Abstract

We propose a mechanism displaying gluon confinement, as defined by the behavior of the propagators, in a model of $SU(2)$ gauge fields. The model originates from an explicitly broken $SU(3)$ gauge theory giving rise to a replica model composed of three mixed $SU(2)$ groups. The mechanism consists in the usual $SU(3)$ Yang-Mills theory in the Landau gauge, with a soft breaking term in such a way as to change the field propagation and group content at low energies. The relation of this soft mass term with the Gribov problem is presented and the link between soft terms and the scaling and decoupling solutions is discussed.

1 Introduction

The problem of gluon confinement is the core of the general investigations of strongly coupled gauge theories. An important aspect of gluon confinement is related to the behavior of the gluon propagator.

Recently this problem has received great attention in different approaches. One of these approaches comes from lattice simulation where the behavior of the gluon propagator in the infrared regime is studied \[1, 2, 3\]. These results display positivity violation thus making impossible a particle interpretation for the gluon excitation at low energies. This is taken as a strong signal of gluon confinement. In the analytical point of view, one possible approach of the confinement problem comes from the analysis of the Gribov copies \[4\], where the Gribov-Zwanziger (GZ) model \[5, 6\], and this refined version, the so-called Refined Gribov-Zwanziger (RGZ) model \[7\], take place. Also, a recently developed model based on the introduction of a replica of the Faddeev-Popov action enjoys a confined gluon propagator \[8\]. Usually, these models provide propagators behaving as

\[ D(p^2) = \frac{p^2}{p^4 + \gamma^4}, \quad (1) \]

where \( D(p^2) \) is the gluon form factor in Euclidean spacetime and \( \gamma \) is a mass parameter. It is easy to notice that a propagator of this type has complex poles, being impossible its identification with a propagation of a physical particle. In other words, it is a suitable candidate to be a confined object.

An important feature that has been studied about propagators like (1) is that they can be seen as a propagation of two unphysical modes with imaginary squared masses \( \pm i\gamma^2 \), named \( i \)-particles \[9\]. In fact, one can immediately notice that the form factor (1) can be written as

\[ \frac{p^2}{p^4 + \gamma^4} = \frac{1}{2} \left( \frac{1}{p^2 - i\gamma^2} + \frac{1}{p^2 + i\gamma^2} \right). \quad (2) \]

Despite the fact that such propagators do not have an interpretation in the physical spectrum, it is still possible to construct composite operators, \( O[A] \), whose the correlation functions exhibit a Källén-Lehmann spectral representation:

\[ \langle O(p)O(-p) \rangle = \int_{\tau_0}^{\infty} d\tau \frac{\rho(\tau)}{\tau + p^2}, \quad (3) \]

where \( \rho(\tau) \) is the positive spectral density and \( \tau_0 \geq 0 \) stands for the threshold. An important feature of expression (3) is that we can move from Euclidean to Minkowski space. Moreover, the positivity of the spectral density \( \rho(\tau) \) enables us to give an interpretation of (3) in terms of physical states with positive norm.

---

1We will refer to this model just as the replica model.
2In the case of the RGZ model the gluon propagator take into account the effects of dimension two condensates and it is more complex. Typically, the gluon form factor looks like

\[ D(p^2) = \frac{p^2 + M^2}{p^4 + (M^2 + m^2)p^2 + (\gamma^4 + M^2m^2)}, \]

where \( M \) and \( m \) are mass parameters associated with the condensates, while \( \gamma \) is the so-called Gribov mass parameter.
3In the GZ model this parameter is known as the Gribov parameter, which is directly associated with the restriction of the Feynman path integrals to the Gribov region.
In the present work, we will study a SU(3) Euclidean Yang-Mills theory and try to explore a well known property of this group, which consists in the fact that it contains three mixed SU(2) groups \[10, 11\]. In the presence of a dimension two condensate, \( \langle d^{abc} A^b_\mu A^c_\mu \rangle \), with \( d^{abc} \) being the totally symmetric structure constant of the SU(3) Lie algebra, the color group symmetry is explicitly broken. However, two of these three SU(2) groups are related in a structure of \( i \)-particles, and, thanks to a residual symmetry, it is possible to write composite operators having a spectral representation like \( \mathcal{M}^{ab} = -\partial_\mu D^{ab}_\mu \).

The paper is organized as follows. In Sect. 2, we make a brief review about the GZ model, the introduction of the \( i \)-particles, and the replica model. In Sect. 3, we introduce the condensate \( \langle d^{abc} A^b_\mu A^c_\mu \rangle \) and write the action corresponding to the model that we desire to study. Also in this section we show how this condensate modifies the gluon propagator and how the \( i \)-particle structure appears between two of the three SU(2) groups. In Sect. 4, the relation of the mass terms, obtained from the introduction of dimension two condensates, and the scaling and decoupling solution is established. The Sect. 5 is dedicated to discuss the Källén-Lehmann spectral representation of the candidates to be a physical observable. Our conclusions are presented in Sect. 6. The symmetry content of the model, characterized by a full set of Ward identities compatible with the Quantum Principle Action \[12\], and the proof of its renormalizability are presented in the Appendix A. And some properties of SU(3) groups are presented in Appendix B.

2 A brief review: the GZ model, \( i \)-particles and the replica model

2.1 The GZ model

In order to clarify the understanding of the Gribov problem and its correlation with our proposal we will present below a description of the problem in the Landau gauge. The Euclidean \( SU(N) \) Yang-Mills action in the Landau gauge is given by:

\[
S_{YM} = \int d^4x \left( \frac{1}{4} F_{\mu\nu}^a F_{\mu\nu}^a + \frac{i}{2g} \partial_\mu A^a_\mu + \bar{c}^a \partial_\mu D^{ab}_\mu c^b \right),
\]

(4)

where

\[
F_{\mu\nu}^a = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + g f^{abc} A^b_\mu A^c_\nu
\]

(5)

and

\[
D^{ab}_\mu = g \delta^{ab} \partial_\mu - g f^{abc} A^c_\mu.
\]

(6)

Here, \( A^a_\mu \) is the gauge field, \( b^a \) is a Lagrange multiplier enforcing the Landau gauge, \( \partial_\mu A^a_\mu = 0 \), \( (c^a, \bar{c}^a) \) are a pair of anti-commuting scalar fields known as the Faddeev-Popov ghost fields, and \( g \) is the coupling constant of the theory. The labels \( (a, b, c, \ldots) \) run to 1 to \( (N^2 - 1) \) and \( f^{abc} \) are the totally anti-symmetric structure constant of the Lie algebra of the generator of SU(\( N \)). Also, this action is left invariant under the following nilpotent BRST transformations:

\[
s A^a_\mu = -D^{ab}_\mu c^b, \quad sc^a = \frac{g}{2} f^{abc} c^b c^c, \quad s\bar{c} = i\bar{c}, \quad sb^a = 0.
\]

(7)

Although the gauge be fixed by the Faddeev-Popov method, Gribov showed in \[14\] that there are still field configurations obeying the Landau gauge linked by gauge transformations, i.e. there are still equivalent configurations, or copies, being taken into account into the Feynman path integral. In other words, the gauge is not completely fixed and the remaining ambiguity is allowed due to the existence of normalizable zero-modes of the Faddeev-Popov operator,

\[
\mathcal{M}^{ab} = -\partial_\mu D^{ab}_\mu.
\]

\[\text{See also} \ [13] \text{ for a pedagogical review.}\]
Gribov also showed that to eliminate these copies the domain of integration of the functional integral should be restricted to a certain region $\Omega$, the so-called Gribov region, that is defined as the set of field configurations performing the Landau gauge condition, for which the Faddeev-Popov operator is strictly positive, namely
\[ \Omega := \{ A^a_\mu | \partial_\mu A^a_\mu = 0, \mathcal{M}^{ab}(A) > 0 \}. \] (9)

Its boundary, $\partial \Omega$, where the first vanishing eigenvalue of the Faddeev-Popov operator shows up, is known as the Gribov horizon.

As in the region $\Omega$ the Faddeev-Popov operator is positive than its inverse must diverge when approaching the horizon, due to the existence of a zero mode. So the restriction to the first Gribov region is implemented requiring that
\[ G(p^2, A) = \frac{\delta^{ab}}{N^2 - 1} (p) (\partial_\mu P^{ab})^{-1} (p) , \] (10)

which is the normalized trace of the ghost connected two point function in momentum space, has no pole for a given nonvanishing value of the momentum $p$, except for the singularity at $p = 0$, corresponding to the first Gribov horizon. At $p \approx 0$ one can write
\[ G(p^2, A) \approx \frac{1}{p^2} \frac{1}{1 - \sigma(p^2, A)} , \] (11)
\[ \sigma(p^2, A) = \frac{N}{N^2 - 1} \frac{1}{p^2} \int \frac{d^4 q}{(2\pi)^4} \frac{(p - q)_\mu P_{\mu \nu}}{(p - q)^2} A^a_\mu (-q) A^a_\nu (q) . \] (12)

From the above expression (12), it follows that the no-pole condition at finite nonvanishing $p$ is
\[ \sigma(p^2, A) < 1 . \] (13)

As $\sigma(p^2, A)$ decreases as $p^2$ increases one can also take
\[ \sigma(0, A) = \frac{1}{4} \frac{N}{N^2 - 1} \int \frac{d^4 q}{(2\pi)^4} \frac{1}{q^2} (A^a_\mu (-q) A^a_\nu (q)) \leq 1 . \] (14)

It is important to emphasize here that we work with the trace of the ghost propagator to find the restriction to the Gribov region. This is a particularity of the Gribov mechanism in the Landau gauge. This is related to the convexity of the Gribov region in the Landau gauge. Other gauges, like the maximal Abelian gauge, does not necessarily present the same property [14, 15, 16].

