AN EXTENSION OF A LOGARITHMIC FORM OF CRAMÉR’S RUIN THEOREM TO SOME FARIMA AND RELATED PROCESSES

Ph. Barbe\(^{(1)}\) and W.P. McCormick\(^{(2)}\)
\(^{(1)}\)CNRS, France, \(^{(2)}\)University of Georgia

Abstract. Cramér’s theorem provides an estimate for the tail probability of the maximum of a random walk with negative drift and increments having a moment generating function finite in a neighborhood of the origin. The class of \((g, F)\)-processes generalizes in a natural way random walks and fractional ARIMA models used in time series analysis. For those \((g, F)\)-processes with negative drift, we obtain a logarithmic estimate of the tail probability of their maximum, under conditions comparable to Cramér’s. Furthermore, we exhibit the most likely paths as well as the most likely behavior of the innovations leading to a large maximum.

Keywords: maximum of random walk, Cramér’s theorem, fractional ARIMA process, ruin probability, large deviations.

1. Introduction. Cramér’s theorem on the maximum of a random walk with negative drift provides an estimate for the tail probability of this maximum when the moment generating function of the increments is finite in a neighborhood of the origin. Specifically, writing \(M\) for the maximum of the random walk, it asserts that there are constants \(c\) and \(\theta\) such that

\[
P\{ M > t \} \sim c e^{-\theta t} \tag{1.1}
\]

as \(t\) tends to infinity; the constants \(c\) and \(\theta\) are explicit, but their formulas are irrelevant to the current discussion. We refer to Feller (1971, §XI.7) for a proof of Cramér’s theorem.

The purpose of this paper is to make a first step toward an extension of Cramér’s result to a wider class of stochastic processes which encompass some fractional ARIMA ones. As explained in Barbe and McCormick (2008) where we dealt with the analogous problem in the heavy tail context, the motivations are manifold. To summarize, besides the original application to insurance mathematics which motivated Cramér, other areas of applications exist, such as queueing theory — the connection between risk and queueing theory was pointed out in Prabhu (1961); see e.g. Janssen (1982) for an account
on this connection; furthermore, on a more fundamental level, a cer-
tain analogy, described in Barbe and McCormick (2008), has been
developed between the asymptotic theory of the usual random walk
and that of some FARIMA processes, and it is natural to investigate
to which extent this analogy carries over in the context of Cramér’s theorem.

Previous authors have considered ruin probabilities associated
with processes with dependent innovations. For instance, using a
martingale technique, Gerber (1982) considered bounded ARMA
increments. His result was extended by Promislow (1991) who
removed the boundedness assumption and dealt with a larger class
of increments. In contrast, using large deviations theory, building
upon the work of Burton and Dehling (1990) as well as Iscoe,
Ney and Nummelin (1985), Nyrhinen (1994, 1995, 1998) considered
increments following a stationary linear process with some having
a Markovian structure. Müller and Pflug (2001) extended some
of Nyrhinen’s results by relating the asymptotic behavior of the
moment generating function of the ruin process at time $n$, as $n$
tends to infinity, to the behavior of its maximum, hence, showing
that the Gärtner-Ellis (Gärtner, 1977; Ellis, 1984) approach in
large deviations leads to a ruin probability estimate. A common
feature of these works is that the processes under consideration
exhibit short range dependence in order to have an explicit behavior
of some moment generating functions. In contrast, the study of
ruin probability associated to continuous time processes has recently
focussed on long range dependent models. For instance, combining
Duffield and O’Connell (1995) with Chang, Yao and Zajic (1999)
yields ruin probability estimates for some nonnecessarily Gaussian
long range memory processes modeled after the fractional Brownian
motion. More precise results were obtained by Hüsler and Piterbarg
(2004) for some Gaussian processes. Our results may be viewed as
a non-Gaussian and discrete analogues of those continuous ones, in
the sense that we are interested in processes exhibiting long range
dependence. Interestingly, for some values of their paramaters, the
processes considered in this paper, suitably rescaled and normalized,
converge to some fractional Brownian motions.

A true extension of Cramér’s theorem to FARIMA processes
seems beyond what one can achieve at the present, and we will only
consider a logarithmic form of it, namely, after taking the logarithm
The paper is organized as follows. The class of stochastic processes which we will consider and the main result are described in the next section. In section 3 we describe the most likely scenario leading to a ruin, that is to a large maximum of the processes under consideration. Section 4 contains a broad outline of the proof. In section 5, we prove some large deviations results which are of independent interest and lead to the proof — inspired by Collamore (1996) — of the results of section 2. The result of section 3 is proved in section 6.

**Notation.** Throughout this paper, if \((a_n)\) and \((b_n)\) are two sequences, we say that ‘\(a_n\) is lower bounded from above by an equivalent of \(b_n\)’ and write \(a_n \lesssim b_n\) if \(a_n \leq b_n(1 + o(1))\) as \(n\) tends to infinity, or, equivalently, if \(\limsup_{n \to \infty} a_n/b_n \leq 1\). The symbol \(\gtrsim\) is defined in an analogous way.

**2. Main result.** Barbe and McCormick (2008) introduced \((g, F)\)-processes as a natural extension of FARIMA processes. To define such a process, we start with a function \(g\) which is real analytic on \((-1, 1)\) and a distribution function \(F\). The function \(g\) has a Taylor series expansion

\[
g(x) = \sum_{i \geq 0} g_i x^i.
\]

Considering a sequence \((X_i)_{i \geq 1}\) of independent and identically distributed random variables with common distribution function \(F\), we define the \((g, F)\)-process \((S_n)_{n \geq 0}\) by \(S_0 = 0\) and

\[
S_n = \sum_{0 \leq i < n} g_i X_{n-i}.
\]

When \(g(x) = (1 - x)^{-1}\), the corresponding process is the random walk associated to the sequence \((X_n)_{n \geq 1}\). Some nonstationary ARMA processes are obtained when \(g\) is a rational function, and FARIMA processes are obtained when \(g(x)\) is the product of some negative power of \(1 - x\) and a rational function in \(x\).

For the process to drift toward minus infinity and mimic the behavior of the random walk involved in Cramér’s theorem, it is
natural to impose that the mean $\mu$ of $F$ is negative and that

$$\lim_{n \to \infty} \sum_{0 \leq i < n} g_i = +\infty. \tag{2.1}$$

Indeed, in this case, the expectation of $S_n$ drifts toward minus infinity. A consequence of (2.1) is that $g$ has a singularity at 1. To obtain a satisfactory theory, we need to restrict the type of singularity by assuming that $g$ is regularly varying at 1 of positive index, meaning, as explained for instance in Bingham, Goldie and Teugels (1989), that there exists a positive $\gamma$ such that for any positive $\lambda$,

$$\lim_{t \to \infty} \frac{g(1 - 1/\lambda t)}{g(1 - 1/t)} = \lambda^\gamma.$$  

This assumption is satisfied by ARIMA processes.

Let $\text{Id}$ be the identity function on the real line. We then consider a function $U$, defined up to asymptotic equivalence by the requirement

$$g(1 - 1/U) \sim \text{Id}$$

at infinity. This function, which plays a key role in our result, is necessarily regularly varying at infinity of index $1/\gamma$. However, for notational simplicity, writing $\Gamma(\cdot)$ for the gamma function, it will be better to use the function

$$V = \Gamma(1 + \gamma)^{1/\gamma} U,$$

which could alternatively be defined by the requirement $g(1 - 1/V) \sim \Gamma(1 + \gamma) \text{Id}$ at infinity.

In order to concentrate on the principles and the key arguments, we assume throughout this paper that the coefficients $g_i$ are nonnegative. This restriction can be overcome with the introduction of the proper tail balance condition.

To have a compact notation, we introduce the kernel

$$k_{\gamma}(u) = \begin{cases} \gamma(1 - u)^{\gamma-1} & \text{if } 0 \leq u < 1, \\ 0 & \text{if } u \geq 1, \end{cases}$$

defined on the nonnegative half-line.

Further notation related to large deviations theory is needed in order to state our main result. As the proof shows, the appearance
of some large deviations formalism is not coincidental. Cramér’s theorem assumes that the moment generating function

\[ \varphi(\lambda) = \mathbb{E}e^{\lambda X_1} \]

is finite in a neighborhood of the origin. A classical consequence of Hölder’s inequality is that \( \log \varphi \) is convex. This implies that the function

\[ \lambda \mapsto \int_0^1 \log \varphi(\lambda k_\gamma(u)) \, du \]

is convex as well on its domain. This function will be of importance in our results. It is not clear a priori that this function is nontrivial in the sense that if \( \gamma \) is less than 1 it could be infinite for all nonvanishing \( \lambda \). This suggests that we should consider two cases, according to the finiteness of the integral involved in (2.2).

The convex conjugate (see e.g. Rockafellar, 1970) of the function involved in (2.2), at a nonnegative argument \( a \), is

\[ J(a) = \sup_{\lambda > 0} \left( a\lambda - \int_0^1 \log \varphi(\lambda k_\gamma(u)) \, du \right). \]

To a moment generating function \( \varphi \) one also associates the corresponding mean function \( m \), which is the derivative \( (\log \varphi)' \) — see Barndorff-Nielsen (1978), Brown (1986) or Letac (1992).

The following convention will be convenient. We say that a \((g,F)\)-process satisfies the standard assumption if it satisfies the following

**Standard assumption.** The function \( g \) is regularly varying of positive index at 1 and its coefficients \((g_i)_{i \geq 0}\) are nonnegative. Moreover \( g_0 \) does not vanish. In case the sequence \((g_n)_{n \geq 0}\) converges to 0, it is asymptotically equivalent to a monotone sequence. The distribution function \( F \) has a moment generating function finite on the nonnegative half-line. The image of the mean function contains the half line \([0,\infty)\).

With respect to the monotonicity requirement for the sequence \((g_n)_{n \geq 0}\) involved in the standard assumption, it will follow from Proposition 1.5.3 in Bingham, Goldie and Teugels (1989) and Lemma 5.1.1 that regular variation of \( g \) implies that \((g_n)_{n \geq 1}\) is asymptotically equivalent to a monotone sequence whenever the index of regular variation of \( g \) is different from 1.
Let \((S_n)_{n\geq 0}\) be a \((g, F)\)-process. If the first \(k\) coefficients \(g_0, g_1, \ldots, g_{k-1}\) vanish and \(g_k\) does not, then \((S_{n+k})_{n\geq 1}\) is a \((g/\text{Id}^k, F)\)-process, and the first Taylor coefficient of \(g/\text{Id}^k\) does not vanish. Thus, in the standard assumption, the condition that \(g_0\) does not vanish bears no restriction.

Note that in the standard assumption, the condition on the moment generating function is stronger than in Cramér’s theorem. The assumption on the mean function is a rather standard one in large deviations theory. Hölder’s inequality implies that \(\log \varphi\) is convex and the mean function is nondecreasing. Our assumption ensures that the equation \(m(\lambda) = x\) has a solution for every positive \(x\).

We also say that a \((g, F)\)-process satisfying the standard assumption has a negative mean if its expectation is negative at all time. Since the innovations are independent and identically distributed, considering the expectation of the process at time 1, this is equivalent to require that the innovations have negative mean.

Our first result treats the case where the integral (2.2) is finite. It calls for many remarks, stated after the theorem, which will clarify both the hypotheses and the conclusion.

**Theorem 2.1.** Consider a negative mean \((g, F)\)-process which satisfies the standard assumption. Assume that either one of the following conditions hold:

(i) \(\limsup_{n \to \infty} \max_{0 \leq i < n} \frac{g_i}{g_n}\) is finite;

(ii) \(\lim_{n \to \infty} \max_{0 \leq i \leq n} \frac{g_i}{g_n} = +\infty\) and \(- \log F\) is regularly varying with index \(\alpha\) such that \(\alpha \gamma > 1\); moreover, \(m'\) is regularly varying.

Then, the function \(J\) is defined and finite on the nonnegative half-line and the maximum \(M\) of the \((g, F)\)-process satisfies

\[
\lim_{t \to \infty} V(t)^{-1} \log P\{ M > t \} = - \inf_{x > 0} xJ(x^{-\gamma}).
\]

We now make some remarks on the conclusion of the theorem, which will be followed by remarks on its assumptions.

Writing \(\theta\) for the negative of the limit involved in its statement, this theorem asserts that

\[
P\{ M > t \} \sim e^{-\theta V(t)(1+o(1))}
\]
as $t$ tends to infinity. This leads to the following observation which may constitute a caveat of pedagogical value. Fix the distribution function $F$ and consider the analytic function $g$ as a parameter. As we increase its singularity at 1, the process drifts toward minus infinity at a faster rate, for its mean at time $n$ is $\mu \sum_{0 \leq i < n} g_i$. One might guess that this makes it harder for the process to reach a high threshold. However, our theorem asserts that the logarithmic order of this probability is $-V(t)$, which becomes larger with $g$. So, making the mean to diverge to minus infinity faster, makes it more likely for the process to reach a high level! This phenomenon will be explained in the next section.

In the same spirit, it will follow from equality (5.2.13) that multiplying the $X_i$ by a scale factor $\sigma$ divides $\theta$ by $\sigma^{1/\gamma}$. Thus, increasing the drift toward minus infinity through a scaling increases the likelihood for $M$ to take very large values.

On a different note, we see that as in Cramér’s theorem, the tail of the distribution function of the increments is involved in the conclusion of Theorem 2.1 only in the constant $\theta$ and not in the logarithmic decay $V$.

It is also of interest to note that if $\gamma$ is greater than 1, then $V \ll \text{Id}$ at infinity. In this case, Theorem 2.1 shows that the distribution of the maximum of the process is subexponential, even though the innovations are superexponential. Such a possibility was observed in a different context by Kesten (1973).

Regarding the assumptions of Theorem 2.1, note that in case (i) we must have $\gamma$ at least 1. In case (ii), the condition that $\max_{0 \leq i \leq n} g_i / g_n$ diverges to infinity is equivalent to the convergence of $(g_n)_{n \geq 0}$ to 0, which forces $\gamma$ to be at most 1.

Let $\beta$ be the conjugate exponent of $\alpha$, that is such that $\alpha^{-1} + \beta^{-1} = 1$. It follows from Kasahara’s theorem (Bingham, Goldie and Teugels, 1989, Theorem 4.12.7) that $-\log F$ is regularly varying of index $\alpha$ if and only if $\log \varphi$ is regularly varying of index $\beta$. Since $\log \varphi$ is convex, its derivative is monotone, and the monotone density theorem combined with Kasahara’s theorem implies that $-\log F$ is regularly varying of index $\alpha$ if and only if $m$ is regularly varying of index $\beta - 1$. The assumption on $m'$ in Theorem 2.1 is stronger. This assumption is not completely satisfactory since its meaning in terms of the distribution function is not clear.

Under the assumptions of Theorem 2.1, we must have $\beta - 2 > -1$. Hence, using Karamata’s theorem in addition to the previous
paragraph, we see that the assumption of Theorem 2.1 on \(- \log F\) and \(m'\) is equivalent to the single assumption that \(m'\) is regularly varying of index \(\beta - 2\) with \(\beta(1 - \gamma) < 1\).

Our second result considers the case where the integral involved in (2.2) is infinite, and hence the function \(J\) in Theorem 2.1 is not defined. This essentially occurs when \(\gamma\) is less than 1 and \(\alpha\gamma\) is at most 1. If \(\gamma\) is less than 1/2 then the centered process \(S_n - ES_n\) converges in \(L^2\). For \(\gamma\) less than 1/2, let \(Z_n\) be the linear process

\[
Z_n = \sum_{i \geq 0} g_i (X_{n-i} - \mu).
\]

In this case, we see that the ruin problem for \(S_n\) is rather similar to that of determining the probability that the process \((Z_n)_{n \geq 1}\) crosses the moving boundary \(t - ES_n\). This problem is of somewhat different nature than what is the focus of this paper, for the centered process is well approximated by a stationary one. Therefore, we will limit ourselves to the case where \(\gamma\) is greater than 1/2.

We write \(|g|_\beta\) for the \(\ell_\beta\)-norm of the sequence of its coefficients, that is for \((\sum_{i \geq 0} |g_i|^{\beta})^{1/\beta}\).

**Theorem 2.2.** Consider a \((g,F)\)-process which satisfies the standard assumption and with \(1/2 < \gamma < 1\). Assume furthermore that \(- \log F\) is regularly varying of index \(\alpha\) greater than 1 and that \(\alpha\gamma < 1\). Let \(\beta\) be the conjugate exponent of \(\alpha\). Then, the maximum \(M\) of the process satisfies

\[
\log P\{ M > t \} \sim |g|_\beta^{-\alpha} \log F(t).
\]

as \(t\) tends to infinity.

Comparing Theorems 2.2 and 2.1, we see that in Theorem 2.2, the condition \(\alpha\gamma < 1\) forces the rate of growth of \(- \log F(t)\), regularly varying of index \(\alpha\), to be much slower than that of \(U(t)\), regularly varying of index \(1/\gamma\).

