Abstract

**Background:** Suan-Zao-Ren Decoction (SZRD) has been widely used to treat neurological illnesses, like dementia, insomnia, and depression. However, mechanisms underlying SZRD’s improvement in cognitive function remains unclear. In this study, we examined SZRD’s effect on APP/PS1 transgenic mice as well as mechanisms associated with SZRD’s action in alleviating neuroinflammation and improving the synaptic plasticity.

**Methods:** The APP/PS1 mice were treated with different dosages of SZRD (12.96 and 25.92 g/kg/d, in L-SZRD and H-SZRD groups, respectively) for four weeks. Morris water maze was conducted to determine changes in behaviors of the mice after the treatment. Meanwhile, in the samples of the hippocampus, Nissl staining and Golgi-Cox staining were used to detect the synaptic plasticity, Western blot (WB) was employed to test expressions of Aβ1-42, APP, ADAM10, BACE1, PS1, IDE, IBA1, GFAP, PSD95 and SYN, as well as the expressions of JAK2, STAT3 and their phosphorylation patterns to detect involvement of JAK2/STAT3 pathway. Besides, we examined the serum contents of IL-1β, IL-6, and TNF-α using ELISA.

**Results:** Compared to the APP/PS1 mice without any treatment, SZRD, especially the L-SZRD, significantly ameliorated cognitive impairment of the APP/PS1 mice with decreases in the loss of neurons and Aβ plaque deposition as well as improvement of synaptic plasticity in the hippocampus (all $P<0.05$). Also, SZRD, in particular, the L-SZRD markedly inhibited the serum IL-6, IL-1β, and TNF-α, while reducing the expression of p-JAK2-Tyr1007 and p-STAT3-Tyr705 in the hippocampus of the APP/PS1 mice (all $P<0.05$).

**Conclusion:** The SZRD, especially the L-SZRD, may improve the cognitive impairment and ameliorate the neural degeneration in APP/PS1 transgenic mice through decreasing Aβ accumulation and inhibiting neuroinflammation via JAK2/STAT3 pathway.

Introduction

Alzheimer’s disease (AD) is a chronic degenerative illness that occurs in the brain and is one of the common kinds of dementia[1, 2]. Based on the AD’s World Report 2018, the patients with AD around the world exceeded 47 million in 2018[3]. One patient is diagnosed with dementia every three seconds[4]. With the growth of the aging population, the AD prevalence in the world is increasing rapidly. It is estimated that AD patients in the world will be more than 150 million by 2050. Currently, the drugs used for AD treatment are composed of Donepezil, rivastigmine, galanthamine and memantine[5, 6]. But their therapeutic effects are limited. These drugs can only alleviate AD-associated with cognitive impairment. But they cannot fundamentally control or reverse the AD pathogenesis[7]. Thus, AD has become a public health problem, and its prevention and treatment are becoming more and more critical.

One typical pathological character of AD is the formation of senile plaques in the brain, which are induced by amyloid-β (Aβ) deposition and neurofibrillary tangles generated by exaggerated phosphorylation of tau protein in the cells[8–10]. The senile plaques and neurofibrillary tangles lead to
the loss of neurons and synaptic dysfunction. Inflammation is a double-edged sword for the pathological process of AD[11, 12]. On the one hand, inflammation can clear Aβ’s deposition. On the other hand, inflammation can also damage neurons and synapses and thereby accelerate the AD’s pathological processes[13]. Although the AD’s pathogenesis is not elucidated clearly, inflammation likely is involved in the AD’s pathological process[14]. Traditionally, microglia are activated in neuroinflammatory conditions to release pro-inflammatory factors to accelerate the AD’s progression and pathology[15]. An epidemiological study has shown that the administration of non-steroidal anti-inflammatory drugs (NSAIDs) can lower AD’s prevalence[16]. Several other studies have confirmed that IL-1β, IL-6, and TNF-α, are significantly increased in the AD experimental model[17–19]. Aβ deposition can cause neuronal loss and synaptic damage. Also, neuroinflammation induced by Aβ deposition aggravates the loss of neurons and the dysfunction of synapses[20]. Therefore, inhibition of Aβ deposition and neuroinflammation may be beneficial to AD’s management.

