Abstract

Purpose: This study was initiated to prove feasibility of hydrogel application in recto-vaginal space in intracavitary brachytherapy (ICBT) of cervical cancer in order to reduce rectal toxicity.

Material and methods: In a case of stage IIB cervical cancer, after external beam radiotherapy (EBRT), we planned ICBT 7 Gy × 3 fractions. In 1st fraction (Plan 1), due to narrow separation between rectum and cervix (0.18 cm), only 5 Gy was delivered at point A (with high-risk clinical target volume [HR-CTV] D90 5.94 Gy, intermediate risk clinical target volume [IR-CTV] D90 4.54 Gy, rectum D2cc 5.72 Gy, bladder D2cc 5.52 Gy, and sigmoid colon 5.82 Gy). In 2nd fraction (Plan 2), interstitial brachytherapy (ISBT) was attempted. For the prescription of 5 Gy, we get dose levels almost similar to the 1st insertion: HR-CTV D90 (6.7 Gy), IR-CTV D90 (3.06 Gy), bladder D2cc (5.7 Gy), rectum D2cc (4.8 Gy), sigmoid colon D2cc (1.3 Gy) (separation = 0.23 cm). During 3rd fraction (Plan 3), prior doing interstitial insertion, we instilled 50 cc of hydroxypropyl methylcellulose (Viscomet®) up to the tip of recto-vaginal septum. A repeat computed tomography (CT) scan was done 4 hours after Plan 3 treatment and it was re-planned (Plan 4) to find out migration of hydrogel if any and its dosimetric impact.

Results: 9 Gy was delivered to point A with a separation of 1.1 cm in Plan 3 (with HR-CTV D90 16.4 Gy, IR-CTV D90 11.3 Gy, rectum D2cc 3.6 Gy, bladder D2cc 6.9 Gy, and sigmoid colon 2.2 Gy). We achieved an optimum cumulative EQD2 dose (HR-CTV D90 98.4 Gy, IR-CTV D90 76.1 Gy, rectum D2cc 67.7 Gy, bladder D2cc 73.2 Gy, and sigmoid colon 59.3 Gy). Hydrogel volume was decreased in Plan 4 without a major dosimetric changes.

Conclusions: Hydrogel instillation is a useful tool for recto-vaginal separation during cervical cancer brachytherapy. It increases therapeutic ratio without any adverse event.

Key words: brachytherapy, cervical cancer, rectal toxicity.
Material and methods

A 56 years old multiparous woman was presented with cervical cancer FIGO (International Federation of Gynecology and Obstetrics) stage IIB. After an magnetic resonance imaging (MRI) confirmed her staging, she was treated with EBRT to a dose of 50.4 Gy in 28 fractions (1.8 Gy/fraction) over 5 weeks along with weekly concurrent injections of cisplatin 40 mg/m². Post EBRT gynecological and imaging assessment showed no residual tumor. She was therefore planned for ICBT. Initially, we planned to deliver a dose of 7 Gy × 3 fractions, one fraction per week. According to our institutional protocol, the patient was admitted one day prior to ICBT application for bowel preparation (digestive enzymes, bisacodyl tablets, and enema). Intracavitary brachytherapy application was done under spinal anesthesia with standard Fletcher-Suit-Delclos (FSD) applicators on 03/09/2014. Computed tomography (CT) of pelvis was done followed by contouring of organs at risk (OAR) (i.e. urinary bladder, rectum, and sigmoid colon), gross tumor volume at brachytherapy (GTVB), and intermediate risk clinical target volume (IR-CTV) [13,14,15] using the high-dose-rate (HDR) plus v2.6 treatment planning system (Eckert & Zieglar, Bebig GmBH, Germany). Due to close proximity of the rectum with the target volume, in spite of optimization, we were able to prescribe only 5 Gy to point A (with doses to HR-CTV D90 5.94 Gy, IR-CTV D90 4.54 Gy, rectum D2cc 5.72 Gy, bladder D2cc 5.52 Gy, and sigmoid colon 5.82 Gy; Plan 1). On reviewing the insertion, internal anatomy, and planning, we found out that the key problem for the high rectal and sigmoid doses was the wall separation between the rec-
tum and the cervix, which was very narrow (average = 0.18 cm) (Figure 1). Treatment was delivered through 60Co HDR brachytherapy unit (Multisource, Eckert & Zieglar, Bebig GmBH, Germany).