In order to perform the restriction to the Gribov region into the partition function, $Z$, the final step is to introduce the no-pole condition with the help of a Heaviside function:
\[ Z = \int D A \delta(\partial A) \theta(1 - \sigma(0, A)) \exp^{-S_{YM}} . \] (15)

This will give rise to a propagator for the gauge field of the type
\[ \langle A^a_\mu (-q) A^b_\nu (q) \rangle = \delta^{ab} \frac{q^2}{q^4 + \gamma^4} \left( \delta_{\mu \nu} - \frac{q_\mu q_\nu}{q^2} \right) , \] (16)

Note that the only allowed singularity at (11) is at $p^2 = 0$, whose meaning is that of approaching the horizon, where $G(p^2, A)$ is singular due to the appearance of zero modes of the Faddeev-Popov operator. Thus we have to take [4]:

\[ \text{In the maximal Abelian gauge we take only the trace of diagonal ghost propagator.} \]
\[ \sigma(0, A) = 1 \quad (17) \]

And thus the Gribov parameter \( \gamma \) is fixed by the gap equation:

\[ \frac{3N g^2}{4} \int \frac{d^4 q}{(2\pi)^4} \frac{1}{q^4 + \gamma^4} = 1. \quad (18) \]

It is clear that the Gribov approach is only the first step in order to consistently treat the problem of zero modes and the Gribov copies in a gauge fixed Yang-Mills theory. The second step is the GZ theory \([5, 6]\), which consists in a renormalizable and local way to implement the restriction to the first Gribov region. In fact, Zwanziger observed that the restriction could be implemented by adding the following term in the action \((14)\):

\[ S_{\text{GZ}} = S_{\text{YM}} + \gamma^4 H(A), \quad (19) \]

where, \( H(A) \) is the so-called horizon function,

\[ H(A) = g^2 \int d^4x \frac{1}{4} f^{abc} A^b_{\mu}(x) [M^{-1}]^{ad}(x, y) f^{dec} A^c_{\mu}. \quad (20) \]

In the Zwanziger approach, the parameter \( \gamma \) is fixed by the equation

\[ \langle H(A) \rangle = 4V(N^2 - 1), \quad (21) \]

where \( V \) is the Euclidean space volume. Notice that the Gribov form factor \((14)\) coincides with the first order of the horizon function \(6^6\):

\[ \frac{H(A)}{4V(N^2 - 1)} = \sigma(0, A) + O(A^3). \quad (22) \]

It is clear that the horizon function is nonlocal, but it can be localized with the help of a suitable set of auxiliary fields. In order to ensure that those extra fields do not introduce extra degrees of freedom they are introduced in the form of a BRST quartet \(7^7\):

\[ s\bar{\varphi}_{ab} = \varphi_{ab}, \quad s\bar{\varphi} = 0, \]
\[ s\varphi_{ab} = \omega_{ab}, \quad s\omega_{ab} = 0, \quad (23) \]

where \((\bar{\varphi}, \varphi)\) are a pair of complex commuting fields, while \((\bar{\omega}, \omega)\) are anti-commutating ones. Now, the local version of the GZ action is then given by:

\[ S_{\text{GZ}}^{\text{local}} = S_{\text{YM}} + \int d^4x \left[ \varphi_{\mu}^{ac} M^{ab}_{\mu} \varphi_{\mu}^{bc} - \bar{\omega}_{\mu}^{ac} M^{ab}_{\mu} \bar{\omega}_{\mu}^{bc} + \gamma^2 g f^{abc} (\varphi_{\mu}^{ab} - \varphi_{\mu}^{bc}) A^c_{\mu} \right]. \quad (24) \]

It is quite easy to notice that this term explicitly breaks the BRST symmetry. Then, following the Zwanziger steps, in order to establish a local, renormalizable and BRST-invariant theory, we define a

\[^6\text{Actually, the form factor can be calculated at all orders and the result is that such coincidence occurs in fact at all orders. In [17], this equivalence is proved at third order, and in [18] it is proved at all orders.}\]

\[^7\text{Actually, the BRST quartet is composed by two BRST doublets, which has the basic structure} \]

\[ sU = V, \quad sV = 0, \]

for a generic pair of fields \((U, V)\), guarantying the nilpotence of the BRST operator, \( s \), i.e. \( s^2 = 0. \)
most general invariant action, which possesses action \( S_{GZ} \) as a particular physical case. Such desired action is then given by:

\[
S_{\text{local-inv}}^{\text{GZ}} = S_{YM} + s \int d^4x \left[ \bar{\omega}^{ac}_{\mu} \mathcal{M}^{ab}_{\nu} \omega^{bc}_{\mu} + Q_{\mu}^{ab} D^{ac}_{\mu} \phi^{cb}_{\nu} + J^{ab}_{\mu} D^{ac}_{\mu} \bar{\phi}^{cb}_{\nu} + \bar{Q}_{\mu}^{ab} J^{ac}_{\mu} \right] = S_{YM} + \int d^4x \left\{ \bar{\omega}^{ac}_{\mu} \mathcal{M}^{ab}_{\nu} \omega^{bc}_{\mu} - \bar{Q}_{\mu}^{ab} D^{ac}_{\mu} \omega^{cb}_{\nu} + f^{abc}(\partial_{\mu} \omega^{ae}_{\nu})(D^{bd}_{\mu} \omega^{de}_{\nu})_{\nu}^{\phi} + \bar{Q}_{\mu}^{ab} D^{ac}_{\mu} \phi^{cb}_{\nu} + \left( \bar{J}^{ab}_{\mu}, J^{ab}_{\mu}, \bar{Q}_{\mu}^{ab}, Q_{\mu}^{ab} \right) \right\},
\]

where, the set of external sources

\[
\{ \bar{J}^{ab}_{\mu}, J^{ab}_{\mu}, \bar{Q}_{\mu}^{ab}, Q_{\mu}^{ab} \}
\]

forms a BRST quartet structure, i.e.

\[
s\bar{Q}_{\mu}^{ab} = \bar{J}^{ab}_{\mu}, \quad s\bar{J}^{ab}_{\mu} = 0, \\
sJ^{ab}_{\mu} = Q_{\mu}^{ab}, \quad sQ_{\mu}^{ab} = 0,
\]

being \((\bar{J}, J)\) a pair of commutating sources and \((\bar{Q}, Q)\) a pair of anti-commutating ones. The last term is a vacuum term permitted by power-counting and it is necessary to obtain the gap equation \( S_{\text{local-inv}}^{\text{GZ}} \) by demanding that the vacuum energy, \( \mathcal{E} \), is independent of \( \gamma^2 \), i.e.

\[
\frac{\partial \mathcal{E}}{\partial \gamma^2} = 0.
\]

The original action \( S_{\text{GZ}} \) can be recovered from \( S_{\text{local-inv}}^{\text{GZ}} \) when these external sources attain their physical values. Namely,

\[
\bar{J}^{ab}_{\mu} \big|_{\text{phys}} = -\bar{J}^{ab}_{\mu} \big|_{\text{phys}} = \gamma^2 \delta^{ab} \delta_{\mu \nu}, \quad \bar{Q}^{ab}_{\mu} \big|_{\text{phys}} = \bar{Q}^{ab}_{\mu} \big|_{\text{phys}} = 0.
\]

After perform a linear shift on the \( \omega^{ab}_{\mu} \) variable,

\[
\omega^{ac}_{\mu} \rightarrow \omega^{ac}_{\mu} - (\mathcal{M}^{-1})^{ab}_{\mu} \left[ \partial_{\nu} \left( g f^{bde}_{\nu} \omega^{dc}_{\mu} D^{de}_{\nu} \phi^{ef}_{\mu} \right) - \gamma^2 g f^{bde}_{\nu} D^{de}_{\nu} \phi^{ef}_{\mu} \right],
\]

one can show that

\[
\left( S_{\text{local-inv}}^{\text{GZ}} \right)_{\text{phys}} \equiv S_{\text{GZ}}^{\text{local}}.
\]

It is important to emphasize here that the Zwanziger approach described above has received some improvements in recent years. In \[19, 20\], the model was formulated in such way that the BRST symmetry breaking appears as a linear breaking, while in \[21\], the breaking appears as a spontaneous breaking, instead of an explicit one.

\[\text{8}\] The renormalization of this formulation was already proven in \[22\].

