INTRODUCTION

The effects of obesity and overweight have been studied in various diseases. It has been known that obesity may cause diabetes, osteoarthritis, cardiovascular diseases, sleep apnea, breast and uterine cancers and other reproductive disorders in women (1-4). Body mass index (BMI) has been widely used to assess the degree of obesity and overweight objectively and used as an indicator in many studies.

Detrimental impacts of obesity and overweight on pregnancy and delivery outcomes have long been investigated. Women with obesity and overweight have higher rates of abortion, preterm birth, cesarean delivery and neonatal complications (5, 6). Several hypotheses have been raised regarding an association between lower fecundity rate and obesity or overweight associated with polycystic ovary syndrome (PCOS) (7-9).

Despite the above mentioned studies, there are only few reports on the effects of obesity and overweight on the outcomes of in vitro fertilization and embryo transfer (IVF-ET) that had reported different results. While some studies reported a decrease in pregnancy and implantation rates in obese women (10-12), others reported no effects of extreme body weights (13, 14).

Average BMI and its impact on the IVF-ET can be different among different ethnic groups. Recently, a difference in the outcomes of IVF-ET between African American and white women was reported with a difference in BMI between the two (15). The effects of obesity and overweight on the IVF-ET outcomes are still unknown in Asian ethnic groups. Data on this is important since the optimal practice and prediction of prognosis in the treatment of infertile couples may be different among different races. The authors sought to elucidate the clinical efficacy of BMI as a predictor of IVF-ET outcomes in Korean women.

MATERIALS AND METHODS

Study subjects

Two hundred and twenty-three IVF-ET cycles using GnRH agonist long protocols were retrospectively analyzed, and oocyte donation and cryopreserved embryo transfer cycles were excluded. All subjects were under 37 yr old. BMI (kg/m²) was calculated as body weight (kg) divided by height squared (m²). The outcomes of IVF-ET were compared between the two groups: BMI < 24 kg/m² (group 1) and BMI ≥ 24 kg/m² (group 2).

IVF-ET protocols

Controlled ovarian hyperstimulation (COH) and IVF-ET were performed as reported previously (16-18). COH was undertaken using subcutaneous triptorelin (Decapeptyl®; Fer-
ring, Sweden) in a long protocol combined with FSH (Metrodin HP; Serono, Switzerland). Treatment with triptorelin (0.1 mg/day) began on day 21 of the preceding cycle and continued until the day of hCG treatment. As for the women with irregular menstrual cycles such as PCOS women, received GnRHa treatment with progesterone withdrawal. Treatment with 2-4 ampules of FSH, depending on the patients’ previous or anticipated responses, was initiated on day 3 of the menstrual cycle. The treatment was then individualized and adjusted according to the response. When the leading follicle reached 18 mm in mean diameter with a serum estradiol (E2) level of 200 pg/mL per mature follicle, 10,000 IU of hCG (Profasi®; Serono, Switzerland) was administered. Oocyte retrieval was performed 36 hr after the hCG injection. The intracytoplasmic sperm injection (ICSI) was performed according to conventional protocols and only on the MII oocytes. Up to four embryos were transferred vaginally on the second or third day after retrieval. The luteal phase was supported by intramuscular progesterone. Cumulative embryo score (CES) was calculated as the number of blastomeres multiplied by the quality of embryo (I-V/V) and used as an indicator of implantation potential. Clinical pregnancy was diagnosed when fetal cardiac activity was confirmed by ultrasonography at 3-4 weeks after embryo transfer.

**Statistical analysis**

All data were analyzed using SPSS ver. 9.0.1. Student’s t-test and chi-square tests were employed as appropriate. A p value <0.05 was regarded as statistically significant.

**RESULTS**

One hundred and eighty-five and 38 cycles fell into the group 1 (BMI < 24 kg/m²) and group 2 (BMI ≥ 24 kg/m²), respectively. There was no difference in their clinical characteristics such as age, number of cycles and basal FSH levels between the two groups (Table 1).

No differences were observed in terms of peak E2 concentrations, endometrial thickness, number of retrieved oocytes and transferred embryos and cumulative embryo scores. However, higher doses of gonadotropins were used in group 2 (30.8 ± 12.7 ampoules vs. 35.4 ± 15.3 ampoules, p=0.051). Clinical pregnancy rate was significantly higher in group 1 (25.9% vs. 10.5%, p=0.041). Implantation rate was also higher in group 1 (12.7% vs. 6.8%, p=0.085) (Table 2).

**DISCUSSION**

Various measures have been used to assess the degree of obesity and overweight including BMI, waist circumference (WC) and waist-hip ratio (WHR). WC is used to assess abdominal obesity, WHR to assess central adiposity, and BMI to assess general body composition (19, 20).

World Health Organization (WHO) defines 18.5 kg/m² to 24 kg/m² as ‘normal’, 25 kg/m² to 30 kg/m² as ‘pre-obese’ and higher than 30 kg/m² as ‘obese’. However, these criteria may not be adequate to be used in Asian women, and this necessitates provision of different standards (21-23).

