 70 mm × 70 mm and a schematic illustration of the arrangement of Au electrodes on the substrate are shown in Figure 9(a) and (b), respectively.

![Figure 9. (a) Photograph of perovskite solar cell measuring 70 mm × 70 mm. (b) Schematic illustration of arrangement of Au electrodes on the substrate.](image)

The measured short-circuit current density, open-circuit voltage, fill factor, and photoconversion efficiency of the present TiO$_2$/CH$_3$NH$_3$PbI$_3$ cell as a function of the distance from the center of the cell are shown in Figure 10(a–d), respectively. The highest efficiency was obtained for the electrode at 12.7 mm from the cell center, which provided a photoconversion efficiency of 3.15%, a $V_{OC}$ of 0.653 V, a $J_{SC}$ of 13.0 mA cm$^{-2}$, and a $FF$ of 0.371. Due to the long diffusion length of exciton [40], the $J_{SC}$ values were nearly constant at ~12 mA cm$^{-2}$ for all electrodes on the solar cell, as observed in Figure 10(a). Although the $FF$ value slightly decreased as the distance ($d$) from the center of the cell increased, the deviation was small, as observed in Figure 9(c). On the other hand, the value of $V_{OC}$ depended fairly on the $d$ values, as observed in Figure 10(b), which led to decreased efficiency, as shown in Figure 10(d). The dependency of $V_{OC}$ values on the $d$ values might be related to the thickness of CH$_3$NH$_3$PbI$_3$ layer prepared on the large substrate by the spin-coating method. The low $V_{OC}$ and $FF$ values would be related to the coverage ratio of CH$_3$NH$_3$PbI$_3$ at the TiO$_2$/CH$_3$NH$_3$PbI$_3$ interface, and further multiple spin-coating of CH$_3$NH$_3$PbI$_3$ layers on the TiO$_2$ mesoporous layer would improve the coverage of CH$_3$NH$_3$PbI$_3$ on the TiO$_2$ mesoporous layer, which would induce the increase in the conversion efficiency of the solar cells.

IPCE spectra of electrodes at 4.2, 12.7, and 22.8 mm from the cell center are shown in Figure 10(e). All spectra show similar changes on the wavelength, which agrees with the $J_{SC}$ results shown in Figure 9(a). The perovskite CH$_3$NH$_3$PbI$_3$ structure showed photoconversion within the whole measurement range of 300–800 nm, which nearly agrees with the
reported energy gaps for the CH$_3$NH$_3$PbI$_3$ phase. Control of the energy levels of the conduction band and valence band is important for carrier transport in the cell. The conversion efficiencies obtained for the present cells are lower than the previously reported values. It might be difficult to control the uniformity of the layer thickness and interfacial structure using the spin-coating. In the present work, the samples were prepared in air, which might result in a decrease in the efficiency of the present cells, and perovskite crystals with higher quality and a uniform surface should be prepared in future works.

Figure 10. Measured (a) short-circuit current density; (b) open-circuit voltage; (c) fill factor and (d) conversion efficiency of TiO$_2$/CH$_3$NH$_3$PbI$_3$ cell as a function of the distance from the center of the cell. (e) IPCE spectra of the same cell.

As a summary, perovskite solar cell devices with a substrate size of 70 mm were produced by a spin-coating method using a mixture solution. The photovoltaic properties of the solar cells and the size effect of the substrate were investigated by J–V and IPCE measurements, and the dependency of their conversion efficiency on the distance from the center of the cell was
investigated. Nearly constant values of short-circuit current density were obtained over a large area, due to the long exciton diffusion length of the $\text{CH}_3\text{NH}_3\text{PbI}_3$ compound. The open-circuit voltage fairly depended on the distance from the center of the cell, which led to a change in conversion efficiency. Optimizing the layer thickness and structure would be important for improving the performance of the devices.

