THE CLASSIFICATION OF SIMPLE SEPARABLE UNITAL LOCALLY ASH ALGEBRAS

GEORGE A. ELLIOTT, GUIHUA GONG, HUAXIN LIN, AND ZHUANG NIU

Abstract. Let $A$ be a simple separable unital locally approximately subhomogeneous C*-algebra (locally ASH algebra). It is shown that $A \otimes Q$ can be tracially approximated by unital Elliott-Thomsen algebras with trivial $K_1$-group, where $Q$ is the universal UHF algebra. In particular, it follows that $A$ is classifiable by the Elliott invariant if $A$ is Jiang-Su stable.

1. Introduction

Recently, several major steps have been taken in the classification of what might be called “well behaved” separable amenable simple unital C*-algebras. The phenomenon of well behavedness itself was explicitly noticed only relatively recently, by Toms and Winter (see [7]) who conjectured that within this class of C*-algebras several properties were equivalent, and that the algebras in this robust subclass (and only these) were the ones that could be classified by means of what might be called the naive Elliott invariants—the ordered $K_0$-group together with the class of the unit, the simplex of tracial states paired naturally with it, and the $K_1$-group. (Other invariants, such as the Cuntz semigroup, might then be helpful for more general classes of amenable C*-algebras.) Breakthroughs in the understanding of the robustness of this class were made by Matui and Sato in [20] and [21].

Perhaps the most striking development in the direction of actually proving isomorphism has been the technique—sometimes referred to as the Winter deformation technique—introduced by Winter in [33] (with refinements by Lin in [17] and Lin and Niu in [19]), through which a class of (separable, amenable, simple unital) C*-algebras which are well behaved in the sense of absorbing tensorially the Jiang-Su algebra $Z$, and are also known to satisfy the UCT, can be classified in terms of the (naive) Elliott invariant if this is true for the subclass of algebras absorbing the universal Glimm UHF C*-algebra $Q$.

Using this, Gong, Lin, and Niu, in [9]—following on earlier work in this direction (see e.g. [14], [22], [23], [24], [15], [33], [17], [19], [16])—have achieved a classification of finite algebras in this well behaved class which is close to being definitive—it is simple to describe and it exhausts completely the possible values of the invariant. (The complementary class, the infinite algebras in the well behaved class under consideration, were dealt with some time ago by Kirchberg and Phillips—[11], [12], [25].)

Unfortunately, while it is believed that all well behaved finite separable amenable simple unital C*-algebras may be ASH algebras (inductive limits of subalgebras of full matrix algebras over commutative C*-algebras)—and, indeed, that the algebra need not be assumed to be well

Date: July 16, 2015.

1
behaved if in addition matrix algebras over it are also finite in the Murray-von Neumann sense (i.e., if the algebra is stably finite)—the class considered by Gong, Lin, and Niu does not on the face of it include the class of all well behaved—“Jiang-Su stable”—simple unital ASH algebras.

Using the recent result of Santiago, Tikuisis, and the present authors \([5]\) that any Jiang-Su stable simple unital ASH algebra has finite nuclear dimension (one of the Toms-Winter well behavedness properties—the important concept of nuclear dimension was introduced by Winter and Zacharias in \([34]\)—and also using the notion of non-commutative cell complex introduced in \([5]\) in the proof of this result—, the present note shows that indeed such an algebra (Jiang-Su stable simple unital ASH) belongs to the class dealt with by Gong, Lin, and Niu. (Even if the ASH algebra has slow dimension growth, so that by \([28]\) and \([31]\) it is indeed Jiang-Su stable, it is not known to belong to the class studied by Gong, Lin, and Niu—the class of rationally tracially approximately point–line algebras—see below.)

N. also thanks Aaron Tikuisis for his comments on the early version of the paper.

2. Noncommutative cell complexes

Definition 2.1 (Definition 2.1 of \([5]\)). The class of noncommutative cell complexes (NCCC) is the smallest class \(C\) of \(C^*\)-algebras such that

1. every finite dimensional algebra is in \(C\); and
2. if \(B \in C\), \(n \in \mathbb{N}\), \(\varphi : B \to M_k(C(S^{n-1}))\) is a unital homomorphism, and \(A\) is given by the pullback diagram

\[
\begin{array}{ccc}
A & \longrightarrow & M_k(C(D^n)) \\
\downarrow & & \downarrow f \circ f_{|S^{n-1}} \\
B & \varphi \longrightarrow & M_k(C(S^{n-1}))
\end{array}
\]

then \(A \in C\).

The reason we consider NCCCs is as follows:

Theorem 2.2 (Theorem 2.15 of \([5]\)). Let \(A\) be a unital subhomogeneous \(C^*\)-algebra. Then \(A\) can be locally approximated by sub-\(C^*\)-algebras which are NCCCs.

Definition 2.3. Let \(A\) be an NCCC, and fix an NC cell complex decomposition of \(A\) with length \(l\) (in the sense that \(A\) is built from a finite dimensional \(C^*\)-algebra \(A_0\) by attaching \(l\) noncommutative cells). Assume that \(A_0 = M_{s_1}(\mathbb{C}) \oplus \cdots \oplus M_{s_r}(\mathbb{C})\) for some natural number \(r\), and denote the attached cell at the \(i\)-th step by \(M_{k_i}(C(D^{n_i}))\).

Consider the spaces

\[
\left\{ \text{pt}\right\}, \ldots, \left\{ \text{pt}\right\}, D^{n_1}, \ldots, D^{n_r}.
\]
and denote them by \( X_1, X_2, \ldots, X_m \), where \( m = r + l \). Denote the matrix orders of the corresponding C*-algebras by
\[
d_1, \ldots, d_r, d_{r+1}, \ldots, d_m.
\]
Then there is a standard embedding
\[
\Pi : A \to \bigoplus_{i=1}^{m} M_{d_i}(C(X_i)).
\]
Denote by \( \Pi_i : A \to M_{d_i}(C(X_i)) \), \( i = 1, \ldots, m \), the projection of \( \Pi \) onto the \( i \)-th direct summand.

**Lemma 2.4.** Let \( A = B \oplus M_k(C(S^{n-1})) \) be an NCCC, and let \( \tau \in \mathcal{M}(A) \). Then there is a decomposition
\[
\tau(f_B, f_D) = \alpha \tau_B(f_B) + \beta \int\limits_{D^n \setminus S^{n-1}} \text{tr}(f_D(x)) d\mu(x), \quad (f_B, f_D) \in A,
\]
where \( \tau_D \in \mathcal{M}(B) \), \( \mu \) is a probability measure on \( D^n \setminus S^{n-1} \), \( \text{tr} \) is the standard trace of \( M_k(C) \), and \( \alpha, \beta \in [0,1] \) with \( \alpha + \beta = 1 \). Moreover, \( \alpha \) and \( \beta \) are unique and \( \tau_B \) (or \( \mu \)) is unique if \( \alpha \) (or \( \beta \)) is not zero.

**Proof.** The uniqueness part of the lemma is clear. Let us show the existence part.

Consider the restriction of \( \tau \) to \( I := M_k(C_0(D^n \setminus S^{n-1})) \subseteq A \). Then it is a trace with norm at most one, and thus there is a probability measure \( \mu \) on \( D^n \setminus S^{n-1} \) such that
\[
\tau((0,g)) = \beta \int\limits_{D^n \setminus S^{n-1}} \text{tr}(g(x)) d\mu(x), \quad g \in M_k(C_0(D^n \setminus S^{n-1})).
\]
Define a linear map \( \tilde{\tau} : A \to \mathbb{C} \) by
\[
\tilde{\tau}((f,g)) = \tau(f,g) - \beta \int\limits_{D^n \setminus S^{n-1}} \text{tr}(g(x)) d\mu(x), \quad (f,g) \in A.
\]
For each \( g \in M_k(C(D^n)) \) and any \( \eta \in (0,1) \), define
\[
\chi_\eta : [0,1] \ni x \mapsto \begin{cases} 
1, & x \in [1-\eta/2,1], \\
\text{linear}, & x \in [1-\eta,1-\eta/2], \\
0, & x \in [0,1-\eta]; 
\end{cases}
\]
and
\[
g_\eta(x) = g(x)\chi_\eta(\|x\|).
\]
Then a direct calculation shows that
\[
(2.1) \quad \tilde{\tau}(f,g) = \tilde{\tau}(f,g_\eta), \quad (f,g) \in A, \ \eta \in (0,1).
\]
It is clear that \( \tilde{\tau} \) is self-adjoint; let us show that it is positive. Let \( (f,g) \in A \) be positive. Define
\[
\delta = \inf\{\tau(f,g_\eta) : \eta \in (0,1)\}.
\]
If \( \delta = 0 \), let us show that \( \tilde{\tau}(f,g) = 0 \). Indeed, in this case, one has
\[
\tau((f,g)) = \tau(f,g_\eta) + \tau(0,g-g_\eta)
\]
and hence

\begin{equation}
\tau((f,g)) = \sup\{\tau(0,g - g_\eta) : \eta \in (0,1)\} = \sup\{\beta \int_{D^n \setminus S^{n-1}} \text{tr}(g - g_\eta) d\mu(x) : \eta \in (0,1)\}.
\end{equation}

Note that for any \(\eta \in (0,1)\),

\[\tilde{\tau}((f,g)) = \tau(f,g) - \beta \int_{D^n \setminus S^{n-1}} \text{tr}(g_\eta(x)) d\mu(x),\]

and since \(\mu\) is a probability measure, the integral \(\beta \int_{D^n \setminus S^{n-1}} \text{tr}(g_\eta(x)) d\mu(x)\) is arbitrarily small if \(\eta\) is small enough. By (2.2), one has that \(\tilde{\tau}((f,g)) = 0\).

If \(\delta > 0\), since \(\mu\) is a probability measure, there is \(\eta \in (0,1)\) such that \(\beta \int_{D^n \setminus S^{n-1}} \text{tr}(g_\eta(x)) d\mu(x) < \delta/2\), and therefore

\[\tilde{\tau}((f,g)) = \tilde{\tau}((f,g_\eta)) = \tau(f,g_\eta) - \beta \int_{D^n \setminus S^{n-1}} \text{tr}(g_\eta(x)) d\mu(x) \geq -\delta/2 = \delta/2 > 0.\]

Therefore, one always has \(\tilde{\tau}((f,g)) \geq 0\), and so \(\tilde{\tau}\) is a positive linear functional. Therefore \(\tilde{\tau}\) is a (positive) trace of \(A\). Note that \(\tilde{\tau}(I) = 0\), and therefore \(\tilde{\tau}\) factors through \(A/I \cong B\), and hence in fact is a trace of \(B\). Therefore, there are \(\alpha \in [0,1]\) and \(\tau_B \in \text{T}(B)\) such that \(\tau(f,g) - \beta \int_{D^n \setminus S^{n-1}} \text{tr}(g_\eta(x)) d\mu(x) = \tilde{\tau}(f,g) = \alpha \tau_B(f)\), \((a,b) \in A\), as desired.

\[\square\]

**Corollary 2.5.** Let \(A\) be an NCCHC with a given decomposition with length \(l\). Then any trace \(\tau\) of \(A\) has a decomposition

\[\tau = \alpha_1 \tau_1 + \alpha_1 \mu_1 + \cdots + \alpha_m \mu_m,\]

where \(m = \text{rank}(K_0(A_0)) + l\), \(\mu_i\) is a probability measure on \(D^{n_i} \setminus S^{n_i - 1}\) if \(X_i = D^{n_i}\), and \(\mu_i\) is the Dirac measure if \(X_i\) consists of a point, \(\alpha_i \in [0,1]\) and \(\alpha_1 + \alpha_2 + \cdots + \alpha_m = 1\). Moreover, the coefficients \(\alpha_i\) are unique.

**Definition 2.6.** Let \(A\) be an NCCHC with a given decomposition, and let \(\tau \in \text{T}(A)\). Referring to Corollary 2.5, define

\[\alpha_i(\tau) = \alpha_i.\]

**Lemma 2.7.** Let \(A\) be a noncommutative cell complex (NCCHC). Then the \(K\)-groups of \(A\) are finitely generated (as abelian groups).
Proof. The statement is true if $A$ is finite dimensional. Assume the statement is true for non-commutative complexes with length at most $l$.

Let $A$ be a noncommutative complex with length $l + 1$. Write

$$A = B \oplus M_k(C(S^{n-1})) M_k(C(D^n)),$$

where $B$ is a noncommutative complex with length $l$. Then there is a short exact sequence

$$0 \rightarrow M_k(C_0(\mathbb{R}^n)) \rightarrow A \rightarrow B \rightarrow 0,$$

and the corresponding six-term exact sequence is

$$
\begin{array}{c}
K_0(C_0(\mathbb{R}^n)) \rightarrow K_0(A) \rightarrow K_0(B) \\
\downarrow \quad \quad \downarrow \\
K_1(B) \rightarrow K_1(A) \rightarrow K_1(C_0(\mathbb{R}^n)).
\end{array}
$$

If $n$ is odd, one has

$$0 \rightarrow K_0(A) \rightarrow K_0(B) \rightarrow \cdots,$$

and

$$0 \rightarrow \mathbb{Z}/m\mathbb{Z} \rightarrow K_1(A) \rightarrow K_1(B) \rightarrow 0,$$

for some positive integer $m$. By the inductive hypothesis, the groups $K_0(B)$ and $K_1(B)$ are finitely generated, and therefore the groups $K_0(A)$ and $K_1(A)$ are finitely generated.

If $n$ is even, a similar argument shows that $K_0(A)$ and $K_1(A)$ are finitely generated. Therefore, the $K$-groups of $A$ are always finitely generated. Hence by induction, the statement holds for all noncommutative cell complexes. \qed

In general, the positive cone of $K_0(A)$ might not be finitely generated; for instance, the positive cone of $K_0(C(S^2))$ is

$$\{(m,n) \in \mathbb{Z}^2 : m > 0\} \cup \{(0,0)\},$$

which is not finitely generated. (On the other hand, consider the image

$$G := \rho(K_0(A)) \subseteq \text{Aff}(T(A)),$$

with respect to the canonical map $\rho$, with the induced order from $\text{Aff}(T(A))$ (i.e., an element $g \in G$ is positive if and only if $g$ is positive in $\text{Aff}(T(A))$), is isomorphic to $\mathbb{Z}$ and so the positive cone of $G$ is finitely generated.)

The following lemma was stated and proved in [11] for the $K_0$-group of an Elliott-Thomsen algebra. The argument in fact shows the following (for the reader’s convenience, we include the proof). (In fact the ordered groups arising are the same.)

**Lemma 2.8** (Theorem 3.14 of [11]). Consider $(\mathbb{Z}^l, (\mathbb{Z}^l)^{+})$ with the standard (direct sum) order. Let $G$ be a subgroup of $\mathbb{Z}^m$, and put $G^{+} = G \cap (\mathbb{Z}^m)^{+}$. Then the positive cone $G^{+}$ is finitely generated (as a semigroup).
Proof. Let us first show that \( G^+ \setminus \{0\} \) has only finitely many minimal elements. Suppose, otherwise, that \( \{q_n\} \) is an infinite set of minimal elements of \( G^+ \setminus \{0\} \). Write

\[
q_n = (m(1, n), m(2, n), \ldots, m(j, n)) \in \mathbb{Z}^m_+,
\]

where \( m(i, n) \) are positive integers (including zero), \( i = 1, 2, \ldots, m \) and \( n = 1, 2, \ldots \). If there is an integer \( M \geq 1 \) such that \( m(i, n) \leq M \) for all \( i \) and \( n \), then \( \{q_n\} \) is a finite set. So we may assume that \( \{m(i, n)\} \) is unbounded for some \( 1 \leq i \leq m \). Passing to a subsequence of \( \{n_k\} \) such that \( \lim_{k \to \infty} m(i, n_k) = +\infty \), we may assume that \( \lim_{n \to \infty} m(i, n) = +\infty \). We may assume that, for some \( j \), \( \{m(j, n)\} \) is bounded. Otherwise, by passing to a subsequence, we may assume that \( \lim_{n \to \infty} m(i, n) = +\infty \) for all \( i \in \{1, 2, \ldots, m\} \). Therefore \( \lim_{n \to \infty} m(i, n) - m(i, 1) = +\infty \). It follows that, for some \( n \geq 1 \), \( m(i, n) > m(i, 1) \) for all \( i \in \{1, 2, \ldots, m\} \). Therefore, \( q_n > q_1 \), which contradicts the fact that \( q_n \) is minimal. By passing to a subsequence, we may write \( \{1, 2, \ldots, m\} = N \cup B \) such that \( \lim_{n \to \infty} m(i, n) = +\infty \) if \( i \in N \) and \( \{m(i, n)\} \) is bounded if \( i \in B \). Therefore, \( \{m(j, n)\} \) has only finitely many different values if \( j \in B \). Thus, by passing to a subsequence again, we may assume that \( m(j, n) = m(j, 1) \) if \( j \in B \). Therefore, for some \( n > 1 \), \( m(i, n) > m(i, 1) \) for all \( n \) if \( i \in N \), and \( m(j, n) = m(j, 1) \) for all \( n \) if \( j \in B \). It follows that \( q_n \geq q_1 \). This is impossible, since \( q_n \) is minimal. This shows that \( G^+ \) has only finitely many minimal elements.