### 2.2 The \( \phi \)-particles

As already seen, eq. \[2\] suggests that a theory presenting Gribov-like propagators, can be rewritten in terms of \( \phi \)-particles, i.e. with propagations of “particles” with complex squared masses. Now, let us take a look on this concept following the lines outlined in \[9\]. Then, we will start with a scalar field toy model exhibiting a confining Gribov-type propagator:

\[
S = \int d^4x \frac{1}{2} \Phi \left( -\partial^2 + 2 \frac{\partial^4}{\partial^2} \right) \Phi,
\]

(32)
where $\theta$ is a mass parameter playing an analogous role of the Gribov parameter $\gamma$. The resulting propagator is the desired Gribov-type:
\[
\langle \Phi(p)\Phi(-p) \rangle = \frac{p^2}{p^4 + 2\theta^4},
\]
and it can be cast in a local form exactly like in the case of the GZ model:
\[
S = \int d^4x \left[ \frac{1}{2} \Phi(-\partial^2)\Phi + \bar{\varphi}(-\partial^2)\varphi + \theta^2 (\varphi - \bar{\varphi}) \right].
\]
As $(\bar{\varphi}, \varphi)$ form a pair of complex field we can decouple the real part from the theory. In fact, defining
\[
\varphi = \frac{1}{\sqrt{2}}(U + iV), \quad \bar{\varphi} = \frac{1}{\sqrt{2}}(U - iV),
\]
one can write
\[
S = \int d^4x \left[ \frac{1}{2} \Phi(-\partial^2)\Phi + \frac{1}{2} V(-\partial^2)V + \sqrt{2i\theta^2} V - \omega(-\partial^2)\omega + \frac{1}{2} U(-\partial^2)U \right].
\]
From now on, we will neglect the decoupled fields $(U, \bar{\omega}, \omega)$ and we will diagonalize the action above by introducing the new field variables:
\[
\Phi = \frac{1}{\sqrt{2}}(\lambda + \eta), \quad V = \frac{1}{\sqrt{2}}(\lambda - \eta).
\]
Thus, we have
\[
S = \int d^4x \left[ \frac{1}{2} \lambda(-\partial^2 + i\sqrt{2\theta^2})\lambda + \frac{1}{2} \eta(-\partial^2 - i\sqrt{2\theta^2})\eta \right],
\]
and the propagators in terms of the new field variables stand by
\[
\langle \lambda(p)\lambda(-p) \rangle = \frac{1}{p^2 + i\sqrt{2\theta^2}}, \quad \langle \eta(p)\eta(-p) \rangle = \frac{1}{p^2 - i\sqrt{2\theta^2}}.
\]
From this expression one immediately sees that the fields $\lambda$ and $\eta$ correspond to the propagation of unphysical modes with complex squared masses $\pm\sqrt{2i\theta}$. These are the so-called $i$-particles of the model. Notice also that, despite the imaginary terms, the action $[39]$ is Hermitian if we require that $\lambda^\dagger = \eta$.

We already argued that the excitations in terms of $i$-particles are unphysical. Nevertheless, following [9], physical states can be introduced by constructing suitable composite operators out of the fields $(\lambda, \eta)$ which exhibit desirable analyticity properties, as encoded in the Källén-Lehmann spectral representation. Such composite operators are obtained by requiring that the $i$-particles fields enter in pairs, i.e. the desired operator contains as many fields of the type $\lambda$ as of the type $\eta$. It ensures that in the corresponding correlation function only complex conjugate pairs of $i$-particles propagate in the Feynman diagrams. In the present case, the simplest example of a local composite operator with the required physical properties is $O(x) = \lambda(x)\eta(x)$. In [9] it was shown that the correlation function $\langle O(p)O(-p) \rangle$ has a well defined Källén-Lehmann spectral representation:
\[
\langle O(p)O(-p) \rangle = \int \frac{d^4q}{(2\pi)^4} \frac{1}{(p-q)^2 - i\sqrt{2\theta^2}} \frac{1}{q^2 + i\sqrt{2\theta^2}} = \int_{\tau_0}^{\infty} d\tau \frac{\rho(\tau)}{\tau + p^2},
\]
with
\[
\rho(\tau) = \frac{1}{(4\pi)^2} \sqrt{1 - \frac{8\theta^4}{\tau^2}}, \quad \tau_0 = 2\sqrt{2\theta^2}.
\]
Furthermore, a model with interacting $i$-particles is dealt in [23].

\[\text{[9] Here we present only the } 4d \text{ result. The results for the spectral density in } 2d \text{ and } 3d \text{ can also be found in [9].}\]
2.3 The replica model

Let us now describe, in few words, the so-called replica model. It was first introduced in \[8\] as an alternative way to solve the Gribov problem. Here, we present the replica model by starting with a scalar field with a quartic self-interaction term:

\[ S = \int d^4x \left[ \frac{1}{2} \Phi(-\partial^2 + m^2)\Phi + g \Phi^4 \right]. \] (42)

Then, we define a replica of the action above,

\[ S' = \int d^4x \left[ \frac{1}{2} \Phi'(-\partial^2 + m^2)\Phi' + g \Phi'^4 \right], \] (43)

with the same parameters \( m \) and \( g \). The two theories interact by a soft term depending on a free parameter, say \( \mu^2 \), and the replica model is then written as

\[ S_{\text{replica}} = \int d^4x \left[ \frac{1}{2} \Phi(-\partial^2 + m^2)\Phi + \frac{1}{2} \Phi'(-\partial^2 + m^2)\Phi' + i\mu^2 \Phi\Phi' + g \Phi^4 + g \Phi'^4 \right]. \] (44)

The replica model (44) enjoys a symmetry which guarantees the existence of an unique mass parameter \( m \) and an unique quartic coupling constant \( g \) for both sectors of the theory (the original starting point model and its replica). This symmetry is often called mirror symmetry and its given by:

\[ \Phi \rightarrow \Phi', \quad \Phi' \rightarrow \Phi. \] (45)

Notice also that, when \( m^2 = 0 \), the propagator of \( \Phi \) field is of the Gribov type, with \( \mu^2 \) playing the role of the Gribov parameter\[^3\]. Thus, it can also be diagonalized in terms of \( i \)-particles. In the deep ultraviolet regime, the two theories completely decouple and we obtain that the \( \Phi \) field is said deconfined exhibiting a Yukawa-like propagator. The \( \mu^2 \) parameter might be fixed by a gap equation like in the GZ model \[^{15}\].

3 The model: The \( SU(3) \) Yang-Mills with dimension 2 condensates

We will begin with the pure Yang-Mills action in the Landau gauge, eq. (41). Taking this action into account and trying not to change the fundamental behavior in the ultraviolet regime we limit ourselves to operators of ultraviolet dimension 2. These type of operators give rise to soft breaking terms. In particular, the mass operator \( \frac{1}{2} A_\mu^a A_\mu^a \) is well understood in the context of the local composite operator method (LCO) \[^{24}\] and is responsible for a Yukawa type propagator. We will focus into another dimension 2 operator. One that is only possible into \( SU(N \geq 3) \), the operator constructed with the symmetric structure constant (see Appendix B) and the gauge field \( A_\mu^a \), i.e. \( \frac{1}{2} d^{abc} A_\mu^b A_\mu^c \).

It is perfectly possible to introduce these two operators in the quantum action and study the renormalizability of both, which is done in Appendix A. In order to introduce the operator \( \frac{1}{2} d^{abc} A_\mu^b A_\mu^c \), it is also necessary to introduce a BRST doublet of sources

\[ s\lambda^a = iJ^a, \quad sJ^a = 0. \] (46)

Then, the BRST invariant action including the dimension 2 operator \( \frac{1}{2} d^{abc} A_\mu^b A_\mu^c \) is given by:

\[ \Sigma = S_{\text{YM}} + s \int d^4x \left( \frac{1}{2} \lambda^a d^{abc} A_\mu^b A_\mu^c - \frac{i\epsilon}{2} \lambda^a J^a + \alpha \lambda^a \partial_\mu A_\mu^a \right), \]

\[ = S_{\text{YM}} + \int d^4x \left( \frac{i}{2} J^a d^{abc} A_\mu^b A_\mu^c + \lambda^a d^{abc} (\partial_\mu A_\mu^b) A_\mu^c - \frac{g}{2} f^{abc} f^{dce} \lambda^e A_\mu^d A_\mu^e + \frac{\epsilon}{2} J^a J^a \right) + \alpha \int d^4x \left( iJ^a \partial_\mu A_\mu^a + \lambda^a \partial_\mu D_\mu^a c^b \right). \] (47)

\[^{10}\]For \( m^2 \neq 0 \) the propagator behaves like the most general RGZ model \[^{7}\].
The $\alpha$ terms are necessary by algebraic renormalization consistency, due to the fact that there is any symmetry to exclude such terms. At this point, it is important to emphasize that, although we introduce the operator consistent with the study of renormalizability via a BRST doublet of sources, here we are interested in bringing the sources for your physical value, following the same procedure of Gribov-Zwanziger. A possible condensation of this operator will give rise to a non-zero expectation value in the vacuum of $J$. It is necessary a non-zero expected value for $J$ so as to satisfy the Gribov condition, which we will show in the next section. Another possible way to obtain this value is by the LCO method which uses the technique of effective potential. We emphasize that it is not necessary to implement the LCO here due to the Gribov condition.