4. Electron transport layers

The electron-transport layers (ETLs) such as $\text{TiO}_2$ are also important for the $\text{CH}_3\text{NH}_3\text{PbI}_3$-based photovoltaic devices. Here, niobium (V) ethoxide was chosen as an additional chemical for $\text{TiO}_2$ [41]. When niobium (Nb) atoms with five valence electrons are introduced at Ti sites with four valence electrons, extra electrons are introduced in the 3d band and could work as a donor. Since the energy level of impurity in the $\text{TiO}_2$ band gap is shallow, transparency could be conserved after the Nb doping [42–46]. Additionally, the radius of Nb ion is close to that of the Ti ion, which leads to a solid solution of titanium and niobium in the anatase-type $\text{TiO}_2$ crystal. The $\text{TiO}_2$ crystal added with Nb is denoted as $\text{Ti(Nb)O}_2$ here.

The XRD patterns and crystal structure of $\text{TiO}_2$ and $\text{Ti(Nb)O}_2$ thin films on the FTO substrate are shown in Figure 11(a) and (b), respectively. Diffraction peaks of $\text{TiO}_2$ 101 are observed, and the intensity increased upon Nb-doping. The XRD data indicate that the d-spacing of $\text{Ti(Nb)O}_2$ (1.802 Å) is almost the same as that of $\text{TiO}_2$ (1.807 Å). The crystallite size seems to increase a little upon Nb addition (28 nm) to $\text{TiO}_2$ (24 nm).

![Figure 11. (a) XRD patterns of $\text{TiO}_2$ and $\text{Ti(Nb)O}_2$ thin films on FTO. (b) Crystal structure of $\text{TiO}_2$.](image)

A scanning electron microscopy (SEM) image of the $\text{Ti(Nb)O}_2$ thin film is shown in Figure 12(a), and the image indicates several particles with sizes of ca. 1 μm on the
smooth surface. Elemental mapping images of Ti and Nb using SEM with energy-dispersive X-ray spectroscopy (EDX) are shown in Figure 12(b) and (c), respectively, which indicate that Ti and Nb elements are homogeneously distributed in the films. The elemental ratio of Ti:Nb was estimated to be ~1.00:0.10 from SEM-EDX analysis. The dispersed particles observed in Figure 12(a) were found to be Nb-rich phase, as observed in Figure 12(c), which resulted in an Nb-rich (ca. 9 atomic %) composition compared with the preparation composition (ca. 5 atomic %). From XRD analysis, no diffraction peak corresponding to Nb and Nb₂O₅ was observed.

Figure 12. (a) SEM image of Ti(Nb)O₂ thin film. Elemental mapping of (b) Ti (Lα) and (c) Nb (Lα).

The sheet resistances of TiO₂ and Ti(Nb)O₂ thin films were measured to be 1.7×10⁶ and 4.2×10⁴ Ω/sq, respectively. The sheet resistance significantly decreased upon Nb addition. The J–V characteristics of Ti(Nb)O₂/CH₃NH₃PbI₃/spiro-OMeTAD photovoltaic cells under illumination are shown in Figure 13(a). The detailed parameters of the best device are listed in Table 2. The Ti(Nb)O₂/CH₃NH₃PbI₃ photovoltaic cell provided an η of 6.63%, a FF of 0.416, a J_sc of 20.8 mA cm⁻², and a V_oc of 0.768 V. The J_sc value was especially improved upon Nb

Figure 13. (a) J–V characteristics of Ti(Nb)O₂/CH₃NH₃PbI₃ photovoltaic cells. (b) Differential absorption spectra of TiO₂ and Ti(Nb)O thin films.
addition, which resulted in increased conversion efficiency. The averaged efficiency ($\eta_{ave}$) of three electrodes on the cells is 6.46%, as listed in Table 2.

| ETL          | $J_{sc}$ (mA cm$^{-2}$) | $V_{oc}$ (V) | $FF$ | $\eta$ (%) | $\eta_{ave}$ (%) |
|--------------|-------------------------|--------------|------|------------|------------------|
| TiO$_2$      | 14.6                    | 0.796        | 0.478| 5.56       | 5.03             |
| Ti(Nb)O$_2$  | 20.8                    | 0.768        | 0.416| 6.63       | 6.46             |

Table 2. Measured parameters of Ti(Nb)O$_2$/CH$_3$NH$_3$PbI$_3$ cells.