To show that \( G^+ \) is generated by these minimal elements, fix an element \( q \in G^+ \setminus \{0\} \). It suffices to show that \( q \) is a finite sum of minimal elements in \( G^+ \). If \( q \) is not minimal, consider the set of all elements in \( G^+ \setminus \{0\} \) which are (strictly) smaller than \( q \). This set is finite. Choose one which is minimal among them, say \( p_1 \). Then \( p_1 \) is minimal element in \( G^+ \setminus \{0\} \), as otherwise there is one smaller than \( p_1 \). Since \( q \) is not minimal, \( q \neq p_1 \). Consider \( q - p_1 \in G^+ \setminus \{0\} \). If \( q - p_1 \) is minimal, then \( q = p_1 + (q - p_1) \). Otherwise, we repeat the same argument to obtain a minimal element \( p_2 \leq q - p_1 \). If \( q - p_1 - p_2 \) is minimal, then \( q = p_1 + p_2 + (q - p_1 - p_2) \). Otherwise we repeat the same argument. This process is finite. Therefore \( q \) is a finite sum of minimal elements in \( G^+ \setminus \{0\} \).

With Lemma 2.8 one has

**Lemma 2.9.** Let \( A \) be an NC cell complex decomposition of \( A \), consider the standard embedding

\[
\Pi : A \to \bigoplus_{i=1}^m M_{d_i}(C(X_i)).
\]

Define

\[
\rho : K_0(A) \ni [p] \mapsto (\text{rank}(\Pi_1(p)), \ldots, \text{rank}(\Pi_m(p))) \in \mathbb{Z}^m.
\]

Clearly, the map \( \rho \) is positive.
Define
\[ G = \rho(K_0(A)) \quad \text{and} \quad G^+ = \rho(K_0(A)) \cap (\mathbb{Z}^m)^+. \]

It follows from Lemma [2.8] that the cone \((G, G^+)\) is a finitely generated ordered group. In order to prove the lemma, one only has to show that there is an isomorphism
\[(G, G^+) \cong (\rho_A(K_0(A)), \rho_A(K_0(A)) \cap \text{Aff}^+(T(A))).\]

Define
\[ \theta : \rho(K_0(A)) \ni (x_1, x_2, \ldots, x_m) \mapsto (\tau \mapsto \sum_{i=1}^m \frac{x_i}{d_i} \alpha_i(\tau)) \in \text{Aff}(T(A)). \]

Then \(\theta\) is injective. Note that for any \(\tau \in T(A)\) with the decomposition
\[ \tau = \alpha_1 \mu_0 + \alpha_2 \mu_2 + \cdots + \alpha_m \mu_m, \]
one has
\[ \rho_A(p)(\tau) = \sum_{i=1}^m \alpha_i \int_{X_i} \text{tr}_i(\Pi_i(p)(x)) d\mu_i(x) \]
\[ = \sum_{i=1}^m \alpha_i \int_{X_i} \frac{\text{rank}(\Pi_i(p))}{d_i} d\mu_{i,j} \]
\[ = \sum_{i=1}^m \frac{\text{rank}(\Pi_i(p))}{d_i} = \theta(\rho(p)), \]
and therefore
\[ \theta(\rho(K_0(A))) = \theta(G) = \rho_A(K_0(A)). \]

It is clear that \(\theta(G^+) \subseteq \rho_A(K_0(A)) \cap \text{Aff}^+(T(A)).\) Moreover, if \(\theta(x_1, \ldots, x_m) \in \text{Aff}^+(T(A)),\) then the affine map \(\tau \mapsto \sum_{i=1}^m \frac{2}{d_i} \alpha_i(\tau)\) is positive, and hence each \(x_i\) must be positive; that is, \(\theta\) induces an order isomorphism between \((G, G^+)\) and \(\rho_A(K_0(A)), \rho(K_0(A)) \cap \text{Aff}^+(T(A)),\) as desired.

**Lemma 2.10.** Let \(A\) be an NCNC. Then, for any finite set \(\mathcal{F} \subseteq \text{Aff}(T(A))\) and any \(\varepsilon > 0\), there are positive continuous affine maps \(\theta_1 : \text{Aff}(T(A)) \to \mathbb{R}^s\) and \(\theta_2 : \mathbb{R}^s \to \text{Aff}(T(A))\) for some \(s \in \mathbb{N}\) such that
\[ \|\theta_2 \circ \theta_1(f) - f\|_\infty < \varepsilon, \quad f \in \mathcal{F}. \]

**Proof.** The statement clearly holds for \(A\) a finite dimensional C*-algebra. Assume that
\[ A = B \oplus_{M_k(C(S^{n-1}))} M_k(C(D^n)), \]
and suppose that the statement holds for \(B\).

Let \((\mathcal{F}, \varepsilon)\) be given. Note that \(\text{Aff}(T(A))\) is the pullback of \(\text{Aff}(T(B))\) and \(C_{\mathbb{R}}(D^n)\) in the same manner as \(A\). For each \(f \in \mathcal{F},\) write it as \(f = (f_B, f_D),\) where \(f_B \in \text{Aff}(T(B))\) and \(f_D \in C_{\mathbb{R}}(D^n).\) Denote by \(\mathcal{F}_B\) the set of \(f_B\)'s.

Since \(B\) satisfies the statement, there are continuous positive affine maps \(\theta_{B,1} : \text{Aff}(T(B)) \to \mathbb{R}^{s_B}\) and \(\theta_{B,2} : \mathbb{R}^{s_B} \to \text{Aff}(T(B))\) such that
\[ \|\theta_{B,2} \circ \theta_{B,1}(f_B) - f_B\|_\infty < \varepsilon/3, \quad f \in \mathcal{F}. \]
Choose $\gamma \in (0, 1)$ such that
\[ ||f_D(x) - f_D(y)|| < \varepsilon/3, \quad f \in \mathcal{F}, \]
provided $\text{dist}(x, y) < \gamma$.
Define
\[ g_\gamma : [0, 1] \ni x \mapsto \begin{cases} 
1, & x \in [0, 1 - \gamma], \\
\text{linear}, & x \in [1 - \gamma, 1 - \gamma/2], \\
0, & x \in [1 - \gamma/2, 1];
\end{cases} \]
and consider the linear map
\[ \chi_\gamma : C(S^{n-1}) \ni f \mapsto (x \mapsto (1 - g_\gamma(||x||)) \cdot f\left(\frac{x}{||x||}\right)) \in C(D^n). \]
Then $\chi_\gamma$ is a positive affine map from $\text{Aff}(T(M_k(C(S^{n-1}))))$ to $\text{Aff}(T(M_k(C(D^n))))$. Note that
\[ \|f_D g_\gamma - (f_D - \chi_\gamma f_D)(S^{n-1})\|_\infty = \sup \{ (1 - g_\gamma(||x||))(f_D(x) - f_D\left(\frac{x}{||x||}\right)) : x \in D^n \} < \varepsilon/3 \]
for any $f \in \mathcal{F}$.

Pick an open cover $\mathcal{U}$ of $D^n$ such that the variation of the function $f_D g_\gamma$ on any open subset in $\mathcal{U}$ is at most $\varepsilon/3$ for any $f \in \mathcal{F}$. Moreover, one requires that the diameter of each open set in $\mathcal{U}$ should be at most $\gamma/4$. Choose $\{\phi_U : U \in \mathcal{U}\}$ to be a partition of unity subordinated to $\mathcal{U}$, and fix $x_U \in U$ for each $U \in \mathcal{U}$.

Put
\[ \mathcal{U}_\gamma = \{ U_i : U \cap S^{n-1} = \emptyset \}, \]
and write $\mathcal{U}_\gamma = \{ U_1, U_2, ..., U_{\mathcal{U}_\gamma} \}$.

Since the diameter of each $U_i \in \mathcal{U}$ is at most $\gamma/4$, one has that if $U \notin \mathcal{U}_\gamma$, then $g_\gamma(x_U) = 0$, and hence
\[ \|f_D g_\gamma - \sum_{U \in \mathcal{U}_\gamma} (f_D g_\gamma)(x_U) \phi_U\| = \|f_D g_\gamma - \sum_{U \in \mathcal{U}_\gamma} (f_D g_\gamma)(x_U) \phi_U - \sum_{U \notin \mathcal{U}_\gamma} (f_D g_\gamma)(x_U) \phi_U\| \]
\[ = \|f_D g_\gamma - \sum_{U \in \mathcal{U}} (f_D g_\gamma)(x_U) \phi_U\| \leq \varepsilon/3. \]

Define
\[ \theta_1 : \text{Aff}(T(A)) \ni (f, g) \mapsto \theta_{B,1}(f) \oplus ((g g_\gamma)(x_{U_i})) \in \mathbb{R}^n \oplus \mathbb{R}^{[\mathcal{U}_\gamma]}, \]
and
\[ \theta_2 : \mathbb{R}^n \oplus \mathbb{R}^{[\mathcal{U}_\gamma]} \ni ((\xi_1, ..., \xi_{s_B}), (\eta_1, ..., \eta_{[\mathcal{U}_\gamma]}) \mapsto (\theta_{B,2}((\xi_1, ..., \xi_{s_B})), \chi_\gamma(\varphi(\theta_{B,2}((\xi_1, ..., \xi_{s_B})))) + \sum_{i=1}^{[\mathcal{U}_\gamma]} \eta_i \phi_{U_i}) \in \text{Aff}(T(A)). \]

Then, a straightforward calculation shows that
\[ \theta_2 \circ \theta_1((f_B, f_D)) = (\theta_{B,2}(\theta_{B,1}(f_B)), \chi_\gamma(\varphi(\theta_{B,2}(\theta_{B,1}(f_B)))) + \sum_{i=1}^{[\mathcal{U}_\gamma]} (f_D g_\gamma)(x_{U_i}) \phi_{U_i}) \]
By the inductive assumption, one has that for any \( f \in F \),
\[
\|f_B - \theta_{B,2}(\theta_{B,1}(f_B))\| < \varepsilon/3 < \varepsilon,
\]
and
\[
\left\| f_D - \left(\chi_\gamma(\varphi(\theta_{B,2}(\theta_{B,1}(f_B)))) + \sum_{i=1}^{[\mathcal{U}_\gamma]} (f_D g_\gamma)(x_{U_i})\phi_{U_i}\right) \right\|_\infty < \varepsilon/3 + \varepsilon/3 \quad \text{(by (2.3))}
\]
\[
= \left\| (f_D - \chi_\gamma(f_D|_{S^{n-1}})) - \sum_{i=1}^{[\mathcal{U}_\gamma]} (f_D g_\gamma)(x_{U_i})\phi_{U_i}\right\|_\infty + \varepsilon/3 \quad \text{(by (2.4))}
\]
\[
\leq \left\| g_\gamma f_D - \sum_{i=1}^{[\mathcal{U}_\gamma]} (f_D g_\gamma)(x_p)\phi_p \right\|_\infty + 2\varepsilon/3 \quad \text{(by (2.5))}
\]
\[
\leq \varepsilon \quad \text{(by (2.5)).}
\]
Therefore
\[
\|\theta_2 \circ \theta_1(f) - f\| < \varepsilon, \quad f \in F,
\]
as desired. \(\square\)

Remark 2.11. In fact, as shown in [4] (Lemma 2.6), the statement of Lemma 2.10 always holds if \( T(A) \) is replaced by an arbitrary compact metrizable Choquet simplex.

3. An existence theorem

Let \( A \) be an NCCC. The main result in this section (Theorem 3.7) is that any almost compatible pair \((\kappa, \gamma)\) from an NCCC to \( Q \) can be lifted to an algebra homomorphism, where \( \kappa : K_0(A) \to \mathbb{Q} \) and \( \gamma : \text{Aff}(T(A)) \to \text{Aff}(T(Q)) \cong \mathbb{R} \).

Lemma 3.1. Let \( P \) be an \( m \times n \) matrix with integer entries, and let \( \xi \in \mathbb{R}^m \) with each entry a positive number (including zero). Assume that each entry of \( P\xi \) is rational. Then, for any \( \varepsilon > 0 \), there is \( \zeta \in \mathbb{Q}^m \) with positive entries (including zero) such that

1. \( P\xi = P\zeta \), and
2. \( \|\xi - \zeta\|_\infty < \varepsilon \).

Proof. By deleting the columns of \( P \) corresponding to the 0’s of \( \xi \), one may assume that each entry of \( \xi \) is strictly positive.

Let us show that
\[ \ker P = \overline{\ker P \cap \mathbb{Q}^m}. \]

It is clear that \( \ker P \supseteq \mathbb{Q}^m \cap \ker P \). Note that \( P \) is rational, so that one can choose a basis of \( \ker P \) (as a real vector space) consisting of rational vectors, from which it follows that
\[ \dim_{\mathbb{R}}(\ker P) \leq \dim_{\mathbb{Q}}(\ker P \cap \mathbb{Q}^m), \]
and hence $\dim_{\mathbb{R}}(\ker P) \leq \dim_{\mathbb{R}}(\ker P \cap \mathbb{Q}^m)$. This forces $\ker P = \mathbb{Q}^m \cap \ker P$.

Again by the rationality of $P$, there is a vector $\eta \in \mathbb{Q}^m$ such that

$$P\eta = P\xi,$$

and hence

$$P^{-1}(\{P\xi\}) = P^{-1}(\{P\eta\}) = \eta + \ker P = \eta + \mathbb{Q}^m \cap \ker P = \eta + \mathbb{Q}^m \cap \ker P.$$

It is clear that

$$\xi \in \eta + \mathbb{Q}^m \cap \ker P.$$

On noting that any entry of $\xi$ is strictly positive, and all vectors in $\eta + \mathbb{Q}^m \cap \ker P$ are rational, for any $\varepsilon > 0$, it follows that there is $\zeta \in \eta + \mathbb{Q}^m \cap \ker P$ such that

$$\|\zeta - \xi\|_{\infty} < \varepsilon$$

and each entry of $\zeta$ is positive. \qed

**Lemma 3.2.** Let $A$ be a unital subhomogeneous $C^*$-algebra such that $\text{Prim}_d(A)$ has finitely many connected components for each $d$. Let $(\mathcal{F}, \varepsilon)$ be given. Then, for any compatible pair $(\kappa, \gamma)$ satisfying, where $\kappa : K_0(A) \to \mathbb{Q} = K_0(\mathbb{Q})$ and $\gamma : \text{Aff}(T(A)) \to \mathbb{R} = \text{Aff}(T(A))$, there is a homomorphism $\phi : A \to \mathbb{Q}$ such that

1. $[\phi]_0 = \kappa$, and
2. $|\gamma(\hat{f})(\text{tr}) - \text{tr}(\phi(f))| < \varepsilon, \quad f \in \mathcal{F},$

where $\text{tr}$ is the canonical trace of $Q$. Moreover, $\phi$ can be chosen to have finite dimensional range.

**Proof.** Without loss of generality, one may assume that $\mathcal{F}$ is inside the unit ball. Since $Q$ has unique trace, it is enough to show that for any $\kappa : K_0(A) \to \mathbb{Q}$ and $\tau \in T(A)$ with

$$\tau(p) = \kappa(p), \quad p \in K_0(A),$$

there is a homomorphism $\phi : A \to \mathbb{Q}$ such that $[\phi]_0 = \kappa$ and

$$|\tau(f) - \text{tr}(\phi(f))| < \varepsilon, \quad f \in \mathcal{F}.$$

By Corollary 2.5, there is a probability measure $\mu_i$ on each $X_i$, and $\alpha_i \in [0, 1]$ with

$$\sum_{i=1}^m \alpha_i = 1$$

such that

$$\tau(a) = \sum_{i=1}^m \alpha_i \int_{X_i} \text{tr}_i(\Pi_i(a))d\mu_i, \quad a \in A,$$

where $\text{tr}_i$ is the canonical trace of $M_{k_i}(\mathbb{C})$. 
Note that for each projection \( p \in A \otimes K \), one has

\[
\tau(p) = \sum_{i=1}^{m} \alpha_i \int_{X_i} \frac{\text{rank} \,(\Pi_i(p))}{d_i} \, d\mu_i = \sum_{i=1}^{m} \frac{\alpha_i \text{rank} \,(\Pi_i(p))}{d_i}.
\]

(3.1)

Since \( K_0(A) \) is finitely generated, there are \( p_1, p_2, \ldots, p_r \in K_0(A) \) which generate \( K_0(A) \). Consider the matrix

\[
P = \begin{pmatrix}
\text{rank}(\Pi_1(p_1)) & \text{rank}(\Pi_2(p_1)) & \cdots & \text{rank}(\Pi_m(p_1)) \\
\text{rank}(\Pi_1(p_2)) & \text{rank}(\Pi_2(p_2)) & \cdots & \text{rank}(\Pi_m(p_2)) \\
\vdots & \vdots & \ddots & \vdots \\
\text{rank}(\Pi_1(p_r)) & \text{rank}(\Pi_2(p_r)) & \cdots & \text{rank}(\Pi_m(p_r)) \\
d_1 & d_2 & \cdots & d_m
\end{pmatrix},
\]

and the vector \( \xi = (\alpha_1/d_1, \alpha_2/d_2, \ldots, \alpha_m/d_m)^T \).

