Abstract

In order to contribute to the butterflies' biodiversity knowledge at Serra do Intendente State Park - Minas Gerais, a study based on collections using Van Someren-Rydon traps and active search was performed. In this study, a total of 395 butterflies were collected, of which 327 were identified to species or morphospecies. 263 specimens were collected by the traps and 64 were collected using entomological hand-nets; 43 genera and 60 species were collected and identified.

Keywords

Espinhaço Mountain Range, Arthropoda, frugivorous butterflies, Peixe Tolo, inventory

Introduction

The Lepidoptera is comprised of butterflies and moths; it is one of the main orders of insects which has approximately 157,424 described species (Freitas and Marini-Filho 2011, Zhang 2011). The butterflies, object of this study, have approximately 19,000 species described worldwide (Heppner 1991). The occurrence of 3,300 species is estimated for
Brazil, with more than 1,600 for Minas Gerais state (Casagrande et al. 1998). The group of butterflies studied belong to the superfamilies Papilionoidea and Hesperioidea and are subdivided into six families: Hesperiidae (Hesperioidea) and Papilionidae, Pieridae, Lycaenidae, Riodinidae, and Nymphalidae (Papilionoidea) (Brown Jr. and Freitas 1999). These insects are characterized as holometabolous, terrestrial, and diurnal. They are plant material chewers in the larval stage and liquid suckers in adulthood (Heppner 1991). Butterflies are insects that inhabit almost all terrestrial natural ecosystems (Freitas et al. 2003) and the presence of these creatures in a habitat is related to the availability of food resources and conditions such as temperature, relative humidity, and sunlight incidence (Brown Jr. and Hutchings 1997). They are divided into two guilds, according to adults' dietary habits: the nectarivorous and those who feed on fermented fruit, excrements, and exudates of decaying plants and animals (Uehara-Prado et al. 2007).

Butterflies are important indicators of environmental quality, because they are diverse, can be easily viewed, captured, identified, and manipulated by researchers (Mielke and Casagrande 1997). They are present throughout the year, and exhibit rapid responses regarding environmental disturbances (Öckinger et al. 2006). The larvae are considered pests of agricultural crops causing important damage leading to economic loss. However, they are important pollinators in adulthood (Isehard and Romanowski 2004, Triplehorn and Johnson 2011).

There are few studies about butterfly biodiversity in the Espinhaço Biosphere Reserve (Wilson 1997). The knowledge of Lepidoptera biodiversity in Minas Gerais, is still scarce (Casagrande et al. 1998). There is no published literature about butterfly biodiversity and distribution for the Espinhaço mountain range within Minas Gerais. The number of Lepidoptera checklists for Brazil is still very small and this effort contributes to a better understanding of biodiversity distribution in the country.

This work inventories butterflies on a state conservation area called Serra do Intendente State Park (PESI), Minas Gerais, Brazil.

Materials and methods

Study Site

The study was conducted in the region of Serra do Espinhaço, more precisely, within the Serra do Intendente State Park (Fig. 2) and the Peixe Tolo Natural Reserve, Minas Gerais (Fig. 1). The park features approximately 13,508 ha and is an important area for Espinhaço mountains biodiversity conservation.
The climate is mesothermal, characterized by mild, humid summers and dry, cold winters. The average annual rainfall is 1,600 mm. The annual mean temperature is 18.7°C (Araujo et al. 2005, Silva et al. 2009). The predominant topography is the mountainous escarpment, mixed with rocky outcrops. The vegetation is mosaic and it is characterized by the presence of striking landscapes of three biomes: Atlantic Forest, Caatinga, and Cerrado (Andrade and Domingues 2013).
Data Collection

The collections began in April 2012 and were completed in February of 2013. During this period four collections (two in the rainy season and two in the dry season) were performed. Each collection was performed for five days. The study area was divided into two areas throughout the Peixe Tolo River basin and in each area, forty Van Someren-Rydon traps were distributed. Twenty traps were located on the right bank and other twenty on the left bank of the Peixe Tolo River (Fig. 3). In these traps, baits made of a mixture of ripe banana and sugarcane syrup was used; the solution was left fermenting for forty-eight hours before exposure in the traps.