Figure 13(b) shows differential absorption spectra of FTO/TiO$_2$ and FTO/Ti(Nb)O$_2$ after subtracting the spectrum of the FTO substrate. These absorption spectra appear to be closely equal. Based on the band structure of indirect transition [60], energy gaps for TiO$_2$ and Ti(Nb)O$_2$ were estimated to be 3.54 and 3.52 eV from Figure 13(b), respectively, which indicate that the energy gaps are almost the same for TiO$_2$ and Ti(Nb)O$_2$.

![Figure 13(b)](image)

Figure 14. (a) EQE and (b) IQE spectra of Ti(Nb)O$_2$/CH$_3$NH$_3$PbI$_3$ cells.

The IPCE of the cells was also investigated, and the external quantum efficiency (EQE) and internal quantum efficiency (IQE) were measured by a spectral response system. The EQE spectra of the photovoltaic cells with the Ti(Nb)O$_2$/CH$_3$NH$_3$PbI$_3$/spiro-OMeTAD structure are shown in Figure 14(a). The perovskite CH$_3$NH$_3$PbI$_3$ phase shows photoconversion efficiencies between 300 and 800 nm. By Nb addition into the TiO$_2$ layer, the perovskite CH$_3$NH$_3$PbI$_3$ structure shows high EQE values of ca. 60% at 500–600 nm and ca. 5% at 800 nm, and the IQE was 0% for ordinary TiO$_2$ at 800 nm. The IQE spectra of Ti(Nb)O$_2$/CH$_3$NH$_3$PbI$_3$/spiro-OMeTAD cells were computed from the reflectance and EQE, as shown...
in Figure 14(b). The IQE of both cells increased in the range of 500–800 nm, which implies that suppression of reflection of light in the range of 500–800 nm could increase the photo-conversion efficiencies of the cells. High IQE values of ~70% are seen in the range of 500–600 nm by the Nb addition in the TiO$_2$ layer.

Two mechanisms could be considered for the decrease in the sheet resistances of TiO$_2$ by the Nb addition. The first mechanism is niobium doping at the titanium sites in the TiO$_2$ crystal. Owing to the XRD and differential absorption results of Figures 11(a) and 13(b), the TiO$_2$ phase still preserved the crystal structure, energy gap, and transparency of anatase TiO$_2$. In addition, a small amount of Nb atoms are widely distributed in the TiO$_2$ phase, as observed by SEM-EDX of Figure 10(c) and (d), which could imply a solid solution of titanium and niobium in the TiO$_2$ structure. The extra electron of Nb might be introduced into the 3d band of Ti and behaves as a donor [60]. The second conceivable mechanism is enhancement of carrier transport by formation of niobium-based particles in the TiO$_2$ layer, as observed in SEM-EDX images. Nanoparticles in electron-transport and hole-transport layers could facilitate the carrier transport [47, 48], and the present niobium-based particles might contribute to the carrier transport. Both mechanisms could provide an increase in carrier concentration and transport, and an improvement of conversion efficiency through the increase in $J_{SC}$.

As a summary, Ti(Nb)O$_2$/CH$_3$NH$_3$PbI$_3$-based photovoltaic devices were fabricated by a spin-coating method using a mixture solution of niobium(V) ethoxide, and the effects of Nb addition into the TiO$_2$ layer were investigated. By adding a simple solution of niobium(V) ethoxide to the TiO$_2$ precursor solutions, the sheet resistance of the Ti(Nb)O$_2$ thin film decreased, and the $J_{SC}$ value increased, which resulted in the increase in conversion efficiency.