By (3.1), one has

\[
P\xi = (\tau(p_1), \tau(p_2), \ldots, \tau(p_r), 1)^T = (\kappa(p_1), \kappa(p_2), \ldots, \kappa(p_r), 1)^T \in \mathbb{Q}^{r+1}.
\]

Then, by Lemma 3.1, there is a positive rational vector \( \xi \in \mathbb{Q}^m \) such that

(3.2) \quad \|\xi - \eta\|_\infty < \varepsilon/(2l(k_1 + \cdots + k_l)).

Write

\[
\zeta = (\beta_1/d_1, \beta_2/d_2, \ldots, \beta_m/d_m)^T.
\]

By (3.2), one has that

(3.3) \quad |\alpha_i - \beta_i| < \varepsilon/2m, \quad 1 \leq i \leq m.

Since \( P\xi = P\zeta \), one has

\[
\sum_{i=1}^{m} \beta_i \frac{\text{rank} \,(\pi_x(p_j))}{d_i} = \sum_{i=1}^{m} \alpha_i \frac{\text{rank} \,(\pi_x(p_j))}{d_i}, \quad j = 1, \ldots, r.
\]

Since \( p_1, p_2, \ldots, p_l \) generate \( K_0(A) \), one has

(3.4) \quad \sum_{i=1}^{m} \beta_i \frac{\text{rank} \,(\pi_x(p))}{d_i} = \sum_{i=1}^{m} \alpha_i \frac{\text{rank} \,(\pi_x(p))}{d_i}, \quad p \in K_0(A).

It also follows from \( P\xi = P\zeta \) that \( \beta_1 + \cdots + \beta_m = 1 \).

Consider \( \tau' \in T(A) \) defined by

\[
\tau'(a) = \sum_{i=1}^{m} \beta_i \int_{X_i} \text{tr} \,(\Pi_i(a)) \, d\mu_i, \quad a \in A.
\]
Then, by \((3.4)\) and \((3.3)\), one has
\[
\tau'(p) = \tau(p), \quad p \in K_0(A),
\]
and
\[
|\tau(f) - \tau'(f)| < \varepsilon/2, \quad f \in \mathcal{F}.
\]

Consider each probability measure \(\mu_i\), and choose a discrete measure \(\tilde{\mu}_i\) such that
\[
\left| \int_{X_i} \text{tr}_i(\Pi_i(f))d\mu_i - \int_{X_i} \text{tr}_i(\Pi_i(f))d\tilde{\mu}_i \right| < \varepsilon/2, \quad f \in \mathcal{F}.
\]

Write
\[
\tilde{\mu}_i = \frac{1}{l_i} \sum_{k=1}^{l_i} \delta_{x_{ik}},
\]
for some \(x_{ik} \in X_i\), where \(\delta_{x_{ik}}\) is the Dirac measure concentrated at \(x_{ik}\). Without loss of generality, one may assume that all \(l_i\) are the same and equal to \(l\) for some \(l\).

Define
\[
\tilde{\tau}(a) = \sum_{i=1}^{m} \beta_i \int_{X_i} \text{tr}_i(\Pi_i(a))d\tilde{\mu}_i, \quad a \in A.
\]

One then has
\[
\tilde{\tau}(p) = \tau(p), \quad p \in K_0(A),
\]
and
\[
|\tau(f) - \tilde{\tau}(f)| < \varepsilon, \quad f \in \mathcal{F}.
\]

Write \(\beta_i = q_i/q\) for natural numbers \(q_i \leq q\). Since \(\sum \beta_i = 1\), one has that
\[
\sum q_i = q.
\]

Define a unital homomorphism by
\[
\phi: A \ni a \mapsto \bigoplus_{i=1}^{m} \bigoplus_{k=1}^{l_i} \left( \pi_{x_{ik}}(a) \oplus \cdots \oplus \pi_{x_{ik}}(a) \right) \in M_N(\mathbb{C}),
\]
where \(N = d_1 \cdots d_mlq\). Then
\[
\text{tr}(\phi(a)) = \frac{\sum_{i=1}^{m} \sum_{k=1}^{l_i} (d_1 \cdots d_{i-1}d_{i+1} \cdots d_m q_i) \text{Tr}(\pi_{x_{ik}}(a))}{d_1 \cdots d_mlq}
\]
\[
= \frac{\sum_{i=1}^{m} \sum_{k=1}^{l_i} (d_1 \cdots d_{i-1}d_{i+1} \cdots d_m q_i) \frac{1}{q} \sum_{k=1}^{l_i} \text{tr}_i(\pi_{x_{ik}}(a))}{d_1 \cdots d_mlq}
\]
\[
= \sum_{i=1}^{m} \frac{q_i}{q} \left( \frac{1}{l_i} \sum_{k=1}^{l_i} \text{tr}_i(\pi_{x_{ik}}(a)) \right) = \tilde{\tau}(a).
\]

Let \(\iota: M_N(\mathbb{C}) \to Q\) be an unital embedding. Then the homomorphism \(\iota \circ \phi\) satisfies the condition of the lemma. \(\square\)
Lemma 3.3. Let $A$ be a NCCC. For any finite set $\mathcal{F} \subseteq A$ and any $\varepsilon > 0$, there is a finite set $\mathcal{H} \subseteq A^+$ such that for any $\sigma > 0$, there is $\delta > 0$ such that if $\tau \in T(A)$ satisfies
\[ \tau(h) > \sigma, \quad h \in \mathcal{H}, \]
there exists $\tau' \in T(A)$ such that
1. $\tau'(p) = \tau(p), \quad p \in K_0(A)$,
2. $|\tau'(f) - \tau(f)| < \varepsilon, \quad f \in \mathcal{F}$, and
3. $\alpha_i(\tau') > \delta$, all $i$.
Moreover, one may require that $\delta$ depends only on $\sigma$.

Proof. If $A = M_{n_1}(\mathbb{C}) \oplus \cdots \oplus M_{n_k}(\mathbb{C})$. Then $\mathcal{H} = \{1_{M_{n_i}(\mathbb{C})} : 1 \leq i \leq k\}$ satisfies the lemma with $\delta = \sigma$ for any given $\sigma$ (in fact, one has that $\tau' = \tau$ in this case).

Let $A = B \oplus_{M_k(C(S^{n-1}))} M_k(C(D^n))$, where $B$ is NCCC, and assume that the lemma holds for $B$.

Let $\mathcal{F} \subseteq A, \varepsilon > 0$ be given. For each $f \in A$, write $f = (f_B, f_D)$ for $f_B \in B$ and $f_D \in M_k(C(D^n))$. Since $B$ is assumed to satisfy the lemma, there is $\mathcal{H}_B$ such that for any $\sigma$, there is $\delta_B(\sigma) > 0$ such that if $\tau_B \in T(B)$ satisfies
\[ \tau_B(h) > \sigma, \quad h \in \mathcal{H}_B, \]
there is $\tau'_B \in T(A)$ such that
\[ \tau'_B(p) = \tau_B(p), \quad p \in K_0(B), \]
\[ |\tau'_B(f_B) - \tau_B(f_B)| < \varepsilon/2, \quad f \in \mathcal{F}, \]
and
\[ \alpha_i(\tau'_B) > \delta_B(\sigma), \quad \text{all } i. \]
Choose $\gamma > 0$ such that
\[ \|f_D(x) - f_D(y)\| < \varepsilon/2, \quad f \in \mathcal{F}, \]
if $\text{dist}(x, y) < \gamma$.
Define
\[ g_\gamma : [0, 1] \ni x \mapsto \begin{cases} 1, & x \in [1 - \gamma/2, 1], \\ \text{linear}, & x \in [1 - \gamma, 1 - \gamma/2], \\ 0, & x \in [0, 1 - \gamma/2]; \end{cases} \]
similarly, define $g_{\gamma/2}$ and $g_{2\gamma}$.
For each $h \in \mathcal{H}_B$ define $h_D \in M_k(C(D^n))$ by
\[ h_D(x) = \begin{cases} 0, & \|x\| \in [0, 1 - \gamma/2], \\ 4\|x\|^{2\gamma-4} \varphi(h)(\frac{\|x\|}{\varphi(h)(\|x\|)}), & \|x\| \in [1 - \gamma/2, 1 - \gamma/4], \\ \varphi(h)(\frac{\|x\|}{\|x\|}), & \|x\| \in [1 - \gamma/4, 1], \end{cases} \]
where $\varphi : B \to M_k(C(S^{n-1}))$ is the gluing map.
For each $h \in \mathcal{H}_B$, define
\[ \tilde{h} = (h, h_D) \in A = B \oplus_{M_k(C(S^{n-1}))} M_k(C(D^n)). \]
Also define $\tilde{g}_{2\gamma} = (0, g_{2\gamma}I_{M_k(C)})$, $\tilde{g}_{\gamma/2} = (0, g_{\gamma/2}I_{M_k(C)}) \in A$.

Then

$$H = \{\tilde{h}, \tilde{g}_{2\gamma}, 1 - \tilde{g}_{\gamma/2} : h \in H_B\}$$

satisfies the condition of the lemma.

Indeed, for any $\sigma > 0$, set

$$\delta = \sigma \delta_B(\sigma).$$

Let $\tau \in T(A)$ be such that

$$\tau(h) > \sigma, \quad h \in H.$$

Without loss of generality, one may assume that

$$\tau((f, g)) = \alpha \tau_B(f) + \beta \int_{D^n \setminus S^{n-1}} gd\mu,$$

where $\mu$ is a discrete probability measure of $D^n \setminus S^{n-1}$. Since $\tau(\tilde{g}_{\gamma}) > \sigma$, one has

$$\beta > \sigma.$$

Write $\mu = \sum_i \beta_i \delta_{x_i}$. For each $x_i$ with $\|x_i\| \geq \frac{\gamma}{2}$, define $\tau_{B,x_i} \in T(B)$ by

$$\tau_{B,x_i}(f) = \frac{1}{k} \text{Tr}(\varphi(f)(\frac{x_i}{\|x_i\|})).$$

Then define the trace

$$\tilde{\tau}((f, g)) = \alpha \tau_B(f) + \beta \left( \sum_{\|x_i\| \geq \frac{\gamma}{2}} \beta_i \tau_{B,x_i}(f) \right) + \beta \left( \sum_{\|x_i\| < \frac{\gamma}{2}} \beta_i \int_{(D^n)^o} gd\left( \frac{1}{\|x_i\|} \sum_{\|x_i\| < \frac{\gamma}{2}} \beta_i \delta_{x_i} \right) \right),$$

where

$$\tilde{\tau}_B(f) = \frac{\alpha \tau_B(f) + \beta \left( \sum_{\|x_i\| \geq \frac{\gamma}{2}} \beta_i \tau_{B,x_i}(f) \right)}{\alpha + \sum_{\|x_i\| \geq \frac{\gamma}{2}} \beta_i \beta_i}, \quad \alpha' = \alpha + \sum_{\|x_i\| \geq \frac{\gamma}{2}} \beta_i \beta_i,$$

and

$$\mu' = \frac{1}{\sum_{\|x_i\| < \frac{\gamma}{2}} \beta_i \delta_{x_i}}, \quad \beta' = \beta \left( \sum_{\|x_i\| < \frac{\gamma}{2}} \beta_i \right).$$

Note that

(3.5) \quad \tau(p) = \tilde{\tau}(p), \quad p \in K_0(A).

By the choice of $\gamma$, one has

(3.6) \quad |\tilde{\tau}(f) - \tau(f)| < \varepsilon/2, \quad f \in F.

Noting that

$$\tilde{\tau}(\tilde{g}_{2\gamma}) = \tau(\tilde{g}_{2\gamma}) \quad \text{and} \quad \tilde{\tau}(1 - \tilde{g}_{\gamma/2}) \geq \tau(1 - \tilde{g}_{\gamma/2}),$$

one has

$$\tilde{\tau}(\tilde{g}_{2\gamma}) > \sigma \quad \text{and} \quad \tilde{\tau}(1 - \tilde{g}_{\gamma/2}) > \sigma.$$
A straightforward calculation shows that
\[ \beta' \geq \tilde{\tau}(\tilde{g}_{2\gamma}) \quad \text{and} \quad \alpha' = \tilde{\tau}(1 - \tilde{g}_{\gamma/2}), \]
and therefore
\[ \beta' > \sigma \quad \text{and} \quad \alpha' > \sigma. \] (3.7)

Also noting that for any \( h \in \mathcal{H}_B \), one has
\[ \tilde{\tau}(\tilde{h}) \geq \tau(\tilde{h}) > \sigma, \]
and
\[ \tilde{\tau}(\tilde{h}) = \alpha' \tilde{\tau}_B(h). \]

Therefore,
\[ \tilde{\tau}_B(h) > \sigma/\alpha' > \sigma, \quad h \in \mathcal{H}_B. \]

By the inductive assumption, there is \( \tau'_B \in \mathcal{T}(B) \) such that
\[ \tau'_B(p) = \tau_B(p), \quad p \in K_0(B), \] (3.8)
\[ |\tau'_B(f_B) - \tilde{\tau}_B(f_B)| < \varepsilon/2, \quad f \in \mathcal{F}, \] (3.9)
and
\[ \alpha_i(\tau'_B) > \delta_B(\sigma), \quad \text{all } i. \] (3.10)

Then the trace
\[ \tau'(f, g) = \alpha' \tau'_B(f) + \beta' \int_{(P^n)_0} g d\mu' \]
satisfies the condition of the lemma. By (3.5) and (3.8), one has
\[ \tau'(p) = \tau(p), \quad p \in K_0(A), \]
Indeed, by (3.6) and (3.9), one has
\[ |\tau'(f) - \tau(f)| < \varepsilon, \quad f \in \mathcal{F}. \] (3.11)

By (3.7) and (3.10), one has
\[ \alpha_i(\tau') > \sigma \delta_B(\sigma), \quad \text{all } i, \]
as desired. \( \square \)

**Lemma 3.4.** Let \( P \) be a \( m \times n \) matrix. Assume that \( m \geq n \) and \( \text{rank}(P) = n \). Let \( \sigma > 0 \) be given. Then, for any \( \varepsilon > 0 \), there is \( \delta > 0 \) such that for any vectors \( \xi \in \mathbb{R}^m \) and \( \kappa \in \mathbb{R}^n \) with

1. \( \xi_i > \sigma, \quad i = 1, \ldots, m, \) and
2. \( \|\kappa - P\xi\|_{\infty} < \delta, \)

there is \( \zeta \in \mathbb{R}^m \) with \( \zeta_i \geq 0, \ i = 1, \ldots, m \) such that

3. \( P\zeta = \kappa, \) and
4. \( \|\xi - \zeta\|_{\infty} < \varepsilon. \)
Proof. Regard $P$ as a linear map from $\mathbb{R}^m \rightarrow \mathbb{R}^n$. Since $\text{rank}(P) = n$, one has that $P$ is surjective. Therefore, for the given $\epsilon < \sigma$, there is $\delta > 0$ such that

$$B_{\|\cdot\|_{\infty}}(0, \delta) \subseteq P(B_{\|\cdot\|_{\infty}}(0, \epsilon)).$$

Then the $\delta$ satisfies the condition of the lemma. Indeed, let $\xi \in \mathbb{R}^m$ and $\kappa \in \mathbb{R}^n$ be given, and satisfy

$$\|\kappa - P\xi\|_{\infty} < \delta.$$

Then

$$\kappa - P(\xi) \in B_{\|\cdot\|_{\infty}}(0, \delta) \subseteq \mathbb{R}^n.$$

By (3.12), there is $\theta \in B_{\|\cdot\|_{\infty}}(0, \epsilon) \subseteq \mathbb{R}^m$ such that

$$P(\theta) = \kappa - P(\xi),$$

and hence

$$P(\xi + \theta) = \kappa.$$

Since each entries of $\xi$ is at least $\sigma > \epsilon$, one has that

$$\xi + \theta \in (\mathbb{R}^+)^m,$$

and therefore

$$\zeta = \xi + \theta$$

is the desired vector. \qed

Remark 3.5. Let $A$ be an NCCC, and let $\kappa : K_0(A) \rightarrow \mathbb{Q}$ be a positive map. Since $A$ is of type I, it is exact; therefore, $\kappa$ (regarded as a state of $K_0(A)$) is induced by a trace. That is, there is $\tau \in T(A)$ such that

$$\kappa(p) = \tau(p), \quad p \in K_0(A).$$

In particular, this implies that $\kappa$ factors through $\rho_A(K_0(A))$.

Lemma 3.6. Let $A$ be an NCCC. Let $(F, \epsilon)$ be given. Let $p_1, p_2, \ldots, p_n \in K_0(A)$ be such that \{p_1, \ldots, p_n\} is a set of generators for $\rho_A(K_0(A))$ (as an abelian group) (still use the same notation for the image of $p_i$). Then, there is a finite set $\mathcal{H} \subseteq A^+$ such that for any $\sigma > 0$, there is $\delta > 0$ such that if $\kappa : K_0(A) \rightarrow \mathbb{Q}$ and $\tau \in T(A)$ satisfy

1. $\tau(h) > \sigma, \quad h \in \mathcal{H},$ and
2. $|\tau(p_i) - \kappa(p_i)| < \delta, \quad i = 1, \ldots, n,$

then there is $\tau' \in T(A)$ such that

3. $|\tau'(f) - \tau(f)| < \epsilon, \quad f \in F,$ and
4. $\tau'(p_i) = \kappa(p_i), \quad i = 1, \ldots, n.$

Proof. Without loss of generality, one may assume that $F$ is contained in the unit ball of $A$. One may also assume that $p_1, p_1, \ldots, p_n \in \rho_A(K_0(A))$ are $\mathbb{Q}$-independent.