The average BMI of study subjects was 21.2 ± 2.8 kg/m² (mean ± S.D.), and as described previously, BMI of 24 kg/m² was used as cutoff in this study. With this cutoff, only 38 cycles corresponded to high BMI group (group 2). A cutoff of 25 kg/m² as in the WHO criteria may be inadequate as a prognostic indicator in IVF-ET cycles of Korean women since the distribution of BMI differs according to ethnicity and environment.

Underweight has also been known to negatively affect the outcomes of IVF-ET (24). Nichols et al. reported the harmful impact of both extremes of BMI on the IVF-ET outcomes (11, 25). From the data of our study subjects, BMI < 18 kg/m² showed a trend of lower pregnancy rates compared to BMI

**Table 1. Clinical characteristics between the women with BMI < 24 kg/m² and those with BMI ≥ 24 kg/m²**

| No. | BMI < 24 kg/m² | BMI ≥ 24 kg/m² |
|-----|---------------|---------------|
| BMI (kg/m²) | 20.3 ± 1.8 | 25.6 ± 1.6 |
| Age (yr) | 32.3 ± 3.2 | 33.3 ± 3.0 |
| Basal FSH (IU/L) | 9.6 ± 5.8 | 7.1 ± 3.3 |
| No. of cycles | 2.3 ± 1.5 | 2.3 ± 1.9 |
| Infertility Factor* | | |
| Ovulatory | 4 (2.2%) | 1 (2.6%) |
| Tubal | 73 (39.5%) | 16 (42.1%) |
| Peritoneal | 42 (22.7%) | 5 (13.2%) |
| Uterine | 11 (5.9%) | 1 (2.6%) |
| Male | 24 (13.0%) | 9 (23.7%) |
| Unexplained | 14 (7.6%) | 1 (2.6%) |
| Others | 17 (9.2%) | 5 (13.2%) |

Values are expressed as mean ± standard deviation.

*Distribution of infertility factors are not significantly different between the two groups.

**Table 2. IVF-ET outcomes between the women with BMI < 24 kg/m² and those with BMI ≥ 24 kg/m²**

| No. | BMI < 24 kg/m² | BMI ≥ 24 kg/m² | p-value |
|-----|---------------|---------------|---------|
| No. | | | |
| E2 on hCG day (pg/mL) | 1,685.3 ± 1,341.9 | 1,894.5 ± 1,449.8 | NS |
| Endometrial thickness (mm) | 11.3 ± 2.1 | 11.7 ± 2.2 | NS |
| Dose of gonadotropins used (ampoules) | 30.8 ± 12.7 | 35.4 ± 15.3 | 0.051 |
| Oocytes retrieved | 9.9 ± 5.8 | 11.7 ± 8.8 | NS |
| Embryos transferred | 3.4 ± 1.0 | 3.4 ± 0.9 | NS |
| CES | 48.6 ± 25.6 | 50.1 ± 26.8 | NS |
| Clinical pregnancy rate (%) | 25.9 (48/185) | 10.5 (4/38) | 0.041 |
| Implantation rate (%) | 12.7 | 6.8 | 0.085 |

Values are expressed as mean ± standard deviation.

CES, cumulative embryo score; NS, not significant.
≥ 18 kg/m² group (data not shown). When subjects of BMI <18 kg/m² were eliminated from the group of BMI <24 kg/m², the difference in pregnancy rate became more significant (p=0.027).

The mechanism of the effects of BMI is uncertain. From oocyte donation model, Wattanakumtornkul et al. reported no difference in the endometrial thickness among women with different BMI (26). Wang et al. reported that the quality of transferred embryos was worse in higher BMI women (27). With these reports and ours that also showed no difference in the endometrial thickness (Table 2), it may possibly assumed that BMI affect ovarian folliculogenesis rather than uterine receptivity.

A higher dose of gonadotropin was necessary in high BMI group in this study (Table 2). This finding is supported by a report of Fedorcsak et al. (28). In regard to the underlying mechanisms, hyperandrogenism and hyperinsulinemia as in the case of chronic anovulation has been suspected (29). Or whether this was just due to the gonadotropin concentrations per unit kg is also subject to further studies.

Intrafollicular hCG concentrations has been studied in relation to BMI by Carrell et al. (30). BMI was inversely related to intrafollicular levels of hCG. If this is a significant mechanism, an increase in the dose of hCG in higher BMI women should be considered, which needs to be confirmed by further studies.

An ethnic difference in the outcomes of IVF-ET was reported between white and African American women (15). In this report, a difference in the BMI was found between the two groups. Therefore, it should be differentiated whether the effects of BMI is confounded by a racial difference. As Korean women are of one nation, comparative studies between white and African American women (15). In this report, a difference in the BMI was found between the two groups. Therefore, it should be differentiated whether the effects of BMI is confounded by a racial difference. As Korean women are of one nation, comparative studies between white and African American women (15).