In the subsequent fraction, with informed consent of the patient, we decided to go for interstitial brachytherapy (ISBT) implant. We inserted 10 metallic needles in two circles and the FSD tandem (previously used angulation) through Syed Neblett gynecological interstitial template on 09/09/2014. However, we failed to deliver the desired 7 Gy and prescribed only 5 Gy instead. For the prescription of 5 Gy, the dose levels were almost similar to the 1st insertion: HR-CTV D$_{90}$ (6.7 Gy), IR-CTV D$_{90}$ (3.06 Gy), bladder D$_{2cc}$ (5.7 Gy), rectum D$_{2cc}$ (4.8 Gy), and sigmoid colon D$_{2cc}$ (1.3 Gy). We could not deliver 7 Gy prescription due to high doses to the OAR in order to keep the EQD$_2$ (equivalent dose in 2 Gy/fraction adding EBRT and brachytherapy doses, and considering $\alpha/\beta$ for OAR = 3 Gy and for tumor = 10 Gy) of bladder D$_{0.1cc}$ < 90 Gy, EQD$_2$ rectum D$_{2cc}$, and sigmoid colon D$_{2cc}$ < 70 Gy as mandated in our institutional protocol. Moreover, in order to get HR-CTV EQD$_2$ of D$_{90}$ > 85 Gy, which is our institutional protocol, this prescription (if followed also in third fraction) would be suboptimal (Plan 2). On reviewing all the steps of the second fraction, we observed that the problem remained the same like the first fraction i.e. narrow space (average = 0.23 cm) between the rectum and the cervix.

Therefore, for the third fraction, with informed consent, we decided to instill hydrogel in the recto-vaginal space. On 12/09/2014 under spinal anesthesia, the patient underwent ISBT with Syed Neblett template (6 needles in inner circle of obturator and central FSD tandem).

### Table 1. Fraction wise and total dose distribution of all insertions

| Insertions | 1st insertion Plan 1 | 2nd insertion Plan 2 | 3rd insertion Plan 3 | Absolute difference from Plan 3 – Plan 2 dose | Relative difference from Plan 3 – Plan 2 dose | EQD$_2$ (EBRT + all BT) |
|------------|----------------------|----------------------|----------------------|---------------------------------------------|---------------------------------------------|------------------------|
| Prescription dose | 5 Gy | 5 Gy | 9 Gy | | | |
| All doses in Gy | | | | | | |
| HR-CTV ($\alpha/\beta = 10$) | | | | | | |
| D$_{90}$ | 5.9 | 6.7 | 16.4 | 9.7 | 48.2 | 98.4 |
| D$_{100}$ | 3.8 | 4.5 | 10.2 | 5.7 | 23.3 | 72.1 |
| V$_{100}$ (%) | 96.3 | 99.3 | 100 | 0.7 | | 98.5 |
| IRCTV ($\alpha/\beta = 10$) | | | | | | |
| D$_{90}$ | 4.5 | 4.5 | 11.3 | 6.8 | 35.6 | 76.1 |
| D$_{100}$ | 2.7 | 3.1 | 4.1 | 1.0 | –16.4 | 56.2 |
| V$_{100}$ (%) | 85.5 | 83.1 | 95.7 | 12.6 | | 88.1 |
| Bladder ($\alpha/\beta = 3$) | | | | | | |
| D$_{0.1cc}$ | 8.4 | 5.7 | 11.2 | 5.5 | 10.4 | 106.3 |
| D$_{1cc}$ | 6.2 | 4.1 | 8 | 3.9 | 6.9 | 80.2 |
| D$_{2cc}$ | 5.5 | 3.6 | 6.9 | 3.3 | 4.7 | 73.2 |
| Rectum ($\alpha/\beta = 3$) | | | | | | |
| D$_{0.1cc}$ | 9.6 | 11.0 | 4.9 | –6.1 | –156.6 | 108.1 |
| D$_{1cc}$ | 6.8 | 6.2 | 4 | –2.2 | –79.6 | 75.7 |
| D$_{2cc}$ | 5.7 | 4.8 | 3.6 | –1.2 | –56 | 67.7 |
| Sigmoid colon ($\alpha/\beta = 3$) | | | | | | |
| D$_{0.1cc}$ | 9.6 | 1.8 | 3.1 | 1.3 | –1.6 | 75.1 |
| D$_{1cc}$ | 6.9 | 1.4 | 2.4 | 1.3 | –1.3 | 62.9 |
| D$_{2cc}$ | 5.9 | 1.3 | 2.2 | 1.1 | –1.6 | 59.3 |