**3. How to go bankrupt?** The purpose of this section is to determine the most likely paths which lead to the maximum of our \((g,F)\)-processes to reach a high threshold. Beyond its relevance to choosing interesting alternatives in change point problems, in the
context of ruin probability, this amounts to find the most likely way of becoming bankrupted. In a different context, high risk scenarios have been the subject of Balkema and Embrechts (2007) monograph where further discussion of the topic may be found. More closely related to the topic of this paper, is the work of Chang, Yao and Zajic (1999) in the continuous setting, who consider the analogous problem for fractional integrals of continuous time processes. In fact we are seeking more information. Not only are we interested in the most likely paths, but we would also like to understand how they arise, and, therefore, have a description of the innovations as well.

In the heavy tail case, it is shown in Barbe and McCormick (2008) that a large value of the maximum of the process is most likely caused by a large value of an innovation. In contrast, in a slightly different setting than that of the current paper, but nonetheless related, for the usual random walk, Csiszár (1984, Theorem 1) shows that a large deviation is likely caused by a cooperative behavior of the increments which pushes the sum upward. More precisely, Csiszár’s result implies that the conditional distribution of the first increment, given that the sum $S_n$ exceeds an unlikely threshold $nu$, converges to the distribution $dF_u(x) = e^{m→(u)x} dF(x)/φ ∘ m→(u)$. The distribution $dF_u$ has mean $u$. For the usual random walk, since the increments are exchangeable given their sum, Csiszár’s result asserts that, loosely, a randomly chosen increment, or a typical increment, has a conditional distribution about $dF_u$. Thus, asymptotically, the bulk of the increments behave like a random variable of mean $u$ under the conditional distribution that the random walk at time $n$ exceeds $nu$. We refer to Diaconis and Freedman (1988) for a refined result in the framework of exponential families.

In general, for $(g, F)$-processes, the innovations are not exchangeable given the value of the process at time $n$, and, paralleling what has been done for the random walk, it is of interest to identify the cooperative behavior of the increments, if any, which makes the process to reach a high level.

Besides a theoretical understanding, this type of conditional limiting result has some bearing on simulation techniques of rare events by importance sampling (Hammersley and Handscomb, 1964). Indeed, when specialized to the regular random walk, Sadowsky (1996) gives a rationale for using the limiting conditional distribution of the increments to simulate unlikely paths of random walks using importance sampling; see also Dieker and Mandjes (2006). Our
result is a key building block to extend this technique to some FARIMA processes, and, more generally, to \((g,F)\)-processes.

To investigate these questions, we consider first the rescaled trajectory

$$S_t(\lambda) = S_{\lfloor \lambda V(t) \rfloor} / t, \quad \lambda \geq 0.$$  

Next, to study the behavior of the innovation, we consider the sequential measure

$$M_t = \frac{1}{V(t)} \sum_{i \geq 1} \delta_{(i/V(t), X_i)}$$

which puts mass \(1/V(t)\) at each pair \((i/V(t), X_i)\). In contrast with a standard empirical measure which would put equal mass on each innovation up to some fixed time, the sequential measure keeps track of the sequential ordering of the innovation through the first component \(i/V(t)\).

Of further interest is also the normalized first time that the process reaches the level \(t\),

$$\mathcal{N}_t = \frac{1}{V(t)} \min \{ n : S_n > t \}.$$  

In order to speak of convergence of the stochastic process \(S_t\), we view it in the Skorohod space \(D[0, \infty)\) equipped with the Skorohod topology (Billingsley, 1968; Lindvall, 1973).

In what follows, we call \([0, \infty) \times \mathbb{R}\) the right half-space. A subset of the right half-space of the form \([a, b] \times \mathbb{R}\) is called a vertical strip.

The measure \(M_t\) belongs to the space \(\mathcal{M}([0, \infty) \times \mathbb{R})\) of \(\sigma\)-finite measures on the right half-space. We consider this space equipped with a topology between those of vague and weak* convergences defined as follows. Let \(C_{K,b}([0, \infty) \times \mathbb{R})\) be the space of all real-valued continuous and bounded functions on the right half-space, supported on a vertical strip. A basis for the topology on \(\mathcal{M}([0, \infty) \times \mathbb{R})\) is defined by the sets

$$\left\{ \mu \in \mathcal{M}([0, \infty) \times \mathbb{R}) : \forall i = 1, \ldots, k, \left| \int f_i d(\mu - \nu) \right| < \epsilon \right\},$$

indexed by

$$\nu \in \mathcal{M}([0, \infty) \times \mathbb{R}), \quad f_i \in C_{K,b}([0, \infty) \times \mathbb{R}), \quad \epsilon > 0.$$
In this paper, except specified otherwise, all convergences of measures on the right half-space are for this topology.

Our next result gives the limit in probability of the various quantities introduced, conditionally on having the process reaching the level $t$, and under the assumptions of Theorem 2.1. We assume that
\[ \tau = \arg \min_{x > 0} x J(x^{-\gamma}) \text{ is unique.} \tag{3.1} \]

Furthermore, we define the constant $A$ to be the solution of
\[ \tau^{-\gamma} = \int_0^1 k_{\gamma}(u) m(Ak_{\gamma}(u)) \, du. \tag{3.2} \]

Let $L$ be the Lebesgue measure. We define the measure $\mathcal{M}$ by its density with respect to the product measure $L \otimes F$,
\[ \frac{d\mathcal{M}}{d(L \otimes F)}(v, x) = \exp(A k_{\gamma}(v/\tau) x) \varphi(k_{\gamma}(v/\tau)). \tag{3.3} \]

In particular, since $k_{\gamma}$ vanishes on $[1, \infty)$, the measure $\mathcal{M}$ coincides with $L \otimes F$ on $[\tau, \infty) \times \mathbb{R}$. We also define the function
\[ S(\lambda) = \int_0^\lambda \gamma(\lambda - v)\gamma^{-1} m(Ak_{\gamma}(v/\tau)) \, dv. \tag{3.4} \]

Writing
\[ S(\lambda) = \lambda^\gamma \int_0^1 k_{\gamma}(v) m(Ak_{\gamma}(v/\tau)) \, dv \]
and using (3.2), we see that $S(\tau) = 1$.

The following result describes the most likely ruin scenario.

**Theorem 3.1.** Under the assumptions of Theorem 2.1, the following hold in probability under the conditional probability given $M > t$ as $t$ tends to infinity:
(i) $N_t$ converges to $\tau$;
(ii) $M_t$ converges to $\mathcal{M}$;
(iii) moreover, if the moment generating function of $|X_1|$ is finite in a neighborhood of the origin, then $S_t$ converges locally uniformly to $S$.

Regarding the hypotheses of Theorem 3.1, under those of Theorem 2.1, the assumption that the moment generating function of $|X_1|$...
is finite in a neighborhood of the origin is weaker than a tail balance condition. A close look at the proof shows that this assumption is used only to prove assertion (ii) — see Lemma 6.3.1.

Loosely speaking, the meaning of assertion (ii) is that the conditional distribution of $X_{[vV(t)]}$ given $M > t$ converges to the measure

$$
\begin{cases}
  e^{A\gamma(1-v/\tau)^{\gamma-1}x} \varphi(A\gamma(1-v/\tau)^{\gamma-1}) \, dF(x) & \text{if } v \leq \tau \\
  dF(x) & \text{if } v > \tau,
\end{cases}
$$

with mean $m(A\gamma(1-v/\tau)^{\gamma-1})$ if $v < \tau$, and $\mu$ if $v \geq \tau$. Thus it asserts that a large value of $M$ is likely caused by a cooperative behavior of the random variables up to a time $\tau V(t)(1+o(1))$, while the remainder of the innovations keep their original distribution. This somewhat confirms that the Cramér ruin model might be unrealistic in some situations. Indeed, Theorem 3.1 shows that for the process to reach the large level $t$, both the increments and the process, from the very beginning, have to follow a very unlikely path. One would think that seeing such a strange path unfolding, a careful insurer would quickly reexamine the model and raise the premium accordingly.

Theorem 3.1 also explains why Theorem 2.1 implies that for those $(g,F)$-processes, adding more drift toward minus infinity may increase the likelihood of a large maximum. Indeed Theorem 3.1 indicates that a large value of the maximum is likely caused by many innovation being large; but if the weights $(g_n)_{n \geq 0}$ are made larger, then comparatively smaller innovation suffices for the maximum of the process to reach a large value, because the coefficients $(g_n)_{n \geq 0}$ amplify the innovations.

We now consider an example of processes of interest and for which the limit involved in Theorems 2.1 or 2.2 can be made explicit. In general this limit must be evaluated by numerical methods.

We consider a Gaussian FARIMA process. More specifically, we consider $F$ to be the Gaussian distribution function with mean $\mu$ and variance $\sigma^2$, and we introduce two polynomials $\Theta$ and $\Phi$, neither of which vanishes at 1. We consider the function $g(x) = (1 - x)^{-\gamma}\Theta(x)/\Phi(x)$, so that the corresponding $(g,F)$-process is a FARIMA($\Phi,\gamma,\Theta$) process whose innovations have a common distribution function $F$. For this specific function $g$ we may take $U(t) = (t\Phi(1)/\Theta(1))^{1/\gamma}$. 

12
The moment generating function of the innovations is
\[ \varphi(\lambda) = e^{\lambda \mu + \sigma^2 \lambda^2 / 2}. \]
The function involved in (2.2) is then
\[ \gamma \int_0^1 \mu \gamma u^\gamma - 1 + \frac{\sigma^2}{2} (\lambda \gamma u^\gamma - 1)^2 \, du = \lambda \mu + \frac{\sigma^2}{2} \lambda^2 \frac{\gamma^2}{2\gamma - 1}. \]
This implies that
\[ J(a) = \sup_\lambda \left( a \lambda - \lambda \mu - \frac{\sigma^2}{2} \lambda^2 \frac{\gamma^2}{2\gamma - 1} \right) \]
\[ = \frac{(a - \mu)^2 (2\gamma - 1)}{2\sigma^2 \gamma^2}. \]
Using standard calculus one more time, we obtain
\[ \inf_{x > 0} x J(x^{-\gamma}) = \frac{2(2\gamma - 1)^{1/\gamma - 1}}{\sigma^2} (-\mu)^{-1/\gamma}. \]
Therefore, the conclusion of Theorem 2.1 is that
\[ \log P\{M > t\} \sim -t^{1/\gamma} \left( \frac{\Phi(1)}{\Theta(1)} \right)^{1/\gamma} \Gamma(1 + \gamma)^{1/\gamma} 2(2\gamma - 1)^{(1/\gamma) - 1} \left( \frac{\mu}{\sigma} \right)^2 (-\mu)^{-1/\gamma} \]
as \( t \) tends to infinity.
To calculate the limiting process \( S \), for simplicity we restrict ourselves to the case where the mean \( \mu \) is \(-1\) and the standard deviation \( \sigma \) is 1. Then, \( m(\lambda) = \lambda - 1 \), and
\[ S(\lambda) = A \int_0^{\lambda \wedge \tau} \gamma (\lambda - v)^{\gamma - 1} \gamma \left( 1 - \frac{v}{\tau} \right)^{\gamma - 1} \, dv - \lambda^\gamma. \]
The following graphic shows the shape of the limiting function when \( \gamma \) is \( 2/3 \), 1 and 2.
We conclude this section by some remarks concerning Theorem 3.1 and its proof. A close look at the proofs of Theorems 2.1 and 3.1 reveals that the same technique allows one to derive a large deviations principle for the process $S_t$ and the measure $M_t$ under the conditional distribution of $M$ exceeding $t$, as $t$ tends to infinity, in the spirit of Collamore (1998).

One can also see that under the assumptions of Theorem 2.1, the large deviations principle for FARIMA processes proved in Barbe and Broniatowski (1998) remains true when the order of differentiation $\gamma$ is between $1/2$ and 1 and that the logarithm of the tail of the distribution function of the innovation is regularly varying with index greater than $1/\gamma$. This has the following interesting consequence about the standard partial sum process, $\Pi_n(\lambda) = n^{-1} \sum_{1 \leq i \leq n \lambda} X_i, 0 \leq \lambda \leq 1$. Consider the Cramér transform of the increment, $I(x) = \sup_\lambda \lambda x - \log \varphi(\lambda)$. Mogulskii’s (1976) theorem (see also Dembo and Zeitouni, 1993, §5.1) asserts that the partial sum process obeys a large deviations principle, in the supremum norm topology. We can write the partial sum process at time $t$ as $\int_0^\lambda d\Pi_n(v) = \int 1_{[0,\lambda]}(v) d\Pi_n(v)$. One could then wonder if some fractional integral of $\Pi_n$ still obeys a large deviations principle. While an integration by parts shows that for $\gamma$ greater than 1, the process $\lambda \in [0,1] \mapsto \int_0^\lambda (\lambda - v)^{\gamma-1} d\Pi_n(v)$ obeys a large deviation, the proof of Theorem 3.1 shows that such a large deviations principle still holds if $1/2 < \gamma < 1$, provided that $\log F$ is regularly varying of index greater than $1/\gamma$. The Gaussian case, $\alpha = 2$ appears to be a boundary one corresponding to $\gamma = 1/2$; and this matches the fact that the Brownian motion belongs to any set of functions with Hölder exponent less than $1/2$.

4. Generalities. The study of first passage times using large deviations is by now a classical topic which has been presented in book form by Freidlin and Wentzell’s (1984). The purpose of this section is to give another short variation on this theme, with a formalism more suitable for the problems considered in this paper. What follows is inspired by the work of Collamore (1998) as well as Duffield and Whitt (1998). However, in contrast to those authors, we are interested in processes which are not Markovian, not mixing and not monotone.

Some notation will purposely be identical to those used in the previous sections, the reason being that they have the same meaning.
when specialized to the context of the previous sections; this will be clear during the proofs of Theorems 2.1, 2.2 and 3.1.

In what follows, sequences are viewed as functions defined on the nonnegative half-line and evaluated at the integers. Therefore, if we write \((a_n)_{n \geq 1}\) for a sequence, we will also speak of the function \(a\), meaning that \(a_n = a(n)\) for every positive integer \(n\). If we are given the sequence, it is understood that the function \(a\) is obtained by a linear interpolation say; other ‘reasonable’ interpolation procedures would do just as well.

In this section we consider a stochastic process \((S_0^n)_{n \geq 1}\) and a sequence \((s_n)_{n \geq 1}\) which diverges to infinity. We are interested in evaluating the probability that the process \((S_0^n)_{n \geq 1}\) crosses the moving boundary \((t + s_n)_{n \geq 1}\) for large values \(t\). In other words, assuming that \(M = \max_{n \geq 1} S_0^n - s_n\) is well defined, we are interested in finding an estimate of

\[
P\{ \exists n \geq 1 : S_0^n > t + s_n \} = P\{ M > t \}
\]

as \(t\) tends to infinity. Assuming that the function \(s\) is regularly varying of positive index \(\gamma\),

\[
s \circ V \sim \text{Id} \quad \text{at infinity.}
\]

there exists a function \(V\), defined, up to asymptotic equivalence, by the relation \(s \circ V \sim \text{Id} \) at infinity. Also of interest is the normalized first passage time at which the process crosses the moving boundary,

\[
N_t = \frac{1}{V(t)} \min\{ n \geq 1 : S_0^n > t + s_n \}.
\]

Suppose that \((S_0^n)_{n \geq 1}\) obeys a large deviations principle in the sense that there exist two functions \(r\) and \(I\) such that for any positive \(x\)

\[
\log P\{ S_0^n > s_n x \} \sim -r_n I(x)
\]

as \(n\) tends to infinity. Since the left hand side of (4.2) is montone in \(x\), so is the right hand side, and, necessarily, \(I\) is monotone as well as continuous almost everywhere. If we assume more, namely that

\[
I \text{ is continuous},
\]

then the asymptotic equivalence in (4.2) holds locally uniformly in \(x\) over the nonnegative half-line, because a pointwise convergent sequence of nondecreasing functions whose limit is continuous converges locally uniformly (see Rudin, 1976, chapter 7, exercise 13).
For our problem, we will be able to assume that

\[ r \text{ is regularly varying of positive index } \rho. \quad (4.4) \]

In this case, \( r \) is asymptotically equivalent to a nondecreasing function, and we will consider, without any loss of generality, that \( r \) is nondecreasing. We define \( \theta \) as

\[ \theta = \inf_{x > 0} x^\rho I(x^{-\gamma} + 1). \quad (4.5) \]

We will also assume that the process is unlikely to reach the moving boundary \( t + s_n \) before a time of order \( V(t) \), in the sense that

\[ \lim_{\epsilon \to 0} \limsup_{t \to \infty} \frac{1}{r \circ V(t)} \log P\{ \exists n : 1 \leq n \leq \epsilon V(t) ; S_n^0 > t + s_n \} \leq -\theta. \quad (4.6) \]

Equipped with these perhaps drastically looking — but to be proved useful — conditions, we have the following.

**Proposition 4.1.** If (4.1)–(4.6) hold, then

\[ \log P\{ M > t \} \sim -\theta r \circ V(t) \]

as \( t \) tends to infinity. Moreover, if

\[ \tau = \arg \min_{x > 0} x^\rho I(x^{-\gamma} + 1) \text{ exists and is unique}, \quad (4.7) \]

then \( N_t \) converges to \( \tau \) in probability given \( M > t \), as \( t \) tends to infinity.

**Remark.** If we replace assumption (4.2) by

\[ \log P\{ S_n^0 > xs_n \} \lesssim -r_n I(x) \quad (4.8) \]

as \( n \) tends to infinity, the proof of Proposition 4.1 shows that

\[ \log P\{ M > t \} \lesssim -\theta r \circ V(t) \]

as \( t \) tends to infinity. This remark will be useful to prove Theorem 2.2.
In order to prove Proposition 4.1, we need the following lemma.