Janus kinase2 (JAK2)/Signal transducer and activator of transcription3 (STAT3) are involved in an important signaling pathway that regulates inflammation in the brain.[21]. Recently, some studies have shown that abnormal activation of the signaling pathway associated with JAK2/STAT3 happened in AD patients[22, 23]. Therefore, modulating the signaling pathway related to JAK2/STAT3 in the brain may effectively inhibit the AD’s pathological process.

Suan-Zao-Ren Decoction (SZRD), a well-known classic Chinese formula, was created by Zhang Zhongjing in Han Dynasty. SZRD consists of five Chinese herbal medications, including Ziziphi Spinosae Semem (Suanzaoren), Poria (Fuling), Chuanxiong Rhizoma (Chuanxiong), Anemarrhenae Rhizoma (Zhimu) and Glycyrrhizae Radix Et Praeparata Cum Melle (Zhigancao).

Since the Han Dynasty, SZRD has been widely used to treat neurological disorders, such as dementia, insomnia, and depression[24, 25]. It effectively improves the learning and memory of AD patients. These are studies showing that SZRD has a potential benefit for the AD treatment. In particular, our previous research has demonstrated that SZRD improves cognitive dysfunction through inhibiting neuroinflammation in APP/PS1 transgenic mice. However, pathological mechanisms underlying SZRD’s anti-neuroinflammation remain indefinite[26]. In this study, we examined SZRD’s effect on APP/PS1 transgenic mice and investigated mechanisms by which SZRD exerts anti-neuroinflammation and improves the synaptic plasticity.

**Methods And Materials**

**Animals**

Forty male APP/PS1 transgenic mice with Specific pathogen-free (SPF), weighing about 30 g, were purchased from Beijing HFK Bioscience Co., Ltd. (certification number SCXK 2014-0004). Six-month-old male C57BL/6J mice were bought from Beijing Vital River Laboratory Animal Technology Co., Ltd. (certification number SCXK 2016-0006). These mice were housed in the Laboratory Animal Center at the
Hubei University of Chinese Medicine. They lived with a 12-hour light/dark cycle under 23–25°C, meeting clean experimental animal feeding standards. All animals freely accessed food and water. Experimental protocols were permitted by the Chinese Association of Accreditation of Laboratory Animal Care and performed following the ethical guidelines.

**Drugs**

SZRD contains five Chinese herbal medications, namely, Ziziphi Spinosae Semem (Suanzaoren, 30 g), Poria (Fuling, 12 g), Chuanxiong Rhizoma (Chuanxiong, 12 g), Glycyrrhizae Radix Et Praeparata Cum Melle (Zhigancao, 6 g), and Anemarrhenae Rhizoma (Zhimu, 12 g), which were obtained from Jiuzhou Tong Pharmaceutical Group Co., Ltd. (Hubei, China). Donepezil hydrochloride (Aricept, 5 mg/tablet, batch number: 1706065) was produced by Eisai Pharmaceutical Co., Ltd. (Jiangsu, China).

**Preparation of SZRD extract**

All herbal ingredients were confirmed by the Department of Chinese Medicine pharmacy at the Hubei University of Chinese Medicine. Referred to Gao's report, the stock solution of SZRD was prepared. Briefly, the raw herbs were boiled in water and filtered after immersing in water for 30 minutes, which then finally made the stock solution[5].

**Reagents and antibodies**

Nissl staining solution was purchased from Servicebio (Wuhan, China; G1036). GolgiStain™ Kit was purchased from FD Neurotechnologies, Inc., (Columbia, USA; #PK401). ELISA Kits for examining, Interleukin 6 (IL-6), Interleukin 1β (IL-1β), and tumor necrosis factor-α (TNF-α) in the mouse were obtained from Cusabio Biotech Co., Ltd. (Wuhan, China; CSB-E08054m, CSB-E08054m, and CSB-E04639m, respectively). The antibodies and their epitopes on the protein molecules are displayed in Table 1, which were used for Western blot in this study.
Table 1
A list of antibodies and their epitopes on the molecule of protein used in this study

| Antibody   | Specificity | Type   | Dilution          | Source  | Catalog No |
|------------|-------------|--------|-------------------|---------|------------|
| Aβ1−42     | Rabbit      | Mono-  | 1:1000 for WB     | ABcam   | ab201060   |