Thus, it implies that we have to choose a direction for $J$. To guide implementation of this choice let analyze some properties of the group SU(3) (Appendix B). We can see that the gauge field $A_\mu$ can be expanded in a base of the SU(3) generators as

$$A_\mu = \sum_{a=1}^{8} A^a_\mu \frac{\lambda^a}{2} = \sum_{a \neq 3, 8} A^a_\mu \frac{\lambda^a}{2} + A^+_\mu \lambda_+ + A^-_\mu \lambda_-,$$

where

$$A^\pm_\mu = \frac{1}{2} \left( \frac{1}{\sqrt{3}} A^8_\mu \pm A^3_\mu \right).$$

And the pure $A$-field sector of the SU(3) Yang-Mills action, i.e.

$$S_{A\text{-field}} = \frac{1}{4} \int d^4x F_{\mu\nu}^a F_{\mu\nu}^a,$$

is left invariant by the transformations

$$\begin{align*}
(A^1_\mu, A^2_\mu) &\to (A^1_\mu, A^2_\mu), \\
(A^+_\mu, A^-_\mu, A^5_\mu) &\to (-A^-_\mu, A^7_\mu, A^6_\mu), \\
(A^-_\mu, A^6_\mu, A^7_\mu) &\to (-A^+_\mu, -A^5_\mu, -A^4_\mu).
\end{align*}$$

Notice that these transformations interchange the groups SU(2)$_{II}$ and SU(2)$_{III}$ and it reminds us the mirror symmetry of the replica model described in the preceding section. However, we can not identify these two subsectors of the theory as a replica model, at least not as originally conceived in [8], because of the presence of hard interaction terms. Furthermore, the only direction that maintains the symmetry is the direction 3. Then, choosing

$$\langle J^a \rangle = m^2 \delta^{a3},$$

we have:

$$i \langle J^a \rangle d^{abc} A^b_\mu A^c_\mu = \frac{im^2}{3} (A^+_\mu A^+ - A^-_\mu A^-) + \frac{im^2}{2} (A^4_\mu A^4 - A^7_\mu A^7) + \frac{im^2}{2} (A^5_\mu A^5 - A^6_\mu A^6).$$

---

11Also, in Landau gauge these extra terms can be absorbed by performing a linear shift of the fields variables $b^a$ and $\bar{c}^a J a \rightarrow ba + i \alpha Ja, \bar{c}a \rightarrow \bar{c}a + i \alpha \lambda a$.

12We are not calculating the value of this condensate. We limit ourselves in this work to study the consequences of its existence.

13Of course that the symmetry can be extended by the ghost and gauge fixing sectors of action.
And, with choice (52), the action (47) gives rise to a propagator of the form:

\[ \left\langle A^\mu_\nu(k)A^\nu_\nu(-k) \right\rangle = \left[ \frac{1}{k^2} \sum_{i=1}^{2} \delta^a_i \delta^b_i + \frac{1}{k^2 + i m^2} \sum_{i=4}^{5} \delta^a_i \delta^b_i + \frac{1}{k^2 - i m^2} \sum_{i=6}^{7} \delta^a_i \delta^b_i \right. \\
\left. + \frac{k^2}{k^4 + \frac{m^2}{3}} (\delta^{ab} \delta^{88} + \delta^{a3} \delta^{b8}) - \delta^{ab} \delta^{88} + \delta^{a3} \delta^{b8}, \delta^a \right] \theta_{\mu\nu}(k), \quad (54) \]

with \( \theta_{\mu\nu}(k) \) being the transverse projector,

\[ \theta_{\mu\nu}(k) = \left( \delta_{\mu\nu} - \frac{k_\mu k_\nu}{k^2} \right) . \quad (55) \]

This calculation is done in the Gell-Mann representation [11], see Appendix B. Although (52) explicitly breaking the group, this is a soft breaking and in the ultraviolet regime is expected that the group structure is recovered. Note that we get a propagator which has the \textit{i}-particle structure [2].

It is important to stress here that in spite of have two massless poles in the propagator it is not necessary that we have physical particles directly associated to this propagator. The interaction terms will mix the \textit{i}-particles with the massless ones. This property can be easily observed if we rewrite the propagator as:

\[ \left\langle A^\mu_\nu(k)A^\nu_\nu(-k) \right\rangle = \left\{ \frac{1}{k^2 + \frac{m^2}{4}} (k^2 \delta^{ab} - i m^2 \delta^{ab3}) + \frac{m^4}{4(k^2 + \frac{m^2}{4})} \left[ \frac{1}{k^2} \sum_{i=1}^{2} \delta^a_i \delta^b_i \\
- \frac{k^2}{3k^4 + \frac{m^2}{3}} (\delta^{ab} \delta^{88} + \delta^{a3} \delta^{b8}) + i \frac{m^2}{3\sqrt{3k}k^4 + \frac{m^2}{3}} (\delta^{ab} \delta^{88} + \delta^{a3} \delta^{b8}) \right] \right\} \theta_{\mu\nu}(k), \quad (56) \]

where \( \delta^{ab3} \) are symmetric structure constants in the 3 direction. In particular, for further use, we also display:

\[ \left\langle A^1_\mu(k)A^1_\nu(-k) \right\rangle = \left\langle A^2_\mu(k)A^2_\nu(-k) \right\rangle = \frac{1}{k^2} \theta_{\mu\nu}(k), \]
\[ \left\langle A^1_\mu(k)A^4_\nu(-k) \right\rangle = \left\langle A^5_\mu(k)A^5_\nu(-k) \right\rangle = \frac{1}{k^2 + \frac{m^2}{2}} \theta_{\mu\nu}(k), \]
\[ \left\langle A^2_\mu(k)A^6_\nu(-k) \right\rangle = \left\langle A^7_\mu(k)A^7_\nu(-k) \right\rangle = \frac{1}{k^2 - \frac{m^2}{2}} \theta_{\mu\nu}(k), \]
\[ \left\langle A^3_\mu(k)A^3_\nu(-k) \right\rangle = \left\langle A^8_\mu(k)A^8_\nu(-k) \right\rangle = \frac{k^2}{k^4 + \frac{m^2}{3}} \theta_{\mu\nu}(k), \]
\[ \left\langle A^8_\mu(k)A^8_\nu(-k) \right\rangle = \left\langle A^8_\mu(k)A^8_\nu(-k) \right\rangle = -\frac{m^2}{\sqrt{3k}k^4 + \frac{m^2}{3}} \theta_{\mu\nu}(k). \quad (57) \]

At this point some considerations about the explicitly breaking of the \( SU(3) \) are necessary. First, as is shown in Appendix B the Gell-Mann matrices grouped as in (11.3) have the same algebraic properties as the Pauli matrices and so determine three natural \( SU(2) \) subalgebras. So taking

\[ h_1 = \lambda^3, \quad h_2 = \lambda^8, \quad e^1_\pm = \lambda^1 \pm i \lambda^2, \quad e^2_\pm = \lambda^6 \pm i \lambda^7, \quad e^3_\pm = \lambda^4 \pm i \lambda^5, \]

it is easy to observe that the \( e^i_\pm \) obeys the following algebra

\[ [h_1, h_2] = 0, \quad \left[ \sqrt{3}h_2 + h_1, e^1_\pm \right] = \pm e^1_\pm, \quad \left[ \sqrt{3}h_2 + h_1, e^2_\pm \right] = \pm \frac{1}{2} e^2_\pm, \quad \left[ \sqrt{3}h_2 + h_1, e^3_\pm \right] = \pm \frac{1}{2} e^3_\pm, \]
\[ \left[ \sqrt{3}h_2 - h_1, e^1_\pm \right] = \mp e^1_\pm, \quad \left[ \sqrt{3}h_2 - h_1, e^2_\pm \right] = \mp \frac{1}{2} e^2_\pm, \quad \left[ \sqrt{3}h_2 - h_1, e^3_\pm \right] = \mp \frac{1}{2} e^3_\pm, \]
\[ e^1_+, e^1_- = 2h_1, \quad e^2_+, e^2_- = \sqrt{3}h_2 - h_1, \quad e^3_+, e^3_- = \sqrt{3}h_2 + h_1. \quad (58) \]
This give rise to the well know weight diagram [11]. Moreover, from the properties of $SU(2)$ representations we know that $2p = m_1; \sqrt{3}q - p = m_2; \sqrt{3}q + p = m_3$, where $(p, q)$ corresponds respectively to the eigenvalues of $h_1$ and $h_2$ ordered as points in $\mathbb{R}^2$. Assuming that the trace of the propagator must be real, the natural choice of the direction of the breaking in $h_1$ give rise to two goldstone bosons associated to $e^1_\perp$. The remaining 2 sets of $SU(2)$ corresponds to a similar structure as the replica model [8].

It is important to stress here that this is not a model for confinement in $SU(3)$. This is essentially an alternative mechanism for Gribov that presents confinement in the remaining two $SU(2)$ groups and has some defined observables associated to the remaining $SU(2)$ groups. In section 5 we will return to these issues in order to define the relationship between observables and the remaining group structure.

In order to make clear the importance of each operator and their relation to the two types of solutions came from the Schwinger-Dyson equations, the scaling type and the decoupling one, in next section we discuss the relation between these solutions and the operators $\frac{1}{2}d^{abc}A^a_{\mu}A^b_{\nu}$ and $\frac{1}{2}A^a_{\mu}A^a_{\nu}$.

### 4 Taking into account the Gribov copies. The scaling type solution for the gluon and ghost propagators

In order to offer a better understanding of the model, a dynamical framework for the parameter $\langle J^a \rangle = m^2 \delta^{a3}$ should be provided, i.e. we should be able to establish a gap equation for that parameter, allowing us to express $m^2$ as a function of the coupling constant $g$, as in the Gribov approximation [4] or in the GZ theory [5, 6]. The most immediate way to achieve a meaningful gap equation for $m^2$ is following the steps detailed in [9] → [18], which consists in restricting the domain of integration in the functional integral to the Gribov region with no-pole condition (14). Note that this condition relies on the observation that the Faddeev-Popov operators are invertible in Gribov region and their inverse are nothing but the twopoint ghost functions [11].