**Lemma 4.2.** Let $r$ be a nondecreasing regularly varying function of positive index. Then

$$\sum_{n \geq k} e^{-r_n} \lesssim k e^{-r_k}$$

as $k$ tends to infinity.

**Proof.** Since $r$ is nondecreasing,

$$\sum_{n \geq k+1} e^{-r_n} \leq \int_{k}^{\infty} e^{-r(x)} \, dx$$

$$= e^{-r_k} \int \{ k \leq x ; r(x) \leq r(k) + u \} e^{-u} \, du \, dx. \quad (4.9)$$

Let $\rho$ be the index of regular variation of $r$. Let $\epsilon$ be an arbitrary positive real number. Using Potter’s bound, if $k$ is large enough and $x \geq k$ then $r(x)/r(k) \geq (1 - \epsilon)(x/k)^{\rho - \epsilon}$. In particular, if moreover $r(x) \leq r(k) + u$, then

$$x \leq k \left( \frac{1}{1 - \epsilon} \left(1 + \frac{u}{r(k)} \right) \right)^{1/(\rho - \epsilon)}.$$

Thus, for $k$ large enough and after permuting the integration with respect to $u$ and $x$, (4.9) is at most

$$k \frac{e^{-r_k}}{(1 - \epsilon)^{1/(\rho - \epsilon)}} \int_{0}^{\infty} \left(1 + \frac{u}{r(k)} \right)^{1/(\rho - \epsilon)} e^{-u} \, du.$$

It follows from Lebesgue’s dominated convergence theorem that this bound is asymptotically equivalent to $k e^{-r_k}/(1 - \epsilon)^{1/(\rho - \epsilon)}$ as $k$ tends to infinity. Since $\epsilon$ is arbitrary, this yields the result. 

**Proof of Proposition 4.1.** The proof of the first assertion consists in establishing the proper upper and lower bounds.

*Upper bound.* Let $\epsilon$ be a positive real number less than 1. For $t$ large enough and uniformly in $n$ between $\epsilon V(t)$ and $V(t)/\epsilon$,

$$r_n = r \left( V(t) \frac{n}{V(t)} \right) \sim r \circ V(t) \left( \frac{n}{V(t)} \right)^{\rho}$$
and
\[
\frac{t}{s_n} = \frac{t}{s(t)\left(\frac{n}{V(t)}\right)} \sim \left(\frac{n}{V(t)}\right)^{-\gamma}
\]
as \(t\) tends to infinity. In particular,
\[
r_nI\left(\frac{t}{s_n} + 1\right) \sim r \circ V(t)\left(\frac{n}{V(t)}\right)^{\gamma} I\left(\left(\frac{n}{V(t)}\right)^{-\gamma} + 1\right)
\]
\[\geq r \circ V(t)\theta.\]
Combining this lower bound with the large deviations assumption (4.2) yields, in the range of \(n\) between \(\epsilon V(t)\) and \(V(t)/\epsilon\) and for \(t\) large enough,
\[
P\{S_0^n > t + s_n\} \leq \exp\left(-r \circ V(t)\theta(1 - \epsilon)\right). \tag{4.10}
\]
It follows that for \(t\) large enough,
\[
P\{\exists n : \epsilon V(t) \leq n \leq V(t)/\epsilon; S_0^n > t + s_n\}
\]
\[\leq \frac{V(t)}{\epsilon} \exp\left(-r \circ V(t)\theta(1 - \epsilon)\right).
\]
Still using the large deviations assumption (4.2), for \(n\) at least \(V(t)/\epsilon\) and \(t\) large enough, we have
\[
P\{S_0^n > t + s_n\} \leq P\{S_0^n > s_n\}
\]
\[\leq e^{-r_n I(1)/2}.
\]
Thus, for \(t\) large enough, using Lemma 4.2,
\[
P\{\exists n : n \geq V(t)/\epsilon; S_0^n > t + s_n\} \leq e^{-r_n I(1)/2}
\]
\[\leq e^{-1}V(t)e^{-r \circ V(t)I(1)/2\epsilon^\nu}.
\]
Taking \(\epsilon\) small enough, it follows that
\[
\log P\{\exists n : n \geq V(t)/\epsilon; S_0^n > t + s_n\} \leq -2r \circ V(t)\theta
\]
as \(t\) tends to infinity. Using assumption (4.6), we conclude that
\[
\log P\{M > t\} \leq -r \circ V(t)\theta
\]
asymptotically.

Lower bound. Let $\epsilon$ be a positive real number and let $x$ be a positive real number such that $x^\rho I(x^{-\gamma} + 1) \leq \theta + \epsilon$. Let $n$ be the integer part of $xV(t)$. Then

$$P\{ M > t \} \geq P\{ S_0^n > t + s_n \}.$$  

Using the large deviations hypothesis (4.2), we deduce

$$\log P\{ M > t \} \gtrsim - r_n I\left( \frac{t}{s_n} + 1 \right)$$

$$\sim - r \circ V(t) x^\rho I(x^{-\gamma} + 1)$$

$$\gtrsim - r \circ V(t) (\theta + \epsilon). \tag{4.11}$$

Since $\epsilon$ is arbitrary, the first assertion of Proposition 4.1 follows.

To prove the second assertion, note that estimate (4.2) with (4.7) imply

$$P\{ |N_t - \tau| > \eta \mid M > t \} \leq \frac{P\{ \exists n : |n - \tau V(t)| > \eta V(t) ; S_0^n > t + s_n \} \cdot P\{ M > t \}}{P\{ M > t \}}$$

tends to 0 as $t$ tends to infinity. The second assertion follows.

5. Proof of results of Section 2. Except if indicated otherwise, we will assume that the mean of the innovations, $\mu$, is $-1$. Other values of $\mu$ will be dealt with by a scaling argument.

To obtain pleasing expressions, for every positive real number $r$ we write $g_{[0,r)}$ for $\sum_{0 \leq i < r} g_i$ and we also write $s_n$ for the negative of the mean of $S_n$, that is $s_n = g_{[0,n)}$ — recall our assumption that $\mu$ is $-1$ until further notice. With the notation of the previous section, $S_0^n$ is the centered process $S_n - ES_n = S_n + s_n$. Moreover, $V$ is defined by $s_{\lfloor V(t) \rfloor} \sim t$ as $t$ tends to infinity.

5.1. Preliminary. The following lemma, relating $g_n$ and $g_{[0,n)}$ to $g(1 - 1/n)$ will be very useful. It essentially restates Karamata’s Tauberian theorem for power series (Bingham, Goldie and Teugels, 1989, Corollary 1.7.3) and is proved in Lemma 5.1.1 in Barbe and McCormick (2008). We state it here for the sake of making the proof easier to read, for it is fundamental in our problem and we will refer to it often.
Lemma 5.1.1. The following asymptotic equivalences hold as $n$ tends to infinity, uniformly in $x$ in any compact subset of the positive half-line,

(i) $g_{[nx]} \sim \frac{x^{\gamma - 1}}{\Gamma(\gamma)} g(1 - 1/n)$, 
(ii) $g_{(0, nx)} \sim \frac{x^\gamma}{\Gamma(1 + \gamma)} g(1 - 1/n)$.

In particular, this implies that $g_n \sim \gamma g_{(0,n)}/n$ as $n$ tends to infinity, so that locally uniformly in any positive $c$,

$$g_{[cV(t)]} \sim \gamma c^{\gamma - 1} \frac{t}{V(t)} \quad (5.1.1)$$

as $t$ tends to infinity.

We introduce the notation $g_{i/n}$ for $\gamma g_i/g_n$ in which the subscript $i/n$ has clearly nothing to do with the division of $i$ by $n$ but serves as a mnemonic for the division of $g_i$ by $g_n$. In particular, $g_{n-i/n}$ is $\gamma g_{n-i}/g_n$. Lemma 5.1.1 asserts that $g_{n-i/n} \sim k_\gamma(i/n)$ as $n$ tends to infinity and $i/n$ stays bounded away from 1.

The following easy lemma is recorded for further reference.

Lemma 5.1.2. Let $c_1 = \liminf_{n \to \infty} g_n$ and $c_2 = \limsup_{n \to \infty} \max_{0 \leq i \leq n} g_{i/n}$.

(i) If $c_1$ is positive, then $U \lesssim \Id/c_1 \Gamma(\gamma)$ at infinity.
(ii) Assume that $c_2$ is finite. If the sequence $(g_n)_{n \geq 0}$ is bounded, then $U \lesssim c_2 \Id/\gamma \max_{i \geq 0} g_i$; otherwise $U = o(\Id)$ at infinity.

Proof. To prove (i), Lemma 5.1.1.i ensures that

$$g(1 - 1/n) \gtrsim \Gamma(\gamma) c_1 n$$

as $n$ tends to infinity. Therefore, since $g$ is regularly varying,

$$\Id \sim g(1 - 1/U) \gtrsim c_1 \Gamma(\gamma) U$$

at infinity, and the result follows.

To prove (ii), let $c$ be a number greater than $c_2$ and let $k$ be an integer such that $g_k$ is positive. Then $g_n \gtrsim \gamma g_k/c$ for any $n$ larger
than some $n_0$. Therefore, on $[0,1)$, the function $g$ is bounded from below by a polynomial of degree $n_0$ plus the function

$$
\frac{\gamma g_k}{c} \sum_{n \geq n_0} x^n = \frac{\gamma g_k}{c(1-x)} x^{n_0}.
$$

This implies that

$$
\text{Id} \sim g(1 - 1/U) \gtrsim (\gamma g_k/c)U
$$
at infinity. Since $c$ and $k$ are arbitrary, this proves assertion (ii).

Our next lemma is perhaps the heart of the proof, which ultimately relies on approximation of Riemann sums by Riemann integral, a modicum of regular variation, and the exponential form of Markov’s inequality.

We define the sequence of probability measures

$$
\Gamma_n = n^{-1} \sum_{1 \leq i \leq n} \delta_{(i/n, g_{n-i/n})}, \quad n \geq 1.
$$

Lemma 5.1.3. The sequence of probability measures $(\Gamma_n)_{n \geq 1}$ converges weakly* to the measure $\int_0^1 \delta_{(u, k_\gamma(u))} du$.

Proof. Let $f$ be a nonnegative continuous and bounded function on $[0,1] \times \mathbb{R}$. We write $|f|_{[0,1] \times \mathbb{R}}$ for its supremum on the strip $[0,1] \times \mathbb{R}$. Let $\epsilon$ be a positive real number less than 1. Note that

$$
n^{-1} \sum_{(1-\epsilon)n < i \leq n} f(i/n, g_{n-i/n}) \leq \epsilon |f|_{[0,1] \times \mathbb{R}}.
$$

Uniformly in $i$ between 1 and $(1-\epsilon)n$, Lemma 5.1.1 shows that $g_{n-i/n} \sim k_\gamma(i/n)$. Thus, since the measure $n^{-1} \sum_{1 \leq i \leq n} \delta_{i/n}$ converges weakly* to the Lebesgue measure on $[0,1]$ as $n$ tends to infinity,

$$
\lim_{n \to \infty} n^{-1} \sum_{1 \leq i \leq (1-\epsilon)n} f(i/n, g_{n-i/n}) = \int_0^{1-\epsilon} f(u, k_\gamma(u)) du ,
$$

and the result follows.  

21
In order to simplify the notation during the proof and make a later scaling argument easier to follow, we write \( \varphi_0 \) for the moment generating function of the centered random variable \( (X_1/\mu) + 1 \). Furthermore, we write

\[
J_0(a) = \sup_{\lambda > 0} \left( a\lambda - \int_0^1 \log \varphi_0(\lambda k_\gamma(u)) \, du \right).
\] (5.1.2)

The equality \( \varphi_0(\lambda) = e^{\lambda \varphi(\lambda/\mu)} \), valid for all \( \lambda \) positive, yields

\[
J_0(a + 1) = \sup_{\lambda > 0} \left( (a + 1)\lambda - \int_0^1 \log \varphi_0(\lambda k_\gamma(u)) \, du \right) = J(-\mu a). \tag{5.1.3}
\]

5.2. Proof of Theorem 2.1. Recall that except if specified otherwise, we consider the mean \( \mu \) to be \(-1\). Also, throughout this subsection, we assume that the hypotheses of Theorem 2.1 hold, even if this is not specified.

The proof is based on a large deviations estimate which is the analogue for \((g,F)\)-process of the classical estimate of Chernoff for the sample mean. The proof requires several lemmas.

Our first lemma will be useful in taking limits in various sums involving the moment generating function.

**Lemma 5.2.1.** Let \( h \) be a continuous function on the nonnegative half-line. Assume \( g \) satisfies the assumption of Theorem 2.1. If \( \lim_{n \to \infty} \max_{0 \leq i \leq n} g_{i/n} = \infty \), assume further that \( h \) is regularly varying of index \( \beta \) less than \( 1/(1 - \gamma) \). Then, locally uniformly in \( \lambda \) in \((0, \infty)\),

\[
\lim_{n \to \infty} n^{-1} \sum_{1 \leq i \leq n} h(\lambda g_{n-i/n}) = \int_0^1 h(\lambda k_\gamma(u)) \, du,
\]

and this limit is finite.

When \( \lim_{n \to \infty} \max_{0 \leq i \leq n} g_{i/n} = \infty \) and \( \gamma = 1 \), the condition on \( h \) should simply be read as \( h \) is regularly varying of some positive index.

**Proof.** Note first that in both cases, \( \lim_{u \to 0} \int_0^u h(\lambda u^{\gamma-1}) \, du = 0 \) and the integral involved in the limit in the lemma is indeed finite.
Once the limit is established for a fixed $\lambda$, it will be clear that using the uniform convergence theorem for regularly varying functions, the limit is locally uniform in $\lambda$. Thus, up to changing the function $h$, it suffices to prove the result only when $\lambda$ is 1.

For any positive real number $c$ we define the function $h_c = h(\cdot \wedge c)$. These functions are continuous and bounded.

If $\limsup_{n \to \infty} \max_{0 \leq i \leq n} g_i/n$ is finite, we take $c$ to be twice this limit, so that for $n$ large enough, $\max_{0 \leq i \leq n} g_i/n$ is at most $c$. Then

$$n^{-1} \sum_{1 \leq i \leq n} h(g_{n-i}/n) = \int h_c(x) d\Gamma_n(v, x)$$

and the result follows from Lemma 5.1.3 and the local uniform continuity in $\lambda$ of the functions $h_c(\lambda \cdot)$.

If $\lim_{n \to \infty} \max_{0 \leq i \leq n} g_i/n$ is infinite, let $\epsilon$ be a positive real number less than 1. Since $\lim_{n \to \infty} \max_{\epsilon n \leq i \leq n} g_i/n = \epsilon^{-1}$ is finite, it suffices to prove that

$$\lim_{\epsilon \to 0} \limsup_{n \to \infty} n^{-1} \sum_{0 \leq i \leq \epsilon n} h(g_i/n) = 0. \quad (5.2.1)$$

Let $\delta$ be a positive real number, small enough so that $\beta(1 - \gamma + \delta)$ is less than 1. Lemma 5.1.1 and Potter’s bound (Bingham, Goldie and Teugels, 1989, Theorem 1.5.6) show that there exists $n_0$ such that whenever $n$ and $i$ are at least $n_0$, then $g_i/n$ is at most $2\gamma(i/n)^{\gamma-1-\delta}$. Since $h$ is regularly varying with positive index $\beta$, it is asymptotically equivalent to a nondecreasing function (Bingham, Goldie and Teugels, 1989, Theorem 1.5.3). Hence, provided $n$ is large enough,

$$n^{-1} \sum_{n_0 \leq i < n} h(g_i/n) \leq 2n^{-1} \sum_{n_0 < i \leq n} h(2\gamma(i/n)^{\gamma-1-\delta})$$

$$\leq 4 \int_{\epsilon}^{\infty} h(2\gamma u^{\gamma-1-\delta}) du.$$

Moreover, for $M$ large enough and as $n$ tends to infinity,

$$n^{-1} \sum_{0 \leq i < n_0} h(g_i/n) \leq n^{-1} n_0 h(M/g_n)$$

$$= O\left(n^{-1} h(n/(g(1-1/n)))\right).$$
This bounds tends to 0 as \( n \) tends to infinity since the function \( x \mapsto x^{-1}h(x/g(1-1/x)) \) is regularly varying with negative index \( \beta(1-\gamma)-1 \). This proves (5.2.1).

Equipped with Lemma 5.2.1, we can prove the following large deviation principle. Recall that we assume for the time being that the distribution function \( F \) has mean \(-1\). We write \( F_0 \) for the cumulative distribution function \( F(\cdot-1) \). As the subscript indicates, its mean is 0.

**Proposition 5.2.2.** Let \((S_n^0)_{n \geq 0}\) be a centered \((g,F_0)\)-process. Under the assumptions of Theorem 2.1, for any nonnegative \( x \),

\[
\lim_{n \to \infty} n^{-1} \log P\{S_n^0 > x g_{[0,n)}\} = -J_0(x).
\]

Moreover, the limit is locally uniform in \( x \) on the set where \( J_0 \) is finite.