Mono-, monoclonal; Poly-, polyclonal; WB, Western blot

Experimental groups

Based on the randomization table, the forty APP/PS1 transgenic mice were allocated randomly into four experimental groups, and each group included ten mice. These groups include: model group, Donepezil group (Donepezil hydrochloride, 9.2 mg/kg/d), L-SZRD (low-dose SZRD group, 12.96 g/kg/d), H-SZRD (high-dose SZRD group, 25.92 g/kg/d). Besides, ten of C57BL/6J mice were assigned to a control group. Intragastric administration in each group with the medical treatment was performed in a volume of 0.2 ml/10 g per day once a day for four weeks. The same amount of normal saline was taken in the mice in the control and model groups.

Morris water maze
We used the Morris water maze (MWM) test to examine mice's cognitive function, especially the spatial learning and memory, after four-week treatments. The MWM contains a pool, a hidden platform, and a video/computer system (version ZH-Morris; Anhui Zhenghua Biological Instrument Co., Ltd.; Anhui, China). The MWM test includes the navigation and spatial probe tests, which were taken and modified as described previously. Briefly, during the navigation test, the mice were trained to escape onto the platform within 60 s in five consecutive days. If the animal could not find the platform in the permitted 60 s, it was directed to the platform and stayed on the platform at least 15 s. On the 7th day, we removed the stage from the pool and carried out the spatial probe test. The video/computer system automatically taped the mouse's movement, the number of times as the mouse crossed the stage within 60 s was documented.

**Preparation of the serum and hippocampus samples**

Following the MWM test, four animals in each group were sacrificed by CO₂ asphyxiation followed by cervical dislocation, and the brain tissues were split into two parts. One portion of the brain was fixed by 4% paraformaldehyde for Nissl Staining and another part treated with the Golgi-Cox staining solution for the Golgi-Cox staining. The blood of the remaining six mice in each group was collected by removing eyeball. Afterward, the blood was centrifuged (3000 rpm) for 10 min at 4°C. The serum was gathered to store at -80°C. The hippocampus tissue was separated on a cold plate and put in liquid nitrogen. It was then kept at -80 °C until use.

**Nissl Staining**

After the mouse's brain was fixed with 4% paraformaldehyde for 24 h, it then was implanted into paraffin. The paraffin-embedded brain sample was serially sliced into sections (6 µm) with a microtome (CM1860S, Leica, Germany). The brain section was dewaxed with xylene and gradient ethanol. It then was rinsed with PBS solution twice, 5 min for each wash. After dustproof atmospheric drying for 24 h, Nissl staining solution was uniformly added to the brain slices, and 95% alcohol was then dropped on the slices to differentiate for 8–10 min. Following rinsing with PBS solution twice (5 min for each time), the brain slices were dehydrated with anhydrous alcohol for 15 min, permeabilized with xylene 15 min, and sealed with neutral gum. Finally, Neurons and Nissl bodies in the hippocampus were observed under a biological microscope, and the images were collected for analysis.

**Golgi-Cox staining**

According to the methods described by Jiang[27] and the instructions for using a Rapid Golgi Stain Kit (FD Neuro-Technologies, Inc., Ellicott City, MD, USA), Golgi–Cox staining was conducted with the Kit. Briefly, at room temperature, brain tissues were submerged in a mixture of solution A and solution B for two weeks. They were then put into solution C for two to seven days. Afterward, the brains were sliced into sections (100 µm) using a microtome (CM1860S, Leica, Germany) and pasted on the glass slide.
After washing with double-distilled water for four min × 2, the slides were immersed in a blend of solution C, solution D, and double-purified water.

**Enzyme-linked immunosorbent assay**

We used enzyme-linked immunosorbent assay (ELISA) to measure the contents of IL-1β, IL-6, and TNF-α in the serum. After thawing the serum samples at room temperature, the serum IL-1β, IL-6, and TNF-α were measured through the specific ELISA kit for each of them. Each sample was measured in 450 nm wavelength with Microplate Reader (Spectra MAX M5, Molecular Devices, USA).