Let $\mathcal{H} \subseteq A^+$ be the subset of Lemma 3.3 with respect to $A$, $F$, and $\epsilon/2$. Then $\mathcal{H}$ satisfies the lemma.
In fact, for any $\sigma > 0$, let $\delta'$ be the constant of Lemma 3.3 with respect to $\sigma$. Consider the $m \times n$ matrix

\[
P = \begin{pmatrix}
\frac{\text{rank}(\Pi_1(p_1))}{d_1} & \frac{\text{rank}(\Pi_2(p_1))}{d_2} & \ldots & \frac{\text{rank}(\Pi_m(p_1))}{d_m} \\
\frac{\text{rank}(\Pi_1(p_2))}{d_1} & \frac{\text{rank}(\Pi_2(p_2))}{d_2} & \ldots & \frac{\text{rank}(\Pi_m(p_2))}{d_m} \\
\vdots & \vdots & \ddots & \vdots \\
\frac{\text{rank}(\Pi_1(p_n))}{d_1} & \frac{\text{rank}(\Pi_2(p_n))}{d_2} & \ldots & \frac{\text{rank}(\Pi_m(p_n))}{d_m}
\end{pmatrix}.
\]

Since $p_1, p_1, \ldots, p_n \in \rho_A(K_0(A))$ are $\mathbb{Q}$-independent, the matrix $P$ has rank $n$ and it satisfies the assumptions of Lemma 3.4. Applying Lemma 3.4 to $\delta'$ (in the place of $\sigma$) and $\varepsilon/2m$, one obtains $\delta$.

Let $(\kappa, \tau)$ be a pair satisfies

\[
|\tau(p_i) - \kappa(p_i)| < \delta, \quad i = 1, \ldots, n,
\]

and

\[(3.13)\quad \tau(h) > \sigma, \quad h \in \mathcal{H}.\]

By (3.13) and Lemma 3.3 there is $\tau' \in T(A)$ such that

\[(3.14)\quad \tau'(p_i) = \tau(p_i), \quad i = 1, \ldots, n,
\]

\[|\tau'(f) - \tau(f)| < \varepsilon/2, \quad f \in \mathcal{F},\]

and

\[\alpha_i(\tau') > \delta', \quad \forall i.\]

Set

\[\xi = (\alpha_1(\tau'), \alpha_2(\tau'), \ldots, \alpha_m(\tau'))^T \quad \text{and} \quad \kappa = (\kappa(p_1), \kappa(p_2), \ldots, \kappa(p_n))^T,\]

and then one has

\[\|P\xi - \kappa\|_\infty = \max\{\tau'(p_i) - \kappa(p_i) : i = 1, \ldots, n\}
\]

\[= \max\{\tau(p_i) - \kappa(p_i) : i = 1, \ldots, n\} \quad \text{(by (3.14))}
\]

\[< \delta\]

By Lemma 3.4 there is a positive vector $\zeta = (\beta_1, \ldots, \beta_m)$ such that

\[(3.15)\quad P\zeta = (\kappa(p_1), \kappa(p_2), \ldots, \kappa(p_n))^T\]

and

\[|\alpha_i - \beta_i| < \varepsilon/2m, \quad \forall i.\]

Consider the trace

\[\tau'' = \sum \beta_i \mu_i.\]

It is clear that

\[|\tau''(f) - \tau(f)| < \varepsilon, \quad f \in \mathcal{F}.\]

By (3.15), one has

\[\tau''(p) = \kappa(p), \quad p \in K_0(A).\]

Moreover, the trace $\tau''$ is indeed a state since $\tau''(1_A) = \kappa([1_A]) = 1$, as desired. \qed
Theorem 3.7. Let $A$ be a unital NCCC, and let $\sigma > 0$. Let $(F, \varepsilon)$ be given. Let $p_1, p_2, \ldots, p_n \in K_0(A)$ be such that the set $\{p_1, \ldots, p_n\}$ generates the group $\rho_A(K_0(A))$ (let us still use the same notation for the image of $p_i$). Then, there is a finite set $H \subseteq A^+$ such that for any $\sigma > 0$, there is $\delta > 0$ such that if $\kappa : K_0(A) \to \mathbb{Q}$ and $\tau \in T(A)$ satisfy

1. $|\tau(p_i) - \kappa[p_i]| < \delta$, $i = 1, \ldots, n$, and
2. $\tau(h) > \sigma$, $h \in H$,

then there is a homomorphism $\phi : A \to Q$ such that

3. $[\phi]_0 = \kappa$, and
4. $|\tau(f) - \text{tr}(\phi(f))| < \varepsilon$, $f \in F$,

where $\text{tr}$ is the canonical trace of $Q$. Moreover, $\phi$ can be chosen to have finite dimensional range.

Proof. Let $H \subseteq A^+$ denote the finite set of Lemma 3.6 with respect to the data $A$, $F$, $\varepsilon/2$. Then $H$ satisfies the theorem.

Indeed, given $\sigma > 0$, consider the constant $\delta$ of Lemma 3.6 with respect to $\sigma$. Let $(\kappa, \tau)$ be a pair as above—$\delta$-compatible on $p_i$, $i = 1, \ldots, n$, and such that $\tau(h) > \sigma$, $h \in H$.

By Lemma 3.6, there is $\tau' \in T(A)$ such that the pair $(\kappa, \tau')$ is exactly compatible on the $p_i$ and $|\tau'(f) - \tau(f)| < \varepsilon/2$, $f \in F$.

Then, by Lemma 3.2, there is a homomorphism $\phi : A \to Q$ such that $[\phi]_0 = \kappa$ and $|\text{tr}(\phi(f)) - \tau'(f)| < \varepsilon/2$, $f \in F$,

and therefore satisfying the condition of the theorem. \qed

4. A decomposition theorem and a uniqueness theorem

Recall (see, for instance, [10])

Lemma 4.1 (The Marriage Lemma). Let $A$ and $B$ be two finite subsets of a metric space. Suppose that for any set $X \subseteq A$, one has

$$\# \{y \in B : \text{dist}(y, X) < \varepsilon\} \geq \#X,$$

then there is a set $B' \subseteq B$ and a one-to-one pairing between $A$ and $B'$ such that the distance between the points in each pair is at most $\varepsilon$.

The following statement is a generalization of the Marriage Lemma due to Gong in an unpublished manuscript:
**Lemma 4.2.** Let $A, B$ be two finite subsets of a metric space with subsets $A_1 \subset A$ and $B_1 \subset B$. Suppose that for each $X \subset A_1$, one has

$$\#\{y \in B : \text{dist}(y, X) < \varepsilon\} \geq \#X$$

and for each $Y \subset B_1$, one has

$$\#\{x \in A : \text{dist}(x, Y) < \varepsilon\} \geq \#Y.$$

Then there are sets $A_2 \subset A$ and $B_2 \subset B$ such that

$$A_1 \subseteq A_2 \quad \text{and} \quad B_1 \subseteq B_2,$$

and the elements of $A_2$ and $B_2$ can be (bijectively) paired to within $\varepsilon$.

**Proof.** The proof is similar to that of [10]. We spell out the details for reader’s convenience. In the case $\#(B_1) = 0$, i.e., $B_1$ is empty, then this is the case of the classical Marriage Lemma (Lemma 4.1) in the case of $A_1$ and $B$. (For this case, $X_0$ can be chosen to be $A_1$.)

We define partial order for $(m, n) \in \mathbb{Z}^+ \times \mathbb{Z}^+$ (where $\mathbb{Z}^+ = \{0, 1, 2, \ldots\}$ is the set of positive integers) by $(m, n) \leq (m_1, n_1)$ if $m < m_1$ and $n < n_1$. We denote $(m, n) < (m_1, n_1)$ if $(m, n) \leq (m_1, n_1)$ and $(m, n) \neq (m_1, n_1)$. We will prove the lemma by induction on $\#(A_1)$ and $\#(B_1)$. That is, we assume that if the result is true for the case $(\#(A_1), \#(B_1)) < (m, n)$ and prove the lemma to be true for the case

$$\#(A_1) = m \quad \text{and} \quad \#(B_1) = n.$$

The rest of the proof divides into two cases.

**Case 1.** For any nonempty set $X \subseteq A_1$,

$$\#\{y \in B : \text{dist}(y, X) < \varepsilon\} \geq \#(X) + 1$$

and for any nonempty set $Y \subseteq B_1$,

$$\#\{x \in A : \text{dist}(x, Y) < \varepsilon\} \geq \#(Y) + 1.$$

Choose any $a \in A_1$, there is a $b \in B$ such that $\text{dist}(a, b) < \varepsilon$. We will pair $a \in A_1$ with $b \in B$. Then let $\tilde{A} = A_1 \setminus \{a\}$ with $\tilde{A}_1 = A_1 \setminus \{a\}$, and $\tilde{B} = B_1 \setminus \{b\}$ with $\tilde{B}_1 = B_1 \setminus \{b\}$ if $b \in B_1$. It is easy to verify that $\tilde{A} \supseteq \tilde{A}_1$ and $\tilde{B} \supseteq \tilde{B}_1$ satisfy the condition of the lemma with $(\#(\tilde{A}_1), \#(\tilde{B}_1)) = \text{either} \ (m - 1, n)$ or $(m - 1, n - 1)$. That is, $(\#(A_1), \#(B_1)) < (m, n)$. By the induction assumption, there is a subset $A_2 \supseteq \tilde{A}_1$ and $B_2 \supseteq \tilde{B}_1$ such that $X_0$ can be paired one by one within $\varepsilon$. Then the sets $A_2 = \tilde{A}_2 \cup \{a\}$ and $B_2 = \tilde{B}_2 \cup \{b\}$ satisfy the lemma.

**Case 2.** The conditions of Case 1 do not hold. Then either there is $X \subseteq A_1$ or $Y \subseteq B_1$ does not satisfy the condition in Case 1. That is, either there is $X \subseteq A_1$ such that

$$\#\{y \in B : \text{dist}(y, X) < \varepsilon\} = \#(X),$$

or there is $Y \subseteq B_1$ such that

$$\#\{x \in A : \text{dist}(x, Y) < \varepsilon\} = \#(Y).$$

Without loss of generality, let us assume there is $Y_1 \subseteq B_1$ such that

$$\#\{x \in A : \text{dist}(x, Y_1) < \varepsilon\} = \#(Y_1).$$
Let \( X_1 = \{ x \in A; \text{dist}(x, Y_1) < \varepsilon \} \). Then for any subset \( Z \subseteq Y_1, \{ x \in A; \text{dist}(x, Z) < \varepsilon \} \subseteq X_1 \) and therefore \( \{ x \in A; \text{dist}(x, Z) < \varepsilon \} = \{ x \in X_1; \text{dist}(x, Z) < \varepsilon \} \) which has at least \( \#(Z) \) elements. That is, \( Y_1 \) and \( X_1 \) satisfy the condition for the classical Pairing Lemma with \( Y_1 = A, X_1 = B \) as in 2.10. Hence \( Y_1 \) and \( X_1 \) can be paired one by one to within \( \varepsilon \).

Let \( \tilde{B} = B \setminus Y_1 \) with subset \( \tilde{B}_1 = B_1 \setminus Y_1 \), and let \( \tilde{A} = A \setminus X_1 \) with subset \( \tilde{A}_1 = A_1 \setminus (X_1 \cap A_1) \). Let us verify that \( \tilde{a} \) self-adjoint elements. That is, \( \text{dist}(\tilde{y}, X) \geq \varepsilon \). Hence \( \tilde{B} \subseteq \tilde{B}_1 \) and \( \tilde{A} \subseteq \tilde{A}_1 \) satisfy the condition of the lemma. Let \( Y \subseteq \tilde{B}_1 \). Then

\[
\{ x \in A; \text{dist}(x, Y \cup Y_1) < \varepsilon \} = \{ x \in \tilde{A}_1; \text{dist}(x, Y) < \varepsilon \} \cup X_1.
\]

Since \( \#(X_1) = \#(Y_1) \) and \( \{ x \in A; \text{dist}(x, Y \cup Y_1) < \varepsilon \} \geq \#(Y) + \#(Y_1) = \#(Y) + \#(X_1) \), we have, \( \{ x \in \tilde{A}_1; \text{dist}(x, Y) < \varepsilon \} \geq \#(Y) \).

Let \( X \subseteq \tilde{A}_1 \). Since for point \( y \in Y_1 \), \( \text{dist}(y, X) > \varepsilon \), we have

\[
\# \{ y \in \tilde{B}; \text{dist}(y, X) < \varepsilon \} = \# \{ y \in B; \text{dist}(y, X) < \varepsilon \} \geq \#(X).
\]

So the conditions of our lemma hold for \( \tilde{A} \subseteq \tilde{A}_1 \) and \( \tilde{B} \subseteq \tilde{B}_1 \) with

\[
\#(\tilde{B}_1) = \#(B_1) - \#(Y_1) < n \quad \text{and} \quad \#(\tilde{A}_1) \leq \#(A_1) \leq m.
\]

So by the inductive assumption, there exist \( \tilde{A}_2 \supseteq \tilde{A}_1 \) and \( \tilde{B}_2 \supseteq \tilde{B}_1 \) such that \( \tilde{A}_2 \) and \( \tilde{B}_2 \) can be paired element by element to within \( \varepsilon \). Then the sets \( A_2 = A_2 \cup X_1 \) and \( B_2 = B_2 \cup Y_1 \) satisfy the lemma. \( \square \)

**Definition 4.3** (See 2.2 of [13]). Let \( A \) be a unital C*-algebra with \( T(A) \neq \emptyset \). Recall that each self-adjoint \( a \in A \) induces \( \hat{a} \in \text{Aff}(T(A)) \) by \( \hat{a}(\tau) = \tau(a), \tau \in T(A) \). Denote this map by \( \rho_A \).

Denote by \( A_i^+ \) the set of positive elements with norm at most 1, and then denote by \( A_{i,q}^+ \) the image of \( A_i^+ \) in \( \text{Aff}(T(A)) \) under the canonical map \( \rho_A \).

As a consequence of this generalized version of the Marriage Lemma, one has

**Lemma 4.4.** Let \( A = B \oplus_{M_k(C(S^n-1))} M_k(C(D^n)) \) be an NCCC with \( n \geq 1 \). Let \( \Delta : A_{i,q}^+ \setminus \{0\} \to (0,1) \) be an order preserving map. Let \( \mathcal{F} \subseteq A \) be a finite set, and let \( \varepsilon > 0, 1 > \gamma > 0 \), and \( M \in \mathbb{N} \). There are finite sets \( \mathcal{H}_1, \mathcal{H}_2 \subseteq A^+ \) and \( \delta > 0 \) such that for any unital homomorphisms \( \phi, \psi : A \to M_m(\mathbb{C}) \) such that

1. \( \tau(\phi(h)), \tau(\psi(h)) > \Delta(h), h \in \mathcal{H}_1, \) and
2. \( |\tau(\phi(h)) - \tau(\psi(h))| < \delta, h \in \mathcal{H}_2, \)

there are unital homomorphisms \( \phi', \psi' : A \to M_m(\mathbb{C}) \) such that

3. \( \|\phi'(f) - \phi(f)\| < \varepsilon, \|\psi'(f) - \psi(f)\| < \varepsilon, f \in \mathcal{F}, \)
4. \( \text{SP}(\phi') \cap B(1-\gamma) = \text{SP}(\psi') \cap B(1-\gamma), \) and each point in \( \text{SP}(\phi') \cap B(1-\gamma) \) has multiplicity at least \( M, \)

where \( B(1-\gamma) \subseteq D^n \) is the closed ball with radius \( 1-\gamma \).

**Proof.** Let \( (\mathcal{F}, \varepsilon) \) be given. For each \( f \in \mathcal{F}, \) write \( f = (f_B, f_D) \) where \( f_B \in B \) and \( f_D \in M_k(C(D^n)) \). Set

\[
\mathcal{F}_B = \{ f_B : f \in \mathcal{F} \} \quad \text{and} \quad \mathcal{F}_D = \{ f_D : f \in \mathcal{F} \}.
\]
Choose \( \eta > 0 \) such that for any \( x, y \in D^n \) with \( \text{dist}(x, y) < 4\eta \), one has
\[
\|f_D(x) - f_D(y)\| < \varepsilon, \quad f \in \mathcal{F}.
\]
Without loss of generality, one may assume that \( 5\eta < \gamma \).