**Proof.** The proof is modeled after the standard one for the mean. We will concentrate on proving a pointwise version in \( x \) because the following purely analytical argument gives the local uniformity. If the pointwise result holds, it asserts that the sequence of nonincreasing functions \((n^{-1} \log P\{S_n > g_{[0,n)} \cdot \})_{n \geq 1}\) converges to the function \(-J_0\); since the limit is continuous, and monotone as a limit of monotone functions, the convergence is locally uniform (see Rudin, 1976, chapter 7, exercise 13).

**Upper bound.** Let \( \lambda \) be a positive real number. Using the exponential Markov inequality,

\[
P\left\{ \frac{\gamma S_n^0}{g_n} > x \frac{g_{[0,n)}}{g_n} \right\} \leq \exp\left( -\lambda x \frac{\gamma g_{[0,n)}}{g_n} + \sum_{1 \leq i \leq n} \log \varphi_0(\lambda g_n - i/n) \right).
\]

This implies that

\[
\limsup_{n \to \infty} n^{-1} \log P\{S_n^0 > x g_{[0,n)}\} \leq \limsup_{n \to \infty}\left( -\lambda x \frac{\gamma g_{[0,n)}}{ng_n} + n^{-1} \sum_{1 \leq i \leq n} \log \varphi_0(\lambda g_n - i/n) \right). \tag{5.2.2}
\]

Note that Lemma 5.1.1 implies that

\[
\frac{\gamma g_{[0,n)}}{ng_n} \sim 1
\]
while Lemma 5.2.1 yields, in view of the fact that $\log \varphi_0$ is regularly varying with index $\beta$, the conjugate exponent to $\alpha$, and $\alpha \gamma > 1$, that

$$n^{-1} \sum_{1 \leq i \leq n} \log \varphi_0(\lambda g_{n-i/n}) \sim \int_0^1 \log \varphi_0(\lambda k_r(u)) \, du$$

as $n$ tends to infinity. Therefore, the right hand side of (5.2.2) tends to

$$-\lambda x + \int_0^1 \log \varphi_0(\lambda k_r(u)) \, du$$

as $n$ tends to infinity. The infimum of this upper bound over all $\lambda$ positive is $-J_0(x)$.

**Lower bound.** We write $\mathbb{1}\{ \}$ for the indicator function of a set. For any fixed $\lambda$, the equality

$$P\left\{ \frac{S_n^0}{g_n} > x \frac{g(0,n)}{g_n} \right\}$$

$$= \left( \prod_{1 \leq i \leq n} \varphi_0(\lambda g_{n-i/n}) e^{-\lambda x g(0,n)/g_n} \right) \int \mathbb{1}\{ \frac{S_n^0}{g_n} \geq x \frac{g(0,n)}{g_n} \} e^{-\lambda x}$$

$$\times e^{-\lambda x \sum_{1 \leq i \leq n} g_{n-i/n} x_i} e^{\lambda x g(0,n)/g_n}$$

$$\times \prod_{1 \leq i \leq n} \varphi_0(\lambda g_{n-i/n}) \, dF_0(x_1) \ldots dF_0(x_n)$$

holds. We write $Q_{\lambda,n}$ for the image measure of the probability measure

$$e^{\lambda \sum_{1 \leq i \leq n} g_{n-i/n} x_i} \prod_{1 \leq i \leq n} \varphi_0(\lambda g_{n-i/n}) \, dF_0(x_1) \ldots dF_0(x_n)$$

through the map

$$(x_1, \ldots, x_n) \mapsto \sum_{1 \leq i \leq n} g_{n-i/n} x_i - x \frac{g(0,n)}{g_n}.$$ 

Writing $R$ for a random variable having distribution $Q_{\lambda,n}$, equality (5.2.3) is equivalent to

$$P\{ S_n^0 > x g(0,n) \}$$

$$= \prod_{1 \leq i \leq n} \varphi_0(\lambda g_{n-i/n}) e^{-\lambda x g(0,n)/g_n} E \mathbb{1}\{ R \geq 0 \} e^{-\lambda R}.$$  (5.2.4)
The moment generating function of $R$ evaluated at $\zeta$ is
\[
E e^{\zeta R} = \frac{E e^{(\lambda + \zeta)gS_n^0/g_n - \zeta x g[0,n)/g_n}}{\prod_{1 \leq i \leq n} \varphi_0(\lambda g_{n-i/n})}
= e^{-\zeta x g[0,n)/g_n} \prod_{1 \leq i \leq n} \frac{\varphi_0((\lambda + \zeta)g_{n-i/n})}{\varphi_0(\lambda g_{n-i/n})}.
\]
(5.2.5)

In particular, taking its logarithmic derivative at 0, the expectation of $R$ is
\[
E R = -xg[0,n)/g_n + \sum_{1 \leq i \leq n} g_{n-i/n}m_0(\lambda g_{n-i/n}),
\]
while its variance is
\[
\sigma_n^2 = \sum_{1 \leq i \leq n} g_{n-i/n}^2m_0'(\lambda g_{n-i/n}).
\]

Using Lemma 5.2.1, we obtain that, locally uniformly in $\lambda$,
\[
E R \sim n \left(-x + \int_0^1 k_\gamma(u)m_0(\lambda k_\gamma(u)) \, du\right).
\]
Since $m_0'$ is assumed regularly varying when $\limsup_{n \to \infty} g_{i/n}$ is infinite,
\[
\sigma_n^2 \sim n \int_0^1 k_\gamma^2(u)m_0'(\lambda k_\gamma(u)) \, du,
\]
and the integral involved in this asymptotic equivalence is well defined — see the discussion following Theorem 2.1, where we showed that in fact $m_0'$ is regularly varying with index $\beta - 2$ with $\beta(1 - \gamma) < 1$.

We consider $\lambda$, depending on $n$, therefore written $\lambda_n$ from now on, such that the expected value of $R$ vanishes. Such sequence exists since the standard assumption guarantees that $m$ is onto the nonnegative real line. Since $m_0$ is monotone, this sequence $\lambda_n$ converges to the root of
\[
-x + \int_0^1 k_\gamma(u)m_0(\lambda k_\gamma(u)) \, du = 0.
\]
Then (5.2.4) implies
\[
P\{ S_n^0 > x g[0,n) \}
\geq \prod_{1 \leq i \leq n} \varphi_0(\lambda_n g_{n-i/n}) e^{-\lambda_n x g[0,n)/g_n} e^{-\lambda_n \sigma_n M}\{ R \geq 0 \} e^{-\lambda_n \sigma_n M Q_{\lambda_n,\sigma_n}[0, M \sigma_n].
\]
Expression (5.2.5) shows that the logarithm of the moment generating function of $R/\sigma_n$ at $\zeta$ is

$$-\frac{\zeta x^\gamma g_0(n)}{\sigma_n g_n} + \sum_{1 \leq i \leq n} \log \varphi_0\left((\lambda_n + \zeta/\sigma_n)g_{n-i/n}\right) - \log \varphi_0(\lambda_n g_{n-i/n}).$$

Using the mean value theorem and given our choice of $\lambda_n$, there exists some $\eta_{i,n}$ between 0 and 1 such that this logarithm is

$$\frac{\zeta^2}{2\sigma_n^2} \sum_{1 \leq i \leq n} g_{n-i/n}^2 m_0'\left((\lambda_n + \eta_{i,n}\zeta/\sigma_n)g_{n-i/n}\right).$$

(5.2.7)

The same argument as in Lemma 5.2.1 shows that (5.2.7) tends to $\zeta^2/2$ as $n$ tends to infinity. Therefore, $R/\sigma_n$ has a standard Gaussian limiting distribution as $n$ tends to infinity, and the right hand side of (5.2.6) is asymptotically equivalent to

$$\exp\left(\sum_{1 \leq i \leq n} \log \varphi_0(\lambda_n g_{n-i/n}) - \lambda_n x^\gamma g_0(n)/g_n\right)e^{O(\sqrt{n})}$$

$$= \exp\left(-nJ_0(x)(1 + o(1))\right)$$

as $n$ tends to infinity. The result follows.

To prove Theorem 2.1 requires a couple of more lemmas related to the function $J_0$.

**Lemma 5.2.3.** The function $J_0$ is positive on the positive half-line.

**Proof.** Let $J_0^*$ be the function

$$J_0^*(\lambda) = \int_0^1 \log \varphi_0(\lambda k_x(u)) \, du.$$ 

Both $J_0^*$ and $J_0'^*$ vanish at the origin, while

$$J_0''(0) = \text{Var}_X \int_0^1 k_x^2(u) \, du$$
is positive. In particular, taking \( \lambda \) to be \( x/J_0''(0) \), we see that as \( x \) tends to 0,
\[
J_0(x) \geq \lambda x - \frac{\lambda^2}{2} J_0''(0) + o(\lambda^2)
\]
\[
\geq \frac{x^2}{2J_0''(0)} + o(x^2).
\]
Thus, \( J_0 \) is positive on an open interval with left endpoint the origin.

Since \( J_0 \) is a supremum of nondecreasing functions of \( x \) it is also nondecreasing and the result follows.

Lemma 5.2.4. For any positive real number \( c \), the function
\[
x \in [0, \infty) \mapsto xJ_0(x^{-\gamma} + c)
\]
tends to infinity at 0 and infinity. Moreover, it reaches its minimum at a positive argument.

Proof. Let \( c \) be a positive real number. Lemma 5.2.3 ensures that \( J_0(c) \) is positive. It follows that \( xJ_0(x^{-\gamma} + c) \) tends to infinity with \( x \).

Assume that \( \gamma \) is at least 1. Since for any positive \( \theta \) the inequality \( J_0(x) \geq x\theta - J_0^*(\theta) \) holds, we see that \( J_0 \) ultimately grows faster than any multiple of the identity. Thus, \( xJ_0(x^{-\gamma} + c) \) tends to infinity as \( x \) tends to 0, and this proves the lemma in this case.

Assume that \( \gamma \) is less than 1. The assumption \( \alpha \gamma > 1 \) ensures that \(- \log F\) is regularly varying of index \( \alpha \) greater than 1. By Kasahara’s (1978) Tauberian theorem (Bingham, Goldie and Teugels, 1989, Theorem 4.12.7), \( \log \varphi_0 \) is regularly varying of index \( \beta \), the conjugate exponent to \( \alpha \). This implies that \( J_0^* \) is also regularly varying of index \( \beta \) at infinity. By Bingham and Teugels’s (1975) theorem (see Bingham, Goldie and Teugels, 1989, Theorem 1.8.10), this implies that \( J_0 \) is regularly varying of index \( \alpha \). Since \( \alpha \gamma \) is greater than 1, it then follows that \( xJ_0(x^{-\gamma} + c) \) tends to infinity as \( x \) tends to 0 (Bingham, Goldie and Teugels, 1989, Proposition 1.3.6). This proves the first part of the lemma.

The second part of the lemma follows, because the function \( xJ_0(x^{-\gamma} + c) \) is continuous on the positive half-line.

Our next lemma shows that the process \( S_n^0 \) is unlikely to reach a high threshold \( t \) before a time of order \( V(t) \).

Lemma 5.2.5. The following holds,
\[
\lim_{\epsilon \to 0} \limsup_{t \to \infty} \frac{1}{V(t)} \log P \{ \exists n : n \leq \epsilon V(t) ; S_n^0 > t \} = -\infty.
\]
Proof. We distinguish according to whether \( \max_{0 \leq i \leq n} g_i/n \) remains bounded or not.

Assume first that \( \limsup_{n \to \infty} \max_{0 \leq i \leq n} g_i/n \) is some finite positive number \( c \). Necessarily, \( \gamma \) is at least 1. In that case, (5.1.1) implies

\[
\max_{0 \leq i \leq \epsilon V(t)} g_i \lesssim \frac{c}{\epsilon^{\gamma - 1}} \frac{t}{V(t)}
\]
as \( t \) tends to infinity. In particular, uniformly in \( i \) nonnegative and at most \( \epsilon V(t) \), and as \( t \) tends to infinity, \( t/g_i \gtrsim V(t) \epsilon^{1-\gamma}/c \). Moreover, Lemma 5.2.1 shows that

\[
\sum_{1 \leq i \leq n} \log \varphi_0(\lambda g_{n-i/n}) \lesssim n \int_0^1 \log \varphi_0(\lambda k_\gamma(u)) \, du
\]
as \( n \) tends to infinity. Then, using the Markov exponential inequality, for any fixed positive \( \lambda \), for any \( n \) large enough and at most \( \epsilon V(t) \),

\[
\log P\{ S_n^0 > t \} \leq -\lambda \frac{\gamma t}{g_n} + \sum_{1 \leq i \leq n} \log \varphi_0(\lambda g_{n-i/n})
\]
\[
\leq -\lambda \gamma \frac{V(t)}{2c} \epsilon^{1-\gamma} + 2n \int_0^1 \log \varphi_0(\lambda k_\gamma(u)) \, du
\]
provided \( t \) is large enough, \( n \) is large enough and less than \( \epsilon V(t) \).

Since \( \gamma \) is at least 1, for \( n \) at most \( \epsilon V(t) \), this upper bound is at most

\[
-V(t) \left( \lambda \gamma \frac{\epsilon^{1-\gamma}}{2c} - 2 \epsilon \int_0^1 \log \varphi_0(\lambda k_\gamma(u)) \, du \right).
\]

It can be made smaller than any negative multiple of \( V(t) \) by first taking \( \lambda \) positive and then \( \epsilon \) small enough. Hence, there exists \( n_0 \) such that

\[
\lim \limsup_{\epsilon \to 0} \max_{n_0 \leq n \leq \epsilon V(t)} \frac{1}{V(t)} \log P\{ S_n^0 > t \} = -\infty \quad (5.2.8)
\]

For \( n \) at most \( n_0 \), recalling that the mean of \( X_i \) is \(-1\), we have, since \( t \) is positive,

\[
P\{ S_n^0 > t \} \leq P\{ n_0 \max_{0 \leq i \leq n_0} g_i \max_{1 \leq i \leq n_0} (X_i + 1) > t \}
\]
\[
\leq n_0 F_0 \left( \frac{t}{n_0 \max_{0 \leq i \leq n_0} g_i} \right).
\]

29
Since the moment generating function of $F_0$ is finite on the nonnegative half-line, Chernoff’s inequality implies that $-\log F \gg \text{Id}$ at infinity. Lemma 5.1.2 shows that in the present case, $U$ grows at most like a multiple of the identity at infinity. This implies that the function $U^{-1} \log F$ tends to minus infinity at infinity. We conclude that (5.2.8) holds with $n_0$ being 1.

We now consider the case where $\max_{0 \leq i \leq n} g_i/n$ tends to infinity with $n$. In this case, the sequence $(g_n)_{n \geq 0}$ converges to 0, and, for any $\eta$ positive, $\log \varphi_0 \lesssim \text{Id}^{\beta+\eta}$ at infinity. Again, we use the exponential Markov inequality
\[
\log \Pr\{S_n^0 > t\} \leq -\lambda t + \sum_{0 \leq i < n} \log \varphi_0(\lambda g_i),
\] (5.2.9)

taking now $\lambda$ of the form $cV(t)/t$ for some positive constant $c$ to be determined.

Since the standard assumption ensures that $(g_n)_{n \geq 0}$ is asymptotically equivalent to a monotone sequence, $\min_{0 \leq i \leq \epsilon V(t)} g_i \gtrsim g_{\lceil \epsilon V(t) \rceil}$ as $t$ tends to infinity. Using (5.1.1), it follows that $\lambda g_i \gtrsim c \gamma^{\gamma-1}$ is large whenever $c$ is large and $\epsilon$ is small. Thus, provided $c$ is large enough, $\epsilon$ is small enough and $n$ is at most $\epsilon V(t),
\[
\sum_{0 \leq i < n} \log \varphi_0(\lambda g_i) \lesssim 2 \sum_{0 \leq i < n} (\lambda g_i)^{\beta+\eta} 
\lesssim 2 \left(\frac{V(t)}{t}\right)^{\beta+\eta} \sum_{0 \leq i \leq \epsilon V(t)} g_i^{\beta+\eta}. \quad (5.2.10)
\]

Since $\beta(\gamma - 1) + 1$ is positive,
\[
\sum_{0 \leq i < n} g_i^{\beta+\eta} \sim \frac{n}{1 + (\gamma - 1)(\beta + \eta)} \left(\frac{g(1 - 1/n)}{\Gamma(\gamma)n}\right)^{\beta+\eta}
\]
as $n$ tends to infinity, and the bound (5.2.10) is at most
\[
2(\gamma c)^{\beta+\eta} \epsilon^{(\gamma-1)(\beta+\eta)+1} \frac{V(t)}{1 + (\gamma - 1)(\beta + \eta)}.
\]

For any fixed $\epsilon$, the upper bound (5.2.10) can be made less than any a priori given negative number times $V(t)$ by taking $c$ large enough. This proves the lemma.
Proof of Theorem 2.1. Comparing (4.2) with Proposition 5.2.2, we may take $r$ to be the identity, so that $\rho$ is 1; furthermore, still referring to assumption (4.2) and Proposition 5.2.2, we see that $I(x) = J_0(x)$. Using (5.1.3), and since the mean $\mu$ is $-1$, it follows that $\theta$, as defined in (4.5), is

$$\theta = \inf_{x>0} xJ_0(x^{-\gamma} + 1) = \inf_{x>0} xJ(x^{-\gamma}).$$

(5.2.11)

Assumptions needed to apply the first part of Proposition 4.1 are satisfied thanks to Lemma 5.1.1, Proposition 5.2.2 and Lemma 5.2.5. Thus Proposition 4.1 yields Theorem 2.1 when $\mu$ is $-1$.

