Abstract
$\alpha$-Dirac-harmonic maps are variations of Dirac-harmonic maps, analogous to $\alpha$-harmonic maps that were introduced by Sacks–Uhlenbeck to attack the existence problem for harmonic maps from closed surfaces. For $\alpha > 1$, the latter are known to satisfy a Palais–Smale condition, and so, the technique of Sacks–Uhlenbeck consists in constructing $\alpha$-harmonic maps for $\alpha > 1$ and then letting $\alpha \to 1$. The extension of this scheme to Dirac-harmonic maps meets with several difficulties, and in this paper, we start attacking those. We first prove the existence of nontrivial perturbed $\alpha$-Dirac-harmonic maps when the target manifold has nonpositive curvature. The regularity theorem then shows that they are actually smooth if the perturbation function is smooth. By $\varepsilon$-regularity and suitable perturbations, we can then show that such a sequence of perturbed $\alpha$-Dirac-harmonic maps converges to a smooth coupled $\alpha$-Dirac-harmonic map.

1 Introduction

Harmonic maps from closed Riemann surfaces and their variants are important both in mathematics as tools to probe the geometry of a Riemannian manifold and in physics as ground states of the nonlinear sigma model of quantum field theory. They represent a borderline case for the Palais–Smale condition and therefore cannot be directly obtained by standard tools. In [19], Sacks–Uhlenbeck introduced the notion of $\alpha$-harmonic maps which for $\alpha > 1$ (which we shall always assume in this paper) makes the problem subcritical for the Palais–Smale condition. To get the existence of harmonic maps, they consider the convergence of $\alpha$-harmonic maps when $\alpha$ decreases to 1. In general, there are bubbles (harmonic spheres) preventing the smooth convergence of $\alpha$-harmonic maps. Fortunately, a nonpositive curva-
ture condition on the target manifold can exclude such bubbles, and they can therefore obtain the existence of harmonic maps into such manifolds in any given homotopy class.

There is another harmonic map type problem which is not only more difficult and subtle, but also has a profound geometric significance. Motivated by the supersymmetric nonlinear sigma model from quantum field theory [6,10], Dirac-harmonic maps from spin Riemann surfaces into Riemannian manifolds were introduced in [4]. Mathematically, they are generalizations of the classical harmonic maps and harmonic spinors. From the variational point of view, they are critical points of a conformal invariant action functional whose Euler–Lagrange equations constitute a coupled elliptic system consisting of a second order equation and a Dirac equation.

In fact, the existence of Dirac-harmonic maps from closed surfaces is a tough problem. Different from the Dirichlet problem (see [12] and the references given there), even if there is no bubble, the limit may still be trivial, in the sense that the spinor part $\psi$ vanishes identically. So far, there are only a few results about the Dirac-harmonic maps from closed surfaces, see [2] and [5] for some existence results of uncoupled Dirac-harmonic maps (here uncoupled means that the map part is harmonic) based on index theory and the Riemann-Roch theorem, respectively. There are also some other interesting approaches, such as the heat flow method [13,23], the variational method [8] and the homology theory approach [9]. In [8] and [9], the authors discussed the existence of nonlinear Dirac-geodesics, which are the critical points of the following action functional:

$$L(\phi, \psi) = \frac{1}{2} \int_{S^1} |\dot{\phi}|^2 ds + \frac{1}{2} \int_{S^1} \langle \psi, D\psi \rangle_{\Sigma S^1 \otimes \phi^* TN} ds - \int_{S^1} F(\phi, \psi) ds,$$ (1.1)

where $s$ is the angular coordinate on $S^1$, $\dot{\phi}$ denotes the $s$-derivative of $\phi$, and $F$ is a nonlinear perturbation satisfying some growth and decay conditions with respect to $\psi$.

In this paper, we shall systematically study critical point theory according to Palais–Smale for $\alpha$-Dirac harmonic maps for $\alpha > 1$. Since the natural space on which the variational integral is defined is not a Hilbert space, but only a Banach space, we need to develop appropriate Banach space tools, like pseudo-gradient flow. Moreover, since our functionals are not bounded from below, we have to look for critical points other than minima, and therefore, we shall need to carefully investigate the Palais–Smale condition. Unfortunately, it follows from [13] that the following action functional does not satisfy the Palais–Smale condition:

$$L^\alpha(\phi, \psi) = \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, D\psi \rangle_{\Sigma M \otimes \phi^* TN}.$$ (1.2)

This is the functional we are interested in, and its critical points are called $\alpha$-Dirac-harmonic maps. Since variational schemes produce only weak solutions, it is also necessary to deal with the issue of their regularity.

In more precise terms, we consider a vector bundle $\Sigma M \otimes TN \to N$ and a function $F : \Sigma M \otimes TN \to \mathbb{R}$. A general element of $\Sigma M \otimes TN$ is written as $(\phi, \psi)$, where $\phi \in N$ and $\psi \in \Sigma M \otimes \phi^* TN$, and we write $F = F(\phi, \psi)$. We shall first prove the Palais–Smale condition for the action functional $L^\alpha$ of perturbed $\alpha$-Dirac-harmonic maps from closed Riemann surfaces:

$$L^\alpha(\phi, \psi) = \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, D\psi \rangle_{\Sigma M \otimes \phi^* TN} - \int_M F(\phi, \psi).$$ (1.3)

The difficulty is to prove the convergence of the map parts, which will be solved by combining the ideas in [22] and [8]. Next, we obtain a special negative pseudo-gradient flow to deform the
configuration space. The existence of a pseudo-gradient vector field is well-known. However, it is generally inexplicit. Our pseudo-gradient flow is special because the spinor part of the pseudo-gradient vector field is explicit. With such a special pseudo-gradient flow and the Palais–Smale condition in hand, by the deformation lemma, we can prove the existence of perturbed $\alpha$-Dirac-harmonic maps. In fact, we get a critical value defined in an explicit way. Last, as for the nontrivialness, it suffices to show that the critical value is strictly bigger than the $\alpha$-energy minimizer defined in (6.1), where we use the linking geometry theory to give a lower bound of the critical value.

As usual in the calculus of variations, we shall need the following standard growth conditions (F1)-(F5) on the nonlinearity $F(\phi, \psi) \in C^{1,1}_{\text{loc}}(\Sigma M \otimes T N, \mathbb{R})$ and its partial derivatives
\[
F_{\phi}(\phi, \psi) = \frac{\partial F}{\partial \phi}(\phi, \psi) \in (T N)^* \cong T N, \quad F_{\psi}(\phi, \psi) = \frac{\partial F}{\partial \psi}(\phi, \psi) \in (\Sigma M \otimes T N)^* \cong \Sigma M \otimes T N \text{ in } d F = F_{\phi} d \phi + F_{\psi} d \psi.
\]

(F1) There exist $p \in (2, 4)$ and $C > 0$ such that
\[
|F_{\phi}(\phi, \psi)| \leq C(1 + |\psi|^{p-1})
\]
for any $(\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N)$.

(F2) There exist $\mu > 2$ and $R_1 > 0$ such that
\[
0 < \mu F(\phi, \psi) \leq \langle F_{\psi}(\phi, \psi), \psi \rangle
\]
for any $(\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N)$ with $|\psi| \geq R_1$.

(F3) There exist $q < 4$ and $C > 0$ such that
\[
F_{\phi}(\phi, \psi) \leq C(1 + |\psi|^q)
\]
for any $(\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N)$.

(F4) For any $(\phi, \psi) \in \mathcal{F}$, we have
\[
F(\phi, \psi) \geq 0.
\]

(F5) As $|\psi| \to 0$, we have
\[
F(\phi, \psi) = o(|\psi|^2) \text{ uniformly in } \phi \in N.
\]

**Theorem 1.1** Let $M$ be a closed surface and $N$ a compact manifold. Suppose $F$ satisfies (F1)-(F5) with $\frac{4\alpha}{3\alpha - 2} \leq \mu \leq p \leq \frac{3}{4}\mu + 1$ for $\alpha \in (1, 2]$. Let $R_1, R_2$ and $\rho$ be as in Lemmas 6.1 and 6.2. Then we have $m_\theta < c_0 < \infty$ and $c_0$ is a critical value of $L^\alpha$ in $\mathcal{F}$.

Here $\theta$ is a given homotopy class of maps, $m_\theta$ is the minimizing $\alpha$-energy in $\theta$, $c_0$ is defined as:
\[
c_0 = \inf_{\gamma \in \Gamma(Q_{\theta; R_1, R_2})} \sup_{\gamma(Q_{\theta; R_1, R_2})} L^\alpha(\gamma(Q_{\theta; R_1, R_2})),
\]
and $\Gamma(Q_{\theta; R_1, R_2})$ is defined in Definition 4.12, $Q_{\theta; R_1, R_2}$ is defined by (6.2). In particular, when $N$ has nonpositive curvature, our solution is nontrivial.

**Corollary 1.2** Let $M$ be a closed surface and $N$ a compact Riemannian manifold with nonpositive curvature. Suppose $F$ satisfies (F1)-(F5) with $\frac{4\alpha}{3\alpha - 2} \leq \mu \leq p \leq \frac{3}{4}\mu + 1$ for $\alpha \in (1, 2]$. Then for any homotopy class $\theta \in [M, N]$, there exists a non-trivial solution $(\phi, \psi) \in W^{1,2\alpha}(M, N) \times H^{1/2}(M, \Sigma M \otimes \phi^* T N)$ to the perturbed $\alpha$-Dirac-harmonic map Eq. (2.11) and (2.12) with $\phi \in \theta$. 

© Springer
Since \( \alpha > 1 \), \( \phi \) in the theorem above is continuous. It is natural to expect the smoothness of the weak solutions. Due to the perturbation \( F \), \( F_\psi \) will produce \( \| \psi \|_{L^4}^3 \) according to the proof in [3]. Therefore, the proof there cannot apply to our situation directly. To overcome it, we need to control the \( L_\infty \)-norm of \( \psi \) first. The same phenomenon happens in the proof of the \( \epsilon \)-regularity. The following regularity theorem shows that such a nontrivial solution is actually smooth.

**Theorem 1.3** Suppose \( F \in C^\infty \) satisfies (F1) and (F3) for some \( p \leq 2 + 2/\alpha \) and \( q \geq 0 \). Then any weakly perturbed \( \alpha \)-Dirac-harmonic map is smooth.

Now, by multiplying \( F(\phi, \psi) \) by constants \( \frac{1}{k} \), we get a sequence of functionals:

\[
L_k^\alpha(\phi, \psi) = \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, \mathcal{D}\psi \rangle_{\Sigma M \otimes \phi^*TN} - \frac{1}{k} \int_M F(\phi, \psi),
\]

where \( F \) satisfies the assumptions in Corollary 1.2 and Theorem 1.3. For example, one can just take \( F = |\psi|^{\alpha-2} \). Thus, we get a sequence of perturbed \( \alpha \)-Dirac-harmonic maps \( \{(\phi_k, \psi_k)\} \), which are the critical points of \( L_k^\alpha \). Furthermore, if such sequence converges smoothly, then the limit will be a critical point of the functional (1.2), which is a \( \alpha \)-Dirac-harmonic map. To do so, we need some uniform regularity estimates. Since the proof of Theorem 1.3 depends on the oscillation of \( \phi \), which may not be uniformly controlled for \( \phi_k \), we want to prove another estimate which is called the \( \epsilon \)-regularity estimate. This kind of estimate was introduced by Sacks and Uhlenbeck for the \( \alpha \)-harmonic maps in [19]. When coupled with the Dirac equation, this was handled [3] for Dirac-harmonic maps and in [12,12] for a sequence of \( \alpha \)-Dirac-harmonic maps \( (\alpha \to 1) \). We have to modify here the growth conditions (F1) and (F3) for the derivatives of \( F \); we need

\[
\begin{align*}
(F6) \quad & |F_\psi(\phi, \psi)| \leq C|\psi|^{r-1} \text{ for } 3 < r \leq 2 + 2/\alpha, \\
(F7) \quad & |F_\phi(\phi, \psi)| \leq C|\psi|^q \text{ for } q > 2.
\end{align*}
\]

**Theorem 1.4** Suppose \( F \) satisfies (F6) and (F7). There is \( \epsilon_0 > 0 \) and \( \alpha_0 > 0 \) such that if \( (\phi, \psi): (D, g_{\beta Y}) \to (N, g_{ij}) \) is a smooth perturbed \( \alpha \)-Dirac-harmonic map satisfying

\[
\int_M (|d\phi|^{2\alpha} + |\psi|^4) \leq \Lambda < +\infty \text{ and } \int_D |d\phi|^2 \leq \epsilon_0
\]

for \( 1 \leq \alpha < \alpha_0 \), then we have

\[
\|d\phi\|_{\tilde{D},1,p} + \|\psi\|_{\tilde{D},1,p} \leq C(D, N, \Lambda, p)(\|d\phi\|_{D,0,2} + \|\psi\|_{D,0,4}),
\]

and

\[
\|\psi\|_{L^\infty(\tilde{D})} \leq C(D, N, \Lambda)\|\psi\|_{D,0,4}
\]

for any \( \tilde{D} \subset D \) and \( p > 1 \), where \( C(D, N, \Lambda, p) \) denotes a constant depending on \( D, N, \Lambda \) and \( p \).

With this \( \epsilon \)-regularity, one can easily prove

**Theorem 1.5** For the \( \alpha_0 \) given in Theorem 1.4 and each \( \alpha \in (1, \alpha_0) \), let \( (\phi_k, \psi_k) \) be the smooth critical points of the functional \( L_k^\alpha \) in (1.5) with uniformly bounded energy:

\[
E_k^\alpha(\phi_k, \psi_k; M) := \int_M (|d\phi_k|^{2\alpha} + |\psi_k|^4) \leq \Lambda < +\infty.
\]
Suppose $F$ satisfies (F6) and (F7). Then there exist a subsequence, still denoted by $\{(\phi_k, \psi_k)\}$, and a smooth $\alpha$-Dirac-harmonic map $(\phi, \psi)$ such that
\[
(\phi_k, \psi_k) \to (\phi, \psi) \text{ in } C^\infty_{\text{loc}}(M)
\] (1.10)

Since the convergence in the theorem above is smooth on $M$, the proof of Theorem 1.1 implies that the action functional of the $\alpha$-Dirac-harmonic map $(\phi, \psi)$ is still strictly bigger than $m_\theta$. Then the convexity of the action functional tells us that $(\phi, \psi)$ is a coupled $\alpha$-Dirac-harmonic map. Thus, we obtain:

**Corollary 1.6** Let $M$ be a closed surface and $N$ a compact Riemannian manifold with non-positive curvature. For the $\alpha_0$ given in Theorem 1.4 and each $\alpha \in (1, \alpha_0)$, if the sequence of perturbed $\alpha$-Dirac-harmonic maps $\{(\phi_k, \psi_k)\}$ satisfies the uniform bounded energy condition (1.9), then there exists a coupled $\alpha$-Dirac-harmonic map from $M$ to $N$ with $\phi$ in the given homotopy class $\theta$.

**Remark 1.7** To get the existence of a Dirac-harmonic map, it is natural to consider the convergence of a sequence of $\alpha$-Dirac-harmonic maps as $\alpha$ decreases to 1. By the joint work of the first author with Lei Liu and Miaomiao Zhu in [12], under the uniform bounded energy condition, there exists a Dirac-harmonic map with the map part in the given homotopy class. However, in general, we cannot guarantee that the limit is nontrivial.

The rest of the paper is organized as follows: In Sect. 2, we derive the Euler–Lagrange equations and define the configuration space. In Sect. 3, we prove the Palais–Smale condition for the action functional of perturbed $\alpha$-Dirac-harmonic maps. In Sect. 4, we construct a special pseudo-gradient vector field and deform our configuration space by a negative pseudo-gradient flow generated by it. Besides, we also recall some facts in linking geometry. In Sect. 5, we prove the uniqueness of $\alpha$-harmonic maps into nonpositive curved manifolds. In Sect. 6, we give the proof of Theorem 1.1 and Theorem 1.2. In Sect. 7, we prove Theorem 1.3. In the last section, we prove Theorem 1.4 and Theorem 1.5.

# 2 Euler–Lagrange equations and configuration space

## 2.1 Euler–Lagrange equations

Let $(M, g)$ be a compact surface with a fixed spin structure. On the spinor bundle $\Sigma M$, we denote the Hermitian inner product by $\langle \cdot, \cdot \rangle_{\Sigma M}$. For any $X \in \Gamma(TM)$ and $\xi \in \Gamma(\Sigma M)$, the usual Dirac operator is defined as $\partial = e_\beta \cdot \nabla_\beta$, where $\beta = 1, 2$ (here and in the sequel, we use the Einstein summation convention). One can find more about spin geometry in [14].

Let $\nabla$ be the Levi-Civita connection on $(M, g)$. There is a connection (also denoted by $\nabla$) on $\Sigma M$ compatible with $\langle \cdot, \cdot \rangle_{\Sigma M}$. Choosing a local orthonormal basis $\{e_\beta\}_{\beta=1,2}$ on $M$, the usual Dirac operator is defined as $\partial := e_\beta \cdot \nabla_\beta$, where $\beta = 1, 2$ (and in the sequel, we use the Einstein summation convention). One can find more about spin geometry in [14].

Let $\phi$ be a smooth map from $M$ to a compact Riemannian manifold $(N, h)$ of dimension $n \geq 2$. Let $\phi^*TN$ be the pull-back bundle of $TN$ by $\phi$ and consider the twisted bundle $\Sigma M \otimes \phi^*TN$. On this bundle there is a metric $\langle \cdot, \cdot \rangle_{\Sigma M \otimes \phi^*TN}$ induced from the metric on $\Sigma M$ and $\phi^*TN$. Also, we have a connection $\nabla$ on this twisted bundle naturally induced from
those on $\Sigma M$ and $\phi^*TN$. In local coordinates $\{y^i\}_{i=1,...,n}$, the section $\psi$ of $\Sigma M \otimes \phi^*TN$ is written as

$$\psi = \psi_i \otimes \partial_{y^i}(\phi),$$

where each $\psi^i$ is a usual spinor on $M$. We also have following local expression of $\tilde{\nabla}$

$$\tilde{\nabla}_\psi = \nabla^i \psi^i \otimes \partial_{y^i}(\phi) + \Gamma^i_{jk}(\phi) \nabla_{e^a} \phi^j (e^a \cdot \psi^k) \otimes \partial_{y^i}(\phi),$$

where $\Gamma^i_{jk}$ are the Christoffel symbols of the Levi-Civita connection of $N$. The Dirac operator along the map $\phi$ is defined as

$$\bar{D}_\phi := e^a \cdot \tilde{\nabla}_{e^a} \psi = \partial \psi^i \otimes \partial_{y^i}(\phi) + \Gamma^i_{jk}(\phi) \nabla_{e^a} \phi^j (e^a \cdot \psi^k) \otimes \partial_{y^i}(\phi),$$

which is self-adjoint $[11]$. Sometimes, we use $\bar{D}_\phi$ to distinguish the Dirac operators defined on different maps. In $[4]$, the authors introduced the functional

$$L(\phi, \psi) := \int_M (|d\phi|^2 + \langle \psi, \bar{D}_\phi \psi \rangle_{\Sigma M \otimes \phi^*TN})$$

with Euler–Lagrange equations

$$\tau^m(\phi) - \frac{1}{2} R_{ij}^m(\psi^i, \nabla \psi^j)_{\Sigma M} = 0,$$

$$\bar{D}_\phi \psi^i = \nabla^i \psi + \Gamma^i_{jk}(\phi) \nabla_{e^a} \phi^j (e^a \cdot \psi^k) = 0,$$

where $\tau^m(\phi)$ is the $m$-th component of the tension field $[11]$ of the map $\phi$ with respect to the coordinate on $N$, $\nabla \psi^i \cdot \psi^j$ denotes the Clifford multiplication of the vector field $\nabla \psi^i$ with the spinor $\psi^j$, and $R_{ij}^m$ stands for the component of the Riemann curvature tensor of the target manifold $N$. By defining

$$\mathcal{R}(\phi, \psi) := \frac{1}{2} R_{ij}^m(\psi^i, \nabla \psi^j)_{\Sigma M} \partial_{y^m},$$

we can write (2.4) and (2.5) in the global form

$$\tau(\phi) = \mathcal{R}(\phi, \psi)$$

$$\bar{D}_\phi \psi = 0.$$

Solutions $(\phi, \psi)$ of (2.7) are called Dirac-harmonic maps from $M$ to $N$.