Fix an \( \eta \)-dense finite subset \( \{x_1, x_2, \ldots, x_l\} \subseteq B(1 - \gamma) \). For each subset \( \{y_1, y_2, \ldots, y_l\} \subseteq \{x_1, x_2, \ldots, x_l\} \), define
\[
h_{\{y_1, \ldots, y_l\}} = \max\{1 - \frac{1}{\eta} \text{dist}(x, \{y_1, \ldots, y_l\}) \},
\]
where \( Y_\eta \) denotes the \( \eta \)-neighborhood of \( Y \) if \( Y \) is a subset of a metric space. Using
\[
\{y_1, y_2, \ldots, y_l\}_2 \neq \{y_1, y_2, \ldots, y_l\}_3 \eta,
\]
choose a positive function \( g_{\{y_1, \ldots, y_l\}} \in C(D^n) \) such that \( 0 < g_{\{y_1, \ldots, y_l\}} \leq 1 \) and
\[
\text{supp}(g_{\{y_1, \ldots, y_l\}}) \subseteq \{y_1, \ldots, y_l\}_2 \setminus \{y_1, \ldots, y_l\}_3 \eta.
\]
For functions \( h_{y_1, \ldots, y_l} \) and \( g_{y_1, \ldots, y_l} \), regard them as the elements
\[
(0, h_{y_1, \ldots, y_l} 1_{\mathbb{M}_k(C(D^n))}), \quad (0, g_{y_1, \ldots, y_l} 1_{\mathbb{M}_k(C(D^n))}) \in A = B \oplus_{\mathbb{M}_k(C(S^{n-1}))} \mathbb{M}_k(C(D^n)),
\]
and still denote them by \( h_{y_1, \ldots, y_l} \) and \( g_{y_1, \ldots, y_l} \), respectively.

Put
\[
\tilde{\mathcal{H}}_1 = \{g_{\{y_1, \ldots, y_l\}} : \{y_1, \ldots, y_l\} \subseteq \{x_1, x_2, \ldots, x_l\}\},
\]
\[
\mathcal{H}_2 = \{h_{\{y_1, \ldots, y_l\}} : \{y_1, \ldots, y_l\} \subseteq \{x_1, x_2, \ldots, x_l\}\},
\]
and
\[
\delta = \min\{\Delta(\hat{g}_{\{y_1, \ldots, y_l\}}) : \{y_1, \ldots, y_l\} \subseteq \{x_1, \ldots, x_l\}\}.
\]
Also pick a finite open cover \( \mathcal{U} \) of \( B(1 - \gamma) \) such that each \( U \in \mathcal{U} \) has diameter at most \( \eta \),
\[
\bigcup_{U \in \mathcal{U}} U \subseteq B(1 - \gamma/2) \quad \text{and} \quad U \setminus \bigcup_{V \neq U} V \neq \emptyset.
\]
Then choose continuous functions \( s_{U,1}, ..., s_{U,M} \in C(D^n) \) such that
\[
\text{supp}(s_{U,i}) \subseteq \bigcup_{V \neq U} V \quad \text{and} \quad \text{supp}(s_{U,i}) \cap \text{supp}(s_{U,j}) = \emptyset, \quad i \neq j.
\]
Regard each \( s_{U,i} \) as an element of \( A \), and put
\[
\mathcal{S} = \{s_{U,i} : U \in \mathcal{U}, i = 1, ..., M\}.
\]
Then \( \mathcal{H}_1 := \tilde{\mathcal{H}}_1 \cup \mathcal{S} \), \( \mathcal{H}_2 \) and \( \delta \) have the property stated in the conclusion of the lemma.

Indeed, let \( \phi, \psi : A \to \mathbb{M}_m(\mathbb{C}) \) be unital homomorphisms satisfying
\[
\tau(\phi(h)), \tau(\psi(h)) > \Delta(\hat{h}), \quad h \in \mathcal{H}_1,
\]
and
\[
|\tau(\phi(h)) - \tau(\psi(h))| < \delta, \quad h \in \mathcal{H}_2.
\]
Let \( Y \subseteq \text{SP}(\phi) \cap B(1 - \gamma) \) be an arbitrary subset. Let

\[
\{y_1, y_2, \ldots, y_t\} \subseteq \{x_1, x_2, \ldots, x_l\}
\]
denote the subset of the points \( y \) satisfying \( \text{dist}(y, Y) < \eta \). Then

\[
\#Y \leq m \cdot \text{tr}(\phi(h_{\{y_1, \ldots, y_t\}})) \leq m \cdot \text{tr}(\psi(h_{\{y_1, \ldots, y_t\}})) + m \cdot \delta \quad \text{(by (4.4))}
\]
\[
\leq \#(\text{SP}(\psi) \cap \{y_1, \ldots, y_t\}_{2\eta}) + m \cdot \Delta(\hat{g}_{y_1, \ldots, y_t}) \quad \text{(by (4.3))}
\]
\[
\leq \#(\text{SP}(\psi) \cap Y_{4\eta}).
\]

The same argument shows that

\[
\#X \leq \#(\text{SP}(\phi) \cap X_{4\eta}), \quad X \subseteq \text{SP}(\psi) \cap B(1 - \gamma).
\]

Then, applying Lemma 4.2 with

\[
A = \text{SP}(\phi) \cap B(1 - \eta), \quad A_1 = \text{SP}(\psi) \cap B(1 - \gamma)
\]
and

\[
B = \text{SP}(\psi) \cap B(1 - \eta), \quad B_1 = \text{SP}(\psi) \cap B(1 - \gamma),
\]
one obtains \( A_2 \) and \( B_2 \) such that

\[
(4.5) \quad \text{SP}(\phi) \cap B(1 - \gamma) \subseteq A_2 \subset \text{SP}(\phi) \cap B(1 - \eta)
\]
and

\[
(4.6) \quad \text{SP}(\psi) \cap B(1 - \gamma) \subseteq B_2 \subset \text{SP}(\psi) \cap B(1 - \eta),
\]
and \( A_2 \) and \( B_2 \) can be paired up to \( 4\eta \).

Write

\[
A_2 = \{z_{\phi,1}, z_{\phi,2}, \ldots, z_{\phi,s}\} \quad \text{and} \quad B_2 = \{z_{\psi,1}, z_{\psi,2}, \ldots, z_{\psi,s}\}
\]
for some \( s \), where

\[
(4.7) \quad \text{dist}(z_{\phi,i}, z_{\psi,i}) < 4\eta, \quad i = 1, \ldots, s.
\]

Then, up to unitary equivalence, there are decompositions

\[
\phi = \tilde{\phi} \oplus \bigoplus_{i=1}^{s} \pi_{z_{\phi,i}} \quad \text{and} \quad \psi = \tilde{\psi} \oplus \bigoplus_{i=1}^{s} \pi_{z_{\psi,i}},
\]
where \( \text{SP}\tilde{\phi} \cap B(1 - \gamma) = \text{SP}\tilde{\psi} \cap B(1 - \gamma) = \emptyset \), and the homomorphisms

\[
\phi^\prime = \phi = \tilde{\phi} \oplus \bigoplus_{i=1}^{s} \pi_{z_{\phi,i}} \quad \text{and} \quad \psi^\prime = \tilde{\psi} \oplus \bigoplus_{i=1}^{s} \pi_{z_{\psi,i}}
\]
have the required properties except the requirement on multiplicity.

Indeed, by (4.7) and (4.1), one has

\[
\|\phi(f) - \phi^\prime(f)\| = 0 < \varepsilon \quad \text{and} \quad \|\psi(f) - \psi^\prime(f)\| < \varepsilon, \quad f \in \mathcal{F}.
\]
By (4.5) and (4.6), one has that
\[ \text{SP} (\phi') \cap B(1 - \gamma) = \{ z_{\phi,1}, ..., z_{\phi,s} \} \cap B(1 - \gamma) = \text{SP} (\psi') \cap B(1 - \gamma). \]

To satisfy the multiplicity condition, one needs to perturb \( \phi' \) and \( \psi' \) further. Since
\[ \phi(s_{U,i}) > \Delta(s_{U,i}) > 0, \quad U \in \mathcal{U}, i = 1, ..., M, \]
one has that for any \( U \in \mathcal{U} \), at least \( M \) of \( \{ z_{\phi,1}, ..., z_{\phi,s} \} \) are inside \( U \setminus \bigcup_{V \not\in U} V \) (counting multiplicity). Then there is a grouping of grouping \( \{ z_{\phi,1}, ..., z_{\phi,s} \} \) such that each group is insider at most one open set \( U \) and has elements at least \( M \) if it is covered by an open set \( U \). Therefore, after a perturbation, one may assume that each point in \( \{ z_{\phi,1}, ..., z_{\phi,s} \} \cap B(1 - \gamma) \) has multiplicity at least \( M \), and hence \( \phi' \) and \( \psi' \) satisfy the desired multiplicity condition. \[ \square \]

**Theorem 4.5.** Let \( A = B \oplus M_k(\mathbb{C}(S^{n-1})) \to M_n(\mathbb{C}) \) be an NCCC, and let \( \Delta : A^+_{1,q} \setminus \{0\} \to (0, 1) \) be an order preserving map. Let \( \mathcal{F} \subseteq A \) be a finite set. Let \( \varepsilon > 0, \eta > 0 \) and \( K \in \mathbb{N} \setminus \{0\} \). There are finite sets \( \mathcal{H}_1, \mathcal{H}_2 \subseteq A^+ \) and \( \delta > 0 \) such that for any unital homomorphisms \( \phi, \psi : A \to M_n(\mathbb{C}) \) such that

1. \( \tau(\phi(h)), \tau(\phi(h)) > \Delta(h), \quad h \in \mathcal{H}_1, \text{ and} \)
2. \( |\tau(\phi(h)) - \tau(\psi(h))| < \delta, \quad h \in \mathcal{H}_2, \)

there exist unital homomorphisms \( \tilde{\phi}, \tilde{\psi} : A \to M_n(\mathbb{C}) \) such that

3. \( \| \tilde{\phi}(f) - \phi(f) \| < \varepsilon, \| \tilde{\psi}(f) - \psi(f) \| < \varepsilon, \text{ f } \in \mathcal{F}, \)
4. \( \tilde{\phi} \text{ and } \tilde{\psi} \text{ have decompositions} \)
\[ \tilde{\phi} = \tilde{\phi}_0 \oplus \tilde{\phi}_1 \oplus \cdots \oplus \tilde{\phi}_1 \quad \text{and} \quad \tilde{\psi} = \tilde{\psi}_0 \oplus \tilde{\psi}_1 \oplus \cdots \oplus \tilde{\psi}_1 \]

such that \( \tilde{\phi}_1 \) and \( \tilde{\psi}_1 \) are unitarily equivalent, and
\[ \text{tr}(\tilde{\phi}_0(a)) \leq \eta \cdot \text{tr}(\tilde{\phi}(a)) \quad \text{and} \quad \text{tr}(\tilde{\psi}_0(a)) \leq \eta \cdot \text{tr}(\tilde{\psi}(a)), \quad a \in \mathcal{F}. \]

**Proof.** The statement holds if \( A \) is finite dimensional. Assume that the statement holds for \( B \), and let us show that the statement holds for \( A \).

Let \( (\mathcal{F}, \varepsilon) \) be given. For each \( f \in \mathcal{F} \), write \( f = (f_B, f_D) \) where \( f_B \in B \) and \( f_D \in M_k(\mathbb{C}(D^n)) \). Set
\[ \mathcal{F}_B = \{ f_B : f \in \mathcal{F} \} \quad \text{and} \quad \mathcal{F}_D = \{ f_D : f \in \mathcal{F} \}. \]

For each \( r > 0 \), define
\[ g_r : [0, 1] \ni x \mapsto \begin{cases} 1, & x \in [0, 1 - r], \\ \text{linear}, & x \in [1 - r, 1 - r/2], \\ 0, & x \in [1 - r/2, 1]; \end{cases} \]

Also define \( \tilde{g}_r = \left(0, g_r(\|x\|)1_{M_k(\mathbb{C}(D^n))}\right) \in A. \)

Pick \( \gamma > 0 \) such that
\[ \|f_D(x) - f_D(y)\| < \varepsilon/8, \quad f \in \mathcal{F}, \text{ dist}(x, y) < \gamma, \]
and consider \( g_{\gamma} \).
Consider the linear map
\[ \chi_\gamma : M_k(C(S^{n-1})) \ni f \mapsto (x \mapsto (1 - g_\gamma(\|x\|)) \cdot f(\frac{x}{\|x\|})) \in M_k(C(D^n)) \]
Clearly, \( \chi_\gamma \) is a positive linear map, and then the map
\[ \Gamma_\gamma : B \ni f \mapsto (\phi(\Gamma_\gamma(f))) \in M_k(M_k(C(D^n))) \]
is positive and injective, where \( \varphi : B \to M_k(C(S^{n-1})) \) is the gluing map.
If \( f \in B \) satisfies that \( \tau(f) = 0, \tau \in T(B) \), then \( \tau(\chi(f)) = 0, \tau \in T(M_k(C(D^n))) \), and therefore
\[ \tau(\Gamma_\gamma(f)) = 0, \tau \in T(A). \]
Hence the map
\[ \Delta_B : B^1_q \ni f \mapsto \Delta(\Gamma_\gamma(f)) \in (0, 1) \]
is well defined and is order preserving.
Applying the inductive hypothesis to \( B \) with \( \Delta_B, F_B, \varepsilon/2, K \) and \( \eta \), one obtains \( H_{B,1}, H_{B,2} \), and \( \delta_B \).
Define
\[ \tilde{H}_{B,1} = \{ \Gamma_\gamma(h) : h \in H_{B,1} \} \quad \text{and} \quad \tilde{H}_{B,2} = \{ \Gamma_\gamma(h) : h \in H_{B,2} \}. \]
Put
\[ \sigma_B = \min \{ \Delta(\tilde{h}) : h \in \tilde{H}_{B,1} \}. \]
Let \( \tilde{\gamma} \) be a positive number such that
\[(4.9) \quad \| \chi_\gamma(h)(x) - \chi_\gamma(h)(y) \| < \min\{ \frac{\Delta(1 - \tilde{g}_\gamma/2)\delta_B}{4}, \frac{\sigma_B}{4} \cdot \frac{\varepsilon}{8} \}, \quad h \in H_{B,1} \cup H_{B,2} \cup F_D \]
for any \( x, y \in D^n \) satisfying \( \text{dist}(x, y) < \tilde{\gamma} \).
Let \( H_{D,1} \subseteq A, H_{D,2} \subseteq A \) and \( \delta_D \) denote the finite sets and constant of Lemma 4.4 with respect to \( F \cup \tilde{H}_{B,1} \cup \tilde{H}_{B,2} \) (in the place of \( F \)), \( \min\{\varepsilon/8, \Delta(1 - \tilde{g}_\gamma/2)\delta_B/8, \sigma_B/8\} \) (in the place of \( \varepsilon \)), \( \tilde{\gamma} \), \( M = \lfloor 2K/\eta \rfloor + 1 \), and \( \Delta \).
Then
\[ \mathcal{H}_1 = \tilde{H}_{B,1} \cup H_{D,1} \cup \{ 1 - \tilde{g}_\gamma/2, \tilde{g}_\gamma \}, \quad \mathcal{H}_2 = \tilde{H}_{B,2} \cup H_{D,2}, \]
and
\[ \delta = \min \{ \Delta(1 - \tilde{g}_\gamma/2)\delta_B/4, \sigma_B/4, \delta_D \} \]
satisfy the statement.
In fact, let \( \phi, \psi : A \to M_m(\mathbb{C}) \) be unital homomorphisms satisfying
\[(4.10) \quad \tau(\phi(h)), \tau(\phi(h)) > \Delta(\hat{h}), \quad h \in \mathcal{H}_1 \]
and
\[(4.11) \quad |\tau(\phi(h)) - \tau(\psi(h))| < \delta, \quad h \in \mathcal{H}_2. \]
Since \( \delta \leq \delta_D \), by Lemma 4.4 there are homomorphisms
\( \phi', \psi' : A \to M_m(\mathbb{C}) \)
such that
\begin{align}
\|\phi'(f) - \phi(f)\| &< \min\{\varepsilon/8, \Delta(1 - g_{\gamma/2})\delta_B/8, \sigma_B/8\}, \quad f \in \mathcal{F} \cup \tilde{\mathcal{H}}_{B,1} \cup \tilde{\mathcal{H}}_{B,2}, \\
\|\psi'(f) - \psi(f)\| &< \min\{\varepsilon/8, \Delta(1 - g_{\gamma/2})\delta_B/8, \sigma_B/8\}, \quad f \in \mathcal{F} \cup \tilde{\mathcal{H}}_{B,1} \cup \tilde{\mathcal{H}}_{B,2},
\end{align}

and
\[
\text{Sp}(\phi') \cap B(1 - \tilde{\gamma}) = \text{Sp}(\psi') \cap B(1 - \tilde{\gamma}) = \{x_1, x_2, ..., x_l\},
\]
for some \(x_1, x_2, ..., x_l \in B(1 - \tilde{\gamma})\) with multiplicity at least \(M\). Therefore, up to unitary equivalence, there are decompositions
\begin{align}
\phi' &= \phi_B' \oplus \bigoplus_{i=1}^{m_{\phi}} \pi_{x_{\phi,i}} \oplus \bigoplus_{i=1}^{l} \pi_{x_i}, \\
\psi' &= \psi_B' \oplus \bigoplus_{i=1}^{m_{\psi}} \pi_{x_{\psi,i}} \oplus \bigoplus_{i=1}^{l} \pi_{x_i},
\end{align}
for some \(m_{\phi}, m_{\psi} \in \mathbb{N}\) and some \(x_{\phi,1}, ..., x_{\phi,m_{\phi}}, x_{\psi,1}, ..., x_{\psi,m_{\psi}} \in D^n\) with \(1 > \|x_{\phi,i}\| \geq \tilde{\gamma}\) and \(1 > \|x_{\psi,j}\| \geq \tilde{\gamma}\).