To obtain the result when $\mu$ is different than $-1$, we index in an obvious way all quantities by the mean $\mu$ in parentheses. We then have, assuming now that $X_i$ has arbitrary mean $\mu$,

$$\varphi(\mu)(\lambda) = \varphi(-1)(-\mu\lambda).$$

(5.2.12)

This implies, for any positive $a$,

$$J(\mu)(a) = J(-1)(a/-\mu).$$

(5.2.13)

Writing $X_{(\mu),i}$ for $X_i$ when the mean is $\mu$, we take $X_{(\mu),i} = -\mu X_{(-1),i}$, which yields $M(\mu) = (-\mu)M(-1)$. Thus,

$$\frac{1}{V(t)} \log \{M(\mu) > t\} = \frac{V(t/-\mu)}{V(t)} \frac{1}{V(t/-\mu)} \log \{M(-1) > t/-\mu\}
\sim -(-\mu)^{-1/\gamma} \inf_{x>0} xJ_{(-1)}(x^{-\gamma}).
= - \inf_{x>0} xJ(\mu)(x^{-\gamma}).$$

5.3. Proof of Theorem 2.2. As for Theorem 2.1, we first prove Theorem 2.2 when $\mu$ is $-1$, which we assume from now on.

Our first lemma is an analogue of Lemma 5.2.1 but in the context of Theorem 2.2.

Note that in the context of Theorem 2.2, the conditions $\alpha \gamma < 1$ and $\gamma > 1/2$ force $\alpha$ to be less than 2. Therefore, its conjugate exponent, $\beta$, is greater than 2.

Lemma 5.3.1. Let $\lambda$ be a regularly varying function of index greater than $(2\gamma - 1)/(\beta - 2)$ and set $\lambda_n = \lambda(n)$. Under the assumptions of Theorem 2.2,

$$\sum_{0 \leq i < n} \log \varphi(\lambda_n g_i) \sim \log \varphi(\lambda_n)|g|_\beta^{\beta}.$$
as $n$ tends to infinity.

**Proof.** Let $\sigma^2$ be the variance of $X_i$. Since $\log \varphi_0 \sim \text{Id}^2 \sigma^2 / 2$ at the origin, for any positive $R$ there exists a positive $c$ such that $\log \varphi_0 \leq c \text{Id}^2$ on $[0, R]$. Using Lemma 5.1.1, this implies

$$\sum_{0 \leq i < n} 1 \{ \lambda_n g_i \leq R \} \log \varphi_0(\lambda_n g_i) \leq c \lambda_n^2 \sum_{0 \leq i < n} g_i^2$$

$$\leq \lambda_n^2 \frac{g(1 - 1/n)^2}{n}. \quad (5.3.1)$$

Let $\epsilon$ be a positive real number. Using Potter's bound, we see that provided $\lambda_n$ and $\lambda_n g_i$ are large enough, and provided that $i$ is large enough for $g_i$ to be less than 1,

$$\frac{1}{2} \beta_i^{\beta + \epsilon} \leq \frac{\log \varphi_0(\lambda_n g_i)}{\log \varphi_0(\lambda_n)} \leq 2 \beta_i^{\beta - \epsilon}. \quad (5.3.2)$$

By a standard regular variation theoretic argument, this implies

$$\sum_{0 \leq i < n} 1 \{ \lambda_n g_i > R \} \log \varphi_0(\lambda_n g_i) \sim \log \varphi_0(\lambda_n) \sum_{0 \leq i < n} g_i^\beta 1 \{ \lambda_n g_i > R \}$$

$$\sim \log \varphi_0(\lambda_n) |g|_\beta \quad (5.3.2)$$

as $n$ tends to infinity — recall that $|g|_\beta$ is finite here, since $\beta(1 - \gamma) > 1$.

Write $\rho$ for the index of regular variation of $\lambda$. Since $\log \varphi_0 \circ \lambda$ is regularly varying of index $\beta \rho$, and $\lambda^2 g(1 - 1/\text{Id})^2 / \text{Id}$ is regularly varying of index $2\rho + 2\gamma - 1$, our assumption that $\rho$ is greater than $(2\gamma - 1)/(\beta - 2)$ ensures that the right hand side of (5.3.2) dominates the right hand side of (5.3.1), and the result holds.

We define the Cramér transform of the centered random variables,

$$I_0(x) = \sup_{\lambda > 0} \lambda x - \log \varphi_0(\lambda).$$

Recall that we assume that $\mu$ is $-1$. We then write $F_0$ for the distribution of the centered random variable $X_i + 1$.

We can now state and prove the following large deviations inequality.
Proposition 5.3.2. Let \( (S_n^0)_{n \geq 0} \) be a centered \((g,F_0)\)-process. Under the assumptions of Theorem 2.2, for any positive \( x \),

\[
\log P\{ S_n^0 > x g_{[0,n)} \} \lesssim -\frac{x^\alpha}{|g|^\beta} I_0(g_{[0,n)})
\]
as \( n \) tends to infinity.

Proof. Recall that under the assumptions of Theorem 2.2, \( \log \varphi_0 \) is regularly varying of index \( \beta \) and \( I_0 \) is regularly varying of index \( \alpha \)— see the proof of Lemma 5.2.4. Define

\[
\lambda(t) = \frac{x^{1/(\beta-1)}}{|g|^\alpha} m^{-}_0(g_{[0,t)}).
\]

This function is regularly varying of positive index \( \gamma/(\beta - 1) \). We define \( \lambda_n \) as \( \lambda(n) \). Using the exponential form of Markov’s inequality and Lemma 5.3.1— applicable since the inequality \( \alpha \gamma < 1 \) implies \( \gamma/(\beta - 1) > (2\gamma - 1)/(\beta - 2) \)—

\[
\log P\{ S_n^0 > x g_{[0,n)} \} \leq -\lambda_n x g_{[0,n)} + \sum_{0 \leq i < n} \log \varphi_0(\lambda_n g_i)
\]
\[
\leq -\frac{x^\alpha}{|g|^\alpha} g_{[0,n)} m^{-}_0 \circ g_{[0,n)}
\]
\[
+ |g|^\beta \frac{x^\alpha}{|g|^\alpha} \log \varphi_0 \circ m^{-}_0(g_{[0,n)}) \left( 1 + o(1) \right).
\]

Since by regular variation \( \log \varphi_0 \sim \text{Id} m^{-}_0 / \beta \) at infinity, the right hand side of the above upper bound is asymptotically equivalent to

\[
\frac{x^\alpha}{|g|^\alpha} (\text{Id} m^{-}_0)(g_{[0,n)}) (-1 + 1/\beta). \tag{5.3.3}
\]

Upon noting that the maximizing value of \( \lambda \) in the definition of \( I_0(\cdot) \) is \( m^{-}_0(\cdot) \), the chain rule yields \( I_0^\prime = m^{-}_0 \). Therefore, \( \text{Id} m^{-}_0 \sim \alpha I_0 \) at infinity. We obtain that (5.3.3) is asymptotically equivalent to

\[
-x^\alpha |g|^\alpha I_0(g_{[0,n)})
\]
as \( n \) tends to infinity. This proves Proposition 5.3.2.

Our next result is yet another large deviations inequality. Its statement is suitable for our application, though its proof gives a somewhat more precise estimate.
Proposition 5.3.3. For any positive real number $\zeta$, 

$$\max_{1 \leq n < \zeta V(t)} \log P\{S_n^0 > t\} \lesssim -\frac{I_0(t)}{|g|^0}$$

as $t$ tends to infinity.

Proof. Let $\lambda(t) = m_0^-(t)|g|^{-\alpha}$. The exponential Markov inequality implies

$$\log P\{S_n^0 > t\} \leq -\lambda(t) t + \sum_{0 \leq i < n} \log \varphi_0(\lambda(t) g_i). \quad (5.3.4)$$

Using Potter’s bound and regular variation of $\log \varphi_0$, there exists a positive $R$ such that uniformly in $n$ positive and less than $\zeta V(t)$,

$$\sum_{0 \leq i < n} \log \varphi_0(\lambda(t) g_i) \mathbb{1}\{\lambda(t) g_i > R\} \lesssim \log \varphi_0(\lambda(t))|g|^\beta. \quad (5.3.5)$$

Moreover, as was shown in the proof of Lemma 5.3.1, there exists a positive real number $c$ such that for any $n$ less than $\zeta V(t)$,

$$\sum_{0 \leq i < n} \log \varphi_0(\lambda(t) g_i) \mathbb{1}\{\lambda(t) g_i \leq R\} \leq c \sum_{0 \leq i < n} \lambda(t)^2 g_i^2$$

$$\leq c \lambda(t)^2 \sum_{0 \leq i < \zeta V(t)} g_i^2$$

$$= O\left(\lambda(t)^2 \frac{t^2}{V(t)}\right).$$

As a function of $t$, this asymptotic upper bound is regularly varying of index

$$\frac{2}{\beta - 1} + 2 - \frac{1}{\gamma} = 2\alpha - \frac{1}{\gamma}.$$

The upper bound (5.3.5) is regularly varying of index $\beta/(\beta - 1) = \alpha$. Since $\alpha\gamma$ is less than 1, we see that $2\alpha - 1/\gamma$ is less than $\alpha$, and, consequently, for $n$ less than $\zeta V(t)$,

$$\sum_{0 \leq i < n} \log \varphi_0(\lambda(t) g_i) \lesssim \log \varphi_0(\lambda(t))|g|^\beta$$

$$\sim (\log \varphi_0) \circ m_0^-(t)|g|^{-\alpha}.$$
This implies that the exponent in the upper bound (5.3.4) is asymptotically bounded by an equivalent of
\[-|g|^{-\alpha} m_0^- (t) t + |g|^{-\alpha} \log \varphi_0 \circ m_0^- (t) = -|g|^{-\alpha} I_0 (t).

The result follows.

We now prove a trivial lower bound.

**Lemma 5.3.4.** For any positive \(n\),
\[
\log P \{ S_n > t \} \gtrsim \log F(t) \left( \sum_{0 \leq i < n} g_i^\beta \right)^{-\alpha/\beta}
\]
as \(t\) tends to infinity.

**Proof.** Let \(x_i = g_i^{1/(\alpha-1)}/ \sum_{0 \leq i < n} g_i^\beta\), so that \(\sum_{0 \leq i < n} g_i x_i = 1\). We have
\[
\log P \{ S_n > t \} \geq \log P \left( \bigcap_{0 \leq i < n} \{ X_i > tx_i \} \right)
= \sum_{0 \leq i < n} \log F(t x_i)
\sim \log F(t) \sum_{0 \leq i < n} x_i^{\alpha}
\]
as \(t\) tends to infinity. The result follows upon calculating
\[
\sum_{0 \leq i < n} x_i^{\alpha} = \left( \sum_{0 \leq i < n} g_i^\beta \right)^{-\alpha/\beta}.
\]

**Proof of Theorem 2.2 Lower bound.** Applying Proposition 5.3.4, for any positive integer \(n\),
\[
\log P \{ M > t \} \geq \log P \{ S_n > t \}
\gtrsim \log F(t) \left( \sum_{0 \leq i < n} g_i^\beta \right)^{-\alpha/\beta}.
\]
Consequently, as \(t\) tends to infinity,
\[
\log P \{ M > t \} \gtrsim \log F(t) |g|^{-\alpha}.
\]
Upper bound. We apply the remark following Proposition 4.1. In the present context, Proposition 5.3.2 shows that (4.8) holds with $r_n = I_0(g_{[0,n)})$ and $I(x) = |g|^{-\alpha}x^\alpha$. Note that $\log F_0 \sim \log F$ at infinity. Since Broniatowski and Fuchs’ (1995) Theorem 3.1 implies that, under the assumption of Theorem 2.2, $-\log F_0 \sim I_0$ at infinity, the function $r$ is regularly varying of index $\alpha \gamma$. Referring to Proposition 4.1, we see that $\theta = |g|^{-\alpha}$ for

$$\inf_{x \geq 0} x^\alpha (x^{-\gamma} + 1)^\alpha = \inf_{x \geq 0} (1 + x^\gamma)^\alpha = 1.$$ 

Since $g_{[0,V(t))} \sim t$, 

$$-r \circ V(t) = -I_0(g_{[0,V(t))}) \sim -I_0(t) \sim \log F(t)$$

as $t$ tends to infinity. Therefore, in view of this and Lemma 5.3.3, we see that condition (4.6) holds. This proves Theorem 2.2 when $\mu$ is $-1$. The same scaling argument as in the end of the proof of Theorem 2.1 allows for the extension to other values of $\mu$.

6. Proof of Theorem 3.1. As for the proof of the results of section 2, we will first prove the result when the mean $\mu$ is $-1$. In the first two subsections, we prove assertion (i) and (ii) respectively. Assertion (iii) requires a distinction between the cases of boundedness or divergence of $\max_{0 \leq i \leq n} g_{i/n}$, and is proved, accordingly, in the third and fourth subsections. A scaling argument, developed in the fifth subsection gives Theorem 3.1 when the mean $\mu$ is arbitrary.

Throughout this section we will use the following obvious fact. Let $E_t$ be an event indexed by $t$. To prove that $P(E_t \mid M > t)$ tends to 0 as $t$ tends to infinity, it suffices to prove that $P(E_t) = o(P\{M > t\})$ as $t$ tends to infinity; indeed, this follows from the definition of conditional probability and monotonicity of measures.

6.1. Proof of Theorem 3.1.i. Assume that $\mu$ is $-1$. Assumptions of Proposition 4.1 are satisfied by virtue of Proposition 5.2.2 and Lemma 5.2.5. From the second assertion of Proposition 4.1 and equality (5.1.3), we deduce that $\mathcal{N}$ converges to $\tau$ in probability as $t$ tends to infinity and conditionally on $M$ exceeding $t$. This is assertion (i) when the mean is $-1$.

6.2. Proof of Theorem 3.1.ii. We assume that $\mu$ is $-1$. Our next lemma is the analogue of Lemma 5.2.1 specialized to the context of
the proof of Theorem 3.1. Recall that \( X_i \) has mean \(-1\) for the time being, and that \( \varphi_0 \) is the moment generating function of the centered random variable \( X_i + 1 \).

**Lemma 6.2.1.** Let \( f \) be a continuous real-valued and bounded function on \([0, 1] \times \mathbb{R}\). For any fixed \( \lambda \),

\[
\lim_{n \to \infty} n^{-1} \sum_{1 \leq i \leq n} E \left( f \left( \frac{i}{n}, X_i \right) \frac{e^{\lambda g_{n-i/n}(X_i+1)}}{\varphi_0(\lambda g_{n-i/n})} \right) = \int f(v, x) \frac{e^{\lambda k_\gamma(v)(x+1)}}{\varphi_0(\lambda k_\gamma(v))} \mathbb{1}_{[0,1]}(v) d(L \otimes F)(v, x).
\]

**Proof.** Let \( c \) be a number larger than \( \lim_{n \to \infty} \max_{0 \leq i \leq n} g_{i/n} \).

Consider the function

\[
\psi(v, y, x) = f(v, x) \frac{e^{\lambda(y \wedge c)(x+1)}}{\varphi_0(\lambda(y \wedge c))}.
\]

For \( n \) large enough and with \( \Gamma_n \) the measure defined prior to Lemma 5.1.3,

\[
n^{-1} \sum_{1 \leq i \leq n} E \left( f \left( \frac{i}{n}, X_i \right) \frac{e^{\lambda g_{n-i/n}(X_i+1)}}{\varphi_0(\lambda g_{n-i/n})} \right) = E \int \psi(v, y, X_1) d\Gamma_n(v, y).
\]

For any fixed \( x \) the function \( \psi(v, y, x) \) is a continuous and bounded function of \((v, y)\) in \([0, 1] \times \mathbb{R}\). By Lemma 5.1.3, the sequence of functions

\[
\psi_n(x) = \int \psi(v, y, x) d\Gamma_n(v, y), \quad n \geq 1,
\]

converges pointwise to the function

\[
\psi(x) = \int_0^1 \psi(u, k_\gamma(u), x) du.
\]

Since

\[
|\psi(v, y, x)| \leq |f|_{[0, 1] \times \mathbb{R}} e^{\lambda c|x+1|} \left| \frac{1}{\varphi_0(0, \lambda c)} \right|,
\]

the dominated convergence theorem implies that \( E\psi_n(X_1) \) tends to \( E\psi(X_1) \) as \( n \) tends to infinity, which is what the lemma asserts. \( \blacksquare \)
Recall that in section 2 we used the notation $\theta$ for
$$\theta = - \lim_{t \to \infty} V(t)^{-1} \log P\{ M > t \}.$$ Considering the definition of $\tau$ in (3.1), that of $J_0$ in (5.1.2), equality (5.1.3), and how $\theta$ was obtained in (5.2.11),
$$\theta = \tau J_0(\tau^{-\gamma} + 1)$$
$$= \tau \sup_{\lambda > 0} \left( (\tau^{-\gamma} + 1)\lambda - \int_0^1 \log \varphi_0(\lambda k_{\gamma}(u)) \, du \right). \quad (6.2.1)$$
Since $m_0$ is onto the nonnegative half-line, the supremum in $\lambda$ in the above formula is achieved for some value $A$. By considering the derivative in $\lambda$, which must vanish at the maximizer $A$, we obtain
$$\tau^{-\gamma} + 1 = \int_0^1 k_{\gamma}(u)m_0(Ak_{\gamma}(u)) \, du. \quad (6.2.2)$$
When $\mu$ is $-1$ as currently, we have $\varphi(\lambda) = e^{-\lambda} \varphi_0(\lambda)$ and, consequently, $m = -1 + m_0$. Therefore, the definition of $A$ in (6.2.2) matches that in (3.2).
As will be apparent in the bound 6.2.8 to come and in its evaluation, the following result is strongly related to Proposition 5.2.2 if one takes $n$ to be about $\tau V(t)$ and $x$ to be about $\tau$ in that proposition.