In this paper, we use the critical point theory to prove the existence problem of Dirac-harmonic maps from closed surfaces. For the one-dimensional case, Takeshi Isobe $[8]$ proves the existence of nontrivial nonlinear Dirac-geodesics on flat tori, which are critical point of

$$\mathcal{L}(\phi, \psi) = \frac{1}{2} \int_{S^1} |\dot{\phi}|^2 ds + \frac{1}{2} \int_{S^1} \langle \psi, \bar{D}_\phi \psi \rangle_{\Sigma S^1 \otimes \phi^*TN} ds - \int_{S^1} F(\phi, \psi) ds,$$

where $s$ is the angular coordinate on $S^1$, $\dot{\phi}$ denotes the $s$-derivative of $\phi$, and $F$ is a nonlinear interaction term satisfying some growth and decay conditions with respect to $\psi$. The Euler–Lagrange equations are:

$$\nabla_{\dot{\phi}} \dot{\phi} - \mathcal{R}(\phi, \psi) + F(\phi, \psi) = 0,$$

$$\bar{D}_\phi \psi - F(\phi, \psi) = 0.$$
In particular, Isobe proved that there exists a non-trivial solution \((\phi, \psi)\) to (2.9) with \(\phi\) in any given free homotopy class of loops on a flat torus. In [9], Isobe reconsidered this problem through homology theory. By constructing and computing a Morse-Floer type homology, he obtains several existence results for perturbed Dirac geodesics. Some of them do not need the curvature restriction on the target manifold.

To generalize Isobe’s result to closed surfaces, we need to overcome two obstacles. One is to prove the Palais–Smale condition in the two dimensional setting, the other is to construct a nice pseudo-gradient vector field. Since the energy functional \(E(\phi) = \int_M |d\phi|^2\) in general does not satisfy the Palais–Smale condition in two dimension, we consider the pull-back bundle \(\phi \in \phi\) where \(R\) space with the following inner product [1,7,9]:

\[
\langle \phi_1, \phi_2 \rangle = \int_M (1 + |d\phi|^2)\langle \phi_1, \phi_2 \rangle + \frac{1}{2} \int_M \langle \phi, D\phi \rangle \Sigma M \otimes \phi^*TN - \int_M F(\phi, \psi).
\]

(2.10)

Similar to the computations in [8], one can get the Euler–Lagrange equations for \(L^\alpha\):

\[
\tau^\alpha(\phi) := \tau((1 + |d\phi|^2)\alpha) = R(\phi, \psi) - F(\phi, \psi),
\]

(2.11)

\[
D\psi = F(\phi, \psi).
\]

(2.12)

### 2.2 Configuration space

We will define a configuration space for our functional \(L^\alpha\). In fact, we focus on \(W^{1,2\alpha}\)-maps (\(\alpha > 1\)) and \(H^{1/2}\)-spinors. By the Nash embedding theorem [16], we can embed \(N\) into Euclidean space \(R^L\) for some large \(L\). We define the \(W^{1,2\alpha}\)-maps on \(N\) as

\[
W^{1,2\alpha}(M, N) := \{ \phi \in W^{1,2\alpha}(M, \mathbb{R}^L) | \phi(x) \in N \text{ for a.e. } x \in M \},
\]

(2.13)

where \(\phi \in W^{1,2\alpha}(M, \mathbb{R}^L)\) means that both \(\phi\) and its weak derivative \(\nabla \phi\) are in \(L^{2\alpha}(M, \mathbb{R}^L)\). By the Sobolev embedding theorem, any \(\phi \in W^{1,2\alpha}(M, N)\) is continuous. Therefore, the pull-back bundle \(\phi^*TN\) is well-defined, and we can consider \(H^{1/2}\)-spinors along \(\phi \in W^{1,2\alpha}(M, N)\) defined as

\[
H^{1/2}(M, \Sigma M \otimes \phi^*TN) := \{ \psi \in H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) | \psi(x) \in \Sigma M \otimes T_{\phi(x)}N \text{ for a.e. } x \in M \},
\]

(2.14)

where \(\mathbb{R}^L = M \times \mathbb{R}^L\) is the trivial \(\mathbb{R}^L\)-bundle over \(M\) and we regard \(T_{\phi(x)}N\) as a subset of \(\mathbb{R}^L\) for each \(x \in M\) by the above embedding.

Consider the Banach space \(\mathcal{F}^{\alpha,1/2} := W^{1,2\alpha}(M, \mathbb{R}^L) \times H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L)\). Since \(\mathcal{F}^{\alpha,1/2}\) is a product space, the norm can be induced from the norms on the two subspaces. We view the map component as the horizontal part and the spinor component as the vertical part. The horizontal part is a Banach space with the usual norm. The vertical part is actually a Hilbert space with the following inner product [1,7,9]:

\[
(Y_1, Y_2)_{1/2, 2} = ((1 + |D|)Y_1, Y_2)_{2},
\]

(2.15)

where \((\cdot, \cdot)_2\) is the \(L^2\)-inner product on \(M\) and \(D := \partial \otimes 1\). With respect to this product structure, we can write

\[
dL^\alpha = dH L^\alpha + dV L^\alpha,
\]

(2.16)

where

\[
dH L^\alpha(\phi, \psi)(X) = (-\tau^\alpha(\phi) + R(\phi, \psi) - F(\phi, \psi), X)_{2}
\]

(2.17)
and
\[ d^V \mathcal{L}^\alpha(\phi, \psi)(Y) = (\nabla^V \mathcal{L}^\alpha(\phi, \psi), Y)_{1/2,2}, \tag{2.18} \]
\[ \nabla^V \mathcal{L}^\alpha(\phi, \psi) = (1 + |\mathbf{D}|)^{-1}(\mathbf{D}\psi - F_\psi(\phi, \psi)). \tag{2.19} \]

Now, we can define a configuration space \( \mathcal{F}^{\alpha,1/2}(M, N) \) as
\[ \mathcal{F}^{\alpha,1/2}(M, N) := \{(\phi, \psi)| \phi \in W^{1,2\alpha}(M, N), \psi \in H^{1/2}(M, \Sigma M \otimes \phi^*TN)\}, \tag{2.20} \]
which is a Banach submanifold of \( \mathcal{F}^{\alpha,1/2} \) with the tangent space at \((\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N)\) being
\[ T_{(\phi, \psi)}\mathcal{F}^{\alpha,1/2}(M, N) = W^{1,2\alpha}(M, \phi^*TN) \times H^{1/2}(M, \Sigma M \otimes \phi^*TN). \tag{2.21} \]
The space \( W^{1,2\alpha}(M, N) \) is a Banach manifold [22] whose tangent space at \( \phi \in W^{1,2\alpha}(M, N) \) is
\[ T_\phi W^{1,2\alpha}(M, N) = W^{1,2\alpha}(M, \phi^*TN) := \{X \in W^{1,2\alpha}(M, \mathbb{R}^L)| X(x) \in T_{\phi(x)}N \text{ for a.e. } x \in M\}. \tag{2.22} \]
So, to see (2.21), it suffices to show the vertical part, which is the same as in [8].

Let us go back to our Lagrangian \( \mathcal{L}^\alpha \). On \( \mathcal{F}^{\alpha,1/2}(M, N) \), since \( H^{1/2} \) can be continuously embedded into \( L^4 \) [21], \( \mathcal{L}^\alpha \) is well-defined if for example \( F(\phi, \psi) \) grows at most like \(|\psi|^4\) as \(|\psi| \to \infty\).

### 3 The Palais–Smale condition

In this section, we prove the Palais–Smale condition for \( \mathcal{L}^\alpha \) for a certain class of nonlinearities \( F \) satisfying (F1)-(F3). From now on, we denote \( \mathcal{F}^{\alpha,1/2}(M, N) \) by \( \mathcal{F} \) for short. Let us recall the Palais–Smale–Morse condition:

**Definition 3.1** A sequence \( \{(\phi_n, \psi_n)\} \subset \mathcal{F} \) is a Palais–Smale sequence if the following are satisfied:

1. \[ \sup_{n \geq 1} |\mathcal{L}^\alpha(\phi_n, \psi_n)| < \infty, \]
2. \[ ||d \mathcal{L}^\alpha(\phi_n, \psi_n)||_{T^*_{(\phi_n, \psi_n)}} \mathcal{F} \to 0. \]

We say \( \mathcal{L}^\alpha \) satisfies the Palais–Smale–Morse condition on \( \mathcal{F} \) if any Palais–Smale sequence has a convergent subsequence in \( \mathcal{F} \). By Sobolev embedding and conditions (F1) (F3), \( d \mathcal{L}^\alpha_{(\phi, \psi)} \) is a bounded linear map on \( \mathcal{F} \). Thus, Zorn’s proposition (see page 30 in [22]) implies \( \mathcal{L}^\alpha \) is \( C^1 \) on \( \mathcal{F} \). Therefore, if \( \mathcal{L}^\alpha \) satisfies the Palais–Smale–Morse condition on \( \mathcal{F} \), and so, any Palais–Smale–Morse sequence has a subsequence converging to a critical point.

The following is the main theorem in this section. The proof for the vertical part follows from [8]. For the horizontal part, the method in [8] is no longer valid, because \( d^H \mathcal{L}^\alpha \) cannot be written as a combination of a linear and a compact operator. Although the proof in [22] can not be applied to our case either, one estimate there inspired us. For completeness, we also give the proof for the spinor part.

**Theorem 3.2** If \( F \) satisfies conditions (F1), (F2), (F3) with \( \frac{4\alpha}{3\alpha-2} \leq \mu \leq \frac{3}{4}\mu + 1 \) for \( \alpha \in (1, 2) \), then \( \mathcal{L}^\alpha \) satisfies the Palais–Smale condition on \( \mathcal{F} \).
Proof We first prove that any Palais–Smale sequence is bounded.

Let \( \{(\phi_n, \psi_n)\} \subset \mathcal{F} \) be a Palais–Smale sequence. By the structure on \( \mathcal{F}^{a,1/2} \), we have

\[
|dL^a(\phi_n, \psi_n)(0, \psi_n)| = |d^V L^a(\phi_n, \psi_n)(\psi_n)| = |(\nabla^V L^a(\phi_n, \psi_n), \psi_n)_{1/2,2}| \\
= |(\mathbf{D}\psi_n - F_\psi(\phi_n, \psi_n), \psi_n)_{2}| \leq \|\psi_n\|_{1/2,2},
\]

(3.1)

where we have used \( \|d^V L^a(\phi_n, \psi_n)\| \to 0 \) as \( n \to \infty \). This implies

\[
2L^a(\phi_n, \psi_n) - dL^a(\phi_n, \psi_n)(0, \psi_n) \\
= \int_M (1 + |d\phi_n|^2)\alpha + \int_M \langle \psi_n, \mathbf{D}\psi_n \rangle - 2 \int_M F(\phi_n, \psi_n) - \int_M \langle \mathbf{D}\psi_n - F_\psi(\phi_n, \psi_n), \psi_n \rangle \\
= \int_M (1 + |d\phi_n|^2)\alpha - 2 \int_M F(\phi_n, \psi_n) + \int_M F(\phi_n, \psi_n), \psi_n \rangle \\
\leq C + \|\psi_n\|_{1/2,2}.
\]

(3.2)

For simplicity, we denote all positive constants that are independent of \( n \) by \( C \).

On the other hand, by (F2), there exists a constant \( C > 0 \) such that

\[
\langle F_\psi(\phi, \psi), \psi \rangle \geq \mu F(\phi, \psi) - C
\]

(3.3)

for any \( (\phi, \psi) \in \mathcal{F}^{a,1/2}(M, N) \). Plugging this into (3.2), we get

\[
\int_M (1 + |d\phi_n|^2)\alpha + (\mu - 2) \int_M F(\phi_n, \psi_n) \leq \|\psi_n\|_{1/2,2} + C.
\]

(3.4)

Integrating (F2), we know

\[
F(\phi, \psi) \geq C|\phi|^\mu - C
\]

(3.5)

for any \( (\phi, \psi) \in \mathcal{F}^{a,1/2}(M, N) \). Plugging this into (3.4) yields

\[
\|\phi_n\|_{1/2,2}^{2\alpha} + \|\psi\|_{\mu}^{\mu} \leq C(\|\psi_n\|_{1/2,2} + 1).
\]

(3.6)

Consider the spectral decomposition

\[
H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) = H^0_0 \oplus H^0_0 \oplus H^+_0
\]

(3.7)

with respect to the operator \( \mathbf{D}:=\delta \otimes 1 \), where \( H^0_0, H^0_0 \) and \( H^+_0 \) are the closures in \( H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) \) of the spaces spanned by the negative, the null and the positive eigenspinors of \( \mathbf{D} \), respectively. Denote by \( P^0_0 : H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) \to H^0_0, P^+_0 : H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) \to H^+_0 \) the corresponding spectral projections. By this decomposition, we write \( \phi_n = \psi_n^0 + \psi_n^0 + \psi_n^0 \), with \( \psi_n^0, \psi_n^0 \), and \( \psi_n^0 \) being \( P^0_0 \psi_n, P^0_0 \psi_n \) and \( P^+_0 \psi_n \), respectively. The square of the \( H^{1/2} \)-norm of \( \psi_n^0 \in H^0_0 \) is equivalent to (11)

\[
\int_M \langle \psi_n^0, \mathbf{D}\psi_n^0 \rangle + \|\psi_n^0\|^2 = \int_M \langle \psi_n^0, \mathbf{D}\psi_n^0 \rangle + \|\psi_n^0\|^2.
\]

(3.8)
Together with (2.2), this implies
\[
\|\psi_{n,0}^+\|^2_{1/2,2} \leq C \int_M \langle \psi_{n,0}^+, D\psi_n \rangle + C \|\psi_{n,0}^+\|^2_2
\]
\[
\leq C \int_M \langle \psi_{n,0}^+, D\psi_n \rangle + C \int_M |d\phi_n| \|\psi_{n,0}^+\|\|\psi_n\| + C \|\psi_n\|^2_2
\]
\[
\leq C \int_M \langle \psi_{n,0}^+, D\psi_n \rangle + C\|\phi_n\|_{L^{1,2}} \|\psi_n\|_{L^4(\mu)} \|\psi_{n,0}^+\|_{L^{4/\alpha}(\mu) - 2} + C \|\psi_n\|^2_2
\]
\[
\leq C \int_M \langle \psi_{n,0}^+, D\psi_n \rangle + C\|\phi_n\|_{L^{1,2}} \|\psi_n\|_{L^{1/2,2}} \|\psi_{n,0}^+\|_{L^{4/\alpha}(\mu) - 2} + C \|\psi_n\|^2_2,
\]
where we have used the Hölder inequality and the Sobolev embedding $H^{1/2} \subset L^4$ for surfaces [21].

Again, as in (3.1), we have
\[
d\mathcal{L}^\nu(\phi_n, \psi_n)(0, \psi_{n,0}^+) = |\int_M (D\psi_n - F_\psi(\phi_n, \psi_n), \psi_{n,0}^+)| \leq \|\psi_{n,0}^+\|_{1/2,2}. (3.10)
\]
This and (F1) give us
\[
|\int_M \langle \psi_{n,0}^+, D\psi_n \rangle| \leq \int_M |F_\psi(\phi_n, \psi_n)| \|\psi_{n,0}^+\| + \|\psi_{n,0}^+\|_{1/2,2}
\]
\[
\leq C \int_M (1 + \|\psi_n\|_{\mu}) \|\psi_{n,0}^+\| + \|\psi_n\|_{1/2,2}
\]
\[
\leq C\|\psi_n\|_{\mu}^{-1} \|\psi_{n,0}^+\|_{\mu/(\mu - p + 1)} + C \|\psi_n\|_{1/2,2}
\]
\[
\leq C\|\psi_n\|_{\mu}^{-1} \|\psi_n\|_{1/2,2} + C \|\psi_n\|_{1/2,2},
\]
where we have used the Hölder inequality and assumption $p \leq \frac{3}{\mu} + 1$.

Now, plugging (3.11) into (3.9), we have
\[
\|\psi_{n,0}^+\|^2_{1/2,2} \leq C(\|\psi_n\|_{\mu}^{p-1} \|\psi_n\|_{1/2,2} + \|\phi_n\|_{1,2} \|\psi_n\|_{1/2,2} \|\psi_{n,0}^+\|_{4\alpha/(3\alpha - 2)}
\]
\[
\quad + \|\psi_n\|^2_2 + \|\psi_n\|_{1/2,2}^2).
\]
Since $\alpha \in (1, 2]$, the Hölder inequality and (3.6) imply
\[
\|\psi_n\|_{2} \leq C(\|\psi_n\|_{4\alpha/(3\alpha - 2)} \|\psi_n\|_{1/2,2}) \leq C(\|\psi_n\|_{1/2,2} + 1)
\]
(3.13)
and
\[
\|\phi_n\|_{1,2\alpha} \leq C(\|\psi_n\|_{1/2,2}^{1/2\alpha} + 1).
\]
Plugging (3.13) and (3.14) into (3.12), we get
\[
\|\psi_{n,0}^+\|^2_{1/2,2} \leq C\|\psi_n\|_{1/2,2}^{(p-1)/\mu} \|\psi_n\|_{1/2,2} + C(\|\psi_n\|_{1/2,2}^{1/2\alpha} + 1) \|\psi_n\|_{1/2,2}(\|\psi_n\|_{1/2,2} + 1)
\]
\[
\quad + C\|\psi_n\|_{1/2,2}^{2/\mu} + C \|\psi_n\|_{1/2,2} + C.
\]
Similarly,
\[
\|\psi_{n,0}^-\|^2_{1/2,2} \leq C\|\psi_n\|_{1/2,2}^{(p-1)/\mu} \|\psi_n\|_{1/2,2} + C(\|\psi_n\|_{1/2,2}^{1/2\alpha} + 1) \|\psi_n\|_{1/2,2}(\|\psi_n\|_{1/2,2} + 1)
\]
\[
\quad + C\|\psi_n\|_{1/2,2}^{2/\mu} + C \|\psi_n\|_{1/2,2} + C.
\]
Since the usual Dirac operator has finite dimensional kernel, \( \dim(H^0) < \infty \). Noting that the \( H^{1/2} \)-norm and the \( L^2 \)-norm are equivalent on \( H^0 \) ([1]), we have
\[
\|\psi_{n,0}\|_{1/2,2}^2 \leq C\|\psi_{n,0}\|_2^2 \leq C\|\psi_n\|_{1/2,2}^2 \leq C(\|\psi_n\|_{1/2,2}^2 + 1).
\]
Combining (3.15), (3.16) and (3.17), we obtain
\[
\|\psi_n\|_{1/2,2}^2 \leq C\|\psi_n\|_{1/2,2}^{(p-1)/\mu}\|\psi_n\|_{1/2,2} + C(\|\psi_n\|_{1/2,2}^2 + 1)\|\psi_n\|_{1/2,2}(\|\psi_n\|_{1/2,2}^2 + 1)
\]
\[
+ C\|\psi_n\|_{1/2,2}^2 + C\|\psi_n\|_{1/2,2}^2 + C.
\]
Since \( \frac{4\alpha}{3\alpha - 2} \leq \mu \leq p \leq \frac{3}{4} \mu + 1 < \mu + 1 \) and \( \alpha \in (1, 2) \), (3.18) tells us that \( \{\psi_n\} \) is uniformly bounded in \( H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) \). Therefore, from (3.14), \( \{\phi_n\} \) is also bounded. Thus, \( \{\phi_n, \psi_n\} \) is a bounded sequence.