5. Halogen doping to CH$_3$NH$_3$PbI$_3$

Effects of Cl-doping CH$_3$NH$_3$PbI$_3$ using a mixture solution of perovskite compounds on the microstructures and photovoltaic properties have been investigated [49]. The $J$–$V$ characteristics of the TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$/spiro-OMeTAD photovoltaic cells under illumination are shown in Figure 15(a), which indicate an effect of Cl-doping to the CH$_3$NH$_3$PbI$_3$ layer. Measured photovoltaic parameters of TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$ cells are summarized in Table 3. The CH$_3$NH$_3$PbI$_3$ cell provided a power conversion efficiency of 6.16%, and the averaged efficiency of four electrodes on the cells is 5.53%, as listed in Table 3. The highest efficiency was obtained for the CH$_3$NH$_3$PbI$_{1.88}$Cl$_{0.12}$ cell, which provided an $\eta$ of 8.16%, a $FF$ of 0.504, $J_{SC}$ of 18.6 mA cm$^{-2}$, and a $V_{OC}$ of 0.869 V. As a Cl composition increased, the $J_{SC}$ and $V_{OC}$ decreased, as shown in Figure 15(b) and Table 3. Energy gaps ($E_g$) of CH$_3$NH$_3$PbI$_3$, CH$_3$NH$_3$PbI$_{2.88}$Cl$_{0.12}$, and CH$_3$NH$_3$PbI$_{1.8}$Cl$_{1.2}$ were estimated to be 1.578, 1.590, and 1.593, respectively, from the optical absorption, which indicated the energy gap of CH$_3$NH$_3$PbI$_3$ increased by the Cl-doping.
Table 3. Measured photovoltaic parameters of TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$ cells.

| Preparation composition | $J_{SC}$ (mA cm$^{-2}$) | $V_{OC}$ (V) | FF | $\eta$ (%) | $\eta_{ave}$ (%) |
|-------------------------|--------------------------|-------------|----|------------|-----------------|
| CH$_3$NH$_3$PbI$_3$      | 17.5                     | 0.844       | 0.416 | 6.16        | 5.53            |

Table 4. Measured and reported structural parameters of CH₃NH₃PbI₃−ₓClₓ.

Figure 17. (a) SEM image of TiO₂/CH₃NH₃PbI₂₈Cl₃₁₂. Elemental mapping images of (b) Pb Mα line, (c) I Lα line, and (d) Cl Kα line.

XRD patterns of CH₃NH₃PbI₃−ₓClₓ thin films on the FTO/TiO₂ are shown in Figure 16(a). The temperature for XRD measurements was ~292 K. The diffraction peaks can be indexed by cubic and tetragonal crystal systems for CH₃NH₃PbI₃ and CH₃NH₃PbI₁₈Cl₁₄ films, respectively. Although the deposited films are a single perovskite phase, broader diffraction peaks due to PbI₂ compound appeared in the CH₃NH₃PbI₃ film, as shown in Figure 16(a). Figure 16(b) shows enlarged XRD patterns at 2θ of ~28.5°. A diffraction peak of 200 for the CH₃NH₃PbI₃ split into diffraction peaks of 004/220 for the CH₃NH₃PbI₁₈Cl₁₄ by the heavy Cl-doping, which indicates the structural transformation from the cubic to tetragonal crystal systems [19]. The heavy Cl-doping suppressed the formation of PbI₂, and no PbCl₂ was detected for the CH₃NH₃PbI₁₈Cl₁₄. For the CH₃NH₃PbI₂₈Cl₃₁₂, a small shoulder is observed just left of the 200 reflection as shown in Figure 16(b), which would be due to the pseudocubic structure between the cubic and tetragonal phases. The measured structural parameters of the CH₃NH₃PbI₃−ₓClₓ are summarized in Table 4.
Figure 17(a) is a SEM image of TiO$_2$/CH$_3$NH$_3$PbI$_{2.88}$Cl$_{0.12}$ and the image shows particles with sizes of ca. 10 μm. Mapping images of Pb, I, and Cl elements by SEM equipped with EDX are shown in Figure 17(b–d), respectively. These mapping images of elements indicate that the dispersed particles observed in Figure 17(a) correspond to the perovskite CH$_3$NH$_3$PbI$_x$Cl$_{1-x}$ phase. The composition ratio of Pb:I:Cl was 1.00:2.70:0.11, which was calculated from their EDX spectra using each element's line after background correction by normalizing the spectrum peaks on the atomic concentration of Pb element. The present result indicates that iodine atoms would be deficient comparing with the starting composition of CH$_3$NH$_3$PbI$_{2.88}$Cl$_{0.12}$ and the deficient I might increase the hole concentration. The CH$_3$NH$_3$PbI$_3$ crystals have perovskite structures, and provide structural transitions from tetragonal to cubic system upon heating at ~330 K [27–29].