**Lemma 6.2.2.** The following holds,
$$\lim_{\varepsilon \to 0} \limsup_{t \to \infty} \sup_{n : |n/V(t) - \tau| < \varepsilon} \left| \frac{A \gamma t + s_n}{g_n V(t)} - \frac{1}{V(t)} \sum_{1 \leq i \leq n} \log \varphi_0(Ag_{n-i/n}) - \theta \right| = 0.$$ **Proof.** Write $n = \nu V(t)$. Since $s$ is regularly varying, $s_n \sim \nu^{\gamma} t$. Moreover, (5.1.1) shows that
$$g_n \sim \gamma \nu^{\gamma-1} \frac{t}{V(t)},$$
and those equivalences hold locally uniformly in $\nu$ thanks to the uniform convergence Theorem (Bingham, Goldie and Teugels, 1989, Theorem 1.2.1). In particular,
$$\frac{t + s_n}{g_n V(t)} \sim \frac{1 + \nu^{\gamma}}{\nu^{\gamma-1}}, \quad (6.2.3)$$
as \( t \) tends to infinity. Applying Lemma 5.2.1, we also have

\[
\frac{1}{V(t)} \sum_{1 \leq i \leq n} \log \varphi_0(Ag_{n-i/n}) \sim \frac{n}{V(t)} \int_0^1 \log \varphi_0(Ak_\gamma(v)) \, dv
\]

\[
\sim \nu \int_0^1 \log \varphi_0(Ak_\gamma(v)) \, dv, \quad (6.2.4)
\]

again locally uniformly in \( \nu \) positive and as \( t \) tends to infinity. Combining (6.2.3) and (6.2.4), we obtain that

\[
A^\gamma \frac{t + s_n}{g_n V(t)} - \frac{1}{V(t)} \sum_{1 \leq i \leq n} \log \varphi_0(Ag_{n-i/n})
\]

\[
= \nu \left(A(\nu^{-\gamma} + 1) - \int_0^1 \log \varphi_0(Ak_\gamma(v)) \, dv\right) + o(1)
\]

\[
(6.2.5)
\]

as \( t \) tends to infinity. When \( \nu \) is \( \tau \), equality (6.2.1) shows that the right hand side in (6.2.5) is \( \theta \). The result follows from the continuity in \( \nu \) of the function involved in the right hand side of (6.2.5).

We can now prove the second assertion of Theorem 3.1. Let \( f \) be a continuous function supported by a vertical strip of the right half-space. Whenever \( \nu \) is a measure on the right half-space, we write \( \nu f \) for \( \int f \, d\nu \). Let \( \epsilon \) be a positive real number. Assume that we have proved that for any real number \( h \) greater than \( M_f \),

\[
\lim_{t \to \infty} P\{ M_t f > h \mid M > t \} = 0. \quad (6.2.6)
\]

If \( h \) is less than \( M_f \), then applying the above relation to \(-f\) and \(-h\), we see that the conditional probability of \( M_t f < h \) given \( M \) exceeds \( t \) tends to 0 as \( t \) tends to infinity. We then conclude that

\[
\lim_{t \to \infty} P\{ |(M_t - M)f| > \epsilon \mid M > t \} = 0.
\]

Thus, as \( t \) tends to infinity, \( M_t f \) converges in probability to \( M f \) conditionally on \( M \) exceeding \( t \). Since \( f \) is arbitrary, this shows that \( M_t \) converges to \( M \) in probability, under the conditional probability that \( M \) exceeds \( t \). This would prove the second assertion of Theorem 3.1, and therefore, it suffices to prove (6.2.6), which we do now.
The proof of the second assertion of Proposition 4.1 shows that for any positive \( \epsilon \),
\[
P\{ M_t f > h \mid M > t \} \leq \sum_{n : |n V(t) - \tau| \leq \epsilon} P\{ M_t f > h \mid S_n^0 > t + s_n \} + o(P\{ M > t \}) \tag{6.2.7}
\]
as \( t \) tends to infinity.

The basic inequality for our proof is the exponential form of Markov’s, which implies that for any positive \( \lambda \),
\[
\log P\{ M_t f > h \mid S_n^0 > t + s_n \} \leq \log P\{ \lambda V(t) M_t f + A \frac{S_n^0}{g_n} > \lambda V(t) h + A \frac{t + s_n}{g_n} \}
\]
\[
\leq - V(t) \left( \lambda h + A \frac{t + s_n}{g_n V(t)} - \frac{1}{V(t)} \log \exp \left( \lambda V(t) M_t f + A \frac{S_n^0}{g_n} \right) \right).
\tag{6.2.8}
\]

The remainder of the proof is somewhat technical, but the next few sentences show that it is very simple in essence. If one looks at the classical Chernoff estimate, one sees that the minimizer in the rate function tends to 0 as one considers deviations nearing the mean. In our case, (6.2.8) is to be considered when \( h \) is close to the anticipated limit \( M_f \). Therefore, we anticipate that we may take \( \lambda \) very small. If this is so, the bound can be linearized in \( \lambda \). The linear term in \( \lambda \) will be positive, while the term measuring the deviation of \( S_n^0 > t + s_n \) should give a contribution very close to \( \theta \). So, the addition of the linear term in \( \lambda \) to the term near \( \theta \) should give a term greater than \( \theta \), which is all that we need.

To proceed rigorously, we define some small — arguably, bewildering — constants. Let \( \delta \) be a positive real number less than 1 such that \( h > (1 + 2\delta) M_f \). Let \( \lambda \) be positive and small enough so that
\[
\lambda |f|_{[0,\infty) \times \mathbb{R}} < \sup \{ x : e^x < 1 + (1 + \delta)x \} \land (1 + \delta)^{-1}. \tag{6.2.9}
\]
Next, let \( \eta \) be small enough so that \( \lambda (h - (1 + 2\delta) M_f) > 3\eta \). Finally, using Lemma 6.2.2, let \( \epsilon \) be a positive real number so that
\[
\limsup_{t \to \infty} \sup_{n : |n V(t) - \tau| < \epsilon} \left| A \frac{t + s_n}{g_n V(t)} - \frac{1}{V(t)} \sum_{1 \leq i \leq n} \log \varphi_0(A g_{n-i/n} - \theta) \right| < \eta. \tag{6.2.10}
\]
To evaluate the upper bound (6.2.8), we first bound the term containing an expectation. Given the constraint (6.2.9) on $\lambda$,

$$e^{\lambda f(i/V(t), X_i)} \leq 1 + (1 + \delta)\lambda f\left(\frac{i}{V(t)}, X_i\right).$$

Recall that $X_i$ is of mean $-1$ currently. Since

$$\lambda V(t)\mathcal{M}_t f + A\gamma S^0_n/ g_n$$

$$= \sum_{1 \leq i \leq n} \left(\lambda f\left(\frac{i}{V(t)}, X_i\right) + Ag_{n-i/n}(X_i + 1)\right) + \sum_{i > n} \lambda f\left(\frac{i}{V(t)}, X_i\right),$$

the term $\mathbb{E} \exp\left(\lambda V(t)\mathcal{M}_t f + A\gamma S^0_n/ g_n\right)$ in (6.2.8) is at most

$$\prod_{1 \leq i \leq n} \mathbb{E}\left(1 + (1 + \delta)\lambda f\left(\frac{i}{V(t)}, X_i\right)\right) e^{Ag_{n-i/n}(X_i+1)}$$

$$\prod_{i > n} \mathbb{E}\left(1 + (1 + \delta)\lambda f\left(\frac{i}{V(t)}, X_i\right)\right).$$

Note the inequality $\log(a + b) \leq \log a + b/a$, valid for any positive $a$ and any $b$ larger than $-a$. To apply this inequality with

$$a = \mathbb{E}e^{Ag_{n-i/n}(X_i+1)}$$

and

$$b = (1 + \delta)\lambda\mathbb{E}f\left(\frac{i}{V(t)}, X_i\right)e^{Ag_{n-i/n}(X_i+1)},$$

we first observe that

$$|b| \leq (1 + \delta)\lambda|f|_{[0, \infty)} \times \mathbb{R} \mathbb{E}e^{Ag_{n-i/n}(X_i+1)}$$

and (6.2.9) ensures that $|b|$ is less than $a$. Therefore, $a + b$ is positive. We then have, referring to the first product of (6.2.11),

$$\log\mathbb{E}\left(1 + (1 + \delta)\lambda f\left(\frac{i}{V(t)}, X_i\right)\right) e^{Ag_{n-i/n}(X_i+1)}$$

$$\leq \log\mathbb{E}e^{Ag_{n-i/n}(X_i+1)}$$

$$+ (1 + \delta)\lambda \frac{\mathbb{E}f\left(i/V(t), X_i\right)e^{Ag_{n-i/n}(X_i+1)}}{\mathbb{E}e^{Ag_{n-i/n}(X_i+1)}}$$

$$= \log \varphi_0(Ag_{n-i/n}) + (1 + \delta)\lambda \mathbb{E}\left(f\left(\frac{i}{V(t)}, X_i\right)e^{Ag_{n-i/n}(X_i+1)}\right).$$

41
Consequently, using the inequality \( \log(1 + x) \leq x \) to handle the second product in the upper bound (6.2.11), we see that the logarithm of (6.2.11) is at most

\[
\sum_{1 \leq i \leq n} \log \varphi_0(A_{g - i/n}) + (1 + \delta) \lambda \sum_{1 \leq i \leq n} \mathbb{E} \left( f \left( \frac{i}{V(t)}, X_i \right) \right) \frac{e^{A_{g - i/n}(X_{i+1})}}{\varphi_0(A_{g - i/n})} + (1 + \delta) \lambda \sum_{i > n} \mathbb{E} f \left( \frac{i}{V(t)}, X_i \right). 
\]

Referring to the upper bound (6.2.8),

\[
\lambda h + A \gamma \frac{t + s_n}{g_n V(t)} - \frac{1}{V(t)} \log \mathbb{E} \exp \left( \lambda V(t) M_t + A \gamma S^0 \right)
\]

is then at least

\[
A \gamma \frac{t + s_n}{g_n V(t)} - \frac{1}{V(t)} \sum_{1 \leq i \leq n} \log \varphi_0(A_{g - i/n}) + \lambda h - (1 + \delta) \lambda \frac{n}{V(t)} \sum_{1 \leq i \leq n} \mathbb{E} \left( f \left( \frac{i}{V(t)}, X_i \right) \right) \frac{e^{A_{g - i/n}(X_{i+1})}}{\varphi_0(A_{g - i/n})} - (1 + \delta) \lambda \frac{n}{V(t)} \sum_{i > n} \mathbb{E} f \left( \frac{i}{V(t)}, X_i \right). 
\]

(6.2.12)

Define \( \nu \) as \( n/V(t) \). Using (6.2.10), Lemma 6.2.1, the equality \( \varphi_0(\lambda) = e^{\lambda} \varphi(\lambda) \) valid here since \( \mu = -1 \), we obtain that (6.2.8) is at most the exponential of \(-V(t)\) times

\[
\theta - \eta + \lambda h - (1 + \delta) \lambda \nu \int f(\nu v, x) \frac{e^{A \gamma (1-v)^{\gamma-1}(x+1)}}{\varphi_0(A \gamma (1-v)^{\gamma-1})} \mathbb{I}_{[0,1]}(v) \, d(L \otimes F)(v, x)
\]

\[
- (1 + \delta) \lambda \nu \int f(\nu v, x) \mathbb{I}_{[1,\infty]}(v) \, d(L \otimes F)(v, x)
\]

\[
= \theta - \eta + \lambda \left( h - (1 + \delta) \nu \frac{\nu}{\tau} \int f \left( \frac{\nu v}{\tau}, x \right) \, d\mathcal{M}(v, x) \right). 
\]

(6.2.13)

If \( \epsilon \) is small enough so that \( \nu/\tau \) is close enough to 1, then

\[
\left| \int \frac{\nu}{\tau} f \left( \frac{\nu v}{\tau}, x \right) \, d\mathcal{M}(v, x) - \mathcal{M} f \right| < \eta/\lambda
\]

42
and (6.2.13) is at least
\[ \theta - \eta + \lambda (h - (1 + \delta)Mf) - \eta, \]
which, by our choice of \( \eta \) is greater than \( \theta + (1 - \delta)\eta \). Hence
\[
\log P \{ M_t f > h; S_n^0 > t + s_n \} \lesssim -V(t)(\theta + (1 - \delta)\eta)
\]
as \( t \) tends to infinity. Since \( V \) is regularly varying, (6.2.7) shows that (6.2.6) holds, and this proves assertion (ii) of Theorem 3.1 when \( \mu \) is \(-1\).

6.3. Proof of Theorem 3.1.iii when \( \max_{0 \leq i \leq n} g_{i/n} \) is ultimately bounded. In essence, the proof consists in writing the process \( S_t \) as a functional of \( M_t \) and showing that the convergence of \( M_t \) to \( M \) implies that of the functional of \( M_t \) to the functional of \( M \). The main difficulty is that the functional is not continuous with respect to our topology on measures. This forces us to develop various approximation results to show that \( S_t \) is approximable by a well behaved functional of \( M_t \).

To proceed, for any measure \( \nu \) on the right half-space for which the integrals
\[
\int \mathbb{1}_{[0,\lambda]}(v)(\lambda - v)^{-1}\gamma^{-1}|x|\,d\nu(v,x), \quad \lambda > 0,
\]
are finite, we define the functional \( \mathcal{E} \) of \( \nu \) evaluated at \( \lambda \) by
\[
\mathcal{E}(\nu)(\lambda) = \int \mathbb{1}_{[0,\lambda]}(v)(\lambda - v)^{-1}\gamma^{-1}x\,d\nu(v,x),
\]
with the convention that \( \mathcal{E}(\nu)(0) = 0 \).

For any function \( f \) defined on some interval \([a, b]\) we write
\[
|f|_{[a, b]} = \sup_{a \leq x \leq b} |f(x)|
\]
for its supremum norm over that interval.

Our first lemma shows that given that \( M \) exceeds a large threshold \( t \), the process \( S_t \) is well approximated by \( \mathcal{E}(M_t) \) locally uniformly.

Lemma 6.3.1. For any positive \( \Lambda \) and \( \epsilon \),
\[
\lim_{t \to \infty} P \left\{ |S_t - \mathcal{E}(M_t)|_{[0,\Lambda]} > \epsilon \mid M > t \right\} = 0.
\]
Proof. Consider the difference $\Delta_t = |S_t - \mathcal{E}(M_t)|_{[0,\Lambda]}$. To analyse it, we rewrite $S_t(\lambda)$ as

$$S_t(\lambda) = \frac{1}{t} \sum_{1 \leq i \leq \lambda V(t)} g_{[\lambda V(t)] - i} X_i$$

$$= \int 1_{[0,\lambda)}(v) \frac{V(t)}{t} g_{[\lambda V(t)] - [v V(t)]} x \, dM_t(v, x)$$

$$+ \frac{1}{t} \mathbb{1}_N(\lambda V(t)) g_0 X_{[\lambda V(t)]}.$$  \hspace{1cm} (6.3.1)

From this expression and the following consequence of (5.1.1),

$$\frac{V(t)}{t} g_{[\lambda V(t)] - [v V(t)]} \sim \gamma(\lambda - v)^{\gamma - 1},$$

the result appears natural, though not proved yet. The proof has four steps.

We fix a positive $\Lambda$ and we consider a positive real number $\eta$.