Therefore, in our case, we have to calculate the twopoint ghost functions [11], with the propagator (51). And the no-pole condition is implemented (see [8] too) by stating that

$$\sigma(0, A) = 1,$$

which yields the gap equation determining the parameter $m^2$, or equivalently $\langle J^a \rangle \langle J^a \rangle$. After some calculation the gap equation yields:

$$1 = g^2 \frac{3}{4} \int \frac{d^Dk}{(2\pi)^D} \frac{1}{k^4 + m^4} + g^2 \frac{1}{16} \int \frac{d^Dk}{(2\pi)^D} \frac{m^4}{k^4} \frac{1}{k^4 + m^4} \left( \frac{1}{k^4 + m^4} \right),$$

(60)

where dimensional regularization, $D = 4 - \epsilon$, has been employed, and we make use of $\delta^{abc} \langle J^c \rangle = (14)$.

The gap equation (60) enables us to express the parameter $m^4$ as a function of the coupling constant $g$. It is clear that the second integral is absolutely converge and do not change the fact that $m$ is determined as a function of a regularization mass $\Lambda$.

Let us now see that our model also recovers the ghost propagator which is enhanced in the infrared as in the usual Gribov approach that is made in detail in the review [13]. The ghost propagator is given by (11) with $\sigma(p^2, A)$ defined by (12). As our gauge field propagator is (54), we have (with $N = 3$):

$$\sigma(p^2, m^2) = 3g^2 \frac{P_\mu P_\nu}{p^2} \int \frac{d^Dk}{(2\pi)^D} \frac{1}{(p - k)^2} \left[ \frac{k^2}{k^4 + m^4} + \left( \frac{m^4}{12(k^4 + m^4)(k^4 + m^4/3)} \right) \right] \theta_\mu(k),$$

\footnote{This general property can be easily seen, for example, in the Gell-Mann representation for the generators.}
Let us analyze the infrared behavior, \( k \approx 0 \), of \( (1 - \sigma(p^2, m^2)) \). Making use of the gap equation (60), which can be rewritten from Lorentz covariance as:

\[
1 = 3g^2 \frac{P_{\mu \nu}}{p^2} \int \frac{d^Dk}{(2\pi)^D} \left[ \frac{1}{k^4 + m^4} + \left( \frac{m^4}{12k^2(k^4 + m^4)} \right) \right] \theta_{\mu \nu}(k),
\]

(61)

We obtain for \( (1 - \sigma(p^2, m^2)) \):

\[
(1 - \sigma(p^2, m^2)) = 3g^2 \frac{P_{\mu \nu}}{p^2} \int \frac{d^Dk}{(2\pi)^D} \left( \frac{1}{p^2 - 2pk} \right) \left[ \frac{1}{k^4 + m^4} + \left( \frac{m^4}{12k^2(k^4 + m^4)} \right) \right] \theta_{\mu \nu}(k)
\]

(62)

\[
= 3g^2 \frac{P_{\mu \nu}}{p^2} \mathcal{P}_{\mu \nu}(p),
\]

where

\[
\mathcal{P}_{\mu \nu}(p) = \int \frac{d^Dk}{(2\pi)^D} \left( \frac{p^2 - 2pk}{(p - k)^2} \right) \left[ \frac{1}{k^4 + m^4} + \left( \frac{m^4}{12k^2(k^4 + m^4)} \right) \right] \theta_{\mu \nu}(k).
\]

(63)

From this expression, one sees that \( \mathcal{P}_{\mu \nu}(p) \) is convergent and non singular at \( p = 0 \). It follows that, for \( p \approx 0 \):

\[
\mathcal{P}_{\mu \nu}(p)_{p \to 0} \approx p^2 \int \frac{d^Dk}{(2\pi)^D} \frac{1}{k^2} \left[ \frac{1}{k^4 + m^4} + \left( \frac{m^4}{12k^2(k^4 + m^4)} \right) \right] \theta_{\mu \nu}(k).
\]

(64)

Thus, it follows that, for small values of the momentum

\[
(1 - \sigma(p^2, m^2))|_{k^2 \approx 0} = C p^2,
\]

(65)

and we recover the ghost propagator which is enhanced in the infrared \( \langle \overline{c}c(p)\rangle \approx \frac{1}{p^4} \) (see equation (11)). We have thus recovered the so-called scaling solution, \( i.e. \) a suppressed gluon propagator which vanishes at the origin (51), and enhanced ghosts, which corresponds to the solution of the GZ theory.

4.1 Taking into account \( \frac{1}{2} A_\mu^a A_\mu^a \) and the decoupling type solution.

Recent lattice numerical simulations [26 27 28 29 31 30] indicates a gluon propagator which is suppressed in the infrared and which attains a finite non-vanishing value at zero momentum, while the ghost propagator turns out to be not enhanced, \( i.e. \) \( \langle \overline{c}c(k)\rangle \approx \frac{1}{k^2} \). This behaviour is known as the decoupling solution and has also been obtained from the analysis of the Schwinger-Dyson equations [32 33 34]. This solution appears in the Gribov-Zwanziger theory when the dynamics of the localizing fields is taken into account. In our model this behaviour is associated to the mass operator \( \frac{1}{2} A_\mu^a A_\mu^a \). Before presenting the equations that characterize the stability of this operator it is important to emphasize that the tad pole presented in (58) despite being ultraviolet convergent has problems in infrared, but not necessarily at \( k = 0 \). The best chance to solve this divergency is introducing a mass term in the action.

The action \( \Sigma \) with a mass term is given by:

\[
\Sigma_\mu = \Sigma + \frac{\mu^2}{2} \int d^4x A_\mu^a A_\mu^a,
\]

(66)
where $\Sigma$ was defined in (47). The BRST variation of the mass term, turns out to be proportional to the equation of motion of $b^a$ i.e

$$\delta \mathcal{S}(\Sigma_\mu) = 0 - \mu^2 \int d^4x \, (\partial_\mu c^\alpha) A^\mu_\alpha = -i\mu^2 \int d^4x \, c^\alpha \frac{\delta \Sigma_\mu}{\delta b^\alpha}, \quad (67)$$

modifying the Slavnov-Taylor to

$$\overline{\mathcal{S}}(\Sigma_\mu) = \int d^4x \left\{ \frac{\delta \Sigma_\mu}{\delta \Sigma_\mu} + \frac{\delta \Sigma_\mu}{\delta L^2} \frac{\delta \Sigma_\mu}{\delta c^\alpha} + i\eta^a \frac{\delta \Sigma_\mu}{\delta \lambda^a} + i\eta^a \frac{\delta \Sigma_\mu}{\delta \lambda^a} \right\} = 0. \quad (68)$$

It is now clear that the gauge propagator changes to a propagator in close relation to the one obtained from the refined Gribov-Zwanziger theory [35, 7, 36]. The new propagator is given by:

$$< A^a_\mu(k) A^b_\nu(-k) > = \left\{ \frac{1}{(k^2 + \mu^2)^2 + m^4} \right\} (\delta^{ab} - i\eta^a x^b) + \frac{m^4}{4((k^2 + \mu^2)^2 + m^4)} \left\{ \frac{1}{(k^2 + \mu^2)^2} \sum_{i=1}^2 \delta^{ai} \delta^{bi} - \frac{1}{3} \left( \frac{k^2 + \mu^2}{(k^2 + \mu^2)^2 + m^4} \right) (\delta^{a8} \delta^{b8} + \delta^{a3} \delta^{b3}) \right. \right.$$  

$$\left. \left. + \frac{i}{\sqrt{3}} \frac{1}{(k^2 + \mu^2)^2 + m^4} (\delta^{a8} \delta^{b8} + \delta^{a3} \delta^{b3}) \right\} \xi_{\mu\nu}, \quad (69)$$

where $m^4$ and $\mu^2$ are obtained by Gribov conditions presented in Appendix A3. This expression has a finite nonvanishing value at zero momentum characterizing the decoupling type solution. It is important to emphasize here that lattice simulation results that have obtained the behaviour of the propagator are making use of the trace of the propagator. Remembering that $d^{ab} = 0$, the dominating term that lattice is capable to see is $\frac{k^2 + \mu^2}{k^4 + 2\mu^2 k^2 + m^4 + \mu^4}$. It is clear that the dynamical origem of this mass parameter needs more explanation and we pretend to do this into a future work.

5 Local composite operator and the Källén-Lehmann spectral representation

Remove the gauge fields of the physical spectrum of the theory is not enough for a model that attempts to offer an alternative, at least in part, to the original Gribov question. It is also necessary to present a candidate for physical observable that displays the Källén-Lehmann spectral representation and corresponds to an invariant composite operator. It is pointed out in [9, 8] that a local composite operator constructed with $i$-particles [9] has one-loop correlation function that exhibits the Källén-Lehmann spectral representation, i.e.

$$\mathcal{I}(p^2) = \int \frac{d^4k}{(2\pi)^4} \left\{ \frac{1}{(p - k)^2 + i\sqrt{2}\nu^2)(k^2 - i\sqrt{2}\nu^2)} \right\}, \quad (70)$$

exhibits a spectral representation, as:

$$\mathcal{I}(p^2) - \mathcal{I}(0) = \int_{2\sqrt{2}\nu^2}^\infty dv \rho(v) \left\{ \frac{1}{v + p^2} - \frac{1}{v} \right\}, \quad (71)$$

where the spectral density $\rho(v) = \frac{1}{16\pi^2 \sqrt{v^2 - 8\nu^2}}$ is positive in the range of integration. This property help us to find an operator that has the desired analyticity properties. Now let us return to the breaking of the
SU(3) group in order to understand the mechanism that permits the existence of physical observables. First of all, one of the desired aspects for one observable is not only that has Källén-Lehmann spectral representation of a particle but also does not carries color index and be gauge invariant. It is clear that the last requirement is not possible due to the explicitly breaking of the BRST symmetry. This is also a problem in the original Gribov-Zwanziger due to the same problem, i.e. the explicitly symmetry breaking. In our case another question emerges, the explicitly breaking of the group structure. Fortunately the last question will be the answer in order to obtain observables that does not carry color index. At least of the remaining group structure.