The XRD results in Figure 16 indicated phase transformation of the CH$_3$NH$_3$PbI$_3$ perovskite structure from tetragonal to cubic system by partial separation of PbI$_2$ from CH$_3$NH$_3$PbI$_3$ phase through the annealing [35], which is related to decrease in the unit cell volume of the cubic CH$_3$NH$_3$PbI$_3$ phase from the normal 261 Å$^3$ to the present 244 Å$^3$, as shown in Table 4. From the SEM-EDX results, the site occupancies of I atom might be smaller than 1, which would also decrease the cell volume. The conversion efficiencies were reported to be increased by the tetragonal to cubic transformation [35].

The X-ray diffraction pattern indicates division of diffraction peaks from C200 to T004/T220 by means of heavy Cl-doping. This designates reduction of the symmetry of the crystal structures from the cubic to tetragonal system, which resulted in decrease of the photoconversion efficiencies. Once a small amount of Cl was added in the CH$_3$NH$_3$PbI$_3$ phase, the cubic structure was still preserved as the pseudocubic phase. The doped Cl atoms would lengthen diffusion length of excitons [7, 40], which would result in the increase of the efficiencies.

EQE spectra of the photovoltaic cell with the TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$/spiro-OMeTAD structure are shown in Figure 18(a). The perovskite CH$_3$NH$_3$PbI$_3$ phase shows photoconversion efficiencies between 300 and 800 nm. In the present work, the energy gap of the CH$_3$NH$_3$PbI$_3$ phase increased from 1.578 to 1.590 eV by Cl-doping, which could contribute to the increase in open-circuit voltage. IQE spectra of TiO$_2$/CH$_3$NH$_3$PbI$_3$ and TiO$_2$/CH$_3$NH$_3$PbI$_{2.88}$Cl$_{0.12}$ were computed from EQE spectra and reflectance, as shown in Figure 18(b). The IQE of both cells increased in the wavelength range of 500–800 nm, and this indicates that improvement of the optical absorption in that range might improve the photoconversion efficiencies of TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$/spiro-OMeTAD cells.

In summary, TiO$_2$/CH$_3$NH$_3$PbI$_{3-x}$Cl$_x$-based photovoltaic devices were fabricated by a spin-coating method using a mixture solution, and effects of PbCl$_2$ addition to the perovskite CH$_3$NH$_3$PbI$_3$ precursor solutions on the photovoltaic properties were investigated. The microstructure analysis showed phase transformation of the perovskite structure from cubic to tetragonal system by heavy Cl-doping to the CH$_3$NH$_3$PbI$_3$ phase. A small amount of Cl-doping (CH$_3$NH$_3$PbI$_{2.9}$Cl$_{0.1}$) at iodine sites increased the efficiencies up to ~8%, and it might be owing to conservation of the cubic perovskite structure and to extension of diffusion length of excitons and energy gap. Both the EQE and IQE increased in the range of 300–800 nm by means of a small amount of Cl-doping, and the IQE data designate that the inhibition of the optical
reflection in the wavelength range of 500–800 nm might improve the photoconversion efficiencies further.

Figure 18. (a) EQE and (b) IQE spectra of CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3} and CH\textsubscript{3}NH\textsubscript{3}Pb\textsubscript{2.92}Cl\textsubscript{0.08} cells.

6. Metal doping to CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3}

The properties of solar cells are dependent on the atomic compositions and the crystal structures of perovskite CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3} compounds. Metal atom and halogen doping such as tin (Sn) and chlorine (Cl)/bromine (Br) at the Pb and I sites, respectively, in the CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3} structure have been investigated [12–14, 50–52]. Particularly, researches of the metal element doping at Pb sites are fascinating in the view of Pb-free devices and influence on the photovoltaic properties.