**Step 1.** Let $\delta$ be a positive real number and define $\Delta_{t,1}(\lambda)$ as

$$\int 1_{[0,\lambda)}(v) \left| \frac{V(t)}{t} g_{[\lambda V(t)] - [v V(t)]} - \gamma(\lambda - v)^{\gamma - 1} \right| x \, dM_t(v, x).$$

The asymptotic equivalence (6.3.2) holds uniformly in the range of $\lambda$ and $v$ such that $0 \leq v < v + \delta < \lambda < \Lambda$. Consequently, for $t$ large enough and uniformly in $\lambda$ in $[\delta, \Lambda]$,

$$\Delta_{t,1}(\lambda) \leq \eta \int 1\{0 \leq v < v + \delta < \lambda\} \gamma(\lambda - v)^{\gamma - 1} |x| \, dM_t(v, x).$$

Since $(\lambda - v)^{\gamma - 1} \leq \Lambda^{\gamma - 1}$ in that range, we further obtain the upper bound, independent of $\lambda$,

$$\Delta_{t,1}(\lambda) \leq \eta \gamma \Lambda^{\gamma - 1} \int 1\{0 < u < u + \delta < \Lambda\} |x| \, dM_t(u, x)$$

$$\leq \eta \gamma \Lambda^{\gamma - 1} \sum_{1 \leq u \leq \Lambda V(t)} |X_i|.$$}

We take $\eta$ small enough so that $\epsilon/\eta \gamma \Lambda^{\gamma}$ exceeds the mean of $|X_1|$. Since the moment generating function of $|X_1|$ is finite in
a neighborhood of the origin, we introduce the Cramér function associated to the distribution of \(|X_1|\),

\[
I_s(x) = \sup_{s > 0} sx - \log \mathbb{E}^s |X_1|.
\]

The Chernoff bound implies,

\[
P\{ |\Delta_{t,1}|_{[\delta,\Lambda]} > \epsilon \} \leq \exp\left( -[AV(t)] I_s\left( \frac{\epsilon}{\eta \gamma \Lambda} \right) \right). \tag{6.3.3}
\]

Since \(I_s(\epsilon/\gamma \Lambda \eta)\) tends to infinity as \(\eta\) tends to 0, we can choose \(\eta\) small enough to guarantee that the upper bound (6.3.3) is negligible compared to the probability that \(M\) exceeds \(t\) by virtue of Theorem 2.1. Consequently,

\[
\lim_{t \to \infty} P\{ |\Delta_{t,1}|_{[\delta,\Lambda]} > \epsilon \mid M > t \} = 0.
\]

**Step 2.** We now consider

\[
\Delta_{t,2}(\lambda) = \left| \int 1_{[(\lambda-\delta,\lambda)}(v) \frac{V(t)}{t} g_{[AV(t)]-\{\epsilon V(t)\}} x dM_t(v, x) \right|.
\]

Let \(c\) be a positive number such that \(\max_{0 \leq i \leq n} g_i \leq cg_n\) for any \(n\) large enough. For \(t\) large enough and uniformly in \(\lambda\) in \([0, \Lambda]\),

\[
\Delta_{t,2}(\lambda) \leq c \frac{V(t)}{t} g_{[AV(t)]} \int 1_{(\lambda-\delta,\lambda)}(v) |x| dM_t(v, x)
\]

\[
\leq 2c\gamma \delta^{-1} \frac{1}{V(t)} \sum_{(\lambda-\delta,\lambda)}^{\lambda\Lambda(t)} |X_i|.
\]

Therefore,

\[
|\Delta_{t,2}|_{[0,\Lambda]} \leq 2c\gamma \delta^{-1} \max_{1 \leq j < \Lambda V(t)} \frac{1}{\delta V(t)} \sum_{j \leq i < j + \delta V(t)} |X_i|. \tag{6.3.4}
\]

Using Bonferroni’s inequality and then Chernoff’s, this implies that for \(t\) large enough,

\[
P\{ |\Delta_{t,2}|_{[0,\Lambda]} > \epsilon \} \leq \Lambda V(t) P\left\{ \sum_{1 \leq i \leq \delta V(t)} |X_i| > \frac{\delta V(t)}{2c\gamma \delta^{-1}} \epsilon \right\}
\]

\[
\leq \Lambda V(t) \exp\left( -[\delta V(t)] I_s\left( \frac{\epsilon}{2c\gamma \delta^{-1}} \right) \right). \tag{6.3.5}
\]
Since $I_* \gg \text{Id}$ at infinity, taking $\delta$ small enough ensures that the upper bound (6.3.5) is negligible compared to the probability that $M$ exceeds $t$.

**Step 3.** We now consider

$$\Delta_{t,3}(\lambda) = \left| \int [\lambda-\delta,\lambda) \gamma(\lambda-v)^{\gamma-1}x \, dM_t(v, x) \right|.$$  

This is at most

$$\gamma\delta^{\gamma-1} \frac{1}{V(t)} \sum_{(\lambda-\delta, V(t)) \leq i < \lambda V(t)} |X_i|.$$  

Comparing with (6.3.4), we deduce from the previous step that for any $\delta$ small enough,

$$\lim_{t \to \infty} \mathbb{P}\{ |\Delta_{t,3}|_{[0,\Lambda]} > \epsilon \mid M > t \} = 0.$$  

**Step 4.** Let

$$\Delta_{t,4}(\lambda) = t^{-1} \mathbb{I}_N(\Lambda V(t)) g_0 X_{[\Lambda V(t)]}.$$  

We see that

$$|\Delta_{t,4}|_{[0,\Lambda]} = t^{-1} g_0 \max_{1 \leq i \leq \Lambda V(t)} X_i.$$  

Thus, Bonferroni’s inequality yields

$$\mathbb{P}\{ |\Delta_{t,4}|_{[0,\Lambda]} > \epsilon \} \leq \Lambda V(t) F(te/g_0).$$  

To prove that this upper bound is negligible compared to the probability that $M$ exceeds $t$, it suffices to show that for any $\epsilon$ and $\eta$ positive, $\lim_{t \to \infty} \log F(\epsilon t) + \eta V(t) = -\infty$. This limit holds for the following reason. Firstly, the finiteness of the moment generating function on the nonnegative half-line implies that $\lim_{t \to \infty} \log F(\epsilon t)/t = -\infty$ for any positive $\epsilon$. Secondly, Lemma 5.1.2 implies that $\limsup_{t \to \infty} V(t)/t$ is finite. Thus, $\lim_{t \to \infty} t^{-1} (\log F(\epsilon t) + \eta V(t)) = -\infty$ for any positive $\epsilon$ and $\eta$, which is more than what we needed.

**Conclusion.** Since $\Delta_t$ is at most the sum $\Delta_{t,1} + \Delta_{t,2} + \Delta_{t,3} + \Delta_{t,4}$, the result follows from the four steps, Bonferroni’s inequality and the fact that $\epsilon$ is arbitrary.

The functional $\mathfrak{E}$ is not well behaved with respect to weak* or vague convergence, because it integrates a function which is
both unbounded in $x$ and discontinuous in $v$. Those are classical problems which arise in large deviations theory when one wants to use a so-called contraction principle, and the remedy is often to use a truncation and a smoothing — in a context closely related to ours, see Bahadur (1971), Groeneboom, Oosterhoff and Ruymgaart (1979), and Hoadley (1967) for the truncation argument. Other approaches, such as Ganesh and O’Connell’s (2002), could likely be used as well. To setup the truncation argument, let $b$ be a positive real number and define, now for any measure $\nu$,

$$\mathfrak{E}(\nu, b)(\lambda) = \int I_{[0, \lambda]}(v) \gamma(\lambda - v)^{\gamma-1} \text{sign}(x)(|x| \wedge b) \, d\nu(v, x).$$

Note that for any positive $\Lambda$,

$$|\mathfrak{E}(\nu, b) - \mathfrak{E}(\nu)|_{[0, \Lambda]} \leq \gamma \Lambda^{\gamma-1} \int I_{[0, \Lambda]}(v)(|x| - b)_+ \, d\nu(v, x). \quad (6.3.6)$$

Our next lemma shows that provided $b$ is large enough, $\mathfrak{E}(\mathcal{M}_t, b)$ is close to $\mathfrak{E}(\mathcal{M}_t)$ in conditional probability given that $M$ exceeds a large $t$.

**Lemma 6.3.2.** For any $\Lambda$ and $\epsilon$ positive,

$$\lim_{b \to \infty} \limsup_{t \to \infty} \mathbb{P}\{ |\mathfrak{E}(\mathcal{M}_t) - \mathfrak{E}(\mathcal{M}_t, b)|_{[0, \Lambda]} > \epsilon \mid M > t \} = 0.$$

**Proof.** The upper bound in (6.3.6) with $\mathcal{M}_t$ substituted for $\nu$ is

$$\gamma \Lambda^{\gamma-1} \frac{1}{V(t)} \sum_{1 \leq i \leq \Lambda V(t)} (|X_i| - b)_+. $$

Therefore, using the exponential Markov inequality, for any positive $a$,

$$\mathbb{P}\{ |\mathfrak{E}(\mathcal{M}_t) - \mathfrak{E}(\mathcal{M}_t, b)|_{[0, \Lambda]} > \epsilon \} \leq \exp\left(-\Lambda V(t)\left(a - \frac{\epsilon}{\gamma \Lambda^\gamma} - \log \mathbb{E}e^{a(|X_i| - b)_+}\right)\right). \quad (6.3.7)$$

By dominated convergence with dominating function $e^{a|X_i|}$, for any fixed $a$,

$$\lim_{b \to \infty} \log \mathbb{E}e^{a(|X_i| - b)_+} = 0.$$
Therefore, taking $a$ such that $ae/\gamma \Lambda^\gamma$ is large enough, we obtain that, provided $b$ is large enough, the right hand side of (6.3.7) is negligible, as $t$ tends to infinity, compared to the probability that $M$ exceeds $t$. The result follows. 

Recall that the measure $\mathcal{M}$ was defined in (3.3). Our next lemma shows that the deterministic functions $\mathcal{E}(\mathcal{M}, b)$ and $\mathcal{E}(\mathcal{M})$ are close provided $b$ is large enough.

**Lemma 6.3.3.** For any positive $\Lambda$,

$$\lim_{b \to \infty} |\mathcal{E}(\mathcal{M}, b) - \mathcal{E}(\mathcal{M})|[0, \Lambda] = 0.$$  

**Proof.** Since $(|x| - b)_+$ is at most $|x|$ and the function $1_{[0, \Lambda]}(v)|x|$ is $\mathcal{M}$-integrable, the dominated convergence theorem ensures that, after substituting $\mathcal{M}$ for $\nu$ in (6.3.6), the right hand side of (6.3.6) tends to 0 as $b$ tends to infinity.

We now calculate $\mathcal{E}(\mathcal{M})$, showing that it is equal to the function $S$ defined in (3.4) and involved in Theorem 3.1.

**Lemma 6.3.4.** For any positive $\lambda$,

$$\mathcal{E}(\mathcal{M})(\lambda) = \int_0^\lambda \gamma(\lambda - v)^{\gamma - 1} m(Ak_\gamma(v/\tau)) \, dv.$$  

**Proof.** It follows from the identity

$$\int x \frac{\exp(Ak_\gamma(v/\tau)x)}{\varphi(Ak_\gamma(v/\tau))} \, dF(x) = m(Ak_\gamma(v/\tau)).$$

We now consider the modulus of continuity of $S_t$ at $\lambda$,

$$\omega_{t, \delta}(\lambda) = \sup \{|S_t(\lambda + v) - S_t(\lambda)| : |v| \leq \delta\}, \quad \delta > 0.$$  

Our next lemma shows that $S_t$ is very likely to be nearly uniformly continuous when $M$ exceeds a large threshold $t$.

**Lemma 6.3.5.** For any positive $\epsilon$ and $\Lambda$,

$$\lim_{\delta \to 0} \limsup_{t \to \infty} P\{ |\omega_{t, \delta}[0, \Lambda] > \epsilon \mid M > t \} = 0.$$
Proof. For any positive \( \delta \), define

\[
\omega_{t, \delta, b}(\lambda) = \sup \left\{ |\mathcal{E}(\mathcal{M}_t, b)(\lambda + v) - \mathcal{E}(\mathcal{M}_t, b)(\lambda)| : |v| \leq \delta \right\}.
\]

Since

\[
|\omega_{t, \delta}|_{[0, \Lambda]} \leq |\omega_{t, \delta, b}|_{[0, \Lambda]} + 2|S_t - \mathcal{E}(\mathcal{M}_t, b)|_{[0, \Lambda]},
\]

Lemmas 6.3.1 and 6.3.2 show that it suffices to prove that for any \( b \),

\[
\lim_{\delta \to 0} \limsup_{t \to \infty} \mathbb{P}\{ |\omega_{t, \delta, b}|_{[0, \Lambda]} > \epsilon \mid M > t \} = 0.
\]

Let \( \lambda_1 \) and \( \lambda_2 \) be two positive real numbers, with \( \lambda_1 < \lambda_2 \leq \lambda_1 + \delta \) and \( \lambda_2 \leq \Lambda \). We bound \( |\mathcal{E}(\mathcal{M}_t, b)(\lambda_2) - \mathcal{E}(\mathcal{M}_t, b)(\lambda_1)| \) as the sum of

\[
\gamma b \int \left( |\mathbb{1}_{[0, \lambda_2]}(v) - \mathbb{1}_{[0, \lambda_1]}(v)| \right) (\lambda_2 - \lambda_1) \gamma^{-1} dM_t(v, x) \quad (6.3.8)
\]

and

\[
\gamma b \int \mathbb{1}_{[0, \lambda_1]}(v) ((\lambda_2 - v) \gamma^{-1} - (\lambda_1 - v) \gamma^{-1}) dM_t(v, x). \quad (6.3.9)
\]

For any \( t \) large enough, (6.3.8) is at most

\[
\gamma b A \gamma^{-1} |M_t((\lambda_1, \lambda_2) \times \mathbb{R})| \leq \gamma b A \gamma^{-1} \left( \lambda_2 - \lambda_1 + \frac{1}{V(t)} \right) \leq \gamma b A \gamma^{-1} 2 \delta.
\]

The second term of (6.3.9) is at most the following function evaluated at \( t \),

\[
\gamma b \frac{1}{V^\gamma} \sum_{1 \leq i \leq \lambda_1 V} \left( (\lambda_2 V - i) \gamma^{-1} - (\lambda_1 V - i) \gamma^{-1} \right).
\]

Using the comparison of a sum with an integral, namely that for any positive real numbers \( 0 < a < b \),

\[
\gamma \sum_{1 \leq i \leq a} (b - i)^{\gamma^{-1}} \left\{ \leq \gamma \int_0^a (b - u)^{\gamma^{-1}} du \leq b^\gamma, \right.
\]

\[
\geq \gamma \int_1^{[a]} (b - u)^{\gamma^{-1}} du = (b - 1)^{\gamma} - (b - [a])^\gamma,
\]

49
we see that $\gamma$ times the sum involved in (6.3.10) is at most
\[
(\lambda_2 V)^\gamma - (\lambda_1 V - 1)^\gamma + (\lambda_1 V - \lfloor \lambda_1 V \rfloor)^\gamma \\
\leq V^\gamma \left( \lambda_2^\gamma - \left( \lambda_1 - \frac{1}{V} \right)^\gamma + \frac{1}{V^\gamma} \right).
\]
Since the function $\text{Id}^\gamma$ is locally uniformly continuous on the non-negative half-line, this implies that (6.3.10) can be made arbitrarily small by taking $t$ large enough and $\delta$ small enough. This proves the lemma.

Next, we setup the smoothing procedure which will allow us to approximate the functional $\mathcal{E}(\cdot, b)$ by a well behaved one. Define the function
\[
\mathbb{I}_\epsilon(v) = \begin{cases} 
1 & \text{if } 0 \leq v \leq 1 - \epsilon, \\
(1 - v)/\epsilon & \text{if } 1 - \epsilon \leq v \leq 1, \\
0 & \text{if } v \geq 1.
\end{cases}
\]
This function is continuous, coincides with $\mathbb{I}_{[0,1)}$ on the complement of $(1 - \epsilon, 1)$ and moreover, $0 \leq \mathbb{I}_{[0,1)} - \mathbb{I}_\epsilon \leq 1$. Define the functional
\[
\mathcal{E}_\epsilon(\nu, b)(\lambda) = \int \mathbb{I}_\epsilon\left( \frac{v}{\lambda} \right) \gamma (\lambda - v)^{\gamma - 1} \text{sign}(x)(|x| \wedge b) \, d\nu(v, x).
\]
The following shows that $\mathcal{E}(\cdot, b)$ is well approximated by $\mathcal{E}_\epsilon(\cdot, b)$ for the measures of interest to us.

**Lemma 6.3.6.** For any positive $\Lambda$ and any $t$ large enough, both $|\mathcal{E}_\epsilon(\mathcal{M}_t, b) - \mathcal{E}(\mathcal{M}_t, b)|_{[0, \Lambda]}$ and $|\mathcal{E}_\epsilon(\mathcal{M}, b) - \mathcal{E}(\mathcal{M}, b)|_{[0, \Lambda]}$ are bounded by $2\gamma\Lambda^{\gamma}\beta e$.

**Proof.** Let $\nu$ be a $\sigma$-finite measure on the right half-space and let $\lambda$ be nonnegative and at most $\Lambda$. Since $0 \leq \mathbb{1}_{[0,1)} - \mathbb{I}_\epsilon \leq \mathbb{1}_{[1-\epsilon,1]}$,
\[
|\{(\mathcal{E}(\nu, b) - \mathcal{E}_\epsilon(\nu, b))(\lambda)\} - \gamma \Lambda^{\gamma-1} b \nu\{(v, x) : 1 - \epsilon \leq v/\lambda \leq 1\}|.
\]
If $\nu$ is $\mathcal{M}$, its first marginal measure is the Lebesgue measure; then $\nu\{(v, x) : 1 - \epsilon \leq v/\lambda \leq 1\}$ is equal to $\lambda \epsilon$, while, if $\nu$ is $\mathcal{M}_t$, it is equal to
\[
\frac{1}{V(t)} \sharp\{i : (1 - \epsilon)\lambda V(t) \leq i \leq \lambda V(t)\} \leq \frac{1}{V(t)}(\lambda \epsilon V(t) + 1).
\]
The result follows.