Next, we show \( \{\psi_n\} \) has a convergent subsequence. As in [8], we write the vertical gradient of \( L^\alpha \) as
\[
\nabla^V L^\alpha(\phi, \psi) = L^V \psi + K_1^V(\phi, \psi) + K_2^V(\phi, \psi).
\]
where
\[
L^V = (1 + |D|)^{-1} D : H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L) \rightarrow H^{1/2}(M, \Sigma M \otimes \mathbb{R}^L)
\]
is bounded linear and
\[
K_1^V(\phi, \psi) = (1 + |D|)^{-1}(\Gamma^i_{jk}(\phi)\nabla e_\alpha \phi^j e_\alpha \cdot \psi^k) \otimes \partial_{y^i}(\phi),
\]
\[
K_2^V(\phi, \psi) = -(1 + |D|)^{-1} F_\psi(\phi, \psi).
\]
Because both \( |\nabla \psi| \) and \( F_\psi(\phi, \psi) \) belong in \( L^r \) with \( r > 4/3 \), both \( K_1^V \) and \( K_2^V \) are compact. We write \( \psi_n = \psi_{n,0} + \psi_0 + \psi_{n,0}^\pm \). Since \( L^V \) is invertible on \( H^0 \) and \( \nabla^V L^\alpha(\phi_n, \psi_n) \rightarrow 0 \), we have
\[
\psi_{n,0} = \alpha(1) - (L^V)^{-1} K(\phi_n, \psi_{n,0}^\pm),
\]
where \( o(1) \rightarrow 0 \) as \( n \rightarrow \infty \). From the boundedness of \( \{\phi_n, \psi_n\} \) and the compactness of \( (L^V)^{-1} K \) on \( H^\pm \), we know \( \psi_{n,0}^\pm \) has a convergent subsequence. Again, since \( \dim H^0 < \infty \), \( \psi_{n,0}^\pm \) also has a convergent subsequence. Thus, \( \{\psi_n\} \) has a convergent subsequence.

Last, for the convergence of \( \{\phi_n\} \), we consider the \( \alpha \)-energy functional
\[
E^\alpha(\phi) := \int_M e^\alpha(d\phi) := \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha.
\]
for any \( \phi \in W^{1,2\alpha}(M, \mathbb{R}^L) \). Then the second derivative of \( e^\alpha \) at \( d\phi \) with respect to the direction \( d\psi \) is
\[
d^2 e^\alpha_{d\phi}(d\varphi, d\psi) = \frac{1}{2} \frac{d^2}{dt^2} \bigg|_{t=0} (1 + (d\phi + td\psi, d\phi + td\psi)) = 2\alpha(\alpha - 1)(1 + |d\phi|^2)^{\alpha-2}(d\phi, d\psi)^2 + \alpha(1 + |d\phi|^2)^{\alpha-1}|d\psi|^2
\]
\[
\geq \alpha|d\phi|^{2\alpha-2}|d\psi|^2.
\]
(3.25)
For any \( \phi_i, \phi_j \in W^{1,2\alpha}(M, \mathbb{R}^L) \), we define
\[
c(t) := b + t(a - b),
\]
(3.26)
where \( a := d\phi_i \) and \( b := d\phi_j \). Then (3.25) implies
\[
d^2 e^\alpha_{c(t)}(a - b, a - b) \geq \alpha |c(t)|^{2\alpha - 2} |a - b|^2.
\] (3.27)

We also have
\[
dE^\alpha_\phi(\varphi) := \frac{d}{dt} \bigg|_{t=0} \int_M e^\alpha(d\phi + t d\varphi) = \int_M d^2 e^\alpha_{d\phi}(d\varphi)
\] (3.28)
and
\[
\int_0^1 d^2 e^\alpha_{c(t)}(a - b, a - b) = de^\alpha_a(a - b) - de^\alpha_b(a - b).
\] (3.29)

Now, we can control \( \|d\phi_i - d\phi_j\|_{2\alpha} \) as follows.
\[
(dE^\alpha_{\phi_i} - dE^\alpha_{\phi_j})(\phi_i - \phi_j) = \int_M (de^\alpha_{d\phi_i} - de^\alpha_{d\phi_j})(d\phi_i - d\phi_j)
\]
\[
\geq \int_M \int_0^1 d^2 e^\alpha_{c(t)}(d\phi_i - d\phi_j, d\phi_i - d\phi_j)
\]
\[
\geq C\|d\phi_i - d\phi_j\|_{2\alpha}^{2\alpha},
\] (3.30)
where the last inequality comes from the Sublemma 3.18 in [22] stated as follows: \( \square \)

**Lemma 3.3** Let \( V \) be a finite dimensional real vector space with a norm \( \| \cdot \| \). Let \( m \) be a positive integer. Then there exists a positive constant \( C \) such that
\[
\int_0^1 |x + ty|^m dt \geq C|y|^m
\] (3.31)
for any \( x, y \in V \).

To estimate the left-hand side of (3.30), we decompose \( d^H L^\alpha \) as
\[
d^H L^\alpha(\phi, \psi) = J^{\phi} + K_1^H(\phi, \psi) + K_2^H(\phi, \psi) + K_3^H(\phi, \psi),
\] (3.32)
where
\[
K_1^H(\phi, \psi) = -\Gamma^m_{ij\beta} \phi^i \phi^j g^{\beta\gamma}(1 + |d\phi|^2)^{\alpha - 1} \frac{\partial}{\partial y^m},
\] (3.33)
\[
K_2^H(\phi, \psi) = -\alpha \frac{1}{2\alpha} R^m_{jkl}(\psi^k, \nabla \phi^j \cdot \psi^l) \frac{\partial}{\partial y^m},
\] (3.34)
\[
K_3^H(\phi, \psi) = -\frac{1}{\alpha} F_\phi(\phi, \psi)
\] (3.35)
and \( J : W^{1,2\alpha}(M, \mathbb{R}^L) \rightarrow (W^{1,2\alpha}(M, \mathbb{R}^L))^* = W^{-1,2\alpha/(2\alpha - 1)}(M, \mathbb{R}^L)\)
\[
J\phi = -\text{div}(1 + |d\phi|^2)^{\alpha - 1} \nabla \phi.
\] (3.36)

By Sobolev embedding, \( K^H = K_1^H + K_2^H + K_3^H : \mathcal{F} \rightarrow (W^{1,2\alpha}(M, \mathbb{R}^L))^* \) is compact.

Again, we can write
\[
J = o(1) - K^H.
\] (3.37)
The boundedness of \(\{\phi_n, \psi_n\}\) and the compactness of \(K^H\) imply that \(J(\phi_n)\) has a convergent subsequence. In particular, for any \(\varepsilon\), there exists an integer \(N_\varepsilon\) such that
\[
|J(\phi_i) - J(\phi_j)|(\phi_i - \phi_j)| \leq \varepsilon\|\phi_i - \phi_j\|_{1,2a}
\]
for \(i, j > N_\varepsilon\). Together with (3.30) and
\[
(dE_{\phi_i}^\alpha - dE_{\phi_j}^\alpha)(\phi_i - \phi_j) = (J(\phi_i) - J(\phi_j))(\phi_i - \phi_j),
\]
we get
\[
\|d\phi_i - d\phi_j\|_{2a} \leq (C\varepsilon\|\phi_i - \phi_j\|_{1,2a})^{\frac{1}{2a}} \leq (C\varepsilon)^{\frac{1}{2a}},
\]
where we have used the boundedness of \(\{\phi_n\}\). Therefore, \(\{d\phi_n\}\) contains a Cauchy subsequence in \(L^{2a}\). Hence, by Sobolev embedding, \(\{\phi_n\}\) has a convergent subsequence. \(\Box\)

4 Negative pseudo-gradient flow and linking geometry

This section consists of two parts. In the first part, we will construct a special pseudo-gradient vector field to deform the configuration space. In the second part, we will recall some important results in linking geometry, which will be used to prove the nontrivialness of the perturbed \(\alpha\)-Dirac-harmonic maps in Sect. 6.

4.1 Negative pseudo-gradient flow

In this section, we want to find a pseudo-gradient vector field with the vertical part being parallel to the vertical gradient \(\nabla^V L^\alpha\). Before doing that, let us recall the definition of a pseudo-gradient vector.

**Definition 4.1** [17] Let \(M\) be a \(C^{r+1}(r \geq 1)\) Finsler manifold and \(f : M \to \mathbb{R}\) be a \(C^1\) function. A vector \(X \in T_pM\) is called a pseudo-gradient vector for \(f\) at \(p\) if \(X\) satisfies

(i) \(\|X\| \leq 2\|df_p\|\),
(ii) \(df_p(X) \geq \|df\|^2\).

A vector field is called a pseudo-gradient vector field for \(f\) if at each point of its domain it is a pseudo-gradient vector for \(f\). It is well-known that

**Lemma 4.2** [17] There exists a locally Lipschitz pseudo-gradient vector field for \(f\) on \(M^* := M - K\), where \(K := \{p \in M | df_p = 0\}\).

On \(F^{\alpha,1/2}(M, N)\), we denote the set of regular points of \(L^\alpha\) by
\[
\tilde{F} := \{\phi, \psi \in F^{\alpha,1/2}(M, N) | dL^\alpha_{(\phi, \psi)} \neq 0\}.
\]

The main result in this section is

**Theorem 4.3** Suppose \(F \in C^{1,1}_{loc}\) in the fiber direction. Then there exists a locally Lipschitz pseudo-gradient vector field \(\omega\) for \(L^\alpha\) on \(\tilde{F}\) of the form of \(\omega = X \oplus a\nabla^V L^\alpha\) for some vector field \(X\) and a constant \(a \in (1, 2)\).
Proof We divide \( \tilde{F} \) into two subsets

\[
A = \{ (\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N) | d^{H}L^{\alpha} = 0, \ d^{V}L^{\alpha} \neq 0 \}, \\
B = \{ (\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N) | d^{H}L^{\alpha} \neq 0 \}.
\]  

(4.2)

For any \( a \in (1, 2) \), \( a \nabla^{V}L^{\alpha} \) always satisfies (i) and (ii) in Definition 4.1 for \( d^{V}L^{\alpha} \). Our assumption implies that \( a \nabla^{V}L^{\alpha} \) is locally Lipschitz. Therefore, it suffices to show that there is a locally Lipschitz vector field that satisfies (i) and (ii) in Definition 4.1 for \( d^{H}L^{\alpha} \).

Over \( B \), since \( d^{H}L \neq 0 \), we have a vector \( \tilde{X}_{\phi} \) for each \( (\phi, \psi) \in B \) such that \( \| \tilde{X}_{\phi} \| = 1 \) and \( d^{H}L_{(\phi, \psi)}(\tilde{X}_{\phi}) > \frac{3}{2} d^{H}L(\phi, \psi) \). Then, set \( X_{\phi} = \frac{3}{2} d^{H}L_{(\phi, \psi)} \tilde{X}_{\phi} \). So \( X_{\phi} \) satisfies Definition 4.1 for \( d^{H}L^{\alpha} \) with strict inequalities in (i) and (ii). Then extend \( X_{\phi} \) to be a \( C^{1} \) vector field in a neighborhood of \((\phi, \psi)\) (say by making it “constant” with respect to a chart at \((\phi, \psi)\) [17]. Therefore, for each point \((\phi, \psi) \in B \), there is a \( C^{1} \) pseudo-gradient vector field \( \omega = X \oplus a \nabla^{V}L^{\alpha} \) for \( L^{\alpha} \) defined in some neighborhood of \((\phi, \psi)\).

For \( A \), we just use the \( C^{1} \) vector field \( \omega = 0 \oplus a \nabla^{V}L^{\alpha} \). Then, for any point in \( \tilde{F} \), we have

\[
\| \omega \| = a \| \nabla^{V}L^{\alpha} \| < 2 \| \nabla^{V}L^{\alpha} \| \leq 2 \| d^{V}L^{\alpha} \|
\]  

(4.3)

and

\[
d^{L_{\alpha}}(\phi, \psi)(\omega) = a \| \nabla^{V}L^{\alpha}(\phi, \psi) \|^{2}.
\]  

(4.4)

So, \( \omega \) satisfies (i) in Definition 4.1. To check (ii), we take any point \((\phi, \psi) \in A \). Then

\[
\| d^{L_{\alpha}}(\phi, \psi) \|^{2} = \| \nabla^{V}L^{\alpha}(\phi, \psi) \|^{2} < a \| \nabla^{V}L^{\alpha}(\phi, \psi) \|^{2}.
\]  

(4.5)

Together with \( L^{\alpha} \in C^{1} \), this implies that

\[
d^{L_{\alpha}}(\phi, \psi')(\omega) = a \| \nabla^{V}L^{\alpha}(\phi', \psi') \|^{2} \geq \| d^{L_{\alpha}}(\phi', \psi') \|^{2}
\]  

(4.6)

holds in some neighborhood \( U \) of \((\phi, \psi)\). So, \( \omega \) also satisfies (ii) in Definition 4.1. Thus, for each point \((\phi, \psi) \in A \), there is a neighborhood \( U \) of \((\phi, \psi)\) such that \( \omega = 0 \oplus a \nabla^{V}L^{\alpha} \) is a pseudo-gradient vector field for \( L^{\alpha} \) in \( U \). Finally, to get the pseudo-gradient vector field in the theorem, we can patch these local pseudo-gradient vector fields together by a partition of unity [17,18]. Thus, we complete the proof.

\( \square \)

Theorem 4.3 gives us a nice pseudo-gradient vector field, but it is only locally Lipschitz. Therefore, its integral curve may not exist globally. To remedy this, it suffices to integrate a truncated pseudo-gradient vector field. The argument can be found in [18]. Different from our case, Isobe [8] used it directly on the gradient of the action functional. Now, we deform our configuration space by integrating the following ODE:

\[
\frac{d}{dt}(\phi_{t}, \psi_{t}) = -\eta(\phi_{t}, \psi_{t}) \omega(\phi_{t}, \psi_{t}),
\]

\( \eta(\phi_{t}, \psi_{t})|_{t=0} = (\phi, \psi) \).

(4.7)  

(4.8)

The function \( \eta \) is chosen such that (4.7) and (4.8) have a global unique solution. In particular, \( \eta \) satisfies \( \eta(\phi, \psi)\| \omega(\phi, \psi) \| \leq 1 \) for all \((\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N) \). See Appendix A in [18].

Note that the solution \( \psi_{t} \) to (4.7) belongs to \( H^{1/2}(M, \Sigma M \otimes \phi_{t}^{*}TN) \) for each \( t \geq 0 \) and the space depends on \( t \). So we translate it into a flow on a function space which does not depend on \( t \). To do so, we consider the parallel transport. For each \( x \in M \), we denote
by \( P_t(x) : T_{\phi(x)}N \to T_{\phi_t(x)}N \) the parallel transport along the curve \( t \mapsto \phi_t(x) \). We put \( \tilde{\psi}_t(x) := (1 \otimes P_t(x)^{-1}) \psi_t(x) \), that is, for \( \psi_t(x) = \psi_t(x) \otimes \frac{\partial}{\partial y^i}(\phi_t(x)) \), we define
\[
\tilde{\psi}_t(x) := \psi_t(x) \otimes P_t(x)^{-1} \left( \frac{\partial}{\partial y^i}(\phi_t(x)) \right) \in \Sigma M \otimes \phi^*TN.
\]
(4.9)

Thus, the vertical part of (4.7) is transformed to
\[
\frac{d}{dt} \tilde{\psi}_t = -a \eta_t(\tilde{\psi}_t) P_t^{-1} \nabla V^\alpha(\phi_t, P_t \tilde{\psi}_t),
\]
(4.10)

where \( \eta_t(\tilde{\psi}_t) = \eta(\phi_t, \psi_t) \) and \( a \) is the constant in Theorem 4.3.

Since the proofs of Lemma 7.2-Lemma 7.6 in [8] only rely on the Sobolev embedding and the vertical part of the gradient vector field, which is kept up to a constant in our case, these nice properties (Lemma 7.2-Lemma 7.6 in [8]) generalize to our configuration space \( \mathcal{F}^{\alpha,1/2}(M, N) \). Due to their usefulness, we list them here and refer to [8] for the proofs.

**Lemma 4.4** Let \( (\phi_t, \psi_t) \) and \( P_t \) be as above. \( P_t \) defines a bounded linear map \( P_t : H^{1/2}(M, \Sigma M \otimes \phi^*TN) \to H^{1/2}(M, \Sigma M \otimes \phi^*TN) \) which depends continuously on \( t \) with respect to the operator norm.

**Lemma 4.5** Let \( \phi, \tilde{\phi} \in W^{1,2\alpha}(M, N) \) be such that \( \| \phi - \tilde{\phi} \|_\infty < \epsilon(N) \). We define \( T_{\phi, \tilde{\phi}} : \Sigma M \otimes T_{\phi(x)}N \to \Sigma M \otimes T_{\tilde{\phi}(x)}N \) by \( T_{\phi, \tilde{\phi}}(x) = 1 \otimes P_{\phi(x), \tilde{\phi}(x)} \), where \( P_{\phi(x), \tilde{\phi}(x)} : T_{\phi(x)}N \to T_{\tilde{\phi}(x)}N \) is the parallel transport along the unique length minimizing geodesic between \( \phi(x) \) and \( \tilde{\phi}(x) \). Then the map \( T_{\phi, \tilde{\phi}} \) defined by \( (T_{\phi, \tilde{\phi}} \psi)(x) = T_{\phi, \tilde{\phi}}(\psi)(x) \) for a.e. \( x \in M \) is a bounded linear map \( T_{\phi, \tilde{\phi}} : H^{1/2}(M, \Sigma M \otimes \phi^*TN) \to H^{1/2}(M, \Sigma M \otimes \tilde{\phi}^*TN) \). Moreover, its operator norm satisfies
\[
\| T_{\phi, \tilde{\phi}} \|_{H^{1/2} \to H^{1/2}} \leq C(\| \phi \|_{1,2\alpha}, \| \tilde{\phi} \|_{1,2\alpha})
\]
(4.11)

for some constant \( C(\| \phi \|_{1,2\alpha}, \| \tilde{\phi} \|_{1,2\alpha}) \) depending only on \( \| \phi \|_{1,2\alpha} \) and \( \| \tilde{\phi} \|_{1,2\alpha} \).

Consider \( T_{\phi, \tilde{\phi}} \) as \( T_{\phi, \tilde{\phi}} : H^{1/2}(M, \Sigma M \otimes \phi^*TN) \to H^{1/2}(M, \Sigma M \otimes \tilde{\phi}^*TN) \). For any \( \psi \in H^{1/2}(M, \Sigma M \otimes \phi^*TN) \subset H^{1/2}(M, \Sigma M \otimes \tilde{\phi}^*TN) \) we have
\[
\| T_{\phi, \tilde{\phi}} \psi - \psi \|_{1/2,2} \leq C(\| \phi \|_{1,2\alpha}, \| \tilde{\phi} \|_{1,2\alpha}, \| \phi - \tilde{\phi} \|_{1,2\alpha}) \| \psi \|_{1/2,2}
\]
(4.12)

for some constant \( C(\| \phi \|_{1,2\alpha}, \| \tilde{\phi} \|_{1,2\alpha}) \) depending only on \( \| \phi \|_{1,2\alpha} \) and \( \| \tilde{\phi} \|_{1,2\alpha} \).

**Lemma 4.6** Let \( \phi, \tilde{\phi} \in W^{1,2\alpha}(M, N) \). We denote by \( P^+(\phi) : F_\phi \to F_\phi^+ \) the spectral projection onto the positive eigenspace of \( \tilde{D}_\phi \). For \( \psi \in F_\phi := H^{1/2}(M, \Sigma M \otimes \phi^*TN) \), we have
\[
\| P^+(\tilde{\phi}) \circ T_{\phi, \tilde{\phi}} \circ P^+(\phi) \psi - P^+(\phi) \psi \|_{1/2,2} \leq C(\| \phi \|_{1,2\alpha}, \| \tilde{\phi} \|_{1,2\alpha}, \| \phi - \tilde{\phi} \|_{1,2\alpha}) \| \psi \|_{1/2,2},
\]
(4.13)

where the \( H^{1/2} \)-norm on the left side is taken in \( H^{1/2}(M, \Sigma M \otimes \tilde{\phi}^*TN) \), \( T_{\phi, \tilde{\phi}} \) is defined as in Lemma 4.5 and \( C(\| \phi \|_{1,2}, \| \tilde{\phi} \|_{1,2\alpha}) \) depending only on \( \| \phi \|_{1,2\alpha} \) and \( \| \tilde{\phi} \|_{1,2\alpha} \).