Analyzing the \( i \)-particles concept presented in \cite{9, 8} we can see that it is impossible to obtain from a Gribov type propagator an observable that do not corresponds to an integral of the type \( (70) \). This does not only suggests that the observables must be constructed taking into account \( i \)-particle type correlators in order to obtain a real particle pole, but also indicates that a mechanism in order to do that must mix two different types of particles as done in \cite{58}. The natural candidates that emerges as possible observables can be associated to the remaining 2 sets of \( \mathcal{L}(SU(2)) \), in particular it is convenient to define the quantities

\[
E_{\mu\nu}^{3+} \equiv \frac{1}{\sqrt{2}}(F_{\mu\nu}^4 + i F_{\mu\nu}^5), \quad E_{\mu\nu}^{3-} \equiv \frac{1}{\sqrt{2}}(F_{\mu\nu}^4 - i F_{\mu\nu}^5), \quad E_{\mu\nu}^{2+} \equiv \frac{1}{\sqrt{2}}(F_{\mu\nu}^6 + i F_{\mu\nu}^7) \quad \text{and} \quad E_{\mu\nu}^{2-} \equiv \frac{1}{\sqrt{2}}(F_{\mu\nu}^6 - i F_{\mu\nu}^7)
\]

that obeys the same algebra as presented in \( (58) \). From these operators it is convenient to define one possible candidate to observable as:

\[
\phi \equiv E_{\mu\nu}^{2+} E_{\mu\nu}^{3+} - E_{\mu\nu}^{2-} E_{\mu\nu}^{3-} = F_{\mu\nu}^4 F_{\mu\nu}^5 - F_{\mu\nu}^6 F_{\mu\nu}^7.
\]

(72)

It should be noted that in spite of the breaking of the BRST symmetry, the candidate to observable must be a singlet. It is important to remember that the \( E_{\mu\nu} \) essentially obeys the same group properties as defined in \( (58) \). Remembering that we are perfroming the breaking in direction 3 or in the notation presented in \( (58) \) \( h_1 \), the algebra between \( h_1 \) and \( e_+^2 e_-^2 \) is given by:

\[
[h_1, e_+^2 e_-^2] = \pm \frac{1}{2} e_\pm^2 \quad [h_1, e_+^3] = \pm \frac{1}{2} e_\pm^3,
\]

(73)

which makes the result algebraic \([h_1, e_+^2 e_-^3 + e_-^3 e_+^2] = 0\) easier to obtain and proving that this operator is invariant under the remaining group charge defined by the algebra \( (73) \). Taking into account the propagators as:

\[
\begin{align*}
< A_\mu^1(k) A_\nu^1(-k) > &= < A_\mu^2(k) A_\nu^2(-k) > = \frac{1}{k^2} \theta_{\mu\nu}(k) \\
< A_\mu^4(k) A_\nu^4(-k) > &= < A_\mu^5(k) A_\nu^5(-k) > = \frac{1}{k^2 + i \frac{m}{2}} \theta_{\mu\nu}(k) \\
< A_\mu^6(k) A_\nu^6(-k) > &= < A_\mu^7(k) A_\nu^7(-k) > = \frac{1}{k^2 - i \frac{m}{2}} \theta_{\mu\nu}(k) \\
< A_\mu^3(k) A_\nu^3(-k) > &= < A_\mu^8(k) A_\nu^8(-k) > = \frac{k^2}{k^4 + \frac{m^4}{3}} \theta_{\mu\nu}(k) \\
< A_\mu^8(k) A_\nu^8(-k) > &= < A_\mu^8(k) A_\nu^8(-k) > = -i \frac{m^2}{\sqrt{3} k^4 + \frac{m^4}{3}} \theta_{\mu\nu}(k),
\end{align*}
\]

(74)

the first candidate which has the desired one-loop correlation function \cite{9} is given by:

\[
< \phi(k) \phi(-k) > = 12 \int_{m^2}^{\infty} dv \frac{\rho(v)}{v + k^2},
\]

\[
\rho(v) = \frac{\sqrt{v^2 - m^4 (v^2 + m^4)}}{\pi^2 v}.
\]

(75)
There is another observable with different value for the mass of the condensate. In order to understand the second candidate to an observable, i.e. that presents the Källén-Lehmann spectral representation of a particle, it is convenient to consider the quadratic part of the action, in particular the term with $A^3_\mu$ and $A^8_\mu$.

$$S_{3,8} = \int d^4x \left\{ \frac{1}{2} A^3_\mu (-\partial^2) A^3_\mu + \frac{1}{2} A^8_\mu (-\partial^2) A^8_\mu + m^2 \frac{i}{\sqrt{3}} A^3_\mu A^8_\mu \right\},$$  \hspace{1cm} (76)

where we have already taken into account the Landau gauge conditions, $\partial_\mu A^3_\mu = 0$ and $\partial_\mu A^8_\mu = 0$. This sector of the action can be diagonalized trivially making the field redefinition:

$$U_\mu = \frac{1}{\sqrt{2}} (A^3_\mu + A^8_\mu)$$
$$V_\mu = \frac{1}{\sqrt{2}} (-A^3_\mu + A^8_\mu).$$  \hspace{1cm} (77)

Therefore

$$S_{3,8} = \int d^4x \left\{ \frac{1}{2} U_\mu (-\partial^2 + i \frac{m^2}{\sqrt{3}}) U_\mu + \frac{1}{2} V_\mu (-\partial^2 - i \frac{m^2}{\sqrt{3}}) V_\mu \right\},$$  \hspace{1cm} (78)

which describes again the $i$-particle structure. In order to write a physical operator that has the desired structure, it is sufficient to study the operator

$$\chi = (\partial_\mu U_\nu - \partial_\nu U_\mu)(\partial_\mu V_\nu - \partial_\nu V_\mu),$$  \hspace{1cm} (79)

where its two-point correlation function can be cast in the form of a Källén-Lehmann spectral representation of a physical particle,

$$< \chi(k) \chi(-k) > = \frac{3}{8} \int_2^{\infty} dv \frac{\rho(v)}{v + k^2},$$
$$\rho(v) = \frac{\sqrt{v^2 - \frac{4}{3} m^4(v^2 + \frac{4}{3} m^4)}}{\pi^2 v}. \hspace{1cm} (80)$$

Again it is convenient to observe that this operator can be associated to the abelian subgroup of the original $SU(3)$ group and it is clear that the mass pole only depends on the mass gap of the $i$-particle. Moreover it is important to stress that due to the fact that the insertion is a soft broken, the group symmetry is recovered in the limit $k \to \infty$.

Therefore, with a break of $SU(3)$, our model displays composite operators that are potential candidates for observable on the remaining group structure, in close analogy with replica model [8]. Note that the operators presented here may be useful in understanding the spectroscopy of glueballs presented, eg in [42], since Gribov approach has shown promising results in this direction, see the recent literature [41] and references therein. This analysis is very complex and requires further investigation.

Here it is important to comment that a dynamical symmetry breaking could be the answer to a BRST invarinante observable. In this case the full BRST operator carries not only the gauge fields but also the auxiliary fields. In this case it could be possible to define a BRST and group invariant colorless physical observable.

6 Conclusions

In this work we have studied the $SU(3)$ Yang-Mills theory in a Landau gauge with a soft mass term proportional to the symmetric structure constant. This soft mass term allow us to treat the Gribov problem
in a local renormalizable action without the need of auxiliary fields like in the Gribov-Zwanziger theory. The confining behavior is thus induced by the soft mass term and the relation with the scaling solution is presented in close analogy to the Gribov mechanism and to the replica model[8]. Also the introduction of the diagonal mass term and the relation with the decoupling solution is discussed. Moreover this can open the possibility of a more general relation between confining behavior and the existence of gauge condensates in the infrared regime. In fact, it would be interesting the possibility of obtaining the value of the mass gap by the local composite operator method and study the relation between the extremum of the effective potential and the Gribov mass gap equation.

The result we have obtained suggests further that the restriction to the first Gribov region could be implemented into other gauges by a simple soft mass term involving the symmetric structure constant that breaks the original group into a more simple group structure with a replica. Further studies aimed at establishing such a connection, in particular for the maximal abelian gauge, in a more precise way is called for and is a topic of current investigation.

Another important point analysed is the physical operators associated to these propagator. Due to the structure of the propagator this is a difficult task. The simple \(i\)-particle structure is not present in these model and the mechanism associated to the \(i\)-particle is much more complex and involves the group structure itself. This is the price to be paid in order to do not double the number of gauge fields or introduce auxiliary localizing fields. Nevertheless we find possible candidates of physical operators associated to this propagator in which the group structure is present in the ultraviolet regime. It is argued that a dynamical breaking mechanism could restore the full BRST invariance of the observable, in particular for \(F_{\mu\nu}(x)F_{\mu\nu}^{\dagger}(x)\) in the target remaining group structure. The construction of all this mechanism for a target remaining group like an SU(3) replica is another topic to be investigated into future works.