**Western Blot**

We used Western blot to detect expressions of Aβ$_{1-42}$, APP, ADAM10, BACE1, PS1, IDE, IBA1, GFAP, PSD95, SYN, JAK2, p-JAK2, STAT3, p-STAT3, and β-actin in the mouse’s hippocampus. In each group, six samples were homogenized using RIPA lysis buffer. The homogenates were subjected to centrifugation (12000 rpm) at 4°C for 20 min for obtaining proteins. The BCA kit was used to detect protein concentration. Afterward, the protein was isolated using 10% SDS-PAGE, and it then was transferred to a Polyvinylidene fluoride (PVDF) membrane (EMD Millipore, Billerica, MA, USA). After reacting with the primary antibody overnight at 4°C, the membrane was immersed in a horseradish peroxidase-conjugated secondary antibody for two hours at room temperature. Subsequently, the greyscale images were obtained and analyzed with Image J software (v1.80; NIH, Bethesda, MD, USA).

**Statistical analysis**

Experimental data were analyzed by using SPSS 19.0 (IBM Corporation, Armonk, NY, USA), and the data were presented as mean ± standard error (SEM). One-way ANOVA was used to make comparisons among multiple groups. If the variance was homogeneous, the LSD tests were used. If not, the Dunnett T3 tests were conducted. Values were considered to be significantly different as $P<0.05$.

**Results**

**The action of SZRD in improving cognitive dysfunction in APP/PS1 transgenic mice**

In the Navigation test, in comparison with the model group, the escape latency was markedly shorter in the Donepezil group and SZRD-treated groups, particularly in the L-SZRD group ($P<0.05$; Fig. 1, panels A and C). No considerable alteration in the escape latency was noticed during the training from the first to third days among all groups. However, starting from the fourth day, mice in the SZRD-treated groups had much shorter escape latency than animals in the model group ($P<0.01$; Fig. 1, panels B and C). Moreover, Donepezil and SZRD augmented the times of crossing stage and the percentage of target quadrant.
search time \((P<0.05\) or \(0.01\); Fig. 1D-1F). These values seemed to be improved more in the L-SZRD group in the H-SZRD group. But there was no significant difference.

**Changes in the loss of hippocampal neurons in CA3 and DG in SZRD-treated APP/PS1 transgenic mice**

The AD’s pathological feature is the loss of in hippocampal neurons[28]. As shown in Fig. 2, compared to controls, the hippocampal neurons in the CA3 and DG were lost significantly in APP/PS1 transgenic mice \((P<0.01)\). However, in comparison with these transgenic mice in the model group, more neurons in CA3 and DG subsets were found \((P<0.05\) or \(0.01)\) in the Donepezil group, and both SZRD-treated groups. L-SZRD or H-SZRD had similar effects. Besides, no neuronal loss was found in CA1 and CA4 subsets in all groups.

**Influence of SZRD on the synaptic plasticity of APP/PS1 transgenic mice**

The changes in dendritic spines are commonly identified using the Golgi-Cox staining. As shown in Fig. 3, the number of spines was decreased significantly in CA1 and DG subsets in APP/PS1 transgenic mice, in comparison with controls \((P<0.01)\). However, compared to the APP/PS1 transgenic mice without any treatment, the spines in CA3 and DG subsets were markedly increased in the transgenic mice treated with Donepezil and SZRD \((P<0.05\) or \(0.01)\). There was no considerable variance in the number of spines between the groups. Further, to explore the possible mechanism by which SZRD protects synapses, we used Western blot to detect the expressions of synaptic-related proteins, such as synaptophysin (SYN) and postsynaptic density protein 95 (PSD95). We found that decreases in SYN and PSD95 in the APP/PS1 transgenic mouse’s hippocampus were extensively reversed following the remedy with Donepezil, L-SZRD, or H-SZRD, especially, with L-SZRD \((P<0.05\) or \(0.01); \) Fig. 3, Panels E-G).