**Lemma 4.7** Let \( \phi : [0, 1] \ni t \mapsto \phi_t \in W^{1,2\alpha}(M, N) \) be piecewise \( C^1 \) and \( P_t(x) : T_{\phi(x)}N \to T_{\phi_t(x)}N \) the parallel transport along the curve \( [0, 1] \ni s \mapsto \phi_s(x) \in N \). Set \( \tilde{D}_t := P_t^{-1} \circ \tilde{D}_\phi \circ P_t \). Then \( K_t := (1 + \tilde{D}_t^2)^{-1/2} \tilde{D}_t - (1 + \tilde{D}_t^2)^{-1/2} \tilde{D}_\phi : H^{1/2}(M, \Sigma M \otimes \phi^*_tTN) \to H^{1/2}(M, \Sigma M \otimes \phi^*_tTN) \) defines a continuous family of compact operators with respect to the operator norm.
Note that the decomposition of $\nabla^V L^\omega$ is not unique. For our purposes, we need to use a decomposition that is different from those presented in (3.19). Let $T > 0$ be arbitrary. For $t \in [0, T]$, we write

$$
\nabla^V L^\omega(\phi_t, \psi_t) = P_{t \to T}^{-1} \circ (1 + \partial_{\phi_t}^2)^{-1/2} \circ D_{\phi_t} \circ P_{t \to T} \psi_t + K(T, t; \phi_t, \psi_t),
$$

where $D_{\phi_t}$ denotes the Dirac operator along the map $\phi_t$, $P_{t \to T}^{-1} = 1 \otimes P_{t \to T}^{-1}$ and $P_{t \to T}^{-1}(x) : T_{\phi_t(x)} N \to T_{\phi_t(x)} N$ is the parallel transport along the curve $[t, T] \ni s \mapsto \phi_t(x) \in N$. Then (4.10) can be written as

$$
\frac{d}{dt} \tilde{\psi}_t = -\eta_t(\tilde{\psi}_t)(L_{T, V} \tilde{\psi}_t + \tilde{K}(T, t; \tilde{\psi}_t)),
$$

where $L_{T, V} := P_{t \to T}^{-1} \circ (1 + \partial_{\phi_t}^2)^{-1/2} D_{\phi_t} \circ P_{t \to T}$ and $\tilde{K}(T, t; \tilde{\psi}_t) = P_{t \to T}^{-1} K(T, t; \phi_t, \psi_t)$. As in Lemma 4.7, $P_{t \to T} L_{T, V} - L_{V} P_{t \to T} : H^{1/2}(M, \Sigma M \otimes \phi^* T N) \to H^{1/2}(M, \Sigma M \otimes \mathbb{R} L)$ is compact and continuously depends on $t$ and $T$. So, $\tilde{K}$ is also compact.

Regarding $\phi_t$ and $\tilde{\psi}_t$ in $\eta_t(\tilde{\psi}_t)$ and $\tilde{K}(T, t; \tilde{\psi}_t)$ as already known functions, integration of of (4.15) yields

$$
\tilde{\psi}_t = \exp \left( - \int_0^t \eta_s(\tilde{\psi}_s) ds L_{T, V} \right) \psi + \tilde{K}(T, t; \psi),
$$

where

$$
\tilde{K}(T, t; \psi) = -\int_0^t \exp \left( \int_0^\tau \eta_s(\tilde{\psi}_s) ds L_{T, V} \right) \eta_s(\tilde{\psi}_s) \tilde{K}(T, \tau; \tilde{\psi}_\tau) d\tau
$$

is a compact map from $[0, 1] \times [0, 1] \times H^{1/2}(M, \Sigma M \otimes \phi^* T N)$ to $H^{1/2}(M, \Sigma M \otimes \phi^* T N)$ (see Lemma 7.3 in [8]).

Since $t \in [0, T]$ is arbitrary, we take $T = t$ and obtain

$$
\tilde{\psi}_t = \exp \left( - \int_0^t \eta_s(\tilde{\psi}_s) ds L_{t, V} \right) \psi + K(t, \psi),
$$

where $K(t, \psi) := \tilde{K}(t, t; \psi) : [0, 1] \times H^{1/2}(M, \Sigma M \otimes \phi^* T N) \to H^{1/2}(M, \Sigma M \otimes \phi^* T N)$ is a compact map.

**Remark 4.8** The advantage of the form of $\tilde{\psi}_t$ in (4.18) is that the bounded linear operator $\exp \left( - \int_0^t \eta_s(\tilde{\psi}_s) ds L_{t, V} \right)$ commutes with the spectral projection of the operator $P_t^{-1} D_{\phi_t} P_t$.

This fact will be used in the section below.

### 4.2 Linking geometry

Before introducing specific definitions and lemmas in linking geometry, let us first explain how we use this theory. As we said in the introduction, since our configuration space is no longer a Hilbert manifold, we have to use the pseudo-gradient flow, which we view as a deformation of the configuration space. Therefore, it is natural to associate with the classical deformation lemma. To use it, it is necessary to define a suitable deformation class according to the special pseudo-gradient flow constructed in the previous subsection. And since our functionals are not bounded from below, we need to look for critical points, which are saddle
points other than minima. Actually, we will use the deformation lemma to prove the following
\[
\c_\theta = \inf_{y \in \Gamma(Q_{\theta}; R_1, R_2)} \sup \mathcal{L}^d(y(Q_{\theta}; R_1, R_2))
\]  
(4.19)
is a critical value, where \( \Gamma(Q_{\theta}; R_1, R_2) \) is the suitable deformation class defined in Definition 4.12, \( Q_{\theta}; R_1, R_2 \) is a subset of the configuration space. To get a nontrivial critical point, we want to show that \( \c_\theta \) is strictly bigger than the \( \alpha \)-energy minimizer \( m_\theta \) defined in (6.1), where we need the linking geometry. Roughly speaking, in the linking geometry, we say two subsets link if the deforming subsets always intersect a fixed subset provided the boundaries of the deforming subsets never intersect that fixed subset. In the following, we will see \( \Gamma(Q_{\theta}; R_1, R_2) \) and \( S_{\theta; \rho} \) link with respect to \( C \). Then, the critical value is bigger or equal to the infimum \( b_{\theta; \rho} \) defined in (6.5). Therefore, the nontrivialness of the critical point is equivalent to \( b_{\theta; \rho} > m_\theta \), which will be proved in Lemma 6.2.

Now, let us see a linking argument within our framework. Since the proofs only rely on those properties generalized in the section above, we again refer to [8] for details. First, let us define a general deformation class.

**Definition 4.9** We define
\[
C := \{ \Theta \in C^0([0, 1] \times \mathcal{F}, \mathcal{F}) : \Theta \text{satisfies the following (1), (2), (3)} \}
\]
(1) \( \Theta(0, (\phi, \psi)) = (\phi, \psi) \) for \( (\phi, \psi) \in \mathcal{F} \).
(2) For \( 0 \leq t \leq 1 \) and \( (\phi, \psi) \in \mathcal{F} \), writing \( \Theta(t, (\phi, \psi)) =: (\phi_t, \psi_t) \), we have \( \phi_t \in W^{1,2\alpha}(M, N) \) and \( \psi_t \in H^{1/2}(M, \Sigma M \otimes \phi_t^*TN) \). Moreover, \( \phi : [0, 1] \ni t \mapsto \phi_t \in W^{1,2\alpha}(M, N) \) is piecewise \( C^1 \).
(3) Let \( (\phi_t, \psi_t) = \Theta(t, (\phi, \psi)) \) be as in (2). For all \( 0 \leq t \leq 1 \), there holds
\[
(P_t^- \oplus P_t^0) \psi_t = P_t^- (P_t \psi) + P_t^0 (P_t \psi) + K(t, \psi),
\]
where \( P_t \psi(x) = (1 \otimes P_t(x) \psi(x)) \) and \( P_t(x) : T_{\phi_t(x)}N \to T_{\phi_t(x)}N \) is the parallel transport along the curve \( [0, 1] \ni s \mapsto \phi_t(x) \in N \), \( P_t^- \) and \( P_t^0 \) are the spectral projection of \( H^{1/2}(M, \Sigma M \otimes \phi_t^*TN) \) onto the negative and the null eigenspaces of \( \partial \phi_t \), respectively. \( K : [0, 1] \times H^{1/2}(M, \Sigma M \otimes \phi_t^*TN) \to H^{1/2}(M, \Sigma M \otimes E) \) is a compact map.

Based on this deformation class, we can talk about the linking relationship between two subsets. As we stated in the beginning of this section, this relationship keeps those two subsets intersecting along the deformation.

**Definition 4.10** Let \( S \subset \mathcal{F} \) be a closed subset and \( Q \subset \mathcal{F} \) a submanifold with relative boundary \( \partial Q \). We say that \( S \) and \( Q \) link with respect to \( C \) if the following holds: For any \( \Theta \in C \) which satisfies \( \Theta(t, \partial Q) \cap S = \emptyset \) for all \( t \in [0, 1] \), we have \( \Theta(t, Q) \cap S \neq \emptyset \) for all \( t \in [0, 1] \).

Now, we can investigate the linking relationship between two explicit subsets.

**Lemma 4.11** For \( \phi_0 \in W^{1,2\alpha}(M, N) \) and \( R_1, R_2, \rho > 0 \) with \( 0 < \rho < R_2 \), we define
\[
S_{\rho} = \{ (\phi, \psi) \in \mathcal{F}^+ : \| \psi \|_{1/2, 2} = \rho \}
\]
and
\[
Q_{R_1, R_2} = \{ (\phi_0, \psi) \in \mathcal{F}^-_{\phi_0} \oplus \mathcal{F}^0_{\phi_0} : \| \psi \|_{1/2, 2} \leq R_1 \} \oplus \{ (\phi_0, r e^+) : 0 \leq r \leq R_2 \},
\]
where \( \mathcal{F} = \mathcal{F}^- \oplus \mathcal{F}^0 \oplus \mathcal{F}^+ \) is the spectral decomposition of \( \mathcal{F} \) with respect to the operator \( D \), i.e., the fiber over \( \phi \in W^{1,2\alpha}(M, N) \), \( \mathcal{F}_\phi := H^{1/2}(M, \Sigma M \otimes \phi^*TN) \) is decomposed as
\[ F_{\phi} = F^{-}_{\phi} \oplus F^{0}_{\phi} \oplus F^{+}_{\phi}, \text{ where } F^{-}_{\phi}, F^{0}_{\phi} \text{ and } F^{+}_{\phi} \text{ are, respectively, the positive, the null, and the negative spaces with respect to the spectral decomposition of the operator } D_{\phi} \text{ and } e^{+}_{\phi} \in F^{+}_{\phi} \text{ is such that } \|e^{+}\|_{1/2, 2} = 1. \text{ Then } S_{\rho} \text{ and } Q_{R_{1}, R_{2}} \text{ link with respect to } C. \]

Last, we give an explicit deformation class, which is corresponding to the negative pseudo-gradient flow. Let \( Q \subset F \) be a submanifold with relative boundary \( \partial Q \). For such \( Q \), we define \( \Gamma(Q) \), a class of deformations of \( Q \), as follows:

**Definition 4.12** We define

\[
\Gamma(Q) := \{ \gamma(1, \cdot) \in C^{0}(F, F) : \gamma \in C^{0}([0, 1] \times F, F) \text{ satisfies the following (1), (2), (3)} \}
\]

1. \( \gamma(0, (\phi, \psi)) = (\phi, \psi) \) for any \((\phi, \psi) \in F.\)
2. \( \gamma(t, (\phi, \psi)) = (\phi, \psi) \) for \( 0 \leq t \leq 1 \) and \((\phi, \psi) \in \partial Q.\)
3. \( \gamma(t, (\phi, \psi)) \) is written as \( \gamma(t, (\phi, \psi)) = (\phi_{t}, \psi_{t}) \), where \( \phi_{t} \in W^{1, 2}(M, N), \psi \in H^{1/2}(M, \Sigma M \otimes \phi_{t}^{*}TN) \) and \( \phi : [0, 1] \ni t \mapsto \phi_{t} \in W^{1, 2}(M, N) \) is piecewise \( C^{1}. \)

Moreover, \( \psi_{t} \) is of the following form:

\[
\psi_{t} = P_{t}(L_{\phi_{t}}(\psi) + K(t, \psi)),
\]

where \( P_{t} \) is as in Definition 4.9, \( K : [0, 1] \times H^{1/2}(M, \Sigma M \otimes \phi^{*}TN) \rightarrow H^{1/2}(M, \Sigma M \otimes \phi^{*}TN) \) is a compact map and \( L_{\phi_{t}}(\psi) = \exp(-\sigma(t, \phi, \psi)L_{t, V})\psi. \) Here \( L_{t, V} = P_{t}^{-1} \circ (1 + D_{\phi_{t}}^{2})^{-1/2} D_{\phi_{t}} \circ P_{t} \) and \( \sigma : [0, 1] \times F \rightarrow \mathbb{R} \) is a continuous bounded function.

By Lemma 4.11, we have the following intersection property:

**Lemma 4.13** Let \( S \subset F \) be a closed subset and \( Q \) a submanifold of \( F \) with the relative boundary \( \partial Q. \) Assume that \( S \subset F^{+} \) and \( S \) and \( Q \) link with respect to \( C. \) Then for any \( \gamma \in \Gamma(Q) \), we have \( \gamma(Q) \cap S \neq \emptyset. \)

As we said in the beginning of this subsection, we will apply Lemma 4.11 and Lemma 4.13 to \( S_{\theta, \rho} \) and \( Q_{\theta, R_{1}, R_{2}} \) to get \( c_{\theta} \geq b_{\theta, \rho} \) in Sect. 6.

### 5 Uniqueness of \( \alpha \)-harmonic maps

In this section, we will prove a result about the uniqueness of \( \alpha \)-harmonic maps. An analogous theorem can be found in [11] (see Theorem 9.7.2) for harmonic maps. The key is still the convexity of the \( \alpha \)-energy function. So we now derive the second variation formula for the \( \alpha \)-energy. Let \( f_{st}(x) := f(x, s, t) \) be a smooth family of maps from \( M \times (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \) to \( N. \) The \( \alpha \)-energy function is defined as

\[
E^{\alpha}(f) = \frac{1}{2} \int_{M} (1 + |df|^{2})^{\alpha},
\] (5.1)
where $df = \frac{\partial f}{\partial x^\alpha} dx^\alpha = \frac{\partial f^i}{\partial x^\alpha} dx^\alpha \otimes \frac{\partial}{\partial f^i}$. In the following, $\nabla$ is the Levi-Civita connection in the pullback bundle $f^*TN$ and everything will be evaluated at $s = t = 0$. Then

$$\frac{\partial^2}{\partial t \partial s} \bigg|_{s=t=0} \left( \frac{1}{2} (1 + |df|^2)^\alpha \right) = \frac{\partial}{\partial t} \left( \alpha (1 + |df|^2)^{(\alpha - 1)} \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \right)$$

$$= \frac{\partial}{\partial t} \left( \alpha (1 + |df|^2)^{(\alpha - 1)} \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \right)$$

where

$$= \alpha (1 + |df|^2)^{(\alpha - 1)} \left( \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \right) + \langle \nabla \nabla V, \nabla W \rangle$$

$$+ 2\alpha (\alpha - 1) (1 + |df|^2)^{(\alpha - 2)} \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \langle \nabla_{\frac{\partial}{\partial s}} W dx^\alpha, df \rangle.$$

Let us set $V := \frac{\partial f}{\partial s} \bigg|_{s=t=0}$ and $W := \frac{\partial f}{\partial t} \bigg|_{s=t=0}$. Then (5.2) becomes

$$\frac{\partial^2}{\partial t \partial s} \bigg|_{s=t=0} \left( \frac{1}{2} (1 + |df|^2)^\alpha \right) = \alpha (1 + |df|^2)^{(\alpha - 1)} \left( \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \right) + \langle \nabla \nabla V, \nabla W \rangle$$

Here, by the Ricci identity, we have

$$\langle \nabla_{\frac{\partial}{\partial t}} \nabla_{\frac{\partial}{\partial s}} df, df \rangle = \langle \nabla_{\frac{\partial}{\partial s}} \nabla_{\frac{\partial}{\partial s}} df, df \rangle + \langle \nabla \nabla V, \nabla W \rangle$$

where we used the definition of the Riemann curvature tensor $R(X, Y)Z = \nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z - \nabla_{[X, Y]} Z$. Plugging (5.4) into (5.3), we obtain the following second variation formula.

**Theorem 5.1** For a smooth family $f = f_{st}$ of finite $\alpha$-energy maps between manifolds $M$ and $N$ with $f_{st}(x) = f_{00}(x)$ for any point $x \in \partial M$ in the case of $\partial M \neq \emptyset$, the second variational formula with $V := \frac{\partial f}{\partial s} \bigg|_{s=t=0}$, $W := \frac{\partial f}{\partial t} \bigg|_{s=t=0}$ is

$$\frac{\partial^2}{\partial t \partial s} \bigg|_{s=t=0} E^\alpha(f) = \alpha \int_M (1 + |df|^2)^{(\alpha - 1)} \left( \langle \nabla \nabla V, \nabla W \rangle - \mathrm{tr}_M \langle R^N(df, V) W, df \rangle_{f^*TN} \right)$$

$$+ 2\alpha (\alpha - 1) \int_M (1 + |df|^2)^{(\alpha - 2)} \langle \nabla_{\frac{\partial}{\partial s}} df, df \rangle \langle \nabla_{\frac{\partial}{\partial s}} W dx^\alpha, df \rangle$$

$$+ \alpha \int_M (1 + |df|^2)^{(\alpha - 1)} \langle \nabla_{\frac{\partial}{\partial s}} \nabla_{\frac{\partial}{\partial s}} df, df \rangle.$$
Since the Euler-Lagrangian equation for a $\alpha$-harmonic map is
\[ \tau^\alpha(f) = \text{tr} \nabla((1 + |df|^2)^{(\alpha-1)}df) = 0, \] (5.6)
under the assumptions of Theorem 5.1, we can deal with the last term in (5.5) as follows
\[ \alpha \int_M (1 + |df|^2)^{(\alpha-1)}(\nabla_{\frac{\partial}{\partial t}} \nabla_{\frac{\partial}{\partial x}} \frac{\partial f}{\partial s} dx^\beta, df) = \alpha \int_M (\nabla_{\frac{\partial}{\partial t}} \frac{\partial f}{\partial s}, \text{tr}((1 + |df|^2)^{(\alpha-1)}df)) \]
\[ = \alpha \int_M (\nabla_{\frac{\partial}{\partial t}} \frac{\partial f}{\partial s}, \text{tr}((1 + |df|^2)^{(\alpha-1)}df)). \] (5.7)

Therefore, plugging (5.7) into (5.5), we have

\**Corollary 5.2** All $\alpha$-harmonic maps to non-positive curved manifolds are stable.

When the target manifold has non-positive curvature, any two homotopic maps can be connected by geodesics. In this case, we also have the convexity of the $\alpha$-energy.

\**Lemma 5.3** Under the assumptions of Theorem 5.1 with $f = f_t$, for $\alpha \geq 1$, if $N$ has non-positive sectional curvature and
\[ |\frac{\partial f}{\partial t}|_{t=0} = 0, \]
then the $\alpha$-energy function is convex, that is,
\[ \frac{d^2}{dt^2} \left|_{t=0} \right. E^\alpha(f_t) \geq \alpha \int_M (1 + |df|^2)^{(\alpha-2)} \left( (1 + |df|^2)|V|^2 + 2(\alpha - 1)(\nabla_{\frac{\partial}{\partial t}} V dx^\beta, df)^2 \right) \geq 0. \] (5.8)

By such convexity, one can get the following uniqueness of $\alpha$-harmonic map as in Theorem 9.7.2 [11].