A Renormalizability

A.1 Equations Compatible with the Quantum Action Principle

The full set of equations compatible with the quantum action principle [12] is given by:

- The Lagrange multiplier and the antighost equation:

\[
\frac{\delta \Sigma}{\delta \beta^a} = i \partial_\mu A_\mu^a \\
\frac{\delta \Sigma}{\delta \xi} + \partial_\mu \frac{\delta \Sigma}{\delta \Omega_\mu^a} = 0.
\] (81)
• The integrated ghost equation:

\[
G^a(\Sigma) = \Delta^a
\]

\[
G^a(\Sigma) = \int d^4x \left\{ \frac{\delta \Sigma}{\delta c^a} - igf^{abc}(c^b \frac{\delta \Sigma}{\delta b^c} + \lambda^b \frac{\delta \Sigma}{\delta j^b}) \right\},
\]

\[
\Delta^a = \int d^4x \left\{ gf^{abc}(\Omega^b_{\mu} + \alpha \partial_{\mu} \lambda^b) A^c_{\mu} - gf^{abc}(L^b_{\mu} c^c + i\varepsilon \lambda^b j^c) \right\}.
\]

(82)

Before presenting all the equations compatible with the quantum action principle it is relevant to note here that the term \( \frac{\epsilon}{2} j^a j^a \) generates a linear breaking in the ghost equation. This will gave us the information that this term does not renormalizes.

• Slavnov-Taylor:

\[
S(\Sigma) = \int d^4x \left\{ \frac{\delta \Sigma}{\delta \Omega^a_{\mu}} \frac{\delta \Sigma}{\delta A^a_{\mu}} + \frac{\delta \Sigma}{\delta L^a} \frac{\delta \Sigma}{\delta c^a} + ib^a \frac{\delta \Sigma}{\delta \lambda^a} + ij^a \frac{\delta \Sigma}{\delta j^a} \right\}
\]

\[
S(\Sigma) = 0
\]

(83)

• Rigid symmetry:

\[
W^a(\Sigma) = \int d^4x \left\{ A^b_{\mu} \frac{\delta \Sigma}{\delta A^c_{\mu}} + c^b \frac{\delta \Sigma}{\delta c^c} + b^b \frac{\delta \Sigma}{\delta b^c} + e^c \frac{\delta \Sigma}{\delta e^a} + \Omega^b_{\mu} \frac{\delta \Sigma}{\delta \Omega^c_{\mu}} + L^b_{\mu} \frac{\delta \Sigma}{\delta L^c} + \lambda^b \frac{\delta \Sigma}{\delta \lambda^c} + j^b \frac{\delta \Sigma}{\delta j^c} \right\}
\]

\[
W^a(\Sigma) = 0
\]

(84)

• SL(2, R):

\[
R(\Sigma) = \int d^4x \left\{ c^d \frac{\delta \Sigma}{\delta c^e} - i \frac{\delta \Sigma}{\delta b^e a} \frac{\delta \Sigma}{\delta L^a} \right\} = 0.
\]

(85)

A.2 Stability of the quantum action

The next step is to characterize the most general counterterm that can be freely added to all orders in perturbation theory respecting all the symmetries presented previously. Following the set up of the Algebraic Renormalization [12], we perturb the classical action \( \Sigma \) by adding an integrated local polynomial in the fields and sources, \( \Sigma_{\text{count}} \), with dimension bounded by four, and with vanishing ghost number. The perturbed action \( (\Sigma + \epsilon \Sigma_{\text{count}}) \), where \( \epsilon \) is an expansion parameter, fulfills, to the first order in \( \epsilon \), the same Ward identities obeyed by the classical action \( \Sigma \), i.e. equations (81)-(85).

\[
\beta_{\Sigma} \Sigma_{\text{count}} = 0, \quad \frac{\delta \Sigma_{\text{count}}}{\delta b^a} = 0, \quad \left( \frac{\delta}{\delta c^a} + \partial_{\mu} \frac{\delta}{\delta \Omega^a_{\mu}} \right) \Sigma_{\text{count}} = 0,
\]

\[
G^a_{\Sigma_{\text{count}}} = 0, \quad W^a_{\Sigma_{\text{count}}} = 0, \quad R_{\Sigma_{\text{count}}} = 0,
\]

(86)

where \( \beta_{\Sigma} \) is given by:

\[
\beta_{\Sigma} = \int d^4x \left\{ \frac{\delta \Sigma}{\delta \Omega^a_{\mu}} \frac{\delta}{\delta A^a_{\mu}} + \frac{\delta \Sigma}{\delta A^a_{\mu}} \frac{\delta}{\delta \Omega^a_{\mu}} + \frac{\delta \Sigma}{\delta L^a} \frac{\delta}{\delta e^a} + \frac{\delta \Sigma}{\delta e^a} \frac{\delta}{\delta L^a} + \frac{\delta}{\delta b^a} \frac{\delta}{\delta \lambda^a} + ib^a \frac{\delta}{\delta \lambda^a} + ij^a \frac{\delta}{\delta j^a} \right\}
\]

(87)

thus, taking into account the general results on the cohomology of Yang-Mills theories, the most general invariant counterterm is:

\[
\Sigma_{\text{count}} = \int d^4x \left\{ \frac{a_0}{4} F^a_{\mu \nu} F^a_{\mu \nu} \right\} + \beta_{\Sigma} \Delta^{-1}.
\]

(88)
The integrated term corresponds to the nontrivial part of the cohomology of $\beta_\Sigma$, while $\Delta^{-1}$ is an integrated polynomial in the fields and sources with ultraviolet dimension 4 and ghost number -1. The ultraviolet dimension and ghost number of all fields and sources are presented in Table 1 below.

Applying all the constraints given in (86) and observing the ultraviolet dimension 4 and ghost number -1, we obtain for $\Delta^{-1}$:

$$\Delta^{-1} = \int d^4x \{ a_1(\Omega^a_\mu + \partial_\mu \bar{\sigma}^a)A^a_\mu + a_2\alpha \partial_\mu \lambda^aA^a_\mu + \frac{a_3}{2} \lambda^a \rho^{abc} A^b_\mu A^c_\mu \}$$

(89)

We see thus that $\Sigma_{\text{count}}$ contains 4 free independent parameters, namely $(a_0, a_1, a_2, a_3)$. These parameters can be reabsorbed by means of a multiplicative renormalization of the gauge coupling constant $g$, off the parameters $(\alpha, \varepsilon)$ and the set of fields and sources $\phi = (A^a_\mu, c^a, b^a, \Omega^a_\mu, L^a, \lambda^a, j^a)$ according to

$$\Sigma(g, \alpha, \phi) + h\Sigma_{\text{count}} = \Sigma(g_0, \alpha_0, \phi_0) + O(h^2),$$

(90)

with

$$g_0 = Z_g g, \quad \alpha_0 = Z_\alpha \alpha, \quad \varepsilon_0 = Z_\varepsilon \varepsilon,$$

$$A^a_\mu = Z^\frac{1}{2}_A A^a_\mu, \quad c^0_0 = Z_c c^0, \quad b^0 = Z_b b^a, \quad \bar{\sigma}^a_0 = Z_{\bar{\sigma}} \bar{\sigma}^a_0,$$

$$\lambda^a_0 = Z_\lambda \lambda^a_0, \quad j^a_0 = Z_j j^a,$$

(91)

and

$$Z_g = 1 - h \frac{a_0}{2}, \quad Z_\alpha = 1 + h(\frac{a_0}{2} - a_2 - a_3), \quad Z_\varepsilon = 1 + h(2a_0 - 2a_3),$$

$$Z^\frac{1}{2}_A = 1 + \frac{h}{2}(a_0 + 2a_1), \quad Z_c = Z_{\bar{\sigma}} = Z_\Omega = 1 - h \frac{a_1}{2}, \quad Z_b = 1 - \frac{h}{2}(a_0 + 2a_1),$$

$$Z_\lambda = 1 - h(\frac{a_0}{2} - \frac{a_1}{2} - a_3), \quad Z_j = 1 - h(a_0 - a_3),$$

(92)

or directly in terms of the multiplicative relations between the renormalization factors $Z$

$$Z_b Z^\frac{1}{2}_A = 1, \quad Z_{\bar{\sigma}} Z_g Z^\frac{1}{2}_A Z_c = 1, \quad Z_\varepsilon Z_j^2 = 1.$$  

(93)

In order to clarify the importance of such relations and the Gribov type propagator, let us follow the Zwanziger prescription and set the sources $\lambda^a, j^a$ respectively to 0, $< j^a >$ with $< j^a > \neq 0$. Taking this into account it is clear that the action is BRST invariant up to a soft breaking term proportional to

$$< j^a >$$

$$s \Sigma(A^a_\mu, \bar{\sigma}^a, c^a, b^a, \lambda^a = 0, L^a = 0, \Omega^a_\mu = 0, j^a = < j^a >) = < j^a > \Delta^a$$

$$\Delta^a = \int d^4x \{ f^{abc} \partial_\mu c^b A^c_\mu - \frac{g}{2} f^{abc} b^c d^{cde} A^d_\mu A^e_\mu + \alpha \partial_\mu D^{abc} b^b \},$$

(94)

just like in the Zwanziger procedure to the Gribov problem and due to the fact that we don’t have localizing fields, the limit $< j^a > \rightarrow 0$ clearly recover the pure Yang-Mills in the deep ultraviolet region.

| fields and sources | $A^a_\mu$ | $c^a$ | $\bar{\sigma}^a$ | $b^a$ | $\lambda^a$ | $j^a$ | $\Omega^a_\mu$ | $L^a$ |
|-------------------|-----------|-------|-----------------|-------|------------|------|--------------|------|
| UV dimension      | 1         | 0     | 2               | 2     | 2          | 3    | 1            | 4    |
| Ghost number      | 0         | 1     | -1              | 0     | -1         | 0    | -1           | -2   |