**SZRD’s action in reducing Aβ deposition in APP/PS1 transgenic mice**

The deposition of Aβ plaque is another essential pathological feature of AD, which is associated with synapse impairment. To investigate the mechanism by which SZRD improves the cognitive dissonance in APP/PS1 transgenic mice, we examined the protein expressions of \(Aβ_{1-42}\) and APP in the hippocampus using Western blot. We found that the expressions of hippocampal \(Aβ_{1-42}\) and APP in APP/PS1 transgenic mice were significantly reduced in Donepezil- and SZRD-treated groups, in comparison with the model group without any treatment \((P<0.05\) or \(0.01); \) Fig. 4, Panels A–C). Moreover, more decreases in \(Aβ_{1-42}\) and APP were observed in the L-SZRD group than those H-SZRD group. To further determine whether SZRD can alleviate APP/PS1 transgenic mice’s cognitive deficits by regulating the activities of Aβ secretase, the expressions of ADAM10, BACE1, IDE, and PS1 in the hippocampus were measured with Western blot. We noted that compared to the model group, the levels of PS1 and BACE1 were declined markedly in the hippocampus in the Donepezil- and SZRD-treated groups, especially in the L-SZRD group \((P<0.05\) or \(0.01); \) Fig. 4, Panels D, F, and G). Also, the expressions of IDE and ADAM10 were notably higher in APP/PS1 mice treated with SZRD than those without treatment \((P<0.05\) or \(0.01); \) Fig. 4, panels D, E, and H). The results showed that in SZRD-treated mice, Aβ production was reduced, and the enzymes related to the degradation of Aβ deposition were increased.
Influence of SZRD on inflammation levels in serum and hippocampus of APP/PS1 transgenic mice

The activation of microglia and astrocytes by the Aβ deposition causes extreme release inflammatory factors, including IL-1β, IL-6, and TNF-α in APP/PS1 mice. In this experiment, we measured the serum concentrations of these inflammatory factors using ELISA. Meanwhile, we examined the expressions of the GFAP and IBA1 in the hippocampus using Western blot. We found that the serum levels of IL-1β, IL-6, and TNF-α were much lower in Donepezil and SZRD-treated groups, notably in the L-SZRD group, than those in the model group (P< 0.05 or 0.01; Fig. 5, Panels A-C). The expressions of hippocampal GFAP and IBA1 in APP/PS1 transgenic mice were significantly enhanced compared to control group (P< 0.05 or 0.01; Fig. 5, Panels D, E, and F). After the treatment with SZRD for four weeks, the GFAP and IBA1 in the hippocampus of the SZRD-treated groups, especially in the L-SZRD group, were diminished significantly in comparison with the model group without the treatment (P< 0.05 or 0.01; Fig. 5, Panels D, E, and F). The data demonstrated that the inflammation conditions in the serum and hippocampus were alleviated in APP/PS1 transgenic mice treated with SZRD.

Down-regulation of the JAK2/STAT3 signaling pathway in the hippocampus by SZRD in APP/PS1 transgenic mice

JAK2/STAT3 signaling pathway, mainly including JAK2/p-JAK2-Tyr1007 and STAT3/p-STAT3-Tyr705, is a crucial inflammatory pathway in the brain[21]. Thus, using Western blot, we examined hippocampal expressions of JAK2/p-JAK2-Tyr1007 and STAT3/p-STAT3-Tyr705 in the mice. We found that the expressions of p-JAK2-Tyr1007 and p-STAT3-Tyr705 were much higher in APP/PS1 mice than those in the control group (P< 0.01; Fig. 6, Panels A, C, and E). However, one month following SZRD treatment, p-JAK2-Tyr1007 and p-STAT3-Tyr705 were reduced markedly in the SZRD-treated groups, particularly in the L-SZRD group, in comparison with the model group (P< 0.05 or 0.01; Fig. 6, Panels A, C, and E). We did not observe among all groups a noticeable difference in the total level of JKA2 and STAT3 in the hippocampus (Fig. 6, Panels B and D).