By (4.10), (4.12) and (4.13), one has
\[
\text{tr}(\phi'(h)), \text{tr}(\psi'(h)) > \frac{7}{8} \Delta(h), \quad h \in \mathcal{H}_{B,1}.
\]

It also follows from (4.11), (4.12) and (4.13) that for any \(h \in \mathcal{H}_{B,1} \cup \tilde{\mathcal{H}}_{B,2},
\[
|\text{tr}(\phi'(h)) - \text{tr}(\psi'(h))| < |\text{tr}(\phi'(h)) - \text{tr}(\psi'(h))| + \Delta(1 - g_{\gamma/2})\delta_B/4 \\
< \delta + \Delta(1 - g_{\gamma/2})\delta_B/4 \leq \Delta(1 - g_{\gamma/2})\delta_B/2.
\]
Therefore, by the decompositions (4.14) and (4.15), one has
\[
|\text{tr}(\phi_B'(h) \oplus (\bigoplus_{i=1}^{m_{\phi}} h(x_{\phi,i})) - \text{tr}(\psi_B'(h) \oplus (\bigoplus_{i=1}^{m_{\psi}} h(x_{\psi,i}))| < \Delta(1 - g_{\gamma/2})\delta_B/2
\]

For each point \(x_{\phi,i}\) (or \(x_{\psi,j}\)), replace the homomorphism \(\pi_{x_{\phi,i}}\) (or \(\pi_{x_{\psi,i}}\)) by the homomorphism \(\pi_{x_{\phi,i}'}\) (or \(\pi_{x_{\psi,i}'}\)), where \(x_{\phi,i}' = x_{\phi,i}/\|x_{\phi,i}\| \in S^{n-1}\) (or \(x_{\psi,i}' = x_{\psi,i}/\|x_{\psi,i}\| \in S^{n-1}\)). By the choice of \(\tilde{\gamma}\) (see 4.9), one has
\begin{align}
\left\|\bigoplus_{i=1}^{m_{\phi}} \pi_{x_{\phi,i}'}(h) - \bigoplus_{i=1}^{m_{\phi}} \pi_{x_{\phi,i}}(h)\right\| &< \min\{\frac{\Delta(1 - g_{\gamma/2})\delta_B}{4}, \frac{\sigma_B}{4}, \frac{\varepsilon}{8}\}, \quad h \in \mathcal{H}_{B_{1,1}} \cup \mathcal{H}_{B_{1,2}} \cup \mathcal{F}_D,
\end{align}
\begin{align}
\left\|\bigoplus_{i=1}^{m_{\psi}} \pi_{x_{\psi,i}'}(h) - \bigoplus_{i=1}^{m_{\psi}} \pi_{x_{\psi,i}}(h)\right\| &< \min\{\frac{\Delta(1 - g_{\gamma/2})\delta_B}{4}, \frac{\sigma_B}{4}, \frac{\varepsilon}{8}\}, \quad h \in \mathcal{H}_{B_{1,1}} \cup \mathcal{H}_{B_{1,2}} \cup \mathcal{F}_D.
\end{align}

Put
\[
\phi_B'' = \phi_B' \oplus \bigoplus_{i=1}^{m_{\phi}} \pi_{x_{\phi,i}'} \quad \text{and} \quad \psi_B'' = \psi_B' \oplus \bigoplus_{i=1}^{m_{\psi}} \pi_{x_{\psi,i}'}.
\]
Since \(x'_{\phi,i}, x'_{\psi,j} \in S^{n-1}\), the homomorphisms \(\phi''_B\) and \(\psi''_B\) factor through \(B\). Define

\[
(4.21) \quad \phi'' = \phi''_B \oplus (\bigoplus_{i=1}^{l} \pi_{x_i}) \quad \text{and} \quad \psi'' = \psi''_B \oplus (\bigoplus_{i=1}^{l} \pi_{x_i}).
\]

By (4.19), (4.20), one has

\[
(4.22) \quad \|\phi'(f) - \phi''(f)\| < \varepsilon/8 \quad \text{and} \quad \|\psi''(f) - \psi'''(f)\| < \varepsilon/8, \quad f \in F.
\]

By (4.19), (4.20), and (4.16), one has

\[
(4.23) \quad \text{tr}(\phi''(h)), \text{tr}(\psi''(h)) > \frac{3}{4} \Delta(\hat{h}), \quad h \in H_{B,1}.
\]

By (4.19), (4.20) and (4.18), one has

\[
(4.24) \quad |\text{tr}(\phi''(h)) - \text{tr}(\psi''(h))| < \frac{3}{4} \Delta(1 - \bar{g}_{\gamma/2}) \delta_B, \quad h \in \hat{H}_{B,2}.
\]

For each point \(x_i\) with \(\|x_i\| > 1 - \gamma\), replace the homomorphism \(\pi_{x_i}\) by \(\pi_{x'_i}\), where \(x'_i = x_i/\|x_i\| \in S^{n-1}\). Clearly, the homomorphism \(\pi_{x'_i}\) factors through \(B\). Also note that for each such \(x_i\), one has

\[
(4.25) \quad \text{tr}(\pi_{x'_i}(h)) > \text{tr}(\pi_{x_i}(h)), \quad h \in \hat{H}_{B,1}.
\]

By the choice of \(\gamma\) (see (4.18)), one also has

\[
(4.26) \quad \|\pi_{x'_i}(f_D) - \pi_{x_i}(f_D)\| < \varepsilon/8, \quad f \in F.
\]

Set

\[
\phi'''_B = \phi'''_B \oplus (\bigoplus_{\|x_i\| \geq 1 - \gamma} \pi_{x'_i}) \quad \text{and} \quad \psi'''_B = \psi'''_B \oplus (\bigoplus_{\|x'_i\| \geq 1 - \gamma} \pi_{x'_i}),
\]

and consider

\[
(4.27) \quad \phi''' = \phi'''_B \oplus (\bigoplus_{\|x_i\| < 1 - \gamma} \pi_{x_i}) \quad \text{and} \quad \psi''' = \psi'''_B \oplus (\bigoplus_{\|x_i\| < 1 - \gamma} \pi_{x_i}).
\]

By (4.26), one has

\[
(4.28) \quad \|\phi''(f) - \phi'''(f)\| < \varepsilon/8 \quad \text{and} \quad \|\psi''(f) - \psi'''(f)\| < \varepsilon/8, \quad f \in F.
\]

By (4.25) and (4.23), one has

\[
(4.29) \quad \text{tr}(\phi'''(h)), \text{tr}(\psi'''(h)) > \frac{3}{4} \Delta(\hat{h}), \quad h \in H_{B,1}.
\]

By (4.24), one has

\[
(4.30) \quad |\text{tr}(\phi'''(h)) - \text{tr}(\psi'''(h))| < \frac{3}{4} \Delta(1 - \bar{g}_{\gamma/2}) \delta_B, \quad h \in \hat{H}_{B,2}.
\]

Denote by

\[
N = \text{rank}(\phi'''_B(1)) = \text{rank}(\psi'''_B(1)).
\]

Then, by (4.29),

\[
\frac{N}{m} \geq \text{tr}(\phi'''(1 - \bar{g}_{\gamma/2})) > \frac{3}{4} \Delta(1 - \bar{g}_{\gamma/2});
\]
and
\[ \frac{m - N}{m} \geq \text{tr}(\phi'''(g_\gamma)) > \Delta(\widehat{g_\gamma}). \]

Therefore
\[ (4.31) \quad \frac{3}{4} \Delta(1 - \widehat{g_\gamma}/2) < \frac{N}{m} < 1 - \Delta(\widehat{g_\gamma}). \]

Then, by considering the unital homomorphisms \( \phi''_B, \psi''_B : B \to M_N(\mathbb{C}) \), it follows from (4.30) and (4.31) that
\[ (4.32) \quad \frac{1}{N}(\text{Tr}(\phi''_B(h)) - \text{Tr}(\phi''_B(h))) = \frac{m}{N}(\text{tr}(\phi''(\Gamma_\gamma(h))) - \text{tr}(\phi''(\Gamma_\gamma(h)))) < \delta_B, \quad h \in \mathcal{H}_{B,2}. \]

It also follows from (4.29) that
\[ \frac{1}{N}\text{Tr}(\phi''_B(h)) \geq \text{tr}(\phi''(\Gamma_\gamma(h))) > \Delta(h), \quad h \in \mathcal{H}_{B,1}, \]

and
\[ \frac{1}{N}\text{Tr}(\psi''_B(h)) \geq \text{tr}(\psi''(\Gamma_\gamma(h))) > \Delta(h), \quad h \in \mathcal{H}_{B,1}. \]

Then, it follows from the inductive hypothesis that there are homomorphisms \( \tilde{\phi}_B, \tilde{\psi}_B : B \to M_N(\mathbb{C}) \) such that
\[ (4.33) \quad \left\| \tilde{\phi}_B(f_B) - \phi''(f_B) \right\| < \varepsilon/2 \quad \text{and} \quad \left\| \tilde{\psi}_B(f_B) - \psi''(f_B) \right\| < \varepsilon/2, \quad f \in \mathcal{F}, \]

and there are decompositions
\[ \tilde{\phi}_B = \tilde{\phi}_{B,0} \oplus \tilde{\phi}_{B,1} \oplus \cdots \oplus \tilde{\phi}_{B,1} \quad \text{and} \quad \tilde{\psi}_B = \tilde{\psi}_{B,0} \oplus \tilde{\psi}_{B,1} \oplus \cdots \oplus \tilde{\psi}_{B,1} \]

with \( \tilde{\phi}_{B,1} \) and \( \tilde{\psi}_{B,1} \) unitarily equivalent and
\[ (4.34) \quad \frac{1}{N}\text{rank}(\tilde{\phi}_{B,0}(a)) \leq \eta \cdot \frac{1}{N}\text{rank}(\tilde{\phi}_B(a)), \quad a \in \mathcal{F}_B, \]
\[ (4.35) \quad \frac{1}{N}\text{rank}(\tilde{\psi}_{B,0}(a)) \leq \eta \cdot \frac{1}{N}\text{rank}(\tilde{\psi}_B(a)), \quad a \in \mathcal{F}_B. \]

By (4.31) and (4.34), one has that for any \( a \in \mathcal{F}_B \), one has
\[ (4.36) \quad \text{tr}(\tilde{\phi}_{B,0}(a)) = \frac{1}{m}\text{rank}(\tilde{\phi}_{B,0}(a)) = \frac{N}{m}\frac{1}{N}\text{rank}(\tilde{\phi}_{B,0}(a)) \leq \eta \cdot \frac{1}{m}\text{rank}(\tilde{\phi}_B(a)) = \eta \cdot \text{tr}(\tilde{\phi}_B(a)), \]

and for the same reason,
\[ (4.37) \quad \text{tr}(\tilde{\psi}_{B,0}(a)) \leq \eta \cdot \text{tr}(\tilde{\psi}_B(a)), \quad a \in \mathcal{F}_B. \]

Consider the map \( \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i} \), there is a decomposition
\[ \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i} = \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i'} \oplus \left( \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i''} \right) \oplus \cdots \oplus \left( \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i'''} \right), \]
where each $x_i'$ and $x_i''$ are same as $x_i$ but with different multiplies, and $x_i'$ has multiplicity at most $K$. Since each $x_i$ has multiplicity at least $M = [2K/\eta] + 1$, one has that

\begin{equation}
\tr( \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i}(a)) \leq \eta \cdot \tr( \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i}(a)), \quad a \in A.
\end{equation}

Then set
\begin{align*}
\tilde{\phi}_0 &= \phi_{B,0} \oplus \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i'} \quad \text{and} \quad \tilde{\psi}_0 = \psi_{B,0} \oplus \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i'}, \\
\tilde{\phi}_1 &= \phi_{B,1} \oplus \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i''} \quad \text{and} \quad \tilde{\psi}_1 = \psi_{B,1} \oplus \bigoplus_{\|x_i\|<1-\gamma} \pi_{x_i''},
\end{align*}

and
\begin{align*}
\tilde{\phi} &= \tilde{\phi}_0 + \tilde{\phi}_{B,1} + \cdots + \tilde{\phi}_{B,K} \quad \text{and} \quad \tilde{\psi} = \tilde{\psi}_0 + \tilde{\psi}_{B,1} + \cdots + \tilde{\psi}_{B,K}
\end{align*}

and these decompositions have the properties required in the statement of the theorem.

Indeed, by \((4.12), (4.13), (4.22), (4.28),\) and \((4.33),\) one has
\begin{align*}
\|\phi(f) - \tilde{\phi}(f)\| &< \|\phi(f) - \phi''(f)\| + \|\phi''(f) - \tilde{\phi}(f)\| < \varepsilon/2 + \varepsilon/2 = \varepsilon, \quad f \in \mathcal{F}, \\
\|\psi(f) - \tilde{\psi}(f)\| &< \|\psi(f) - \psi''(f)\| + \|\psi''(f) - \tilde{\psi}(f)\| < \varepsilon/2 + \varepsilon/2 = \varepsilon, \quad f \in \mathcal{F}.
\end{align*}

It is also clear that $\tilde{\phi}_1$ and $\tilde{\psi}_1$ are unitarily equivalent, and it follows from \((4.36), (4.38)\) and \((4.38)\) that the maps $\tilde{\phi}_0$ and $\tilde{\psi}_0$ satisfy the desired trace condition. \hfill \Box

Recall (from \([9]\))

**Lemma 4.6** (Lemma 4.13 of \([9]\)). Let $A$ be a unital separable nuclear residually finite dimensional $C^*$-algebra satisfying the UCT, and let $\Delta : A_{1,q}^+ \setminus \{0\} \to (0,1)$ be an order preserving map. For any finite set $\mathcal{F} \subseteq A$ and any $\varepsilon > 0$, there exist $\delta > 0$, a finite set $\mathcal{G} \subseteq A$, a finite set $\mathcal{P} \subseteq K(A)$, a finite set $\mathcal{H} \subseteq A_{1}^+ \setminus \{0\}$, and an integer $K \geq 1$ satisfying the following condition: For any two unital $\mathcal{G}$-$\delta$-multiplicative linear maps $\phi_1, \phi_2 : A \to M_n(\mathbb{C})$ (for some integer $n$) and any unital homomorphism $\psi : A \to M_m(\mathbb{C})$ with $m \geq n$ such that

\begin{enumerate}
\item $\tau \circ \psi(g) \geq \Delta(g), \quad g \in \mathcal{H},$
\item $[\phi_1]_\mathcal{P} = [\phi_2]_\mathcal{P},$
\end{enumerate}

there exists a unitary $U \in M_{Km+n}(\mathbb{C})$ such that
\begin{align*}
\left\| \phi_1(f) \oplus \psi(f) \oplus \cdots \oplus \psi(f) - u^*(\phi_2(f) \oplus \psi(f) \oplus \cdots \oplus \psi(f))u \right\| < \varepsilon, \quad f \in \mathcal{F}.
\end{align*}
Theorem 4.7. Let $A$ be an NCCC. Let $\Delta : A_{+}^{+} \setminus \{0\} \to (0,1)$ be an order preserving map. Let $(F,\varepsilon)$ be given. Then there are finite sets $G \subseteq A$, $H_{1} \subseteq A^{+}$, $H_{2} \subseteq A^{+}$ and $P \subseteq K(A)$, and positive numbers $\delta, \sigma > 0$ satisfying the following condition:

If $\phi, \psi : A \to M_{m}(C)$ are unital $G$-$\delta$-multiplicative maps such that

(1) $[\phi]_{P} = [\psi]_{P}$,
(2) $\text{tr}(\phi(h)) > \Delta(\hat{h})$ and $\text{tr}(\phi(h)) > \Delta(\hat{h})$, $h \in H_{1}$, and
(3) $|\text{tr}(\phi(h)) - \text{tr}(\psi(h))| < \sigma$, $h \in H_{2}$,

then there is a unitary $u \in M_{m}(C)$ such that

$$\|\phi(f) - u^{*}\psi(f)u\| < \varepsilon, \quad f \in F.$$  

Proof. Applying Lemma 4.6 to the data $A$, $\Delta/4$, and $(F,\varepsilon/3)$, one obtains $(G', \delta', P, H, K)$ satisfying the conditions of Lemma 4.6.

Applying Theorem 4.5 to the data $A$, $\Delta/2$, $F \cup H$, min\{\varepsilon/6, \Delta(H)/4\}$ (in place of $\varepsilon$), $\eta = 1/2K$, and $K$, one obtains $H_{1}$, $H_{2}$, and $2\sigma$ (in place of $\delta$) satisfying the conclusion of Theorem 4.5. Without loss of generality, one may assume that $H_{1}$ and $H_{2}$ are in the unital ball of $A$.

Applying Corollary 5.5 of [9] to $F \cup H_{1} \cup H_{2}$, min\{\varepsilon/6, \Delta(H_{1})/2, \Delta(H_{2})/2, \sigma/4\}, min\{1/2K, \Delta(H_{1})/2, \Delta(H_{2})/2, \sigma/4(1 + \sigma)\},

one obtains $(G, \delta)$.