Table 1: Quantum numbers of fields and sources.
A.3 Nonrenormalization of the soft mass term, simple one loop prove

Following closely the arguments presented by Sorella in [8] we will prove that there is no one loop correction to the soft mass term. The argument is based on dimensional regularization with minimal subtraction and the fact that, at least at one loop, the tadpole diagram in the two point $A - A$ is related to an integral of the type.

\[
\int \frac{d^Dk}{(2\pi)^D} f^{abc} f^{bec} < A^d_\mu(k) A^c_\nu(k) >, \quad D = 4 - \epsilon
\]  

which can be rewritten as

\[
\int \frac{d^Dk}{(2\pi)^D} \left( f^{abc} f^{bec} \frac{k^2}{k^4 + m^4} - i f^{abc} f^{bec} \frac{m^4}{4(k^4 + m^4)} \left( \frac{1}{k^2} \right)^2 \sum_{i=1}^{2} \delta \delta_i \delta \delta_i - \frac{1}{3} \left( \frac{k^2}{k^4 + m^4} \right) (\delta \delta^3 \delta \delta^3 + \delta \delta^3 \delta \delta^3) \right) + i \frac{m^2}{\sqrt{3}} \frac{1}{k^4 + m^4} (\delta \delta^3 \delta^3 + \delta \delta^3 \delta^3) \right) \right) \]  

(96)

Now in order to prove that all terms do not contribute to the mass, at least in first order of perturbation theory, let us analyse the different terms of this integral. The first term give rise to:

\[
\int \frac{d^Dk}{(2\pi)^D} \frac{k^2}{k^4 + \mu^4} = \int \frac{d^Dk}{(2\pi)^D} \frac{1}{k^2} - \int \frac{d^Dk}{(2\pi)^D} \frac{\mu^4}{k^2(k^4 + \mu^4)},
\]  

(97)

corresponding respectively to an integral that is zero by dimensional and a power counting ultraviolet convergent one. The second term to be analysed is of the form:

\[
\int \frac{d^Dk}{(2\pi)^D} \frac{1}{k^4 + \mu^4} = \int \frac{d^Dk}{(2\pi)^D} \frac{1}{k^2} - \int \frac{d^Dk}{(2\pi)^D} \frac{\mu^4}{k^2(k^4 + \mu^4)},
\]  

(98)

Recursively the same argument is applied to the third integral, showing thus that no divergent terms proportional to $< j^3 >$ arise. Also, from the absence of one-loop counterterm of the kind $< j^a > \frac{1}{2} f^{abc} A_\mu^b A_\mu^c$, it follows that

\[
< j^a >_0 \frac{1}{2} f^{abc} (A_\mu^b)_0 (A_\mu^c)_0 = < j^a > \frac{1}{2} f^{abc} A_\mu^b A_\mu^c,
\]  

(99)

so that we obtain

\[
< j^a >_0 = Z_{<j>} < j^a >, \quad Z_{<j>} Z_A = 1,
\]  

(100)

meaning that the renormalization factor of the soft parameter $< j^a >$ can be expressed in terms of the gluon renormalization factor $Z_A$.  

B Taking a closer look at the $SU(3)$ group

B.1 General considerations

The $SU(N)$ group is the group of the $N \times N$ unitary matrices with determinant equals to one:

\[
SU(N) := \{ U \mid UU^\dagger = 1, \det(U) = 1 \}.
\]  

(101)

\[\text{A purely algebraic proof, valid to all orders, of the non-renormalization properties of the soft parameter is under investigation. Also the possibility of obtaining the value of } < j^a >, \text{ by the local composite operator method[24, 37].}\]
The matrices $U \in SU(N)$ can be written as

$$U(\omega) := \exp (i\omega^a T^a)$$

(102)

where $\omega^a$ is a parameter, the label $a$ runs from 1 to $(N^2 - 1)$, and $T^a$ are the generators of the group, obeying the following relations:

$$[T^a, T^b] = i f^{abc} T^c,$$

$$\{T^a, T^b\} = \frac{1}{N} \delta^{ab} + d^{abc} T^c.$$  

(103)

In equation (103) $[,]$ stands for the commutator, while $\{\}$ for the anti-commutator; $f^{abc}$ are structure constants, which are anti-symmetric by odd successive permutations, i.e.

$$f^{abc} = -f^{bac} = -f^{acb} = -f^{cba};$$

and $d^{abc}$ are the components of the completely symmetric invariant rank-3 tensor of the group.

### B.2 The $SU(2)$ group

Before discuss the $SU(3)$ case it is useful to spend a few words on the $SU(2)$ case. In this case there are three generators and they are related with the Pauli matrices, $\sigma^a$, as follows:

$$T^a = \frac{\sigma^a}{2}, \quad (a = 1, 2, 3),$$

(105)

where,

$$\sigma^1 = (0), \quad \sigma^2 = (0), \quad \sigma^3 = (1).$$

(106)

Also, we have

$$f^{abc} = \varepsilon^{abc}, \quad d^{abc} = 0,$$

(107)

and then

$$\left[ \frac{\sigma^a}{2}, \frac{\sigma^b}{2} \right] = i \varepsilon^{abc} \frac{\sigma^c}{2}, \quad \left\{ \frac{\sigma^a}{2}, \frac{\sigma^b}{2} \right\} = \frac{1}{2} \delta^{ab}.$$  

(108)

### B.3 The $SU(3)$ group

In the $SU(3)$ group there are eight generators associated with the Gell-Mann matrices, $\lambda^a$, in an analogous way as the Pauli matrices for $SU(2)$,

$$T^a = \frac{\lambda^a}{2}, \quad (a = 1, \ldots, 8).$$

(109)

The Lie algebra of the generators of $SU(3)$ is then given by

$$\left[ \frac{\lambda^a}{2}, \frac{\lambda^b}{2} \right] = i f^{abc} \frac{\lambda^c}{2}, \quad \left\{ \frac{\lambda^a}{2}, \frac{\lambda^b}{2} \right\} = \frac{1}{3} \delta^{ab} + d^{abc} \frac{\lambda^c}{2}. $$

(110)

Here, the generators obey the anti-symmetric and symmetric Jacobi identities:

$$\left[ \lambda^a, [\lambda^b, \lambda^c] \right] + [\lambda^c, [\lambda^a, \lambda^b]] + [\lambda^b, [\lambda^c, \lambda^a]] = 0,$$

$$\left[ \lambda^a, \{\lambda^b, \lambda^c\} \right] + [\lambda^c, \{\lambda^a, \lambda^b\}] + [\lambda^b, \{\lambda^c, \lambda^a\}] = 0.$$
These identities give rise to the following useful relations:
\[
\begin{align*}
    f^{abc} f^{cde} + f^{ade} f^{dbc} + f^{bde} f^{dca} &= 0, \\
    f^{abc} d^{abc} + f^{ade} d^{dbc} + f^{bde} d^{dca} &= 0.
\end{align*}
\] (111)

In particular, the second equation of (111) is satisfied for \( SU(N \geq 3) \) and the first one is valid for any value of \( N \). Another interesting feature of the \( SU(3) \) group is that its generators can be grouped in sets which obeys the same algebraic properties of the Pauli matrices determining then three \( SU(2) \) subalgebras. Defining
\[
    \lambda_\pm = \frac{1}{2} (\sqrt{3} \lambda_8 \pm \lambda_3),
\] (112)
the three \( SU(2) \) groups embedded in the \( SU(3) \) are given by:
\[
\begin{align*}
    SU(2)_I & : \left( \frac{\lambda_1}{2}, \frac{\lambda_2}{2}, \frac{\lambda_3}{2} \right), \\
    SU(2)_{II} & : \left( \frac{\lambda_4}{2}, \frac{\lambda_5}{2}, \frac{\lambda_+}{2} \right), \\
    SU(2)_{III} & : \left( \frac{\lambda_6}{2}, \frac{\lambda_7}{2}, \frac{\lambda_-}{2} \right).
\end{align*}
\] (113)

**B.3.1 The Gell-Mann matrices and the structure constants of \( SU(3) \)**

The Gell-Mann matrices are given by
\[
\begin{align*}
    \lambda_1 &= (0), \quad \lambda_2 = (0), \quad \lambda_3 = (1), \\
    \lambda_4 &= (0), \quad \lambda_5 = (0), \quad \lambda_6 = (0), \\
    \lambda_7 &= (0), \quad \lambda_8 = \frac{1}{\sqrt{3}} (1). \quad (114)
\end{align*}
\]

The nonzero structure constants are:
\[
\begin{align*}
    f^{123} &= 1, \quad f^{147} = -f^{156} = f^{246} = f^{257} = f^{345} = -f^{367} = \frac{1}{2}, \quad f^{458} = f^{678} = \frac{\sqrt{3}}{2}. \quad (115)
\end{align*}
\]

The nonzero components of the symmetric tensor \( d^{abc} \) are:
\[
\begin{align*}
    d^{118} &= d^{228} = d^{338} = -d^{888} = \frac{1}{\sqrt{3}}, \\
    d^{448} &= d^{558} = d^{668} = d^{778} = -\frac{1}{2\sqrt{3}}, \\
    d^{146} &= d^{157} = -d^{247} = d^{256} = d^{344} = d^{855} = -d^{366} = -d^{377} = \frac{1}{2}. \quad (116)
\end{align*}
\]