Discussion

Cognitive dysfunction is a typical clinical symptom of AD, and Aβ deposition is an essential pathological feature of AD[29]. The APP/PS1 transgenic mice have apparent perceptive dysfunction and pathological characteristics of Aβ deposition. Thus, this model can mimic AD’s clinical and pathological features and is suitable for AD research[30]. In this study, the learning and memory were assessed in APP/PS1 transgenic mice using the navigation and spatial probe tests. We noticed that, in the navigation test, the escape latency was much longer in APP/PS1 mice than that in control group. This observation indicated the APP/PS1 mice have visible learning disabilities. In the spatial probe test, compared to control group, we observed decreases in the times of crossing platform as well as the proportion of target quadrant search time in APP/PS1 transgenic mice, which showed visible memory impairment. However, after treatment with SZRD, we found that SZRD, in particular, the L-SZRD, shortened the escape latency in APP/PS1 transgenic mice. Also, SZRD, especially, the L-SZRD increased the times of crossing platform as
well as the target quadrant search time in APP/PS1 transgenic mice. Our findings suggest that SZRD can manage the cognitive dysfunction of mice with AD.

Neurons are crucial to hippocampal-dependent learning and memory[31]. Many studies showed a noticeable loss of hippocampal neurons in patients and experimental animals with AD[32, 33]. But mechanisms underlying the loss neurons in AD are still unclear. Recently, there is evince showing that the neurons in the hippocampus of rats were decreased markedly after Aβ1-42 injection into the lateral ventricles. Also, the reduction in hippocampal neurons was uncovered in APP/PS1 mice and other AD models. In this study, we observed a significant decrease in hippocampal neurons in the CA3 and DG regions of APP/PS1 mice. After treatments with SZRD, especially, L-SZRD, the neurons in CA3 and DG subsets were increased. These results suggest that SZRD may reverse the loss of hippocampal neurons in APP/PS1 transgenic mice.

Synapse serves as the biological basis of cognitive function and participates in hippocampal-dependent learning and memory[34]. Synapse damages, including changes in synaptic structure and function, cause cognitive dysfunction[35]. Many studies have shown that the synaptic dendritic spines in the hippocampus are significantly decreased in the subjects with AD, and cognitive dysfunction can be improved as the number of synaptic dendritic spines is increased[36–38]. Synaptophysin (SNY) is the biological marker of synaptic formation. Postsynaptic densification protein 95 (PSD95) is one critical protein involved in signal transmission in the synapse. Both SNY and PSD95 play an essential role in synaptic plasticity[39]. With this respect, several studies have demonstrated that the protein expressions of SYN and PSD95 in the AD’s hippocampus were enhanced significantly, and decreases in these protein expressions can restrain cognitive decline[40, 41]. In this study, using Golgi-Cox staining, we found that the dendritic spines in hippocampal CA3 and DG subsets in APP/PS1 mice were markedly reduced, and the protein levels of SYN and PSD95 in the hippocampus were decreased as well. However, in SZRD, particularly L-SZRD, increased the dendritic spines in CA3 and DG subsets as well as protein expressions of SYN and PSD95 in the hippocampus. Our findings suggest that SZRD may improve synaptic plasticity in APP/PS1 mice.

Aβ deposition depends on the hydrolysis of APP, which is regulated through α, β, and γ secretase[42]. The α-secretase is mainly composed of the ADAM family. ADAM10 can reduce the pathological damage of AD by inhibiting the production of Aβ1-42[43]. BACE1 and PS1 are parts of β- and γ-secretase, respectively. They can promote the production of Aβ1-42. Therefore, inhibiting the expression of BACE1 and PS1 can reduce Aβ production. IDE has the function to degrade Aβ, which thus clears the Aβ deposition in AD. In this study, we found that the protein expressions of Aβ1-42 and APP in the hippocampus were significantly enhanced in APP/PS1 mice, contrasted to controls, indicating hippocampal Aβ deposition in the mice with AD. After treatments with SZRD, notably, L-SZRD, the hippocampal expressions of Aβ1-42 and APP were decreased obviously in APP/PS1 mice, which indicated that SZRD might inhibit Aβ generation. Meanwhile, we also found that in APP/PS1 mice, hippocampal BACE1 and PS1 were augmented significantly, while ADAM10 and IDE were markedly
reduced. These changes in APP/PS1 mice were reversed obviously following the treatment with SZRD. As such, our results suggest that SZRD can reduce Aβ deposition by enhancing α-secretase and degrading enzyme and reducing β-secretase and γ-secretase.