EBRT – external beam radiotherapy, BT – brachytherapy, EQD$_2$ – equivalent dose in 2 Grey per fraction, HR-CTV – high risk clinical target volume, D$_{0.1cc}$ – minimum dose received by 90% of the volume expressed as a percentage of the prescription dose, D$_{90}$ – minimum dose received by 100% of the volume expressed as a percentage of the prescription dose, IR-CTV – intermediate risk clinical target volume, D$_{1cc}$ – the minimum doses to the highest irradiated 0.1 cc volume, D$_{2cc}$ – the minimum doses to the highest irradiated 1 cc volume, D$_{2cc}$ – the minimum doses to the highest irradiated 2 cc volume.
During this procedure, instillation of the hydrogel was also performed. After Foley’s catheterization, a Cusco’s self-retaining bivalve speculum was introduced, the os was identified, and a 50 cc syringe was filled with hydroxypropyl methylcellulose (Viscomet®). The needle of the syringe was inserted through the recto-vaginal septum. One index finger was kept per rectally to feel the passage of the needle of instilling syringe. Slowly, the hydrogel was instilled along the recto-vaginal septum. The needle was then carefully withdrawn while pushing the hydrogel as high as possible into the septum (Figure 2). After this, the ISBT insertion was done. The patient underwent a plain CT scan of pelvis with 2.5 mm slice thickness. The whole procedure was uneventful. We contoured the hydrogel area separately (Plan 3). We did a repeat CT scan with applicator in situ after the treatment was over (about 4 hours after hydrogel insertion) to find out any migration of hydrogel. We also contoured and planned virtually on this image dataset (Plan 4) and compared it dosimetrically with the third fraction insertion (Figure 3).

Table 2. Comparative dosimetry of Plan 3 and Plan 4

| Insertions | 3rd insertion Plan 3 | Plan 4 | Difference |
|-----------|---------------------|--------|------------|
| Prescription dose | 9 Gy               | 9 Gy   |            |
| HR-CTV (α/β = 10) |                    |        |            |
| D0.1cc    | 16.4                | 15.63  | -0.77      |
| D1cc      | 10.2                | 10.36  | 0.15       |
| V100 (%)  | 100                 | 100    | 0          |
| IR-CTV (α/β = 10) |                    |        |            |
| D0.1cc    | 11.3                | 9.12   | -2.18      |
| D1cc      | 4.1                 | 4.58   | 0.48       |
| V100 (%)  | 95.7                | 90.6   | -5.1       |
| Bladder (α/β = 3) |                    |        |            |
| D0.1cc    | 11.2                | 10.63  | -0.57      |
| D1cc      | 8                   | 8.17   | 0.17       |
| D2cc      | 6.9                 | 7.06   | 0.66       |
| Rectum (α/β = 3) |                    |        |            |
| D0.1cc    | 4.9                 | 5.16   | 0.26       |
| D1cc      | 4                   | 4.19   | 0.19       |
| D2cc      | 3.6                 | 3.71   | 0.11       |
| Sigmoid colon (α/β = 3) |            |        |            |
| D0.1cc    | 3.1                 | 1.97   | -1.13      |
| D1cc      | 2.4                 | 1.63   | -0.73      |
| D2cc      | 2.2                 | 1.47   | -0.73      |
| Hydrogel contour volume (cc) | 9.3 | 7.2 | -2.1 |
| Hydrogel volume dimension: | | | |
| supero-inferior × anterio-posterior × medio-lateral (cm) | 4 × 1 × 2.5 | 5 × 0.8 × 2 |