\**Theorem 5.4** Let $M$ be a compact manifold and $N$ a complete Riemannian manifold. Assume that $N$ has non-positive curvature. Let $f_0, f_1 : M \to N$ be homotopic $\alpha$-harmonic maps ($\alpha \geq 1$). Then there exists a family $f_t : M \to N$ ($t \in [0, 1]$) of $\alpha$-harmonic maps connecting them, for which the $\alpha$-energy $E^\alpha(f_t)$ is independent of $t$, and for which every curve $\gamma \alpha(t) := f_t(x)$ is geodesic, and $\frac{\partial}{\partial t} | \gamma \alpha(t) |$ is independent of $x$ and $t$. If $N$ has negative curvature, then $f_0$ and $f_1$ either are both constant maps, or they both map $M$ onto the same closed geodesic or they coincide. If $M$ has boundary $\partial M$ and $f_0|_{\partial M} = f_1|_{\partial M}$, then $f_0 = f_1$.

\section{6 Existence results}

In this section, we will prove the existence of perturbed $\alpha$-Dirac-harmonic maps. To this end, in addition to the results showed in the previous sections, we still need some more preparations.

Let $N$ be a compact Riemannian manifold and $\theta \in [M, N]$ be a free homotopy class of maps in $N$. We define $\mathcal{F}_\theta = \{(\phi, \psi) \in \mathcal{F}^{\alpha,1/2}(M, N) : \phi \in \theta \}$. For each $\alpha$, it is well-known that there exists an $\alpha$-energy minimizing map $\phi_0 \in \theta$ in the class $\theta$ [19]. From now on, we fix $\alpha > 1$. Denote
\[ m_\theta := \inf \left\{ \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha : \phi \in W^{1,2\alpha}(M, N) \cap \theta \right\} = \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha. \] (6.1)
Now, we fix such a map $\phi_0 \in \theta$ in the following. For $R_1, R_2 > 0$ and $0 < \rho < R_2$, we define

$$Q_{\theta; R_1, R_2} = \{ (\phi_0, \psi) \in \mathcal{F}_{\theta, \phi_0}^- \oplus \mathcal{F}_{\theta, \phi_0}^0 : \| \psi \|_{1/2, 2} \leq R_1 \} \oplus \{ (\phi_0, r e^+) : 0 \leq r \leq R_2 \}$$

(6.2)

and

$$S_{\theta; \rho} = \{ (\phi, \psi) \in \mathcal{F}_{\theta}^+ : \| \psi \|_{1/2, 2} = \rho \},$$

(6.3)

where $e^+ \in \mathcal{F}_{\theta, \phi_0}^+$ is such that $\| e^+ \|_{1/2, 2} = 1$ and $\mathcal{F}_{\theta, \phi} = \mathcal{F}_{\theta}^- = H^{1/2}(M, \Sigma M \otimes \phi^* T N)$ is the fiber over $\phi$ of the fibration $\mathcal{F}_{\theta} \to W^{1, 2\alpha}(M, N) \cap \theta$. $\mathcal{F}_{\theta}^+, \mathcal{F}_{\theta}^0$ are similar to the ones in Lemma 4.11.

We also define

$$a_{\theta; R_1, R_2} = \sup \{ \mathcal{L}^\alpha (\phi, \psi) : (\phi, \psi) \in \partial Q_{\theta; R_1, R_2} \}$$

(6.4)

and

$$b_{\theta; \rho} = \inf \{ \mathcal{L}^\alpha (\phi, \psi) : (\phi, \psi) \in S_{\theta; \rho} \}.$$  

(6.5)

In view of the linking geometry proved in Sect. 4, giving good estimates for $a_{\theta; R_1, R_2}$ and $b_{\theta; \rho}$ is crucial to both the existence and the nontrivialness of critical points of $\mathcal{L}^\alpha$. So, we will prove these estimates in the next two subsections.

### 6.1 Estimate of $a_{\theta; R_1, R_2}$

In this subsection, we shall prove the following estimate.

**Lemma 6.1** There exists $R_1, R_2 > 0$ such that $a_{\theta; R_1, R_2} \leq m_{\theta}$ provided $F$ satisfies (F2) and (F4) $F(\phi, \psi) \geq 0$ for any $(\phi, \psi) \in \mathcal{F}$.

**Proof** Write $\psi = \psi^- + \psi^0 + re^+$, we have

$$\mathcal{L}^\alpha (\phi_0, \psi) = m_{\theta} + \frac{1}{2} \int_M \langle \psi^-, \mathcal{D}_{\phi_0} \psi \rangle + C(e^+) r^2 - \int_M F(\phi_0, \psi),$$

(6.6)

where $C(e^+) = \frac{1}{2} \int_M \langle \mathcal{D}_{\phi_0} e^+, e^+ \rangle > 0$.

By (F2), we get

$$\int_M F(\phi_0, \psi) \geq C \int_M |\psi|^{\mu} - C.$$  

(6.7)

On the other hand, Hölder’s inequality implies

$$\int_M |\psi^- + \psi^0|^2 + r^2 \int_M |e^+|^2 = \int_M |\psi^- + \psi^0 + re^+|^2 \leq C \left( \int_M |\psi|^{\mu} \right)^{2/\mu}.  

(6.8)

Combining these, we obtain

$$\mathcal{L}^\alpha (\phi_0, \psi) \leq m_{\theta} + \frac{1}{2} \int_M \langle \psi^-, \mathcal{D}_{\phi_0} \psi \rangle + C(e^+) r^2 - C \left( \int_M |\psi^- + \psi^0|^2 + r^2 \int_M |e^+|^2 \right)^{\mu/2} + C.$$  

(6.9)
Since the square of the $H^{1/2}$-norm of $\psi^- \in \mathcal{F}_{\phi_0}^-$ is equivalent to $-\int_M \langle \psi^-, D_{\phi_0} \psi^- \rangle$, there exists $C(\phi_0) > 0$ such that
\[
\int_M \langle \psi^-, D_{\phi_0} \psi^- \rangle \leq -C(\phi_0) \| \psi^- \|_{1/2,2}^2. \tag{6.10}
\]
Plugging (6.10) into (6.9) and noting that the $L^2$-norm is equivalent to the $H^{1/2}$-norm on $\mathcal{F}_{\theta, \phi_0}^-$, one gets
\[
\mathcal{L}^\alpha (\phi_0, \psi) \leq m_\theta + C (e^+) r^2 - C(\phi_0) \| \psi^- \|_{1/2,2}^2 - C(\| \psi_0 \|_{1/2,2}^\mu + r^\mu) + C. \tag{6.11}
\]
We choose $R_2 > 0$ such that $C (e^+) r^2 - C r^\mu + C \leq 0$ for $r \geq R_2$. This is possible because $\mu > 2$. We then set $M_1 = \max_{0 \leq r \leq R_2} (C (e^+) r^2 - C r^\mu + C) > 0$ and take $R_1$ such that $C(\phi_0) \| \psi^- \|_{1/2,2}^2 + C \| \psi_0 \|_{1/2,2}^\mu \geq M_1$ whenever $\| \psi^- + \psi_0 \|_{1/2,2}^2 = \| \psi^- \|_{1/2,2}^2 + \| \psi_0 \|_{1/2,2}^\mu \geq R_1^2$.

For such $R_1$ and $R_2$, the lemma holds. Indeed, any point in $\partial Q_{R_1, R_2}$ is in one of the following three subsets:

1. $\| \psi^- + \psi_0 \|_{1/2,2} = R_1$ and $0 \leq r \leq R_2$;
2. $\| \psi^- + \psi_0 \|_{1/2,2} \leq R_1$ and $r = 0$;
3. $\| \psi^- + \psi_0 \|_{1/2,2} \leq R_1$ and $r = R_2$.

For (1) and (3), by (6.11), the choices of $R_1$ and $R_2$ imply $\mathcal{L}^\alpha (\phi_0, \psi) \leq m_\theta$.

For (2), by (F4), we have
\[
\mathcal{L}^\alpha (\phi_0, \psi) = m_\theta + \frac{1}{2} \int_M \langle \psi^-, D_{\phi_0} \psi^- \rangle - \int_M F(\phi_0, \psi) \leq m_\theta - \int_M F(\phi_0, \psi) \leq m_\theta. \tag{6.12}
\]

This case analysis completes the proof.

\[\square\]

### 6.2 Estimate of $b_{\theta, \rho}$

In this subsection, we will prove the following:

**Lemma 6.2** For $R_2$ in Lemma 6.1, there exists $0 < \rho < R_2$ such that
\[
b_{\theta, \rho} > m_\theta \tag{6.13}
\]
provided $F$ satisfies (F1), (F4) and
\[
(F5) \quad F(\phi, \psi) = o(\| \psi \|^2) \text{ uniformly in } \phi \in N \text{ as } |\psi| \to 0.
\]

The proof requires some preparations. For $(\phi, \psi) \in S_{\theta, \rho}$, we have
\[
\mathcal{L}^\alpha (\phi, \psi) = \frac{1}{2} \int_M (1 + |d\phi|^2) \psi + \frac{1}{2} \int_M \langle \psi, D\psi \rangle_{\Sigma M \otimes \Phi^* T N} - \int_M F(\phi, \psi). \tag{6.14}
\]

We first estimate the term $\frac{1}{2} \int_M \langle \psi, D\psi \rangle_{\Sigma M \otimes \Phi^* T N}$. For this, we define
\[
\lambda^+ (\phi) = \inf \left\{ \int_M \langle \psi, D\psi \rangle : \| \psi \|_{1/2,2} = 1, \psi \in \mathcal{F}_\Phi^+ \right\}. \tag{6.15}
\]
Thus,
\[ \int_M \langle \psi, D\psi \rangle \geq \lambda^+(\phi)\rho^2 \]  \hspace{1cm} (6.16)
for \((\phi, \psi) \in S_{\theta, \rho}.

First of all, we investigate some properties of \(\lambda^+(\phi)\).

**Lemma 6.3** For any \(\phi \in \theta \cap W^{1,2\alpha}(M, N)\), we have \(\lambda^+(\phi) > 0\).

**Proof** By definition of \(\lambda^+(\phi)\), \(\lambda^+(\phi) \geq 0\) for any \(\phi \in \theta \cap W^{1,2\alpha}(M, N)\). To prove the lemma, we assume on the contrary that \(\lambda^+(\phi) = 0\) for some \(\phi \in \theta \cap W^{1,2\alpha}(M, N)\). In other words, there exist \(n, n_0 \in \mathcal{F}^+_\phi\) such that

\[ \|\psi_n\|_{1/2,2} = 1 \text{ and } \int_M \langle \psi_n, D\psi_n \rangle \to 0 \]  \hspace{1cm} (6.17)
as \(n \to \infty\).

We assume that (taking a subsequence if necessary) there exists \(\psi_\infty \in \mathcal{F}^+_\phi\) such that \(\psi_n \to \psi_\infty\) weakly in \(H^{1/2}\) and \(\psi_n \to \psi_\infty\) strongly in \(L^2\) as \(n \to \infty\).

As before, the square root of \(\psi \mapsto \int_M \langle \psi, D\psi \rangle + \|\psi\|_2^2\) defines a norm on \(\mathcal{F}^+_\phi\) which is equivalent to the \(H^{1/2}\)-norm. By the weak lower semi-continuity of the norm, we get

\[ \int_M \langle \psi_\infty, D\psi_\infty \rangle + \|\psi_\infty\|_2^2 \leq \lim_{n \to \infty} \left( \int_M \langle \psi_n, D\psi_n \rangle + \|\psi_n\|_2^2 \right) \]  \hspace{1cm} (6.18)

By (6.17) and (6.18) and \(\int_M \langle \psi_\infty, D\psi_\infty \rangle \geq 0\) (since \(\psi_\infty \in \mathcal{F}^+_\phi\)), we obtain \(\int_M \langle \psi_\infty, D\psi_\infty \rangle = 0\). This implies \(\psi_\infty = 0\). Then there is a constant \(C\) such that

\[ 1 = \|\psi_n\|_{1/2,2}^2 \leq C \left( \int_M \langle \psi_n, D\psi_n \rangle + \|\psi_n\|_2^2 \right) \to 0 \]  \hspace{1cm} (6.19)
as \(n \to \infty\). This is a contradiction. So we complete the proof.

We next prove:

**Lemma 6.4** The map \(W^{1,2\alpha}(M, N) \ni \phi \mapsto \lambda^+(\phi) \in \mathbb{R}\) is continuous.

**Proof** Let \(\phi \in W^{1,2\alpha}(M, N)\). By the definition of \(\lambda^+(\phi)\), for any \(\varepsilon > 0\), there exists \(\psi_\varepsilon \in \mathcal{F}^+_\phi\) such that

\[ \|\psi_\varepsilon\|_{1/2,2} = 1 \text{ and } \int_M \langle \psi_\varepsilon, D\psi_\varepsilon \rangle < \lambda^+(\phi) + \varepsilon. \]  \hspace{1cm} (6.20)

Let \(\tilde{\phi} \in W^{1,2\alpha} \cap L^\infty(M, N)\) be another map such that \(\|\phi - \tilde{\phi}\|_{W^{1,2\alpha} \cap L^\infty}\) is small. Because \(\psi_\varepsilon \notin \mathcal{F}^+_\phi\) in general, we cannot use \(\psi_\varepsilon\) as a test spinor to estimate \(\lambda^+(\tilde{\phi})\). In order to get a suitable test spinor, we need parallel translation. Denote by \(t(N) > 0\) the injectivity radius of \(N\). For any \(y, z \in N\) with \(d(y, z) < t(N)\) (\(d(y, z)\) is the geodesic distance between \(y\) and \(z\) in \(N\)), \(P_{y,z}\) defined as in Lemma 4.5 depends smoothly on \(y, z\). By Lemma 4.5, \(T_{\phi, \Phi, \psi_\varepsilon} \in \mathcal{F}^+_\Phi\).

To make it belong to \(\mathcal{F}^+_\Phi\), we need to modify it.

We define \(\tilde{\psi}_\varepsilon := P^+(\tilde{\phi})T_{\phi, \tilde{\phi}, \psi_\varepsilon} \in \mathcal{F}^+_\Phi\). By Lemma 4.6, we have

\[ \|\tilde{\psi}_\varepsilon - \psi_\varepsilon\|_{1/2,2} \leq C(\|\phi\|_{1,2\alpha}, \|\tilde{\phi}\|_{1,2\alpha})\|\phi - \tilde{\phi}\|_{1,2\alpha}. \]  \hspace{1cm} (6.21)
Lemma 6.5

Palais–Smale condition for \( \alpha > 1 \).

Reversing the roles of \( \phi \) and \( \tilde{\phi} \) in (6.23), we arrive at
\[
|\lambda^+(\phi) - \lambda^+(\tilde{\phi})| \leq C(\|\phi\|_{1,2\alpha}, \|\tilde{\phi}\|_{1,2\alpha})\|\phi - \tilde{\phi}\|_{1,2\alpha}.
\]

This completes the proof.

Let \( \mathcal{M}^\alpha(\theta) = \{\phi \in \theta \cap W^{1,2\alpha}(M, N) : E^\alpha(\phi) = m_\theta\} \) be the set of energy minimizing maps in the class \( \theta \), where \( E^\alpha \) is defined in (3.24). Because the \( \alpha \)-energy of \( \phi \) satisfies the Palais–Smale condition for \( \alpha > 1 \) [22], we know

Lemma 6.5 \( \mathcal{M}^\alpha(\theta) \) is compact for \( \alpha > 1 \).

As a corollary of Lemmas 6.3, 6.4 and 6.5, we have:

Corollary 6.6 There exist \( \delta(\theta) \) and \( \lambda^+(\theta) > 0 \) such that for any \( \phi \in \theta \cap W^{1,2\alpha}(M, N) \) with \( \text{dist}(\phi, \mathcal{M}^\alpha(\theta)) := \inf\{\|\phi - \varphi\|_{W^{1,2\alpha}} : \varphi \in \mathcal{M}^\alpha(\theta)\} < \delta(\theta) \), there holds \( \lambda^+(\phi) \geq \lambda^+(\theta) \).

Proof Suppose the corollary is not true, then there exist \( \phi_n \in \theta \cap W^{1,2\alpha}(M, N) \) such that \( \lambda^+(\phi_n) \to 0 \) and \( \text{dist}(\phi_n, \mathcal{M}^\alpha(\theta)) \to 0 \). By the compactness of \( \mathcal{M}(\theta) \), after taking a subsequence if necessary, we assume that there is \( \phi_\infty \in \mathcal{M}(\theta) \) such that \( \phi \to \phi_\infty \) in \( W^{1,2\alpha}(M, N) \). By Lemmas 6.3 and 6.4, we have \( \lambda^+(\phi_n) \to \lambda^+(\phi_\infty) > 0 \), which is a contradiction.

We also need to investigate the maps far away from the set \( \mathcal{M}^\alpha(\theta) \).

Lemma 6.7 Let \( \delta(\theta) > 0 \) be as in Corollary 6.6. There exists \( \epsilon(\theta) \) such that for any \( \phi \in \theta \cap W^{1,2\alpha}(M, N) \) with \( \text{dist}(\phi, \mathcal{M}^\alpha(\theta)) \geq \delta(\theta) \), we have \( \frac{1}{2} \int_M (1 + |d\phi|^2)^\alpha \geq m_\theta + \frac{1}{n} \).

Proof For any fixed \( \alpha > 1 \), if such an \( \epsilon(\theta) \) does not exist, then there exist \( \{\phi_n\} \) such that
\[
\text{dist}(\phi_n, \mathcal{M}^\alpha(\theta)) \geq \delta(\theta)
\]
and
\[
\frac{1}{2} \int_M (1 + |d\phi_n|^2)^\alpha \leq m_\theta + \frac{1}{n}.
\]

Since \( m_\theta \) is the minimizing energy of \( E^\alpha \), \( \{\phi_n\} \) is a minimizing sequence for \( E^\alpha \). Therefore, the Palais–Smale condition implies that, after taking a subsequence if necessary, there is a critical point \( \phi_\infty \in \theta \cap W^{1,2\alpha}(M, N) \) of \( E^\alpha \) such that \( \phi_n \to \phi_\infty \) strongly in \( W^{1,2\alpha}(M, N) \).

In fact, \( \phi_\infty \in \mathcal{M}^\alpha(\theta) \). This contradicts (6.25).
Now, we can prove Lemma 6.2.

**Proof of Lemma 6.2** Let \((\phi, \psi) \in S_{\theta, \rho}\) be arbitrary. If \(\phi\) satisfies \(\text{dist}(\phi, \mathcal{M}^\alpha(\theta)) < \delta(\theta)\), by Corollary 6.6, we have
\[
\frac{1}{2} \int_M (1 + |\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, \mathcal{D}\psi \rangle \geq m_\theta + \frac{\lambda^+(\phi)}{2} \|\psi\|_{1/2}^2
\]
(6.27)
\[
\geq m_\theta + \frac{\lambda^+(\theta)}{2} \rho^2.
\]
If \(\phi\) satisfies \(\text{dist}(\phi, \mathcal{M}^\alpha(\theta)) \geq \delta(\theta)\), Lemma 6.7 implies
\[
\frac{1}{2} \int_M (1 + |\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, \mathcal{D}\psi \rangle \geq m_\theta + \varepsilon(\theta).
\]
(6.28)

Therefore, we have
\[
\frac{1}{2} \int_M (1 + |\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, \mathcal{D}\psi \rangle \geq m_\theta + \min \left\{ \frac{\lambda^+(\theta)}{2} \rho^2, \varepsilon(\theta) \right\}.
\]
(6.29)

On the other hand, by (F1), (F4), (F5), for any \(\varepsilon > 0\) there exist \(C_\varepsilon\) such that
\[
0 \leq F(\phi, \psi) \leq \varepsilon |\psi|^2 + C_\varepsilon |\psi|^p
\]
(6.30)
for any \((\phi, \psi) \in F\).