Then $G$, $\delta$, $\sigma$, $H_{1}$, $H_{2}$, and $P$ satisfy the conclusion of the theorem. Indeed, let $\phi, \psi : A \to M_{m}(C)$ be $G$-$\delta$-multiplicative maps such that

(1) $[\phi]_{P} = [\psi]_{P}$,
(2) $\text{tr}(\phi(h)) > \Delta(\hat{h})$ and $\text{tr}(\phi(h)) > \Delta(\hat{h})$, $h \in H_{1}$, and
(3) $|\text{tr}(\phi(h)) - \text{tr}(\psi(h))| < \sigma$, $h \in H_{2}$.

By Theorem 5.5 of [9], there are $\phi_{0}, \phi_{1}, \psi_{0}, \psi_{1} : A \to M_{m}(C)$ such that $\phi_{0}, \psi_{0}$ are $G'$-$\delta'$-multiplicative, $\phi_{1}, \psi_{1}$ are homomorphisms, such that

(4.39) $\|\phi(a) - \phi_{0}(a) \oplus \phi_{1}(a)\| < \min\{\varepsilon/6, \Delta(H_{1})/2, \Delta(H_{2})/2, \sigma/4\}$, $a \in F \cup H_{1} \cup H_{2}$,

(4.40) $\|\psi(a) - \psi_{0}(a) \oplus \psi_{1}(a)\| < \min\{\varepsilon/6, \Delta(H_{1})/2, \Delta(H_{2})/2, \sigma/4\}$, $a \in F \cup H_{1} \cup H_{2}$,

and

$$\text{tr}(\phi_{0}(1)) = \text{tr}(\psi_{0}(1)) < \min\{1/2K, \Delta(H_{1})/2, \Delta(H_{2})/2, \sigma/4(1 + \sigma)\}.$$  

Consider the unital homomorphisms $\phi_{1}, \psi_{1} : A \to pM_{m}(C)p$, where $p = \phi_{1}(1) = \psi_{1}(1)$. One has that

(1) $\tau(\phi_{1}(h)), \tau(\phi_{1}(h)) > \Delta(\hat{h})/2$, $h \in H_{1}$, and
(2) $|\tau(\phi_{1}(h)) - \tau(\psi_{1}(h))| < 2\sigma$, $h \in H_{2}$,

where $\tau \in T(pM_{m}(C)p)$.  

By Theorem 4.6, up to unitary equivalence, there are homomorphisms \( \phi', \psi', \mu : A \to pM_m(\mathbb{C})p \) such that
\[
\frac{1}{2K} \cdot \tau(\phi_1(a)) \quad \text{and} \quad \frac{1}{2K} \cdot \tau(\psi_1(a)) \leq 1 - \Delta(h)
\]
and
\[
\Delta(h) > 1 - \Delta(h)
\]
and
\[
\tau(\phi'(a)) \leq \frac{1}{2K} \cdot \tau(\phi_1(a)) \quad \text{and} \quad \tau(\psi'(a)) \leq \frac{1}{2K} \cdot \tau(\psi_1(a)), \quad a \in \mathcal{F} \cup \mathcal{H}, \tau \in T(pM_m(\mathbb{C})p).
\]
Therefore, one has that
\[
\tau(\mu(h)) > \frac{1}{4} \Delta(h), \quad h \in \mathcal{H}, \tau \in T(qM_m(\mathbb{C})q),
\]
where \( q = \mu(1) \). Consider the map
\[
(\phi_0 \oplus \phi_1') \oplus (\mu \oplus \cdots \mu) \quad \text{and} \quad (\psi_0 \oplus \psi_1') \oplus (\mu \oplus \cdots \mu),
\]
and note that
\[
\text{tr}(\phi_0(1) \oplus \phi_1'(1)) = \text{tr}(\psi_0(1) \oplus \psi_1'(1)) < \text{tr}(\mu(1)).
\]
It then follows from Lemma 4.7 that there is a unitary \( u \in M_m(\mathbb{C}) \) such that for any \( a \in \mathcal{F} \),
\[
\left\| (\phi_0(a) \oplus \phi_1'(a)) \oplus (\mu(a) \oplus \cdots \mu(a)) - u^*( (\psi_0(a) \oplus \psi_1'(a)) \oplus (\mu(a) \oplus \cdots \mu(a)) )u \right\| < \frac{\varepsilon}{3}.
\]
It then follows from (4.39), (4.40), (4.41), and (4.42) that
\[
\left\| \phi(a) - u^* \psi(a) u \right\| < \varepsilon, \quad a \in \mathcal{F},
\]
as desired. \( \square \)

Note that \( \text{KL}(A, Q) \cong \text{Hom}(K_0(A), K_0(Q)) \), a straightforward consequence is

**Corollary 4.8.** Let \( A \) be an NCCC. Let \( \Delta : A^+_1 \setminus \{0\} \to (0,1) \) be an order preserving map. Let \( (\mathcal{F}, \varepsilon) \) be given. Then there are finite sets \( \mathcal{H}_1 \subseteq A^+ \) and \( \mathcal{H}_2 \subseteq A^+ \) and a positive number \( \delta > 0 \) satisfying the following condition:

If \( \phi, \psi : A \to Q \) are unital homomorphisms such that

1. \( [\phi]_0 = [\psi]_0 \),
2. \( \text{tr}(\phi(h)) > \Delta(h) \) and \( \text{tr}(\psi(h)) > \Delta(h) \), \( h \in \mathcal{H}_1 \), and
3. \( |\text{tr}(\phi)(h) - \text{tr}(\psi)(h)| < \delta \), \( h \in \mathcal{H}_2 \),

then there is a unitary \( u \in Q \) such that
\[
\left\| \phi(f) - u^* \psi(f) u \right\| < \varepsilon, \quad f \in \mathcal{F}.
\]
It is also worth pointing out the following corollary:

**Corollary 4.9.** Let $A$ be a subhomogeneous C*-algebra. Let $\Delta : A^+_{\ellq} \setminus \{0\} \to (0,1)$ be an order preserving map. Let $(\mathcal{F}, \varepsilon)$ be given. Then there are finite sets $\mathcal{G} \subseteq A$, $\mathcal{H}_1 \subseteq A^+$, $\mathcal{H}_2 \subseteq A^+$ and $\mathcal{P} \subseteq K(A)$, and positive numbers $\delta, \sigma > 0$ satisfying the following condition:

If $\phi, \psi : A \to M_m(\mathbb{C})$ are unital $\mathcal{G}$-$\delta$-multiplicative maps such that

1. $[\phi]|_\mathcal{P} = [\psi]|_\mathcal{P}$,
2. $\text{tr}(\phi(h)) > \Delta(\hat{h})$ and $\text{tr}(\phi(h)) > \Delta(\hat{h})$, $h \in \mathcal{H}_1$, and
3. $|\text{tr}(\phi(h)) - \text{tr}(\psi(h))| < \sigma$, $h \in \mathcal{H}_2$,

then there is a unitary $u \in M_m(\mathbb{C})$ such that

$$\|\phi(f) - u^*\psi(f)u\| < \varepsilon, \quad f \in \mathcal{F}.$$ 

**Proof.** This follows the fact that any subhomogeneous C*-algebra can be locally approximated by NCCCs (Theorem 2.15 of [5]). \qed

5. **Tracial factorization and tracial approximation**

Recall that

**Definition 5.1** ([13], [2]). Let $\mathcal{S}$ be a class of unital C*-algebras. A C*-algebra $A$ is said to be tracially approximated by the C*-algebras in $\mathcal{S}$, and one writes $A \in \text{TA}\mathcal{S}$, if the following condition holds: For any finite set $\mathcal{F} \subseteq A$, any $\varepsilon > 0$, and any nonzero $a \in A^+$, there is a nonzero sub-C*-algebra $\mathcal{S} \subseteq A$ such that $\mathcal{S} \in \mathcal{S}$, and if $p = 1_{\mathcal{S}}$, then

1. $\|pf - fp\| < \varepsilon$, $f \in \mathcal{F}$,
2. $pf \in \mathcal{S}$, $f \in \mathcal{F}$, and
3. $1 - p$ is Murray-von Neumann equivalent to a subprojection of $\overline{aa}a$.

One particularly important class $\mathcal{S}$ of building blocks is the class of Elliott-Thomsen algebras.

**Definition 5.2.** ([6], [1]) A C*-algebra $C$ is said to be an Elliott-Thomsen algebra if

$$C = \{(a,f) \in E \oplus (F \otimes C([0,1])) : f(0) = \varrho_0(a), f(1) = \varrho_1(a)\}$$

for some finite dimensional C*-algebras $E$, $F$, where $\varrho_0, \varrho_1 : E \to F$ are unital homomorphisms. Denote by $\pi_{\infty}$ the standard quotient map

$$\pi_{\infty} : A \ni (a,f) \mapsto a \in E.$$ 

Let us denote the class of unital Elliott-Thomsen algebras by $\mathcal{C}$, and denote the class of unital Elliott-Thomsen algebras with trivial $K_1$-group by $\mathcal{C}_0$.

**Remark 5.3.** In fact, by Corollary 29.3 of [9], one has $\text{TA}\mathcal{C} = \text{TA}\mathcal{C}_0$.

**Remark 5.4.** In fact, the class of unital Elliott-Thomsen algebras is exactly the class of NCCCs with dimensions of cells at most one; see [5].

For $\text{TA}\mathcal{C}_0$ algebras, one has the following classification theorem.
Theorem 5.5 (Corollary 28.7 of [9]). Let $A, B$ be unital separable amenable simple C*-algebras satisfying the UCT. Assume that $A, B$ are Jiang-Su stable, and assume that $A \otimes Q \in \text{TA}_0$ and $B \otimes Q \in \text{TA}_0$. Then $A \cong B$ if and only if $\text{Ell}(A) \cong \text{Ell}(B)$.

In this section, let us show that for any separable simple unital locally ASH algebra $A$, one has that $A \otimes Q \in \text{TA}_0$.

Theorem 5.6. Let $A$ be a unital simple separable locally approximately subhomogeneous (ASH) C*-algebra satisfying $A \cong A \otimes Q$. Then, for any finite set $F \subseteq A$ and any $\varepsilon > 0$, there exist an Elliott-Thomsen algebra $C$ with $K_1(C) = \{0\}$, a unital completely positive linear map $\Phi : A \to C$, and a unital embedding $\Psi : C \to A$ such that

1. $\Phi$ is $F$-multiplicative, and
2. $|\tau(f) - \tau(\Psi(\Phi(f)))| < \varepsilon$, $f \in F$, $\tau \in T(A)$.

Proof. Without loss of generality, one may assume that $1 \in F$ and each element of $F$ is self-adjoint and has norm at most 1.

Let $A$ be a unital separable simple locally ASH algebra satisfying $A \cong A \otimes Q$. By Theorem 2.15 of [5], the C*-algebra $A$ can be locally approximated by unital NCCCs. Therefore, without loss of generality, one may assume that there is a sub-C*-algebra $A_1 \subseteq A$ such that $A_1$ is a NCCC and $F \subseteq A_1$.

Put $G_{A_1} = \rho_{A_1}(K_0(A_1))$, $G_{A_1}^+ = \rho_{A_1}(K_0(A_1)) \cap \text{Aff}^+(T(A_1))$, $u_{A_1} = \rho_{A_1}([1])$,

and fix a set $\{p_1, ..., p_n\}$ which generates the group $G_{A_1}$. Note that by Lemma 2.9, the positive cone $G_{A_1}^+$ is finitely generated.

For each $h \in A_+$, define

$\Delta(h) = \inf\{\tau(\iota(h)) : \tau \in T(A)\}$,

where $\iota : A_1 \to A$ is the embedding map. Since $A$ is simple, the map $\Delta$ induces an order preserving map from $A_+^{1,\theta}$ to $(0, 1)$. Let us still denote this by $\Delta$.

Let $\mathcal{H}_1 \subseteq (A_1)_+$, $\mathcal{H}_2 \subseteq (A_1)_+$ and $\delta_0 > 0$ be the finite sets and constant of Corollary 4.8 with respect to $\mathcal{F} : \mathcal{F}, \varepsilon/4$, and $\Delta/4$.

Let $\mathcal{H}$ be the subset of Theorem 3.7 with respect to $A_1$, $\mathcal{F} \cup \mathcal{H}_1 \cup \mathcal{H}_2$ (in the place of $\mathcal{F}$), $\min\{\varepsilon/4, \delta_0/4, \Delta(\hat{h})/4 : h \in \mathcal{H}_1\}$ (in the place of $\varepsilon$). Put

$\sigma = \frac{1}{2} \min\{\Delta(\hat{h}) : h \in \mathcal{H}\}$,

and denote by $\delta_1$ the constant of Theorem 3.7 with respect to $\sigma$.

Put

$G = \rho_A(K_0(A))$, $G^+ = \rho_A(K_0(A)) \cap \text{Aff}^+(T(A))$, $u = \rho_A([1])$.

Then $(G, G^+, u)$ is a unperforated order-unit group, and there is a natural pairing between $(G, G^+, u)$ and $T(A)$ induced by $\rho_A$. Still denote this pairing map by $\rho_A$. Note that one has the
following commutative diagram:

\[
\begin{array}{ccc}
K_0(A_1) & \xrightarrow{[\iota_0]} & K_0(A) \\
\downarrow \rho_{A_1} & & \downarrow \rho_A \\
G_{A_1} & \xrightarrow{(\iota)_*} & G.
\end{array}
\]

Consider \(\((G, G^+, u), T(A), \rho_A\)\). By Theorem 5.2.2 of [1], there is an inductive system \(C' = \varinjlim(C_i', \eta_i')\) with \(C_i' \in C_0\) and \(\eta_i\) injective such that there is an isomorphism

\[
\Xi : \((G, G^+, u), T(A), \rho_A\) \to \((K_0(C'), K_0(C'), [1]), T(C'), \rho_C')\).
\]

Consider \(C = C' \otimes Q = \varinjlim(C_i, \eta_i)\), where \(C_i = C_i' \otimes Q\) and \(\eta_i = \eta_i' \otimes \text{id}_Q\). One has

\[
\((G, G^+, u), T(A), \rho_A) \cong ((K_0(C), K_0(C), [1]), T(C), \rho_C),
\]

and let us still denote by \(\Xi\) the isomorphism. In the remaining part of the paper, let us also use \(\Xi\) to denote its restriction to \(G\) or to \(\text{Aff}(T(A))\), depending on the context.

Consider the following diagram:

\[
\begin{array}{ccc}
G_{A_1} & \xrightarrow{[\iota_0]} & G \\
K_0(C_1) & \xrightarrow{[\eta_1]} & K_0(C_2) \\
\downarrow & & \downarrow \\
& \cdots & \\
& K_0(C) & \\
\end{array}
\]

Since the positive cone of \(G_{A_1}\) is finitely generated (Lemma 2.9), the positive map \([\iota_0]\) can be lifted to a positive homomorphism \(G_{A_1} \to K_0(C_n)\) for sufficiently large \(n\). Without loss of generality, one may assume that \([\iota_0]\) has a lifting \(\kappa : G_{A_1} \to K_0(C_1)\), making the diagram commutative:

\[
\begin{array}{ccc}
G_{A_1} & \xrightarrow{[\iota_0]} & G \\
\downarrow \kappa & & \downarrow \Xi \\
K_0(C_1) & \xrightarrow{[\eta_1]} & K_0(C_2) \\
\downarrow & & \downarrow \\
& \cdots & \\
& K_0(C) & \\
\end{array}
\]

By Lemma 2.10, after a telescoping of the inductive system \((C_i, \eta_i)\), there is also an approximate lifting, making the diagram of affine function spaces,

\[
\begin{array}{ccc}
\text{Aff}(T(A_1)) & \xrightarrow{(\iota)_*} & \text{Aff}(T(A)) \\
\downarrow \gamma & & \downarrow \Xi \\
\text{Aff}(T(C_1)) & \xrightarrow{(\eta_1)_*} & \text{Aff}(T(C)) \\
\downarrow & & \downarrow \\
& \cdots & \\
& \text{Aff}(T(C)) & \\
\end{array}
\]

approximately commutative, and such that

\[
(5.1) \quad |\tau(\kappa([p_i])) - \gamma([p_i])(\tau)| < \delta_1, \quad \tau \in T(C_i), \quad 1 \leq i \leq n,
\]

\[
(5.2) \quad \gamma(h)(\tau) > \frac{1}{2}\Delta(h) > \sigma, \quad h \in \mathcal{H} \cup \mathcal{H}_1, \quad \tau \in T(C_1),
\]

It also follows from (5.5) and (5.4) that for any $\tau \in T(A), f \in \mathcal{F}$.

Write

$$C_1 = C'_1 \otimes Q = \{(a, f) \in E \oplus (F \otimes C([0, 1])) : f(0) = \varrho_0(a), f(1) = \varrho_1(a)\},$$

where

$$E = \bigoplus_{i=1}^p Q, \quad F = \bigoplus_{j=1}^l Q,$$

for natural numbers $p, l$, and $\varrho_0, \varrho_1 : E \to F$ are unital homomorphisms.