It remains unclear how inflammatory responses cause brain injury. Some investigators have demonstrated that inflammation contributes to AD's pathogenesis[44–46]. The inflammation in AD is associated with multiple factors. Aβ deposition is considered as an essential cause. In this respect, Aβ deposition induces microglia's activation to generate pro-inflammatory factors, including IL-1β, IL-6, and TNF-α, which finally cause neuroinflammation[47]. In the present study, we found that serum levels of IL-1β, IL-6, and TNF-α were much upper in the APP/PS1 mice than those in controls. Besides, the protein expressions of hippocampal IBA1 and GFAP were increased substantially in APP/PS1 mice. These results indicate neuroinflammation occurs in mice with AD. However, in APP/PS1 mice treated with SZRD, we observed a significant reduction in IL-1β, IL-6, and TNF-α in blood as well as the protein expressions of IBA1 and GFAP in the hippocampus. Our findings suggest that SZRD may alleviate neuroinflammation in the hippocampus of AD.

The signaling pathway associated with JAK2/STAT3 is closely related to the inflammation, oxidative stress, and apoptosis, which mainly affects the AD's pathological process through inflammation regulation[21]. JAK2 represents the Janus kinase (JAK) family and is activated at the Tyr1007 site by IL-1β, IL-6, and TNF-α. Phosphorylated JAK2 promotes the activation of STAT3 at the Tyr705 site, which finally leads to neuroinflammation and apoptosis[48–50]. There is evidence showing that the signaling pathway related to JAK2/STAT3 is activated in AD, and the inhibition of this signaling pathway can alleviate neuroinflammation in AD[23, 51]. In this study, we observed that in comparison with control group, the expressions of hippocampal p-JAK2-Tyr1007 and p-Tyr705-STAT3 were augmented extensively in APP/PS1 mice. At the same time, the expressions of JAK2 and STAT3 were unchanged. These results demonstrated the JAK2/STAT3-associated signaling pathway in the hippocampus is initiated in mice with AD. After the treatment with SZRD, particular, L-SZRD, in the APP/PS1 mice, the expressions of hippocampal p-JAK2-Tyr1007 and p-Tyr705-STAT3 were significantly decreased. Our findings suggest that SZRD may down-regulate the signaling pathway associated with JAK2/STAT3 in the hippocampus and improve AD.

**Conclusion**

In summary, our study shows that SZRD can alleviate cognitive impairment by reducing neuronal loss and synaptic damage in APP/PS1 transgenic mice. Also, SZRD can attenuate neuroinflammation and inhibit the excitation of microglia in APP/PS1 mice, which likely is associated with its blockade of JAK2/STAT3-related signaling pathway. SZRD's anti-inflammatory action suggests that SZRD may have a beneficial effect on AD.

**Abbreviations**
SZRD: Suan-Zao-Ren Decoction; WB: Western blot; ELISA: Enzyme-linked immunosorbent assay; IL-6: Interleukin-6; IL-1β: Interleukin-1β; TNF-α: Tumor necrosis factor-α; Aβ1-42: Amyloid peptide 1-42; APP: Amyloid precursor protein; ADAM10: A disintegrin and metalloproteinase 10; BACE1: β-secretase 1; PS1: Presenilin 1; IDE: Insulin-degrading enzyme; IBA1: Ionized calcium binding adaptor molecule 1; GFAP: Glial fibrillary acidic protein; PSD95: Postsynaptic density proteins 95; SYN: Synaptophysin; JAK2: Janus kinase 2; STAT3: Signal transducer and activator of transcription 3

Declarations

Ethics approval and consent to participate

This study was approved by the animal experiment committee of Hubei University of Chinese Medicine (Approval No. 81573865), and the experimental procedures were conducted in accordance with the ethical standards of the Chinese Association of Accreditation of Laboratory Animal Care.

Consent for publication

Not applicable.

Availability of data and materials

The data used to support the current study are available from the corresponding author on reasonable request.

Competing interests

The authors declare that they have no competing interests.

Funding

This work was supported by the National Key R&D Program Key for a key Research Project of the Modernization of Traditional Chinese Medicine No. 2018YFC1705600 and 2019YFC1708502.