Now take \(\varepsilon = \frac{\lambda^+(\theta)}{4}\) and write \(C = C_\varepsilon\). By (6.29), (6.30) and Sobolev embedding, we obtain
\[
\mathcal{L}^\alpha(\phi, \psi) = \frac{1}{2} \int_M (1 + |\phi|^2)^\alpha + \frac{1}{2} \int_M \langle \psi, \mathcal{D}\psi \rangle - \int_M F(\phi, \psi)
\]
\[
\geq m_\theta + \min \left\{ \frac{\lambda^+(\theta)}{2} \rho^2, \varepsilon(\theta) \right\} - \frac{\lambda^+(\theta)}{4} \int_M |\psi|^2 - C \int_M |\psi|^p.
\]
(6.31)

There exists \(0 < \rho_0 < R_2\) such that for \(0 < \rho < \rho_0\), we have
\[
\min \left\{ \frac{\lambda^+(\theta)}{2} \rho^2, \varepsilon(\theta) \right\} = \frac{\lambda^+(\theta)}{2} \rho^2
\]
(6.32)
and
\[
\frac{\lambda^+(\theta)}{4} \rho^2 - C \rho^p > 0.
\]
(6.33)

Thus, for any \(\rho \in (0, \rho_0)\), we have \(\mathcal{L}^\alpha(\phi, \psi) \geq m_\theta + \frac{1}{2} \rho^2 \varepsilon(\theta)\). This implies
\[
b_{\theta, \rho} \geq m_\theta + \frac{1}{2} \rho^2 \varepsilon(\theta) > m_\theta.
\]
(6.34)

Hence, we complete the proof. \(\square\)

**Remark 6.8** It follows from the proof above that the estimate (6.13) is uniform in \(k\) if we replace \(F\) by \(\frac{1}{k} F\) instead.
6.3 Critical value of $\mathcal{L}^\alpha$

We define

$$c_\theta = \inf_{\gamma \in \Gamma(Q_{\theta;R_1,R_2})} \sup \mathcal{L}^\alpha(\gamma(Q_{\theta;R_1,R_2})), \quad (6.35)$$

where $\Gamma(Q_{\theta;R_1,R_2})$ is defined in Definition 4.12. By Lemma 4.7, one can prove that $\Gamma(Q_{\theta;R_1,R_2})$ is closed under composition as in [8]. Once having this property, we obtain the following main existence result in this paper:

**Theorem 6.9** Let $M$ be a closed surface and $N$ a compact manifold. Suppose $F$ satisfies (F1) -- (F5) with $\frac{4\alpha}{3\alpha - 2} \leq \mu \leq p \leq \frac{3}{4}\mu + 1$ for $\alpha \in (1, 2]$. Let $R_1, R_2$ and $\rho$ be as in Lemmas 6.1 and 6.2. Then we have $m_\theta < c_\theta < \infty$ and $c_\theta$ is a critical value of $\mathcal{L}^\alpha$ in $\mathcal{F}$.

**Proof** By Lemmas 4.11 and 4.13, we know $\gamma(Q_{\theta;R_1,R_2}) \cap S_{\rho;\rho} \neq \emptyset$ for any $\gamma \in \Gamma(Q_{\theta;R_1,R_2})$. Therefore, Lemma 6.2 implies

$$c_\theta \geq \inf_{(\phi, \psi) \in S_{\rho;\rho}} \mathcal{L}^\alpha(\phi, \psi) = b_{\theta;\rho} > m_\theta. \quad (6.36)$$

On the other hand, since the identity map belongs to $\Gamma(Q_{\theta;R_1,R_2})$ and $Q_{\theta;R_1,R_2}$ is bounded, by Sobolev embedding, we get

$$c_\theta \leq \sup \mathcal{L}^\alpha(Q_{\theta;R_1,R_2}) < \infty. \quad (6.37)$$

It remains to show that $c_\theta$ is a critical value of $\mathcal{F}^\alpha$. Suppose this is not the case, we set $\bar{\varepsilon} = \frac{b_{\theta;\rho} - m_\theta}{2} > 0$. By integrating (4.7) (see Deformation Lemma in [18,20]), we can find $0 < \varepsilon < \bar{\varepsilon}$ and $\Phi \in \Gamma(Q_{\theta;R_1,R_2})$ such that

$$\Phi(1, \mathcal{L}^\alpha_{c_\theta + \varepsilon}) \subset \mathcal{L}^\alpha_{c_\theta - \varepsilon}, \quad (6.38)$$

where $\mathcal{L}^\alpha_{c} = \{(\phi, \psi) \in \mathcal{F}_{\theta} : \mathcal{L}^\alpha(\phi, \psi) < c\}$. Here, note that our negative pseudo-gradient flow belongs to $\Gamma(Q_{\theta;R_1,R_2})$ by (4.18). Also, observing that $a_{\theta;R_1,R_2} \leq m_\theta < c_\theta - \bar{\varepsilon}$, we have $\Phi(1, (\phi, \psi)) = (\phi, \psi)$ for any $(\phi, \psi) \in \partial Q_{\theta;R_1,R_2}$.

Choose $\gamma \in \Gamma(Q_{\theta;R_1,R_2})$ such that $\mathcal{L}^\alpha(\gamma(1, Q_{\theta;R_1,R_2})) < c_\theta + \varepsilon$. Since $\Phi \circ \gamma \in \Gamma(Q_{\theta;R_1,R_2})$ as we said before the theorem, we have the following contradiction

$$c_\theta \leq \sup \mathcal{L}^\alpha(\Phi(1, \gamma(1, Q_{\theta;R_1,R_2}))) < c_\theta - \varepsilon. \quad (6.39)$$

Thus we complete the proof. \(\Box\)

Theorem 6.9 gives us a solution to the perturbed $\alpha$-Dirac-harmonic map Eqs. (2.11) and (2.12). Let us denote this solution by $(\phi_\theta, \psi_\theta)$. From (F5), we know $F(\phi, 0) = 0$ and $F_\theta(\phi, 0) = 0$ for any $\phi \in N$. Therefore, we cannot exclude the possibility that the solution in Theorem 6.9 is a trivial solution, that is, $\psi_\theta = 0$. If $\psi_\theta = 0$, then $F_\phi(\phi_\theta, 0) = 0$ by (F5), which tells us that $\phi_\theta$ is an $\alpha$-harmonic map. On the other hand, $\mathcal{L}^\alpha(\phi_\theta, \psi_\theta) = c_\theta > m_\theta$. Therefore, the $\alpha$-energy of $\phi_\theta$ is $\frac{1}{2} \int_M (1 + |d\phi_\theta|^2)^{\alpha} = c_\theta > m_\theta$. So, we get a corollary:

**Corollary 6.10** Under the assumption of Theorem 6.9, we get a critical point $(\phi_\theta, \psi_\theta)$ with value $c_\theta$. Then one of the following holds:

1. There exists a non-trivial perturbed $\alpha$-Dirac-harmonic map $(\phi_\theta, \psi_\theta)$ on $N$; or
2. There exists an energy non-minimizing $\alpha$-harmonic map $\phi_\theta$ in $\theta$. 

\(\square\) Springer
In particular, when \( N \) has non-positive curvature, Theorem 5.4 excludes the possibility (2) in the corollary above. Finally, we obtain an existence result about nontrivial perturbed \( \alpha \)-Dirac-harmonic maps.

**Theorem 6.11** Let \( M \) be a closed surface and \( N \) a compact Riemannian manifold with non-positive curvature. Suppose \( F \) satisfies (F1) – (F5) with \( \frac{4\alpha}{3\alpha - 2} \leq \mu \leq \frac{3}{2} \mu + 1 \) for \( \alpha \in (1, 2] \). Then for any homotopy class \( \theta \in [M, N] \), there exists a non-trivial solution \( (\phi, \psi) \in W^{1,2}(M, N) \times H^{1/2}(M, \Sigma M \otimes \phi^*TN) \) to the perturbed \( \alpha \)-Dirac-harmonic map equations (2.11) and (2.12) with \( \phi \in \theta \).

### 7 Regularity theorem

In this section, we are going to prove a regularity theorem for weakly perturbed \( \alpha \)-Dirac-harmonic maps with \( \alpha \in (1, 2] \). Precisely, we want to prove:

**Theorem 7.1** Suppose \( F \in C^\infty \) satisfies (F1) and (F3) for some \( p \leq 2 + 2/\alpha \) and \( q \geq 0 \). Then any weakly perturbed \( \alpha \)-Dirac-harmonic map is smooth.

Since the smoothness is a local property, we will prove Theorem 7.1 locally. So let we fix a domain \( \Omega \subset M \), which is mapped into a local chart \( \{ y^i \}_{i=1,...,n} \) on \( N \). Then a weakly perturbed \( \alpha \)-Dirac-harmonic map \( (\phi, \psi) \) is a weak solution to the following system:

\[
\text{div}((1 + |d\phi|^2)^{\alpha - 1} \nabla m^m) = -\Gamma_{ij}^{m} \phi^i \phi^j \partial^\gamma (1 + |d\phi|^2)^{\alpha - 1} + \frac{1}{2\alpha} R_{ijkl}^m \psi^k \cdot \nabla \phi^l \cdot \psi^j \alpha \quad \text{(7.1)}
\]

\[
\partial^m \psi^m = -\Gamma_{ij}^{m} \nabla \phi^i \cdot \psi^j + F_{\psi}^m (\phi, \psi). \tag{7.2}
\]

As we said in the introduction, we have to control the \( L^\infty \)-norm of \( \psi \) first. Since \( (\phi, \psi) \in \mathcal{F}^{\alpha, 1/2} \), by the Sobolev embedding, we can prove that \( \psi \) actually belongs to \( W^{1, s} \) for any \( 2 < s < 2\alpha \).

**Lemma 7.2** Let \( (\phi, \psi) \in \mathcal{F}^{\alpha, 1/2} \) be a weak solution of (7.1) and (7.2). Suppose \( F \) satisfies (F1) for some \( p \leq 2 + 2/\alpha \). Then \( \psi \in C^{0, \gamma} (M, \Sigma M \otimes \phi^*TN) \) for any \( 0 < \gamma < 1 - \frac{1}{\alpha} \).

**Proof** Since \( M \) is closed, it is sufficient to prove the interior estimate. That is, we can apply the equation (7.2) and the elliptic estimate for the first order equation (see [4]) to the spinor multiplied by a cut-off function. For simplicity, we still use \( \psi \) instead. The Hölder inequality implies

\[
\| \nabla \phi \cdot \psi \|_{s_0} \leq \| \nabla \phi \|_{a s_0} \| \psi \|_{\frac{a s_0}{a - 1}} \quad \text{(7.3)}
\]

for any \( a, s_0 > 1 \). We set

\[
as_0 = 2\alpha \quad \text{and} \quad \frac{a s_0}{a - 1} = 4. \tag{7.4}\]

Then \( 4/3 < s_0 = \frac{4\alpha}{a + 2} \leq 2 \). By (F1), to make \( F_{\psi} \in L^{s_0} \), we need \( p \leq 2 + 2/\alpha \). If \( s_0 = 2 \), that is, \( \alpha = 2 \) and \( p \leq 3 \), then the elliptic estimate for the first order equation (see [4])
implies \( \psi \in W^{1,2} \cap L^r \) for any \( r > 1 \). If \( s_0 < 2 \), then, by Sobolev embedding and (7.2), we have \( \psi \in L^{r_0} \), where \( r_0 = \frac{2s_0}{2-s_0} = \frac{4\alpha}{2-\alpha} > 4 \). Again, by setting

\[
as_1 = 2\alpha \quad \text{and} \quad \frac{as_1}{a-1} = r_0, \tag{7.5}\n\]

we have \( s_1 = \frac{2\alpha r_0}{2\alpha + r_0} \). To make \( F_\psi \in L^{s_1} \), it is sufficient to set \( \frac{\alpha + 2}{\alpha} s_1 \leq r_0 \), that is, \( s_1 \leq \frac{\alpha r_0}{\alpha + 2} \).

Since \( r_0 > 4 \), \( \frac{2\alpha r_0}{2\alpha + r_0} < \frac{\alpha r_0}{\alpha + 2} \). Now, we take \( s_1 = \frac{2\alpha r_0}{2\alpha + r_0} \). Then \( s_1 > s_0 \) and

\[
2 - s_1 = \frac{4\alpha + 2r_0 - 2\alpha r_0}{2\alpha + r_0} = \frac{2(\alpha - 1)}{2\alpha + r_0} \left( \frac{2\alpha}{\alpha - 1} - r_0 \right). \tag{7.6}\n\]

If \( r_0 = \frac{4\alpha}{2-\alpha} \geq \frac{2\alpha}{\alpha - 1} \), that is, \( \alpha \geq 4/3 \), we have \( s_1 \geq 2 \). Then \( \psi \in W^{1,2} \cap L^r \) for any \( r > 1 \).

Otherwise, for \( \alpha < 4/3 \), we get \( s_1 < 2 \). By Sobolev embedding, we have

\[
r_0 < r_1 = \frac{2s_1}{2 - s_1} = \frac{4\alpha r_0}{4\alpha + 2r_0 - 2\alpha r_0}. \tag{7.7}\n\]

Again, if \( r_1 \geq \frac{2\alpha}{\alpha - 1} \), that is, \( \alpha \geq 6/5 \), we have \( s_2 = \frac{2\alpha r_1}{2\alpha + r_1} \geq 2 \). Then \( \psi \in W^{1,2} \cap L^r \) for any \( r > 1 \).

Otherwise, we get \( r_2 = \frac{2s_2}{2 - s_2} \). Repeating this procedure, for each \( \alpha \), after finitely many steps, we obtain \( r_i \geq \frac{2\alpha}{\alpha - 1} \). Then \( \psi \in W^{1,2} \cap L^r \) for any \( r > 1 \). By Hölder’s inequality, \( \psi \in W^{1,s} \) for any \( 2 < s < 2\alpha \). Then \( \psi \in C^{0,\gamma} \) for any \( 0 < \gamma < 1 - \frac{2}{\alpha} < 1 - \frac{1}{\alpha} \). Thus, we complete the proof.

\( \square \)

Now, following the idea in [3], we need two lemmas. One is

**Lemma 7.3** Let \((\phi, \psi)\) be a weak solution of (7.1) and (7.2). Suppose \( F \) satisfies (F3) for some \( q \geq 0 \). For any \( \varepsilon > 0 \), there is a \( \rho > 0 \) such that

\[
\int_{B(x_1, \rho)} (1 + |d\phi|^2)^{\alpha-1} |\nabla \phi|^2 \eta^2 \leq \varepsilon \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{\alpha-1} |\nabla \eta|^2 + C\varepsilon \left( \int_{B(x_1, \rho)} |\psi|^q \eta^{\frac{q}{2}} \right)^{\frac{1}{2}}
+ C\varepsilon \int_{B(x_1, \rho)} (1 + |\psi|^q) \eta^2. \tag{7.8}\n\]

where \( B(x_1, \rho) \subset \Omega, \eta \in W_0^{1,2\alpha}(B(x_1, \rho, \mathbb{R}) \text{ and } C \text{ only depends on } N \text{ and the constant in (F3).} \)

**Proof** Denote \( G = (G^1, \ldots, G^n) \), where

\[
G^m = \Gamma_{ij}^{m} \phi^i_{\beta} \phi^j_{\gamma} g^{\beta\gamma} (1 + |d\phi|^2)^{\alpha-1} - \frac{1}{2\alpha} R_{ijkl}^m \langle \psi^k, \nabla \phi^i \cdot \psi^j \rangle + \frac{1}{\alpha} F^m_{\phi}(\phi, \psi). \tag{7.9}\n\]

Then the weak form of (7.1) is

\[
\int_{\Omega} (1 + |d\phi|^2)^{\alpha-1} g^{\beta\gamma} \nabla_{\beta} \phi^i \nabla_{\gamma} \zeta^j g_{ij} = \int_{\Omega} G^i \zeta^i g_{ij} \tag{7.10}\n\]

for any \( \zeta \in W^{1,2\alpha}(\Omega, \mathbb{R}^L) \). Now, we choose \( \zeta(x) = (\phi(x) - \phi(x_1))^2 \), then

\[
\nabla_{\beta} \zeta^i = \nabla_{\beta} \phi^i \eta^2 + 2(\phi^i(x) - \phi^i(x_1))\eta \nabla_{\beta} \eta. \tag{7.11}\n\]
Plugging this into (7.10), one gets

\[
\int_{B(x_1, \rho)} G^i \xi^j g_{ij} = \int_{B(x_1, \rho)} \left(1 + |d\phi|^2\right)^{a-1} \nabla_\beta \phi^i \nabla_\gamma \xi^j g^{\beta \gamma} g_{ij} \\
= \int_{B(x_1, \rho)} \left(1 + |d\phi|^2\right)^{a-1} \nabla_\beta \phi^i g_{ij} g^{\beta \gamma} (\nabla_\gamma \phi^i \eta^2 + 2(\phi^i(x) - \phi^i(x_1)) \eta \nabla_\gamma \eta) \\
= \int_{B(x_1, \rho)} \left(1 + |d\phi|^2\right)^{a-1} |\nabla \phi|^2 \eta^2 \\
+ 2 \int_{B(x_1, \rho)} \left(1 + |d\phi|^2\right)^{a-1} \eta (\phi^i(x) - \phi^i(x_1)) g_{ij} \nabla_\beta \phi^j \nabla_\gamma \eta.
\]  

(7.12)

Now, we estimate the left-hand side of (7.12).

\[
\int_{B(x_1, \rho)} G^i \xi^j g_{ij} = \int_{B(x_1, \rho)} \Gamma^i_{klm} \phi^l \beta^k g^{\beta \gamma} g_{ij} (\phi^j(x) - \phi^j(x_1))(1 + |d\phi|^2)^{a-1} \eta^2 \\
- \frac{1}{2 \alpha} R_{k\ell m} (\psi^l, \nabla \phi^k, \phi^m, \eta)(\phi^j(x) - \phi^j(x_1)) g_{ij} \eta^2 \\
+ \frac{1}{\alpha} F_{ij} (\eta, \phi)(\phi^j(x) - \phi^j(x_1)) g_{ij} \eta^2 \\
\leq C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \phi|^2 \eta^2 \\
+ C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \left(\int_{B(x_1, \rho)} |\nabla \phi|^2\right)^{\frac{1}{2}} \left(\int_{B(x_1, \rho)} |\phi|^4 \eta^4\right)^{\frac{1}{2}} \\
+ C \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |\psi|^9) \eta^2.
\]

(7.13)

where we have used (F3). For the second term in the right-hand side of (7.12), we have

\[
\left|2 \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} \eta (\phi^i(x) - \phi^i(x_1)) g_{ij} g^{\beta \gamma} \nabla_\beta \phi^i \nabla_\gamma \eta\right| \\
\leq 2 \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \phi| |\nabla \eta| |\eta| \\
\leq \frac{1}{2} \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \phi|^2 \eta^2 \\
+ 2 \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)|^2 \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \eta|^2
\]

(7.14)

By estimates (7.13), (7.14) and (7.12), we have

\[
\frac{1}{2} \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \phi|^2 \eta^2 \\
- 2 \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \eta|^2 \\
\leq C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{a-1} |\nabla \phi|^2 \eta^2
\]
\[ + C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \left( \int_{B(x_1, \rho)} |\nabla \phi|^2 \right)^{\frac{1}{2}} \left( \int_{B(x_1, \rho)} |\psi|^4 \right)^{\frac{1}{2}} \]
\[ + C \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |\psi|^q) \eta^2. \quad (7.15) \]

Since \( \phi \) is continuous, we can choose \( \rho \) so small that \( C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| < \frac{1}{4} \). Then
\[ \int_{B(x_1, \rho)} (1 + |\phi|^2)^{\alpha - 1} |\nabla \phi|^2 \eta^2 \leq 8 \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)|^2 \int_{B(x_1, \rho)} (1 + |\phi|^2)^{\alpha - 1} |\nabla \eta|^2 \]
\[ + 4C_N \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \|\phi\|_{1.2} \left( \int_{B(x_1, \rho)} |\psi|^4 \right)^{\frac{1}{2}} \]
\[ + 4C \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \int_{B(x_1, \rho)} (1 + |\phi|^q) \eta^2. \quad (7.16) \]

Now, take \( \rho \) still smaller so that \( \sup_{B(x_1, \rho)} |\phi(x) - \phi(x_1)| \max\{8, \|\phi\|_{1.2}\} \leq \varepsilon \). Then
\[ \int_{B(x_1, \rho)} (1 + |\phi|^2)^{\alpha - 1} |\nabla \phi|^2 \eta^2 \leq \varepsilon \int_{B(x_1, \rho)} (1 + |\phi|^2)^{\alpha - 1} |\nabla \eta|^2 \]
\[ + C\varepsilon \left( \int_{B(x_1, \rho)} |\psi|^4 \right)^{\frac{1}{2}} \]
\[ + C\varepsilon \int_{B(x_1, \rho)} (1 + |\phi|^q) \eta^2, \quad (7.17) \]

where \( C \) only depends on \( N \) and the constant in (F3).