We now prove assertion (iii) of Theorem 3.1. Combining Lemmas 6.3.1, 6.3.2, 6.3.6 and 6.3.3, we deduce that as \( t \) tends to infinity and for any \( \lambda \) fixed, \( S_t(\lambda) \) converges in probability to \( \mathbb{E}(\mathcal{M})(\lambda) \) conditionally on \( M \) exceeds \( t \). Lemma 6.3.5 turns this pointwise convergence to a locally uniform one. The result follows from Lemma 6.3.4.

6.4. Proof of Theorem 3.1.iii when \( \max_{0 \leq i < n} g_{i/n} \) tends to infinity. When \( \max_{0 \leq i < n} g_{i/n} \) tends to infinity, the proof of Theorem 3.1 requires an extra truncation, in part because the function \( v \in [0, \lambda) \mapsto (\lambda - v)^{\gamma - 1} \) is no longer bounded when \( \gamma \) is less than 1, and in part because the various functionals introduced in the previous subsection are not well behaved with respect to the convergence of measures.

To setup this truncation, we first prove the following lemma.

**Lemma 6.4.1.** For any real number \( B \) greater than 1, define

\[
i_B(t) = \max\left\{ i \in \mathbb{N} : \frac{V(t)}{t} g_i > B \right\}.
\]

(i) If \( \gamma \) is less than 1, then

\[
i_B(t) \sim (B/\gamma)^{1/(\gamma - 1)} V(t) \quad \text{and} \quad g_{[0, i_B(t))} \sim (B/\gamma)^{\gamma/(\gamma - 1)} t
\]

as \( t \) tends to infinity.

(ii) If \( \gamma \) is 1, then

\[
i_B(t) = o(V(t)) \quad \text{and} \quad g_{[0, i_B(t))} = o(t)
\]

as \( t \) tends to infinity.

**Proof.** (i) Lemma 5.1.1 and Theorem 1.5.3 in Bingham, Goldie and Teugels (1989) show that the sequence \( (g_n)_{n \geq 0} \) is asymptotically equivalent to a nonincreasing sequence. Then, the asymptotic equivalence for \( i_B \) follows from (5.1.1), and that for \( g_{[0, i_B]} \) follows from Lemma 5.1.1.

(ii) When \( \gamma \) is 1, the standard assumption ensures that the sequence \( (g_n)_{n \geq 1} \) is asymptotically equivalent to a nonincreasing
sequence. For any positive real number $c$ fixed, (5.1.1) shows that $g_{[cV(t)]} \sim t/V(t)$, and this forces $i_B(t)$ to be negligible compared to $V(t)$. The assertion on $g_{[0,i_B(t)]}$ follows from Lemma 5.1.1.

Define the function

\[ h(B) = \begin{cases} 2(B/\gamma)^{1/(\gamma-1)} & \text{if } \gamma < 1, \\ 1/B & \text{if } \gamma = 1. \end{cases} \]

Lemma 6.4.1 implies that for any fixed $B$, the function $i_B$ is ultimately less than $h(B)V$. One sees that when $\gamma$ is 1, the inequality $i_B < h(B)V$ holds ultimately for any positive function $h$. Our choice of $h(B) = 1/B$ in this case is entirely arbitrary and any positive function which tends to 0 at infinity could be used in what follows.

For any positive real number $B$, define

\[ S_{B,t}(\lambda) = \frac{1}{V(t)} \sum_{0 \leq i < \lambda V(t)} \left( \frac{V(t)}{t} g_i \wedge B \right) X_{[\lambda V(t)]-i}. \]

Our next lemma shows that given that $M$ exceeds a large level $t$ the process $S_t$ is well approximated by $S_{B,t}$ provided that $B$ is large enough.

**Lemma 6.4.2.** For any positive $\Lambda$ and $\epsilon$,

\[ \lim_{B \to \infty} \limsup_{t \to \infty} P\{ |S_t - S_{B,t}|_{[0,\Lambda]} > \epsilon \mid M > t \} = 0. \]

**Proof.** In this proof, it is convenient to extend the sequence $(X_i)_{i \geq 1}$ to a sequence $(X_i)_{i \in \mathbb{Z}}$ of independent and identically distributed random variables. Moreover, we define the centered random variables $Z_i = |X_i| - E|X_i|$, $i \in \mathbb{Z}$.

We rewrite $(S_t - S_{B,t})(\lambda)$ as

\[ \frac{1}{V(t)} \sum_{0 \leq i < \lambda V(t)} \left( \frac{V(t)}{t} g_i - B \right)^+ X_{[\lambda V(t)]-i}. \]

Since $(\frac{V(t)}{t} g_i - B)^+$ vanishes for $i$ greater than $i_B(t)$, Lemma 6.4.1 and the discussion which follows shows that for any fixed $B$ greater than 1, for any $t$ large enough and any positive $\lambda$,

\[ |(S_t - S_{t,B})(\lambda)| \leq \frac{1}{V(t)} \sum_{0 \leq i < h(B)V(t)} \frac{V(t)}{t} g_i |X_{[\lambda V(t)]-i}| \]

\[ = \frac{1}{t} \sum_{0 \leq i < h(B)V(t)} g_i Z_{[\lambda V(t)]-i} + \frac{E|X_1|}{t} g_{[0,h(B)V(t)]}. \]
Let \( \epsilon \) be a positive real number. Since

\[
\frac{E[X_1]}{t} g_{[0,h(B)V(t)]} \sim E[X_1|h(B)\gamma]
\]
as \( t \) tends to infinity, we take \( B \) so large that \( t^{-1}E[X_1|g_{[0,h(B)V(t)]}] \) is less than \( \epsilon/2 \) ultimately. Then (6.4.1) shows that there exists \( t_0 \), which does not depend on \( \lambda \), such that for any \( t \) at least \( t_0 \) the probability that \( |S_t - S_{t,B}|(\lambda) \) exceeds \( 2\epsilon \) is at most

\[
\text{P}\left\{ \sum_{0 \leq i < h(B)V(t)} g_i Z \left[ \lambda V(t) \right] - i > \frac{t}{g_{[0,h(B)V(t)]}} \epsilon g_{[0,h(B)V(t)]} \right\}.
\]

(6.4.2)

Define \( J_* \) as \( J \) but substituting the distribution of \( Z_i \) for that of \( X_i - E[X_i] \). Note that \( t/g_{[0,h(B)V(t)]} \sim h(B)^{-\gamma} \). Then Proposition 5.2.2 implies that the logarithm of (6.4.2) is asymptotically equivalent to \( V(t) \) times

\[
-h(B)J_*(\frac{\epsilon}{h(B)^{\gamma}})
\]
as \( t \) tends to infinity. Since the logarithmic tail of the distribution function of \( Z_i \) is regularly varying of index \( \alpha \) greater than 1, so is \( J_* \). Thus, given our choice of \( h \), we can find \( B \) large enough so that the negative of (6.4.3) is greater than \( 3\theta \) — recall that \( \theta \) was defined in section 2. Thus, for \( t \) large enough, (6.4.2) is at most \( \exp(-2\theta V(t)) \).

Since

\[
|S_t - S_{t,B}|(\lambda, \Lambda) = \max_{0 \leq i < \Lambda V(t)} |S_t - S_{t,B}(i/V(t))|
\]

Bonferroni’s inequality implies

\[
\text{P}\{ |S_t - S_{t,B}|(\lambda, \Lambda) > \epsilon \} = o(\text{P}\{ M > t \})
\]
as \( t \) tends to infinity, and this proves the lemma.

To prove Theorem 3.1 under assumption (ii) of Theorem 2.1, we mostly repeat its proof under the assumption (i) of Theorem 2.1, substituting \( (\lambda - v)^{-1} \land B \) for \( (\lambda - v)^{-1} \) and substituting the bound \( (\lambda - v)^{-1} \land B \leq B \) for the bound \( (\lambda - v)^{-1} \leq \Lambda^{-1} \). We indicate the changes that are needed, from which it should be clear how the arguments need to be changed.

Instead of the functional \( \mathfrak{E}(\nu) \), we define

\[
\mathfrak{E}_B(\nu)(\lambda) = \int 1_{[0,\lambda]}(v)(\nu)((\lambda - v)^{-1} \land B) x \nu(x),
\]

53
and instead of the functional $\mathcal{E}(\nu, b)$, we define

$$\mathcal{E}_B(\nu, b)(\lambda) = \int 1_{(0,\lambda)}(v) \gamma((\lambda - v)^{-1} \wedge B) \text{sign}(x)(|x| \wedge b) \, d\nu(v, x).$$

In what follows, we state the analogues of the lemmas of subsection 6.3. We do not indicate the proof when it is identical to that of the previous subsection up to the substitutions indicated above.

Our first lemmas are the analogues of Lemmas 6.3.1, 6.3.2, and 6.3.3.

**Lemma 6.4.3.** For any positive $\Lambda$ and $\epsilon$,

$$\lim_{B \to \infty} \limsup_{t \to \infty} P\{ |S_{B,t} - \mathcal{E}_B(M_t)|_{[0,\Lambda]} > \epsilon \mid M > t \} = 0.$$

**Lemma 6.4.4.** For any positive $\Lambda$ and $\epsilon$,

$$\lim_{B \to \infty} \limsup_{b \to \infty} \limsup_{t \to \infty} P\{ |\mathcal{E}_B(M_t) - \mathcal{E}_B(M_t, b)|_{[0,\Lambda]} > \epsilon \mid M > t \} = 0.$$

**Lemma 6.4.5.** For any positive $\Lambda$,

$$\lim_{B \to \infty} \limsup_{b \to \infty} |\mathcal{E}_B(M, b) - \mathcal{E}_B(M)|_{[0,\Lambda]} = 0.$$

Instead of the functional $\mathcal{E}_\epsilon(\nu, b)$, we define

$$\mathcal{E}_{B,\epsilon}(\nu, b)(\lambda) = \int 1_{\epsilon}(v/\lambda) \gamma((\lambda - v)^{-1} \wedge B) \text{sign}(x)(|x| \wedge b) \, d\nu(v, x).$$

**Lemma 6.4.6.** For any positive $\Lambda$ and any $t$ large enough, both $|\mathcal{E}_{B,\epsilon}(M_t, b) - \mathcal{E}_B(M_t, b)|_{[0,\Lambda]}$ and $|\mathcal{E}_{B,\epsilon}(M, b) - \mathcal{E}_B(M, b)|_{[0,\Lambda]}$ are bounded by $2\gamma B \epsilon$.

Referring to Lemma 6.3.6, instead of considering the modulus of continuity of $S_t$, we consider that of $S_{B,t}$. With an obvious notation, we have the following.

**Lemma 6.4.7.** For any positive $\epsilon$, $\Lambda$ and $B$,

$$\lim_{\delta \to 0} \limsup_{t \to \infty} P\{ |\omega_{B,t,\delta}|_{[0,\Lambda]} > \epsilon \mid M > t \} = 0.$$
Lemmas 6.2.1 and 6.2.2 and the conclusion of the proof do not depend on $\gamma$. This proves Theorem 3.1 under assumption (ii) of Theorem 2.1.

6.5. Scaling argument. We proved Theorem 3.1 when $\mu$ is $-1$. To allow for other negative values, as we did at the end of section 5.2, we index relevant quantities by the mean $\mu$ in parentheses so as to make more transparent the scaling properties of various expressions.

Considering the innovations of the process, we first set $X(\mu), i = (-\mu)X(-1), i$, $i \geq 1$, so that $M(\mu) = (-\mu)M(-1)$. Thus, the conditional probability given $M(\mu)$ exceeds $t$ is the conditional probability given $M(-1)$ exceeds $t/(-\mu)$.

The random variables

$$N(\mu), t = \frac{V(t/\mu)}{V(t)} N(-1), t/\mu$$

converges to $(-\mu)^{-1/\gamma} \tau(-1)$ given $M(-1) > t/\mu$ as $t$ tends to infinity. Referring to how $\tau$ is defined in (3.1), equality (5.2.13) implies

$$\tau(\mu) = (-\mu)^{-1/\gamma} \tau(-1).$$

(6.5.1)

Therefore, as $t$ tends to infinity, $N(\mu), t$ converges to $\tau(\mu)$ given that $M(\mu)$ exceeds $t$.

We write $M(\mu), t$ as

$$M(\mu), t = \frac{V(t/\mu)}{V(t)} \frac{1}{\sum_{i \geq 1} \delta \left( \frac{V(t/\mu)}{V(t)} \cdot \frac{1}{V(t/\mu)}, -\mu X(-1), i \right)}$$

$$= \frac{V(t/\mu)}{V(t)} \int \delta \left( \frac{V(t/\mu)}{V(t)}, -\mu x \right) dM(-1), t/\mu(v, x).$$

Given $M(-1) > t/(-\mu)$, we proved that the measures $M(-1), t/\mu$ converge to $M(-1)$. It follows that given $M(\mu) > t$, the measures $M(\mu), t$ converge to

$$M(\mu) = (-\mu)^{-1/\gamma} \int \delta \left( (-\mu)^{-1/\gamma} v, -\mu x \right) dM(-1)(v, x).$$

(6.5.2)

Thus we need to check that this definition of $M(\mu)$ coincides with that in (3.3). With $M(\mu)$ defined as in (6.5.2), we have, for any
bounded and continuous function \( f \) on the right half-space,

\[
\mathcal{M}_{(\mu)} f = (-\mu)^{-1/\gamma} \int f((-\mu)^{-1/\gamma} v, -\mu x) \, d\mathcal{M}_{(-1)}(v, x)
\]

\[
= (-\mu)^{-1/\gamma} \int f((-\mu)^{-1/\gamma} v, -\mu x) \times \frac{\exp(A_{(-1)} k_\gamma(w/\tau_{(-1)}) x)}{\varphi(-1)(A_{(-1)} k_\gamma(v/\tau_{(-1)}))} \, dv \, dF(-1)(x).
\]

The change of variable \( w = (-\mu)^{-1/\gamma} v \) and equality (6.5.1) yield

\[
\mathcal{M}_{(\mu)} f = \int \mathcal{E} f(w, X_{(\mu)}, 1) \times \frac{\exp(A_{(-1)} k_\gamma(w/\tau_{(\mu)}) X_{(\mu), 1}/(-\mu))}{\varphi(-1)(A_{(-1)} k_\gamma(w/\tau_{(\mu)}))} \, dw. \quad (6.5.3)
\]

Equality (5.2.12) implies

\[
m_{(-1)}(\lambda) = \frac{1}{-\mu} m_{(\mu)} \left( \frac{\lambda}{-\mu} \right). \quad (6.5.4)
\]

Thus, \( A_{(-1)} \) being defined in (3.2), we have,

\[
\tau_{(-1)}^{-\gamma} = \int_0^1 k_\gamma(u) m_{(-1)}(A_{(-1)} k_\gamma(u)) \, du
\]

\[
= \frac{1}{-\mu} \int_0^1 k_\gamma(u) m_{(\mu)} \left( \frac{A_{(-1)} k_\gamma(u)}{-\mu} \right) \, du.
\]

It then follows from (6.5.1) that

\[
\tau_{(\mu)}^{-\gamma} = \int_0^1 k_\gamma(u) m_{(\mu)} \left( \frac{A_{(-1)} k_\gamma(u)}{-\mu} \right) \, du.
\]

Given (3.2), this implies

\[
A_{(\mu)} = A_{(-1)}/(-\mu). \quad (6.5.5)
\]

Thus, referring to (6.5.3) and using (5.2.12), we obtain that \( \mathcal{M}_{(\mu)} f \) is equal to

\[
\int \mathcal{E} f(w, X_{(\mu)}, 1) \frac{\exp(A_{(\mu)} k_\gamma(w/\tau_{(\mu)}) X_{(\mu), 1})}{\varphi_{(\mu)}(A_{(\mu)} k_\gamma(w/\tau_{(\mu)}))} \, dw.
\]
This shows that definition (6.5.2) for $\mathcal{M}(\mu)$ coincides with that in (3.3).

We finally prove the convergence of the process $S(\mu),t$. Since

$$S(\mu),t(\lambda) = \frac{S(\mu),[\lambda V(t)]}{t} = \frac{-\mu S_{(-1),[\lambda V(t)-\mu V(t)]/V(t)-\mu]}{(-\mu) t/(-\mu)},$$

the process $S(\mu),t$ converges to $S_{(-1)}((-\mu)^{1/\gamma} \cdot )$ given $M_{(-1)} > t/\mu$, as $t$ tends to infinity. Using the definition of $S_{(-1)}$ in (3.4), the limiting process at $\lambda$ is

$$S_{(-1)}((-\mu)^{1/\gamma} \lambda) = \int_0^\lambda \gamma(-\mu)^{1/\gamma} - v)^{\gamma-1} \cdot m_{(-1)}(A_{(-1)}k_\gamma(v/\tau_{(-1)})) \, dv.$$

The change of variable $v = (-\mu)^{1/\gamma} w$, equalities (6.5.4), (6.5.1), and (6.5.5) yield that the limiting process at $\lambda$ is

$$\int_0^\lambda \gamma(\lambda - w)^{\gamma-1} m(\mu)(A_{(\mu)}k_\gamma(w/\tau_{\mu})) \, dw,$$

which matches the definition of $S(\mu)$ in (3.4). This proves Theorem 3.1 for arbitrary means.