Authors’ contributions

QHL, YGW, and LLH equally contributed to the work; QHL, HYS, and PW designed and conceived the study; QHL, YGW, and LLH carried out the experiments and wrote the paper. All authors have read and approved the manuscript.

Acknowledgements

None.

Figures
Figure 1

Improvement of cognitive deficits by SZRD on in APP/PS1 transgenic mice. A. Illustrative tracings of the mice's movements in the presence of the hidden platform, which were generated from the navigation tests. B. Mice's escape latencies in each day during the six consecutive days. C. Bar graphs showing the escape latencies of mice in each group. D. Representative tracings of the mice's movements in the absence of the hidden platform, which were obtained from the probe tests. E. The mean times of the
mice’s crossing the stage within 60 s. F. The proportion of searching time at which the mice stayed in the target quadrant. The data are presented as mean ± SEM (n=10 in each group). **P<0.01 vs. Control group; #P<0.05 and ##P<0.01 vs. Model group.

Figure 2

Changes in neuronal loss in hippocampal CA3 and DG of APP/PS1 transgenic mice treated with and without SZRD. A. microscopic images show neuronal labels by Nissl staining in the hippocampus after
treatment with and without SZRD for four weeks (×400 magnifications; scale bar represents 50 μm). B. The neuronal number in the regions of CA1 and CA3. C. The neuronal number in the regions of CA4 and DG. The data are presented as mean ± SEM (n=4 in each group). **P<0.01 vs. Control group; #P<0.05 and ##P<0.01 vs. Model group.

Figure 3
Influence of SZRD on the synaptic plasticity of APP/PS1 transgenic mice. A. Representative Golgi-Cox staining in the hippocampus of CA3 after treatment with and without SRZD for four weeks (magnification, ×400; scale bar represents 20 μm). B. The neuronal number in the areas of CA3. C. Representative Golgi-Cox staining in the hippocampus of DG after treatment with and without SRZD for four weeks (magnification, ×400; scale bar represents 20 μm). D. The neuronal number in the areas of DG. E. Examples of original Western blotting bands showing expressions of PSD95 and SYN in the hippocampus. F. Relative protein level of PSD95. G. Relative protein level of SYN. The data are presented as mean ± SEM (n=4 in each group). **P<0.01 vs. Control group; #P<0.05 and ##P<0.01 vs. Model group.
Changes in Aβ deposition in the mice's hippocampus. A. Examples of original Western blotting bands showing hippocampal expressions of APP and Aβ1-42. B. Relative protein level of APP expression. C. Relative protein level of Aβ1-42 expression. D. Examples of original Western blotting bands showing expressions of ADAM10, BACE1, PS1 and IDE in the hippocampus. E. Relative protein level of ADAM10. F. Relative protein level of BACE1. G. Relative protein level of PS. H. Relative protein level of IDE. The data are presented as mean ± SEM (n=6 in each group). **P<0.01 vs. Control group; #P<0.05 and ##P<0.01 vs. Model group.

Figure 5

The action of SZRD in alleviating inflammation levels in serum and hippocampus of APP/PS1 transgenic mice. A. The serum content of TNF-α. B. The serum content of IL-1β. C. The serum content of IL-6. D. Examples of original Western blotting bands showing expressions of IBA1 and GFAP in the hippocampus. E. Relative protein level of IBA1. F. Relative protein level of GFAP. The data are presented as mean ± SEM (n=6 in each group). **P<0.01 vs. Control group; #P<0.05 and ##P<0.01 vs. Model group.
Figure 6

Influence of SZRD on the JAK2/STAT3 signal pathway in the hippocampus of APP/PS1 transgenic mice. A. Examples of original Western blotting bands showing expressions of JAK2, p-JAK2-Tyr1007, STAT3 and p-STAT3-Tyr705 in the hippocampus. B. Relative protein level of JAK2. C. Relative protein level of p-JAK2-Tyr1007. D. Relative protein level of STAT3. E. Relative protein level of p-STAT3-Tyr705. The data are expressed as mean ± SEM (n=6 in each group). **P<0.01 vs. control group; #P<0.05 and ##P<0.01 vs. model group.