The other lemma is

**Lemma 7.4** Let \( \phi \in W^{1,2\alpha+2} \cap W^{3,2\alpha} (B(x_0, R), N) \) and \((\phi, \psi)\) be a weak solution of (7.1) and (7.2). Suppose \( F \in C^\infty \) satisfies (F1) and (F3) for some \( p \leq 2 + 2/\alpha \) and \( q \geq 0 \). Then for \( R \) small enough, we have
\[ \|\nabla^2 \phi\|_{L^2(B(x_0, \frac{8R}{2}))} \leq C \|d\phi\|_{L^{2\alpha}(B(x_0, R))}, \quad (7.18) \]
where \( C_1 > 0 \) is a constant depending on \( |\phi|_{C^0(M,N)}, R, \|\psi\|_{L^\infty(M, \Sigma M \otimes \phi^* T N)} \) and the constants in (F1) and (F3).

**Proof** Choose a local coordinate \( \{y^i\} \) in a neighborhood \( U \) of \( \phi(x_0) \) such that \( \Gamma^i_{jk}(\phi(x_0)) = 0 \). Let \( R \) be so small that \( B := B(x_0, R) \) is mapped into \( U \) by \( \phi \). Since \( \phi \) is continuous, we can choose \( R \) small enough such that \( |\phi(x) - \phi(x_0)| < \delta \) for a given \( \delta \) to be determined later. Then (7.2) implies
\[ |\delta \psi| \leq |\Gamma^i_{jk}(\phi(x)) - \Gamma^i_{jk}(\phi(x_0))| |d\phi||\psi|^k| + |F_\psi(\phi, \psi)| \]
\[ \leq C_N |\phi(x) - \phi(x_0)||d\phi||\psi| + |F_\psi(\phi, \psi)| \]
\[ \leq C_N \delta |d\phi||\psi| + |F_\psi(\phi, \psi)| \quad (7.19) \]
Noting that \( \partial(\psi) = \eta \phi + \nabla \eta \cdot \phi \), we get
\[
\|\partial(\psi)\|_{L^4/3(B)} \leq \|\eta \phi + \nabla \eta \cdot \phi\|_{L^4/3(B)} + \|\nabla \cdot \phi\|_{L^4/3(B)} \leq C \delta \|\phi\|_{L^4/3(B)} + \|\psi\|_{L^4/3(B)} + \|\nabla \eta\|_{H^1/2(B)} (7.20)
\]
where we have replaced the constant \( C \) in (F1) by \( C_1 \), and \( C(1, \|\psi\|_{L^\infty}) \) denotes a constant depending on \( C_1 \) and \( \|\psi\|_{L^\infty(B)} \).

By the elliptic estimate for the first order equation (see [4]), we have
\[
\|\nabla(\psi)\|_{L^4/3(B)} + \|\psi\|_{L^4(B)} \leq CR(\delta(\psi))_{L^4/3(B)}, (7.21)
\]
Now, choose \( R \) and \( C_0 \) so that \( CR \delta \|d\phi\|_{L^2(B)} < \frac{1}{2} \). We obtain from (7.20) and (7.21) that
\[
\|\nabla(\psi)\|_{L^4/3(B)} + \|\psi\|_{L^4(B)} \leq C \|\nabla \eta\|_{H^1/2(B)} + C(1, \|\psi\|_{L^\infty}) \|\eta\|_{L^4/3(B)} (7.22)
\]
which implies
\[
\|\nabla \eta\|_{L^4/3(B)} + \|\psi\|_{L^4(B)} \leq C \|\nabla \eta\|_{H^1/2(B)} + C(1, \|\psi\|_{L^\infty}) \|\eta\|_{L^4/3(B)} (7.23)
\]
For \( \xi \in W^{1,2\alpha}(B, \mathbb{R}^L) \), we have
\[
\int_B (1 + |d\phi|^2)^{\alpha-1} g^{\beta\gamma} \nabla_\beta \phi \nabla_\gamma \xi = - \int \text{div}((1 + |d\phi|^2)^{\alpha-1} \nabla \phi) \xi = \int_B G \xi. (7.24)
\]
Choosing \( \xi = g^{\sigma\tau} \nabla_\sigma(\xi^2 \nabla_\tau \phi) \), where \( \xi \in C_0^\infty(B, \mathbb{R}) \) will be determined later, we get
\[
\int_B g^{\beta\gamma} g^{\sigma\tau} \nabla_\sigma((1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi) \nabla_\gamma(\xi^2 \nabla_\tau \phi)
= - \int_B g^{\beta\gamma} g^{\sigma\tau}(1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi \nabla_\sigma \nabla_\gamma(\xi^2 \nabla_\tau \phi)
= - \int_B g^{\beta\gamma} g^{\sigma\tau}(1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi \nabla_\gamma \nabla_\sigma(\xi^2 \nabla_\tau \phi) - \xi^2 (R^M)_{\beta\gamma\tau} \nabla_\rho \phi (7.25)
\]
Note that
\[
g^{\beta\gamma} g^{\sigma\tau} \nabla_\sigma((1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi) \nabla_\gamma(\xi^2 \nabla_\tau \phi)
= g^{\beta\gamma} g^{\sigma\tau}(1 + |d\phi|^2)^{\alpha-1} \nabla_\sigma \nabla_\beta \phi + 2(\alpha - 1)(1 + |d\phi|^2)^{\alpha-2} \nabla_\sigma(\nabla_\beta \phi, \nabla_\gamma \phi)\nabla_\beta \phi
\cdot (\xi^2 \nabla_\gamma \nabla_\tau \phi + 2 \xi \nabla_\gamma \xi \nabla_\tau \phi)
= (1 + |d\phi|^2)^{\alpha-1} (\nabla_\beta \phi)^2 \xi^2 + 2 \xi(1 + |d\phi|^2)^{\alpha-1} g^{\beta\gamma} g^{\sigma\tau} \nabla_\sigma \nabla_\beta \phi \nabla_\gamma \xi \nabla_\tau \phi
+ (\alpha - 1)(1 + |d\phi|^2)^{\alpha-2} g^{\beta\gamma} g^{\sigma\tau} \nabla_\sigma \nabla_\gamma \phi \nabla_\beta \phi \nabla_\gamma \xi (7.26)
\]
We control the last three terms as follows:

\[
|2\xi (1 + |d\phi|^2)^{\alpha-1} g^{\beta\gamma} \nabla^2_{\alpha\beta} \phi \nabla^2_{\gamma\tau} \phi| \leq 2(1 + |d\phi|^2)^{\alpha-1} |d\phi||\xi\nabla\xi||\nabla^2\phi|, \tag{7.27}
\]

\[
|2(\alpha - 1)(1 + |d\phi|^2)^{\alpha-2} g^{\beta\gamma} g^{\sigma\tau} \langle \nabla_\sigma \nabla_\phi, \nabla_\tau \phi \rangle \nabla_\beta \phi \nabla^2_{\gamma\tau} \phi \xi^2| \leq 2(\alpha - 1)(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi|^2 \xi^2, \tag{7.28}
\]

\[
|4\xi (\alpha - 1)(1 + |d\phi|^2)^{\alpha-2} g^{\beta\gamma} g^{\sigma\tau} \langle \nabla_\sigma \nabla_\phi, \nabla_\tau \phi \rangle \nabla_\beta \phi \nabla_\gamma \phi \xi| \leq 4(\alpha - 1)(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi||\nabla\phi|^3|\xi\nabla\xi| \leq 4(\alpha - 1)(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi||\nabla\phi||\xi\nabla\xi|. \tag{7.29}
\]

Plugging these estimates into (7.26), we have

\[
g^{\beta\gamma} g^{\sigma\tau} \nabla_\sigma ((1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi \nabla_\gamma \phi) \nabla_\phi (\xi^2 \nabla_\tau \phi) \geq (1 - 2(\alpha - 1))(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi|^2 \xi^2 - (2 + 4(\alpha - 1))(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi||\nabla\phi||\xi\nabla\xi| \tag{7.30}
\]

\[
\geq \frac{1}{2}(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi|^2 \xi^2 - 3(1 + |d\phi|^2)^{\alpha-1}|\nabla^2\phi||\nabla\phi||\xi\nabla\xi|. \tag{7.31}
\]

For the integrands in the left-hand side of (7.25), we have the estimates

\[
- \int_B g^{\beta\gamma} g^{\sigma\tau} (1 + |d\phi|^2)^{\alpha-1} \nabla_\beta \phi \left( R^M \right)_{\gamma\tau} \nabla_\rho \phi \xi^2 \leq C_M (1 + |d\phi|^2)^{\alpha-1} |\nabla^2\phi|^2 \xi^2 \tag{7.32}
\]

and

\[
g^{\sigma\tau} \nabla_\sigma G \nabla_\tau \phi \xi^2 \leq |d\phi||\nabla G|^2 \leq C_N |\xi^2| \nabla \phi \left( (1 + |d\phi|^2)^{\alpha-1} |d\phi|^3 + (1 + |d\phi|^2)^{\alpha-1} |\nabla^2\phi| \right.
\]

\[
+ (\alpha - 1)(1 + |d\phi|^2)^{\alpha-2} |\nabla^2\phi||\nabla\phi||\xi\nabla\phi| + |\nabla^2\phi||\nabla\phi||\psi| + |\nabla^2\phi||\nabla\psi||\psi| + |\nabla^2\phi||\nabla\psi||\psi|^2 + C_3 (1 + |\psi|^2)|d\phi|^2 \xi^2 + C_3 (1 + |\psi|)^2|d\phi||\nabla\psi||\xi^2|, \tag{7.33}
\]

where we have replaced the constant $C$ in (F3) by $C_3$ and take $C_N > 1$. By (7.30), (7.31) and (7.32), (7.25) becomes

\[
\int_B (1 + |d\phi|^2)^{\alpha-1} |\nabla^2\phi|^2 \xi^2 \leq 6 \int_B (1 + |d\phi|^2)^{\alpha-1} |\nabla^2\phi||\nabla\phi||\xi\nabla\phi| + C_M \int_B (1 + |d\phi|^2)^{\alpha-1} |\nabla^2\phi|^2 \xi^2
\]

\[
+ C_N \int_B (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla^2\phi|^2 + C_N \int_B (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla^2\phi|^2 \xi^2
\]

\[
+ C_N \int_B |\nabla^2\phi||\nabla\phi||\psi| \xi^2 + C_N \int_B |\nabla^2\phi||\nabla\psi||\psi| \xi^2 + C_N \int_B |\nabla^2\phi||\nabla\psi||\psi|^2 \xi^2 + C_3 (1 + |\psi|^2)|d\phi|^2 \xi^2 + C_3 (1 + |\psi|)^2|d\phi||\nabla\psi||\xi^2| \]

\[
=: I + II + III + IV + V + VI + VII + VIII + IX.
\]
For small $\varepsilon_1 > 0$, we have
\[ I \leq 6\varepsilon_1 \int_B (1 + |d\phi|^2)\varepsilon^{-1} |\nabla^2 \phi|^2 \varepsilon^2 + \frac{6}{\varepsilon_1} \int_B (1 + |d\phi|^2)\varepsilon^{-1} |d\phi|^2 |\nabla \xi|^2 \]  
(7.34)
and
\[ IV \leq CN\varepsilon_1 \int_B (1 + |d\phi|^2)\varepsilon^{-1} |\nabla^2 \phi|^2 \varepsilon^2 + \frac{CN}{\varepsilon_1} \int_B (1 + |d\phi|^2)\varepsilon^{-1} |d\phi|^4 \varepsilon^2. \]  
(7.35)
Choosing $\eta = |d\phi|\xi$ in (7.23), we obtain
\[ \||\nabla \psi||d\phi|\xi||L^{4/3}(B) + ||\psi|d\phi|\xi||L^{4}(B) \leq C\||\nabla (|d\phi|\xi)||\psi||L^{4/3}(B) \]
\[ + C(C_1, \||\psi||L^{\infty})||d\phi|\xi||L^{4/3}(B). \]  
(7.36)
Now, we control the remaining terms in the right-hand side of (7.33) as follows:
\[ V \leq CN\varepsilon_1 \int_B |d\phi|^2 |\psi|^4 \varepsilon^2 + \frac{CN}{\varepsilon_1} \int_B |d\phi|^4 \varepsilon^2 \]
\[ \leq CN\varepsilon_1 \left( \int_B |\psi|^4 \right)^{1/2} \left( \int_B |\psi|^4 |d\phi|^4 \varepsilon^4 \right)^{1/2} + \frac{CN}{\varepsilon_1} \int_B |d\phi|^4 \varepsilon^2 \]  
(7.37)
\[ \leq 2CN^2\varepsilon_1 \left( \int_B |\psi|^4 \right)^{1/2} \||\nabla (|d\phi|\xi)||\psi||L^{4/3}(B) \]
\[ + 2CN^2(C_1, \||\psi||L^{\infty})\varepsilon_1 \left( \int_B |\psi|^4 \right)^{1/2} |||d\phi|\xi||L^{4/3}(B) + \frac{CN}{\varepsilon_1} \int_B |d\phi|^4 \varepsilon^2, \]
where we denote $C(C_1, \||\psi||L^{\infty})^2$ by $C^2(C_1, \||\psi||L^{\infty})$. By
\[ \||\nabla (|d\phi|\xi)||\psi||L^{4/3}(B) \]
\[ \leq 2|||\nabla^2 \phi||\psi||L^{4/3}(B) + 2|||d\phi||\nabla \xi||\psi||L^{4/3}(B) \]
\[ \leq 2 \left( \int_B |\nabla^2 \phi|^2 \varepsilon^2 \right) \left( \int_B |\psi|^4 \right)^{1/2} + 2 \left( \int_B |d\phi|^2 |\nabla \xi|^2 \right) \left( \int_B |\psi|^4 \right)^{1/2} \]  
(7.38)
\[ \leq 2 \left( \int_B |\psi|^4 \right)^{1/2} \left( \int_B |\nabla^2 \phi|^2 \varepsilon^2 + \int_B |d\phi|^2 |\nabla \xi|^2 \right), \]
we have
\[ V \leq 4CN^2\varepsilon_1 \left( \int_B |\psi|^4 \right)^{1/2} \left( \int_B |\nabla^2 \phi|^2 \varepsilon^2 + \int_B |d\phi|^2 |\nabla \xi|^2 \right) \]
\[ + 2CN^2(C_1, \||\psi||L^{\infty})\varepsilon_1 \left( \int_B |\psi|^4 \right)^{1/2} |||d\phi|\xi||L^{4/3}(B) + \frac{CN}{\varepsilon_1} \int_B |d\phi|^4 \varepsilon^2, \]  
(7.39)
\[ VI \leq CN|||\nabla (|d\phi|\xi)|||L^{4/3}(B) ||d\phi|\xi||L^{4}(B) \]
\[ \leq 2CN^2|||\nabla^2 (|d\phi|\xi)|||L^{4/3}(B)^2 + 2CN^2(C_1, \||\psi||L^{\infty})||d\phi|\xi||L^{4/3}(B) \]
\[ \leq 4CN^2 \left( \int_B |\psi|^4 \right)^{1/2} \left( \int_B |\nabla^2 \phi|^2 \varepsilon^2 + \int_B |d\phi|^2 |\nabla \xi|^2 \right) \]
\[ + 2CN^2(C_1, \||\psi||L^{\infty})||d\phi|\xi||L^{4/3}(B), \]  
(7.40)
\[ VII \leq \frac{1}{2} \int_B |\nabla^2 \phi|^2 \varepsilon^2 + \frac{C^2}{2} \int_B |d\phi|^2 |\psi|^4 \varepsilon^2. \]
\[
\begin{align*}
&\leq \frac{1}{2} \int_B |\nabla^2 \phi|^2 \xi^2 + C_N^2 C^2 \left( \int_B |\psi|^4 \right)^{1/2} \| \nabla (|d\phi| \xi) \| \| \psi \|_{L^{4/3}(B)}^2 \\
&+ C_N^2 C^2 (C_1, \|\psi\|_{L^{\infty}}) \left( \int_B |\psi|^4 \right)^{1/2} \|d\phi| \xi \|_{L^{4/3}(B)}^2 \\
&\leq \frac{1}{2} \int_B |\nabla^2 \phi|^2 \xi^2 + 2 C_N C^2 \left( \int_B |\psi|^4 \right) \left( \int_B |\nabla^2 \phi|^2 \xi^2 + \int_B |d\phi|^2 |\nabla \xi|^2 \right) \\
&+ C_N^2 C^2 (C_1, \|\psi\|_{L^{\infty}}) \left( \int_B |\psi|^4 \right)^{1/2} \|d\phi| \xi \|_{L^{4/3}(B)}^2
\end{align*}
\]

and

\[
IX \leq C (C_3, \|\psi\|_{L^{\infty}}) R^{1/2} \|d\phi| \nabla \psi \| \xi \|_{L^{4/3}(B)} \\
\leq C (C_3, \|\psi\|_{L^{\infty}}) R^{1/2} + C (C_3, \|\psi\|_{L^{\infty}}) R^{1/2} \|d\phi| \nabla \psi \| \xi \|_{L^{4/3}(B)}^2 \\
\leq 2 C (C_3, \|\psi\|_{L^{\infty}}) R^{1/2} \left( \int_B |\psi|^4 \right)^{1/2} \left( \int_B |\nabla^2 \phi|^2 \xi^2 + \int_B |d\phi|^2 |\nabla \xi|^2 \right)
\]

\[
\quad + C (C_3, \|\psi\|_{L^{\infty}}) R^{1/2},
\]

where we have used \(0 \leq \xi \leq 1\). Plugging these estimates into (7.33) and choosing \(\varepsilon_1\) and \(R\) so small that

\[
\max\{4 C_N C^2, 2 C (C_3, \|\psi\|_{L^{\infty}}) \} (1 + \|\psi\|_{L^4(B)}^4) < \frac{1}{12}\]

and \((6 + C_N) \varepsilon_1 < \frac{1}{12}\),

we get

\[
\frac{1}{12} \int_B (1 + |d\phi|^2)^{\alpha - 1} |\nabla^2 \phi|^2 \xi^2 \\
\leq \frac{6}{\varepsilon_1} \int_B (1 + |d\phi|^2)^{\alpha - 1} |d\phi|^2 |\nabla \xi|^2 + \frac{C_N}{\varepsilon_1} \int_B (1 + |d\phi|^2)^{\alpha - 1} |d\phi|^4 \xi^2 \\
+ C \int B (1 + |d\phi|^2)^{\alpha - 1} |\nabla \phi|^2 \xi^2 + C_N \int_B (1 + |d\phi|^2)^{\alpha - 1} |d\phi|^4 \xi^2 \\
+ \frac{1}{3} \int_B |d\phi|^2 |\nabla \xi|^2 + \frac{C_N}{\varepsilon_1} \int_B |d\phi|^4 \xi^2 + 5 C_N^2 C^2 (C_1, \|\psi\|_{L^{\infty}}) \|d\phi\|_{L^{4/3}(B)}^2 \\
+ C (C_3, \|\psi\|_{L^{\infty}}) (1 + \|d\phi\|_{L^2}^2).
\]

Therefore, we obtain

\[
\int_B (1 + |d\phi|^2)^{\alpha - 1} |\nabla^2 \phi|^2 \xi^2 \\
\leq C \int_B (1 + |d\phi|^2)^{\alpha - 1} |d\phi|^2 |\nabla \xi|^2 + C \int_B (1 + |d\phi|^2)^{\alpha - 1} |d\phi|^4 \xi^2 + C \int_B |d\phi|^{2\alpha} + C.
\]

Now, for \(\varepsilon > 0\), let \(\rho > 0\) be as in Lemma 7.3, and choose a cut-off function \(\xi \in C_0^\infty(B(x_1, \rho)) \subset B(x_0, R)\) such that

\[
0 \leq \xi \leq 1, \xi = 1 \text{ in } B(x_1, \rho/2), |\nabla \xi| \leq \frac{4}{\rho} \text{ in } B(x_1, \rho).
\]
Denoting $B_p := B(x_1, \rho)$ for simplicity, we get
\[
\int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^4 \xi^2 \leq 2 \varepsilon \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |\nabla (|d\phi|\xi)|^2 + 2 \varepsilon \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla \xi|^2
\]
\[
+ C \varepsilon \left( \int_{B_p} |d\phi|^4 |\nabla \xi|^4 \right)^{\frac{1}{2}} + C \int_{B_p} |d\phi|^2.
\]

It follows from (7.36) and (7.38) that
\[
\| \psi \|_{1/3(B_p)}^2 \leq 2 C^2 \| \nabla (|d\phi|\xi) \psi \|_{1/3(B_p)}^2 + 2 C (C_1, \| \psi \|_{L^\infty}) \| d\phi \|_{1/3(B_p)}^2
\]
\[
\leq 4 C^2 \left( \int_{B_p} |d\phi|^4 \right)^{\frac{1}{2}} \left( \int_{B_p} |\nabla^2 \phi|^2 \xi^2 + \int_{B_p} |d\phi|^2 |\nabla \xi|^2 \right)
\]
\[
+ 2 C^2 (C_1, \| \psi \|_{L^\infty}) \| d\phi \|_{1/3(B_p)}^2.
\]

Therefore,
\[
\int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^4 \xi^2 \leq 2 \varepsilon \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |\nabla^2 \phi|^2 \xi^2 + 2 \varepsilon \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla \xi|^2
\]
\[
+ C \varepsilon \left( \int_{B_p} |\nabla^2 \phi|^2 \xi^2 + \int_{B_p} |d\phi|^2 |\nabla \xi|^2 \right)
\]
\[
+ C \varepsilon \| d\phi \|_{1/3(B_p)}^2 + C \int_{B_p} |d\phi|^2
\]
\[
\leq C \varepsilon \left( \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |\nabla^2 \phi|^2 \xi^2 + \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla \xi|^2 \right)
\]
\[
+ C \int_{B_p} |d\phi|^{2\alpha} + C.
\]

where the constants $C$ are different between lines as before. Substituting (7.48) into (7.45), we have
\[
\int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |\nabla^2 \phi|^2 \xi^2 \leq C \int_{B_p} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 |\nabla \xi|^2 + C \int_{B_p} |d\phi|^{2\alpha} + C.
\]
hence,
\[
\int_{B_{\rho/2}} (1 + |d\phi|^2)^{\alpha-1} |\nabla^2 \phi|^2 \leq \frac{C}{\rho^2} \int_{B_{\rho}} (1 + |d\phi|^2)^{\alpha-1} |d\phi|^2 + C \int_{B_{\rho}} |d\phi|^{2\alpha} + C
\]  
(7.50)

Covering \( B(x_0, \frac{\rho}{2} ) \) with \( B(x_1, \frac{\rho}{2} ) \) and using (7.50) we obtain (7.18).