The objective here is to investigate photovoltaic properties and microstructures of photovoltaic devices with perovskite-type CH\textsubscript{3}NH\textsubscript{3}Pb\textsubscript{1−x}Sb\textsubscript{x}I\textsubscript{3} compounds, prepared by a spin-coating technique in ordinary air. Antimony (Sb) is an element in the group 15 and might work as electronic carriers at the Pb sites in the group 14. Effects of SbI\textsubscript{3} addition to a CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3} mixed solution on the microstructures and photovoltaic properties were investigated [53, 54].

The J–V characteristics of the TiO\textsubscript{2}/CH\textsubscript{3}NH\textsubscript{3}Pb\textsubscript{1−x}Sb\textsubscript{x}I\textsubscript{3}/spiro-OMeTAD photovoltaic cells under illumination are shown in Figure 19(a), which indicate an effect of Sb addition to CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3}. The measured photovoltaic parameters of TiO\textsubscript{2}/CH\textsubscript{3}NH\textsubscript{3}Pb\textsubscript{1−x}Sb\textsubscript{x}I\textsubscript{3} cells are summarized in Table 5.

The CH\textsubscript{3}NH\textsubscript{3}PbI\textsubscript{3} cell provided a power conversion efficiency of 6.56\%, and the averaged efficiency of four electrodes on the cells is 6.37\%, as listed in Table 5. The highest efficiency was obtained for the CH\textsubscript{3}NH\textsubscript{3}Pb\textsubscript{0.97}Sb\textsubscript{0.03}I\textsubscript{3} cell, which provided an η of 9.07\%, a FF of 0.560, a J\textsubscript{SC} of 19.2 mA cm\textsuperscript{−2}, and a V\textsubscript{OC} of 0.843V. As the x value (preparation composition of Sb)
increased, the efficiencies decreased, as shown in Figure 19(b) and Table 5. An η of 9.7% was also reported by addition of SbI₃ and NH₄Cl to the CH₃NH₃PbI₃ [54].

*Figure 19.* (a) J–V characteristics of TiO₂/CH₃NH₃Pb₁₋ₓSbxI₃ photovoltaic cells. (b) Conversion efficiencies of CH₃NH₃Pb₁₋ₓSbxI₃ as a function of Sb concentration.

| Sb (x) | J_SC (mA cm⁻²) | V_OC (V) | FF | η (%) | ηave (%) |
|--------|----------------|---------|----|-------|----------|
| 0.00   | 17.0           | 0.758   | 0.509 | 6.56  | 6.37     |
| 0.01   | 16.0           | 0.789   | 0.534 | 6.74  | 6.41     |
| 0.02   | 16.9           | 0.792   | 0.518 | 6.94  | 6.72     |
| 0.03   | 19.2           | 0.843   | 0.560 | 9.07  | 8.47     |
| 0.05   | 15.7           | 0.755   | 0.575 | 6.82  | 5.61     |
| 0.07   | 14.7           | 0.692   | 0.502 | 5.11  | 4.07     |

Preparation compositions of Sb are indicated by x.

*Table 5.* Measured photovoltaic parameters of TiO₂/CH₃NH₃Pb₁₋ₓSbxI₃ cells.

IPCE spectra of the CH₃NH₃PbI₃ and CH₃NH₃Pb₀.₉₇Sb₀.₀₃I₃ cells are shown in Figure 20. The perovskite CH₃NH₃Pb₁₋ₓSbxI₃ shows photoconversion efficiencies between 300 and 800 nm. The IPCE was improved in the range of 350–770 nm by adding a small amount of Sb.