HR-CTV – high risk clinical target volume, D0.1cc – minimum dose received by 90% of the volume expressed as a percentage of the prescription dose, D1cc – minimum dose received by 100% of the volume expressed as a percentage of the prescription dose, V100 – percentage of the target volume covered by 100% of the minimum dose received by 100% of the volume expressed as a percentage of the prescription dose, IR-CTV – intermediate risk clinical target volume, D0.1cc – the minimum doses to the highest irradiated 0.1 cc volume, D1cc – the minimum doses to the highest irradiated 1 cc volume, D2cc – the minimum doses to the highest irradiated 2 cc volume

Results

The instilled hydrogel area was optimally visible on planning CT between the anterior rectal wall and the posterior vaginal wall. The average width of separation was 1.1 cm, length of 5 cm. The patient was planned and we were able to deliver 9 Gy with an optimized dose distribution in the HR-CTV and OAR. Fraction-wise and total doses of CTV and OAR including the relative and absolute dosimetric changes from Plan 2 & Plan 3 are detailed in Table 1. Dosimetric comparison of Plan 3 and Plan 4 are given in Table 2. The hydrogel volume was decreased on Plan 4 with superior-inferior expansion (9.3 cc in Plan 3 [supero-inferior × anterio-posterior × medio-lateral: being 4 × 1 × 2.5 cc, respectively] versus 7.2 cc in Plan 4 [5 × 0.8 × 2 cm respectively]) without any major change in other dosimetric parameters.

Post implant days were uneventful. The patient was examined after 6 weeks. There was neither a residual tumor nor any adverse event. The patient remains in follow-up till date without any late toxicity and is in complete remission.

Discussion

Most of the studies using hydrogel for rectal separation are in prostate cancer. In the first published report of this kind, Susil et al. showed that a decrease of rectal V90 Gy significantly from 23% baseline value to 15%, 4%, and 0% was possible with 5 mm, 10 mm, and 15 mm separation, respectively [10]. This finding was confirmed in further clinical studies [11,12,13,14,15,16]. In their study, Prada et al. demonstrated that the measured rectal dose for HDR boost was significantly lower by about 2 Gy in prostate cancer patients [16]. Marrnitz et al. demonstrated the use of recto-vaginal separation using hydrogel in EBRT for cervical cancer [12]. They achieved a median separation width of 10 mm, length of 32 mm.

To the best of our knowledge, our study is the first to report about rectal separation using hydrogel in brachytherapy for cervical cancer. We tried to increase the separation between the rectum and the cervical tissue in this difficult case where the septum width was very narrow (< 1 cm: 0.23 cm). The idea was to deliver optimum dose to tumor target, keeping the rectal dose as low as possible. The average separation width achieved was 11 mm. The favorable dosimetric impact is depicted in Table 1. We observed no adverse events during and after the procedure. The hydrogel volume was easily visible in CT scans with a slight mi-
gration, and the minor reduction noted in Plan 4 had no major impact on the dosimetric parameters.

Conclusions
Hydrogel instillation may be a useful tool for rectovaginal separation during brachytherapy of cervical cancer. It appears to increase the therapeutic ratio without any adverse event. Considering this to be the first report of its kind, we plan to prospectively try this approach in selected patients in the future.