On each interval $[0, 1]_j$, choose a partition

$$0 = t_0 < t_1 < t_2 < \cdots < t_{k-1} < t_k = 1$$

such that

$$\gamma(\hat{f})(\tau_s) - \gamma(\hat{f})(\tau_{t_i}) < \min\{\varepsilon/4, \delta_0/2\}, \quad s \in [t_i, t_{i+1}], f \in \mathcal{F} \cup \mathcal{H}_2,$$

where $\tau_s = \text{tr} \circ \pi_s$ and tr is the canonical trace of Q. One may assume that $k$ is sufficiently large that

$$2\pi/(k - 1) < \varepsilon/8.$$

For each $0 < i < k$, define

$$\kappa_i = [\pi_{t_i}]_0 \circ \kappa : K_0(A_1) \to K_0(Q) \cong \mathbb{Q},$$

and

$$\gamma_i = (\pi_{t_i})_* \circ \gamma : \text{Aff}(T(A_1)) \to \text{Aff}(T(Q)) \cong \mathbb{R}.$$

By (5.1), each pair $(\kappa_i, \gamma_i)$ is $\delta_1$-compatible on $[p_i], 1 \leq i \leq n$. By (5.2), one has that

$$\gamma_i(\hat{h})(\text{tr}) > \sigma, \quad h \in \mathcal{H}.$$

Therefore, by Theorem 3.7, there is a homomorphism $\phi_i : A_1 \to Q$ such that

$$[\phi_i]_0 = \kappa_i$$

and

$$\gamma_i(\hat{h})(\text{tr}) - \text{tr}(\phi_i(h)) < \min\{\varepsilon/4, \delta_0/4, \Delta(\hat{h})/4 : h \in \mathcal{H}_1\}, \quad h \in \mathcal{F} \cup \mathcal{H}_1 \cup \mathcal{H}_2.$$

Together with (5.2), it then follows that

$$\text{tr}(\phi_i(h)) > \gamma_i(\hat{h})(\text{tr}) - \frac{1}{4}\Delta(\hat{h}) > \frac{1}{4}\Delta(\hat{h}), \quad h \in \mathcal{H}_1.$$
Since \( \pi_i \) is homotopic to \( \pi_{i+1} \), it is clear that \( [\kappa_i] = [\kappa_{i+1}] \), 1 \( \leq i \leq k - 2 \), and therefore

\[(5.8) \quad \begin{array}{l}
\phi_0 = \phi_{i+1}, \quad 1 \leq i \leq k - 2.
\end{array}
\]

Denote by \( \pi_\infty : C_1 \to E \) the standard quotient map, and consider

\[
\kappa_\infty = [\pi_\infty]_0 \circ \kappa : K_0(A_1) \to K_0(E) \quad \text{and} \quad \gamma_\infty = [\pi_\infty] \circ \gamma : \text{Aff}(T(A_1)) \to \text{Aff}(T(E)).
\]

The same argument as above shows that there is a homomorphism \( \phi_\infty : A_1 \to E \) such that

\[(5.9) \quad \begin{array}{l}
[\phi_\infty]_0 = \kappa_\infty,
\end{array}
\]

and

\[(5.10) \quad \left| \gamma_\infty(h)(\tau) - \tau(\phi_\infty(h)) \right| < \min \{ \varepsilon/4, \delta_0/4, \Delta(h)/4 : h \in H_1 \}, \quad h \in H_1 \cup H_2, \quad \tau \in T(E).
\]

Define

\[
\phi_0 = \phi_0 \circ \phi_\infty \quad \text{and} \quad \phi_k = \phi_1 \circ \phi_\infty
\]

and consider the restrictions of these maps to the \( j \)-th direct summand; still denote them by \( \phi_0 \) and \( \phi_k \) respectively. It then follows from \((5.9)\) that

\[(5.11) \quad [\phi_0]_0 = [\phi_k] = [\phi_i]_0, \quad 1 \leq i \leq k - 1,
\]

and it follows from \((5.10)\) and \((5.2)\) that

\[(5.12) \quad \text{tr}(\phi_0(h)), \text{tr}(\phi_k(h)) > \frac{1}{4} \Delta(h), \quad h \in H_1.
\]

Moreover, with \((5.10)\) and \((5.4)\), the same argument as that of \((5.7)\) shows that

\[(5.13) \quad |\text{tr}(\phi_0(h)) - \text{tr}(\phi_1(h))| < \delta_0 \quad \text{and} \quad |\text{tr}(\phi_{k-1}(h)) - \text{tr}(\phi_k(h))| < \delta_0, \quad h \in H_2.
\]

Thus, with \((5.11)\), \((5.6)\), \((5.12)\), \((5.7)\) and \((5.13)\), Corollary 4.8 implies that there are unitaries \( u_1, u_2, \ldots, u_{k-1} \in Q \) such that

\[
\|\phi_i(f) - u_{i+1}^* \phi_{i+1}(f) u_{i+1}\| < \varepsilon/4, \quad f \in \mathcal{F} \cdot \mathcal{F}, \quad 0 \leq i \leq k - 2.
\]

Define \( v_0 = 1 \), and

\[
v_i = u_i u_{i-1} \cdots u_1, \quad i = 1, \ldots, k - 1.
\]

Then, for any \( 0 \leq i \leq k - 2 \) and any \( f \in \mathcal{F} \cdot \mathcal{F} \), one has

\[
\|\text{Ad}(v_i) \circ \phi_i(f) - \text{Ad}(v_{i+1}) \circ \phi_{i+1}(f)\| = \|\phi_i(f)(u_i \cdots u_1) - (u_{i+1} \cdots u_1) \phi_{i+1}(f)(u_{i+1} \cdots u_1)\| < \varepsilon/4.
\]

Replacing each homomorphism \( \phi_i \) by \( \text{Ad}(v_i) \circ \phi_i \) for \( i = 1, \ldots, k - 1 \), and still denoting it by \( \phi_i \), one has

\[
\|\phi_i(f) - \phi_{i+1}(f)\| < \varepsilon/4, \quad f \in \mathcal{F} \cdot \mathcal{F}, \quad 0 \leq i \leq k - 2.
\]

Note that the replacement of \( \phi_i \) does not change the induced map on the invariant, and hence one still has

\[
[\phi_{k-1}]_0 = [\phi_k]_0,
\]
By (5.14), the map \( \Phi \) such that
\[
\|w^*\phi_k(f)w - \phi_k(f)\| < \varepsilon/4, \quad f \in \mathcal{F},
\]
and
\[
|\text{tr}(\phi_k(h)) - \text{tr}(\psi_k(h))| < \delta_0, \quad h \in \mathcal{H}_2.
\]
Applying Corollary 4.8 again, we obtain a unitary \( w \in Q \) such that
\[
\|w^*\phi_k(f)w - \phi_k(f)\| < \varepsilon/4, \quad f \in \mathcal{F} \cdot \mathcal{F}.
\]
Since \( Q \) is AF, and any unitary in a finite dimensional C*-algebra can be connected to the identity along a path with length at most \( \pi \) (i.e., it has exponential length at most \( \pi \)), there are unitaries
\[
1 = w_0, w_1, ..., w_{k-2}, w_{k-1} = w \in Q
\]
such that
\[
\|w_i - w_{i-1}\| < 2\pi/(k - 1) < \varepsilon/8.
\]
Hence,
\[
\|w_i^*\phi_i(f)w_i - w_{i+1}^*\phi_{i+1}(f)w_{i+1}\| < 3\varepsilon/8, \quad f \in \mathcal{F} \cdot \mathcal{F}, 0 \leq i \leq k - 2.
\]
Replace each homomorphism \( \phi_i \) again by \( \text{Ad}(w_i) \circ \phi_i \), \( 1 \leq i \leq k - 1 \), and still denote it by \( \phi_i \).
One then has
\[
\|\phi_i(f) - \phi_{i+1}(f)\| < 3\varepsilon/8, \quad f \in \mathcal{F} \cdot \mathcal{F}, 0 \leq i \leq k - 1.
\]
Define the positive linear map \( \phi : A_1 \to C([0, 1], Q) \) by
\[
\Phi_j(f)(t) = \frac{t_{i+1} - t}{t_{i+1} - t_i} \phi_i(f) + \frac{t - t_i}{t_{i+1} - t_i} \phi_{i+1}(f), \quad \text{if } t \in [t_i, t_{i+1}].
\]
By (5.14), the map \( \Phi_j \) is \( \mathcal{F} \)-\( \varepsilon \)-multiplicative. It also follows from (5.4) that if \( t \in [t_i, t_{i+1}] \), then, for any \( f \in \mathcal{F} \),
\[
\gamma(\hat{f})(\tau_t) - \tau_t(\Phi_j(f)) \leq \gamma(\hat{f})(\tau_{t_i}) - \tau_t(\Phi_j(f)) + \varepsilon/4 \quad \text{(by (5.4))}
\]
\[
= \gamma_i(\hat{f})(\text{tr} - \frac{t_{i+1} - t}{t_{i+1} - t_i} \text{tr}(\phi_i(f)) + \frac{t - t_i}{t_{i+1} - t_i} \text{tr}(\phi_{i+1}(f))) + \varepsilon/4
\]
\[
\leq \gamma_i(\hat{f})(\text{tr} - \text{tr}(\phi_i(f))) + 5\varepsilon/8 \quad \text{(by (5.14))}
\]
\[
< \varepsilon/4 + 5\varepsilon/8 = 7\varepsilon/8 \quad \text{(by (5.3))}.
\]
Repeat this construction for all \( j = 1, ..., t \), and note that the maps \( \Phi_1, \Phi_2, ..., \Phi_t \) induce a map \( \Phi : A_1 \to C_1 \). Since each \( \Phi_j \) is \( \mathcal{F} \)-\( \varepsilon \) multiplicative, the map \( \Phi \) is \( \mathcal{F} \)-\( \varepsilon \)-multiplicative. By (5.15), one has
\[
\|\gamma(\hat{f})(\tau_t) - \tau_t(\Phi(f))\| < 7\varepsilon/8, \quad f \in \mathcal{F}, \tau \in T(C_1).
\]
Now, let us construct an embedding \( \Psi : C_1 \to A \) such that
\[
|\tau(f) - \tau(\Psi(\Phi(f)))| < \varepsilon, \quad f \in \mathcal{H}, \tau \in T(A).
\]
Since $A \cong A \otimes Q$, the subgroup $H := \ker \rho_A \subseteq K_0(A)$ is divisible, and therefore the exact sequence

$$0 \longrightarrow H \longrightarrow K_0(A) \overset{\rho_A}{\longrightarrow} G \longrightarrow 0$$

splits. Pick a decomposition

$$K_0(A) = G \oplus H.$$

Since $K_0(A)$ is weakly unperforated, the order on $(G \oplus H)$ is completely determined by that on $G$.

Define

$$\kappa' : G \ni g \mapsto (g, 0) \in G \oplus H = K_0(A).$$

Then $\kappa'$ is a positive homomorphism, and the pair

$$(\kappa' \circ (\Xi^{-1}|_{K_0(C)}), \Xi|_{\text{Aff}(T(C))})$$

is compatible. It induces a positive homomorphism

$$\theta : Cu^\sim(C) \to Cu^\sim(A).$$

By Theorem 1 of [26], there is a homomorphism $\psi : C \to A$ such that the Cuntz map induced by $\psi$ is $\theta$. In particular, one has that

$$\psi_* = \Xi^{-1}|_{\text{Aff}(T(C))}. \tag{5.17}$$

Then the map

$$\Psi = \psi \circ \eta_{l,\infty}$$

satisfies the conclusion of the theorem (together with $\Phi$). Indeed, since $C$ is simple, the map $\psi$ is an embedding, and therefore $\Psi$ is an embedding. Moreover, for any $f \in \mathcal{F}$, one has

$$\left| \tau(\xi(f)) - \tau(\Psi \circ \Phi(f)) \right|$$

$$= \left| \left(\xi_* \hat{f}\right)(\tau) - \left(\Psi_* \left(\left(\Phi_* \left(\hat{f}\right)\right)(\tau)\right) \right) \right|$$

$$= \left| \left(\left(\xi_* \hat{f}\right)(\tau) - \left(\psi_* \left(\left(\eta_{l,\infty} \circ \Phi_* \left(\hat{f}\right)\right)(\tau)\right) \right) \right| \right.$$

$$\leq \left| \left(\xi_* \hat{f}\right)(\tau) - \left(\Xi^{-1} \circ \eta_{l,\infty} \circ \gamma \right)(\hat{f})(\tau) \right| + 7\varepsilon/8 \quad \text{(by (5.16))}$$

$$\leq \varepsilon/8 + 7\varepsilon/8 = \varepsilon \quad \text{(by (5.3))},$$

as desired. \hfill \Box

**Remark 5.7.** With a slight modification (a perturbation of the linear map $\gamma$), the same argument as Theorem 5.6 shows that the same statement holds for C*-algebras which are tracially approximated by subhomogeneous C*-algebras.

The passage from Theorem 5.6 to the actual tracial approximation is an application of the following very important theorem due to Winter:
Theorem 5.8 (Theorem 2.2 of [32]). Let \( S \) be a class of separable unital C*-algebras which have a finite presentation with weakly stable relations. Suppose further that \( S \) is closed under taking direct sums and under taking tensor products with finite dimensional C*-algebras, and that \( S \) contains all finite dimensional C*-algebras.

Let \( A \) be a separable, simple, unital C*-algebra with \( \dim_{\text{nuc}} A < \infty \) and \( T(A) \neq \emptyset \), and let \(( A \xrightarrow{\sigma_i} B_i \xrightarrow{\varrho_i} A )_{i \in \mathbb{N}} \) be a system of maps with the following properties:

1. \( B_i \in S, \ i \in \mathbb{N} \),
2. \( \varrho_i \) is an embedding for each \( i \in \mathbb{N} \),
3. \( \sigma_i \) is a completely positive contraction for each \( i \in \mathbb{N} \),
4. \( \bar{\sigma}_i : A \to \prod_{i \in \mathbb{N}} B_i / \bigoplus_{i \in \mathbb{N}} B_i \) induced by \( \sigma_i \) is a unital homomorphism,
5. \( \sup\{|\tau(\varrho_i\sigma_i(a) - a)| : \tau \in T(A)\} \to 0 \), as \( i \to \infty \) for each \( a \in A \).

Then \( A \otimes Q \in TA_S \).

With this and Theorem 5.6, one has

Theorem 5.9. Let \( A \) be a unital simple separable locally ASH C*-algebra. Then \( A \otimes Q \in TA_C^0 \), where \( C_0 \) is the class of unital Elliott-Thomsen algebras with trivial \( K_1 \)-group. In particular, if \( A \cong A \otimes Z \), where \( Z \) is the Jiang-Su algebra, then \( A \) is classifiable (by means of the naive Elliott invariant). (The converse is also true.)

Proof. By Theorem 3.1 of [5], one has \( \text{dr}(A \otimes Q) \leq 2 \), and in particular, \( \dim_{\text{nuc}}(A \otimes Q) \leq 2 < +\infty \). It then follows from Theorems 5.6 and 5.8 that \( A \otimes Q \in TA_C^0 \). By the classification theorem of [9] (based in particular on the deformation technique of [33] and [17]—see also [19]), the C*-algebra \( A \) is classifiable.

Corollary 5.10. Let \( A \) be a simple separable unital locally ASH (respectively, locally AH) algebra. Then \( A \otimes Z \) is an ASH (respectively, AH) algebra.

Proof. By Theorem 5.9, the C*-algebra \( A \otimes Z \) is classifiable by means of the Elliott invariant. By [11] and [8], the Elliott invariant for separable, Jiang-Su stable, simple, unital, finite C*-algebras (in particular, locally ASH algebras) is exhausted by ASH algebras (by Theorem 3 of [8], finiteness implies stable finiteness in this setting). Furthermore, by [30], the Elliott invariant for separable, Jiang-Su stable, simple, unital, locally AH algebras is exhausted by AH algebras. (In both settings, the models have no dimension growth.)

The classification of locally ASH algebras (Theorem 5.9) in fact allow us to recover the recent classification result for the C*-algebra of a minimal homeomorphism—assumed to have mean dimension zero but not to be uniquely ergodic ([27], [18]—the uniquely ergodic case was dealt with in [3], or in [29] on the case the space is finite dimensional):

Corollary 5.11 (Corollary 5.3 of [18]). Let \( X \) be a compact metrizable space, and let \( \sigma : X \to X \) be a minimal homeomorphism. Then the C*-algebra \( (C(X) \rtimes_{\sigma} Z) \otimes Z \) is classifiable. In particular, if \( (X, \sigma) \) has mean dimension zero, the C*-algebra \( C(X) \rtimes_{\sigma} Z \) is classifiable.
Proof. By Theorem 4.1 of [5], the C*-algebra \((C(X) \rtimes_\sigma \mathbb{Z}) \otimes Q\) is locally ASH. By Theorem 5.9, the C*-algebra \((C(X) \rtimes_\sigma \mathbb{Z}) \otimes Q\) belongs to the class \(\text{TA}_{\mathbb{C}^0}\), and hence the C*-algebra \((C(X) \rtimes_\sigma \mathbb{Z}) \otimes \mathbb{Z}\) is classifiable.

If \((X,\sigma)\) has mean dimension zero, then it follows from [3] that
\[
C(X) \rtimes_\sigma \mathbb{Z} \cong (C(X) \rtimes_\sigma \mathbb{Z}) \otimes \mathbb{Z},
\]
and so the C*-algebra \(C(X) \rtimes_\sigma \mathbb{Z}\) is classifiable. \(\square\)