Now we can prove the main theorem in this section.

**Proof of Theorem 7.1** First we show that \( \phi \in W^{2,2} \cap W^{1,4}(B(x_0, \frac{\rho}{2} ), N) \). This can be done just by replacing weak derivatives by difference quotients in the proof of Lemma 7.4. Denote
\[
\Delta^h \phi(x) := \frac{\phi(x + hE_i) - \phi(x)}{h},
\]  
(7.51)

where \((E_1, \cdots, E_L)\) is an orthonormal basis of \(\mathbb{R}^L\) and \(h \in \mathbb{R}\). \(\Delta^h = (\delta^h_1, \cdots, \delta^h_L)\). Similar to (7.45), we have
\[
\int_{B(x_0, R)} |\nabla (\Delta^h \phi) |^2 \xi^2
\leq C \int_{B(x_0, R)} (1 + |\Delta^h \phi|^2) |\nabla \xi|^2 + C \int_{B(x_0, R)} (1 + |d\phi|^2)^{\alpha-1} |\nabla \phi|^2 |\Delta^h \phi|^2 \xi^2
+ C \int_{B(x_0, R)} |d\phi|^{2\alpha} + C
\]  
(7.52)

Using
\[
C \int_{B(x_0, R)} (1 + |\Delta^h \phi|^2) |\nabla \xi|^2 \leq C \int_{B(x_0, R)} (1 + |d\phi|^2)^{\alpha} |\nabla \xi|^2
\]  
(7.53)

and applying the Lemma 7.3 to the second term in the right-hand side of (7.52), we obtain
\[
\int_{B(x_1, \frac{\rho}{2} )} |\nabla (\Delta^h \phi) |^2 \xi^2 \leq \frac{C}{\rho^2} \int_{B(x_1, \rho)} (1 + |d\phi|^2)^{\alpha} + C.
\]  
(7.54)

Then by Lemma A.2.2 in [11] implies the weak derivative \(\nabla^2 \phi\) exists and (7.18) still holds.

Since \(\phi \in W^{2,2}\), we have \(\phi \in W^{1,p}\) for any \(p > 0\). Together with the Lemma 7.2 and the equation (7.1), we know \(\phi \in W^{2,p}\) for any \(p > 0\). Thus, \(\phi \in C^{1,\gamma}\). By the elliptic estimates for the Eq. (7.2), we have \(\psi \in C^{1,\gamma}\). Then the standard arguments yield that both \(\phi\) and \(\psi\) are smooth. This completes the proof.

\[\square\]

8 \(\alpha\)-Dirac-harmonic maps

In this section, we want to approximate the \(\alpha\)-Dirac-harmonic maps by the perturbed \(\alpha\)-Dirac-harmonic maps. Precisely, by Theorem 6.11 and Theorem 7.1, we have a sequence of perturbed \(\alpha\)-Dirac-harmonic maps \((\phi_k, \psi_k)\), which are the critical points of the functionals
\[
\mathcal{L}_\alpha^k (\phi, \psi) = \frac{1}{2} \int_M (1 + |d\phi|^2)^{\alpha} + \frac{1}{2} \int_M \langle \psi, \mathcal{D} \psi \rangle M \otimes_{\phi^*TN} - \frac{1}{k} \int_M F(\phi, \psi),
\]  
(8.1)
where $F$ satisfies the assumptions in Theorem 6.11 and Theorem 7.1. If $(\phi_n, \psi_n)$ converges to $(\phi, \psi)$ smoothly, then we get the existence of nontrivial $\alpha$-Dirac-harmonic maps. We now come to the $\varepsilon$-regularity estimate which gives a uniform control on the sequence in Sobolev space.

**Theorem 8.1** Suppose $F$ satisfies

(F6) $|F_\psi(\phi, \psi)| \leq C|\psi|^r - 1$ for $3 < r \leq 2 + 2/\alpha$,

(F7) $|F_\phi(\phi, \psi)| \leq C|\psi|^q$ for $q \geq 0$.

There is $\varepsilon_0 > 0$ and $\alpha_0 > 0$ such that if $(\phi, \psi): (D, g_{\beta\gamma}) \to (N, g_{ij})$ is a smooth perturbed $\alpha$-Dirac-harmonic map satisfying

$$\int_M (|d\phi|^{2\alpha} + |\psi|^4) \leq \Lambda < +\infty \text{ and } \int_D |d\phi|^2 \leq \varepsilon_0$$

(8.2)

for $1 \leq \alpha < \alpha_0$, then we have

$$\|d\phi\|_{\tilde{D}, 1, p} + \|\psi\|_{\tilde{D}, 1, p} \leq C(D, N, \Lambda, p)(\|d\phi\|_{D, 0, 2} + \|\psi\|_{D, 0, 4}),$$

(8.3)

for any $\tilde{D} \subset D$ and $p > 1$, where $C(D, N, \Lambda, p)$ denotes a constant depending on $D, N, \Lambda$ and $p$.

Note that (8.4) is a consequence of the proof of Lemma 7.2 and (F6). This is different from the proof in [3]. The proof of Theorem 8.1 is based on the following lemma, which is a generalization of Lemma 6.1.2 in [15].

**Lemma 8.2** There are $\varepsilon_0 > 0$ and $\alpha_0 > 0$ such that if $(\phi, \psi)$ and $F$ satisfy (8.2) and (F6), (F7), respectively, then

$$\|\phi\|_{D_1, 1, 4} \leq C(N, D_1)(\|d\phi\|_{D_1, 0, 2} + \|\psi\|_{D_1, 0, 4} + \|\psi\|_{D_1, 2, 0}).$$

(8.5)

**Proof** Choose a cut-off function $\eta \in [0, 1]$ with $\eta|_{D_1} \equiv 1$ and $\text{Supp}(\eta) \subset D$. As before, $(\phi, \psi)$ locally satisfies the system

$$\text{div}((1 + |d\phi|^2)^{\alpha - 1} \nabla \phi^m) = -\Gamma^m_{ijkl} \phi^i_\beta \phi^j_\gamma g^{\beta\gamma} (1 + |d\phi|^2)^{\alpha - 1} + \frac{1}{2\alpha} R^m_{ijkl} (\psi^k, \nabla \phi^j \cdot \psi^l)$$

$$- \frac{1}{\alpha} F_\phi^m (\phi, \psi),$$

(8.6)

$$\phi \psi^m = -\Gamma^m_{ij} \nabla \phi^j \cdot \psi^i + F_\psi^m (\phi, \psi).$$

(8.7)

(8.6) implies

$$\Delta \phi^m + (\alpha - 1) \frac{(\nabla^2 \phi, \nabla \phi) \nabla \phi^m}{1 + |d\phi|^2} \leq |\Gamma^m_{ijkl} \phi^i_\beta \phi^j_\gamma g^{\beta\gamma}| + \frac{1}{2\alpha} |R^m_{ijkl} (\psi^k, \nabla \phi^j \cdot \psi^l)|$$

$$+ \frac{1}{\alpha} |F_\phi^m (\phi, \psi)|.$$

(8.8)

Then

$$|\eta \Delta \phi| \leq (\alpha - 1)|\eta \nabla^2 \phi| + C_N |\nabla \phi \nabla \phi \eta| + \frac{1}{2\alpha} C_N |\psi|^2 |\nabla \phi \eta| + C |\psi|^q \eta.$$  

(8.9)
Since
\[ |\eta \nabla^2 \phi| = |\nabla^2 (\eta \phi) - \nabla \eta \nabla \phi - \nabla^2 \eta \phi| \leq |\nabla^2 (\eta \phi)| + C(|\phi| + |d\phi|) \] (8.10)
and
\[ |\nabla \phi \eta| = |\nabla (\phi \eta) - \phi \nabla \eta| \leq |\nabla (\phi \eta)| + C|\phi|, \] (8.11)
we have
\[ |\eta \Delta \phi| \leq (\alpha - 1)|\nabla^2 (\eta \phi)| + C_N |\nabla \phi \nabla (\phi \eta)| + \frac{C_N}{2} |\psi|^2 |\nabla \phi \eta| + C|\psi|^q \eta + C(|\phi| + |d\phi|). \] (8.12)
Therefore,
\[ |\Delta (\eta \phi)| \leq (\alpha - 1)|\nabla^2 (\eta \phi)| + C_N |\nabla \phi \nabla (\phi \eta)| + C_N |\psi|^2 |\nabla \phi \eta| + C|\psi|^q \eta + C(|\phi| + |d\phi|). \] (8.13)
Thus, for any \( p > 1 \), we get
\[ \|\Delta (\eta \phi)\|_{D,0,p} \leq (\alpha - 1)\|\eta \phi\|_{D,2,p} + C_N \|\nabla \phi \nabla (\phi \eta)\|_{D,0,p} + C_N \|\psi|^2 \nabla \phi \eta\|_{D,0,p} + C\|\psi|^q \eta\|_{D,0,p} + C\|\phi\|_{D,1,p}. \] (8.14)
Without loss of generality, we assume \( \int_D \phi = 0 \) so that \( \|\phi\|_{D,1,p} \leq C\|d\phi\|_{D,0,p} \). By taking \( p = 4/3 \) in the inequality above and Hölder’s inequality, we obtain
\[ \|\nabla \phi \nabla (\phi \eta)\|_{D,0,4/3} \leq \|\nabla \phi\|_{D,0,4/3} \|\nabla (\phi \eta)\|_{D,4/3}, \] (8.15)
\[ \|\psi|^2 \nabla \phi \eta\|_{D,0,4/3} \leq \|\psi\|_{D,0,4}^2 \|\nabla \phi \eta\|_{D,0,2}, \] (8.16)
and
\[ \|\|\psi|^q \eta\|_{D,0,4/3} \leq \|\psi\|_{D,0,4}^q. \] (8.17)
On the other hand, let \( c(p) \) be the operator norm of \( \Delta^{-1} : L^p(D) \to W^{2,p}(D) \cap W^{1,2}_0(D) \). Then we get
\[ \|\Delta (\eta \phi)\|_{D,0,p} \geq (c(p))^{-1} \|\eta \phi\|_{D,2,p}. \] (8.18)
Plugging the above estimates into (8.14), we have
\[ ((c(4/3))^{-1} - (\alpha - 1))\|\eta \phi\|_{D,2,4/3} \leq C(N, D_1)(\|\nabla \phi\|_{D,0,2} \|\phi \eta\|_{D,1,4} + \|\psi\|_{D,0,4}^2 \|d\phi\|_{D,0,2} + \|\psi\|_{D,0,4}^q \|d\phi\|_{D,0,4/3}). \] (8.19)
Together with the Sobolev inequality \( \|\phi \eta\|_{D,1,4} \leq C_1 \|\phi \|_{D,2,4/3} \), this implies
\[ ((c(4/3))^{-1} - (\alpha - 1))C_1^{-1} \leq C(N, D_1)(\|\psi\|_{D,0,4}^2 + \|d\phi\|_{D,0,2} + \|\psi\|_{D,0,4}^q \|d\phi\|_{D,0,4/3}). \] (8.20)
Now we choose \( \alpha_0, \varepsilon_0 > 0 \) such that
\[ (c(4/3))^{-1} - (\alpha_0 - 1) > \frac{1}{2}(c(4/3))^{-1} \] (8.21)
and
\[ \varepsilon_0 \leq \frac{1}{2} \left( \frac{(c(4/3))^{-1} - (\alpha_0 - 1)}{C(N, D_1)} \right), \] (8.22)
then we get (8.5). Thus we complete the proof.

\[ \square \]

**Proof of Theorem 8.1** Choose \( \tilde{D} \subset D_2 \subset D_1 \subset D \) and a cut-off function \( \eta \in [0, 1] \) with \( \eta|_{D_2} \equiv 1 \) and \( \text{Supp}(\eta) \subset D_1 \). Taking \( p = 2 \) in (8.14) on \( D_1 \) (we temporarily assume \( \int_{D_1} \phi = 0 \), we have
\[
\| \Delta(\eta \phi) \|_{D_1,0,p} \leq (\alpha - 1)\| \eta \phi \|_{D_1,2,2} + C_N \| \nabla \phi \nabla (\phi \eta) \|_{D_1,0,2} + C_N \| \psi^2 \nabla \phi \eta \|_{D_1,0,2} + C \| \| \psi \|^q \eta \|_{D_1,0,2} + C \| \phi \|_{D_1,1.2}. \] (8.23)
As in the proof of Lemma 8.2, we get
\[
\| \eta \phi \|_{D_1,2,2} \leq C(N, D_1)(\| \nabla \phi \|^2_{D_1,0,4} + \| \psi \|^2_{D_1,0,4} \| \nabla \phi \|_{D_1,0,4} + \| \psi \|^q \| \phi \|_{D_1,0,2} + \| \phi \|_{D_1,1.2}) \leq C(N, D_1)(\| \phi \|^2_{D_1,1.4} + \| \psi \|^4_{D_1,0,4} + \| \psi \|^q_{D_1,0,4} + \| \phi \|_{D_1,1.4}). \] (8.24)
By Lemma 8.2, we obtain
\[
\| \phi \|_{D_2,2,2} \leq C(N, D_1)(\| \psi \|^2_{D_1,0,4} + \| \psi \|^4_{D_1,0,4} + \| \phi \|_{D_1,0,2} + \| \phi \|_{D_1,1.2}) \leq C(N, D_1)(\| \psi \|^2_{D_1,0,4} + \| \psi \|^4_{D_1,0,4} + \| \phi \|_{D_1,0,2}). \] (8.25)
The Sobolev inequality gives us
\[
\| d\phi \|_{D_2,0,p} \leq C(N, D_1)(\| \psi \|^2_{D_1,0,4} + \| \psi \|^4_{D_1,0,4} + \| \psi \|^q_{D_1,0,4} + \| \phi \|^2_{D_1,0,4} + \| \phi \|_{D_1,0,2}) \leq C(D, N, \Lambda, p)(\| \psi \|^q_{D_1,0,4} + \| \phi \|^2_{D_1,0,4} + \| \phi \|_{D_1,0,2}). \] (8.26)
for any \( p > 1 \). This also holds for \( \phi \) without \( \int_{D_1} \phi = 0 \).

Now, since \( \phi \in W^{1,p} \) and \( \psi \in L^p \) for any \( p > 1 \), the estimates in the theorem follow from the standard \( L^p \)-estimate for the Dirac operator and the \( W^{2,p} \)-estimate for the Laplace operator immediately.

\[ \square \]

With the \( \varepsilon \)-regularity in hand, one can easily prove the following theorem.

**Theorem 8.3** Let \( (\phi_k, \psi_k) \) be smooth critical points of the functional \( L_k^\alpha \) in (8.1) with uniformly bounded energy:
\[
E_\alpha(\phi_k, \psi_k; M) := \int_M (|d\phi|^2 + |\psi|^4) \leq \Lambda < +\infty. \] (8.27)
Suppose \( F \) satisfies (F6) and (F7). Then there are a subsequence, still denoted by \( \{(\phi_k, \psi_k)\} \), and a smooth \( \alpha \)-Dirac-harmonic map \( (\phi, \psi) \) such that
\[
(\phi_k, \psi_k) \rightarrow (\phi, \psi) \text{ in } C^\infty_{\text{loc}}(M) \] (8.28)
Define the energy concentration set to be
\[ S := \bigcap_{r > 0} \{ x \in M \mid \lim_{k \to \infty} E(\phi_k; B(x, r)) \geq \varepsilon_0 \} \] (8.29)
where \( \varepsilon_0 \) is the positive constant in Theorem 8.1 and \( B(x, r) \) is the geodesic ball in \( M \) with center at \( x \) and radius \( r \). Suppose \( S \) is not empty, let us say \( p \in S \). By the definition, we have
\[ E(\phi_k; B(x_k, r_k)) = \frac{\varepsilon_0}{2} \] (8.30)
with \( x_k \to p \) and \( r_k \to 0 \) as \( k \to \infty \). Let
\[ u_k(x) = \phi_k(x_k + r_k x), \quad v_k(x) = r_k^{\frac{1}{2}} \psi_k(x_k + r_k x). \] (8.31)
Then (8.30) becomes
\[ E(u_k; B_1) = \frac{\varepsilon_0}{2}. \] (8.32)
However,
\[ E_\alpha(u_k; B_1) := \int_{B_1} |du_k|^{2\alpha} = r_k^{2\alpha-2} \int_{B(x_k, r_k)} |d\phi_k|^{2\alpha} \leq r_k^{2\alpha-2} \Lambda \to 0 \] (8.33)
as \( k \to \infty \). This contradicts (8.32). Thus, \( S \) is empty.

Now, for any point \( x \in M \), there exist \( r > 0 \) and a subsequence of \( k \to \infty \) such that
\[ E(\phi_k; B(x, r)) < \varepsilon_0. \] (8.34)
Then by the \( \varepsilon \)-regularity Theorem 8.1 and standard elliptic theory, we have
\[ \|\phi_k\|_{C^l(B(x, r/4))} + \|\psi_k\|_{C^l(B(x, r/4))} \leq C \] (8.35)
for any \( l > 0 \). Since \( \{(\phi_k, \psi_k)\} \) has uniformly bounded energy, up to a subsequence if necessary, \( \{(\phi_k, \psi_k)\} \) has a weak limit \( (\phi, \psi) \). Then the regularity Theorem 7.1 tells us that \( (\phi, \psi) \) is a smooth \( \alpha \)-Dirac-harmonic map, and (8.35) implies (8.28).

\[ \square \]