XRD patterns of CH₃NH₃Pb₁₋ₓSbxI₃ cells on the FTO/TiO₂ are shown in Figure 21(a). The diffraction peaks can be indexed by a cubic crystal system (Pm3m) for the CH₃NH₃Pb₁₋ₓSbxI₃ thin films. Although the deposited films are a single perovskite structure, broader diffraction peaks due to the PbI₂ compound appeared in the CH₃NH₃PbI₃ film, as shown in Figure 21(a). The Sb addition suppressed the formation of PbI₂ and most of PbI₂ was not detected for the CH₃NH₃Pb₁₋ₓSbxI₃ cells with x > 0.03. Figure 21(b) shows measured lattice constants a of CH₃NH₃Pb₁₋ₓSbxI₃ as a function of Sb concentration. A small
increase in lattice constants $a$ is observed for $x = 0.03$ and 0.05, and further addition of Sb decreases the lattice constants, which seems to be a significant difference from the error bar. The XRD result of $\text{CH}_3\text{NH}_3\text{PbI}_3$ in Figure 21(a) showed the existence of PbI$_2$ after annealing at 100°C for 15 min. This would indicate partial separation of PbI$_2$ from $\text{CH}_3\text{NH}_3\text{PbI}_3$ after annealing, which also might correspond to the smaller lattice constant $a$ (6.266 Å) of the cubic perovskite structure, compared with that (6.391 Å) of $\text{CH}_3\text{NH}_3\text{PbI}_3$ single crystal reported in Ref. [27].

Increase in the photoconversion efficiencies could be explained by two mechanisms. The first mechanism is Sb doping effect at the Pb atom sites. The ionic valence of Sb is three, and it is higher compared with that of Pb$^{2+}$. Then, the excess charge of Sb$^{3+}$ might work as carriers in the $\text{CH}_3\text{NH}_3\text{Pb}_{1-x}\text{Sb}_x\text{I}_3$ crystal, and the $J_{SC}$ values were improved. The second mechanism is described as follows: I$^-$ ions might be attracted at the I sites by Sb$^{3+}$ with more ionic valence.
compared with that of Pb\(^{2+}\), which resulted in the suppression of PbI\(_2\) elimination from CH\(_3\)NH\(_3\)PbI\(_3\) and in the increase of lattice constants \(a\) of CH\(_3\)NH\(_3\)PbI\(_3\). The suppression of PbI\(_3\) would improve the interfacial structure of TiO\(_2\)/CH\(_3\)NH\(_3\)PbI\(_3\), which might result in improvement of \(V_{\text{OC}}\). The lattice constants are expected to be decreased by an increase in the amount of Sb with an ionic size smaller than Pb. Other elemental dopings such as Ge, Tl, and In at the Pb sites were also reported \[55, 56\].

In summary, TiO\(_2\)/CH\(_3\)NH\(_3\)Pb\(_{1-x}\)Sb\(_x\)I\(_3\)-based photovoltaic devices were fabricated, and the effects of SbI\(_3\) addition to the perovskite CH\(_3\)NH\(_3\)PbI\(_3\) precursor solutions on the photovoltaic properties were investigated. The microstructures of the devices indicated that the lattice constant of CH\(_3\)NH\(_3\)Pb\(_{1-x}\)Sb\(_x\)I\(_3\) increased a little, and that the formation of PbI\(_2\) was inhibited by the addition of a small amount of Sb, which led to the improvement of the conversion efficiencies to \(\sim 9\%\). The IPCE also increased in the range of 350–770 nm by the addition of Sb.

7. Conclusion

Various TiO\(_2\)/CH\(_3\)NH\(_3\)PbI\(_3\)-based photovoltaic devices were fabricated and characterized. Especially, effects of metal doping and halogen doping to the perovskite and TiO\(_2\) were investigated. Microstructure analysis indicated the changes of the perovskite structure, which resulted in the improvement of photovoltaic properties of the devices. Various elemental dopings to the perovskite structure could be studied further both by experiments and theoretical calculations as follows: Cs, Rb, and K doping to the CH\(_3\)NH\(_3\) positions for stability of the structure; Ge, Sn, and Sb doping to the Pb positions for improvement of the semiconducting properties; Cl, Br, and F doping to the I positions for enhancement of carrier mobility.