Throughout the collection period, active search of butterflies was performed in order to capture non-frugivorous butterflies. The specimens collections were conducted throughout the day, starting around 10am until 3pm. The butterflies captured were immediately killed through abdomen compression in order to avoid damage that could compromise identification.

Data analysis

The collected material was mounted, identified and labeled in the PUC Minas Natural Sciences Museum entomological collection laboratory. The identification of the individuals was made using Devries (1997), Freitas et al. (2003), D' Abrera (1987b), D'Abrera (1987a), D'Abrera (1988) and the website Butterflies of America (accessible at http://butterfliesofamerica.com/). Genera and species were confirmed by Dr. André Freitas, from the Department of Animal Biology, Universidade Estadual de Campinas. Furthermore, a comparison with available identified species in the Lepidoptera collection in the Invertebrates Laboratory (PUC Minas) was performed.
Data resources

In this study 394 individuals were captured, and 327 were identified. Sixty-seven individuals were not identified to genus or species due to bad specimen conditions or incipient systematics.

The families represented in this study were: Nymphalidae, Pieridae, Hesperiidae, Lycaenidae, Papilionidae and Riodinidae. A total of 299 individuals belonging to the Nymphalidae, 15 from the Pieridae, four from the Hesperiidae, four from the Lycaenidae, three from the Papilionidae, and one species from the Riodinidae.

A total of 263 butterflies were collected in traps and 63 using entomological hand-nets. The collections gathered specimens belonging to 43 genera and 60 species (Table 1). During the rainy seasons 181 individuals were collected in which 177 were collected by traps and 4 by entomological hand-nets (Table 2). In the dry seasons 145 individuals were collected: of those, 86 were collected in traps and 59 by entomological hand-nets (Table 3).

| Species                           | Traps | Active Search |
|----------------------------------|-------|---------------|
| Adelpha pleasure (Hübner, 1823)  | 1     | 0             |

Discussion

The present study showed greater richness of species than the studies performed by Santana (2005), Rosa et al. (2011), Pedrotti et al. (2011), Favretto (2012), Ramos Soares et al. (2012). However, compared with records for several Brazilian states such as recorded by Isehard and Romanowski (2004), Marchiori and Romanowski (2006), Emery et al. (2006), Dessuy and Morais (2007), Pinheiro et al. (2008), Isehard et al. (2010), Ritter et al. (2011), Zacca and Bravo (2012), and Bogiani et al. (2012), the number of species found is lower. This fact could very well be explained by the sampled area size and sampling effort (Table 4).
In southeastern Brazil Mielke and Casagrande (1997) recorded 426 species in an area of 33,000 ha, for the Morro do Diabo State Park – São Paulo whereas the study by Brown Jr. and Freitas (2000a) in Santa Tereza – Espirito Santo, 297 species were registered in an area of 332,000 ha. In the state of Minas Gerais, Motta (2002) recorded 251 species in an area of 30 hectares in a region of Uberlândia; Silva et al. (2007) registered 91 species of butterflies in the PUC Minas Forest located in Belo Horizonte, in 7.0 ha; Ramos Soares et al. (2012) found 78 species in Americo Rene Giannetti Municipal Park with 0.018 ha.

| Study                                   | State (Brazil) | Biome                                | Sampled area | Richness |

The Nymphalidae was the family with greatest richness; this diversity can be explained by the fact that this family has great diversity in morphology and habits, as well as in environments with varying vegetation types (Brown Jr. and Freitas 1999) such as found in the Serra do Intendente State Park and the Peixe Tolo Natural Reserve.

In this study, the largest number of individuals collected (145) belongs to the subfamily Satyrinae. This family is important in analyses of disturbance studies (Devries and Walla 2001), in addition to being excellent predictors of the butterfly fauna of the Atlantic Forest (Brown Jr. and Freitas 2000b). From this subfamily, 12 individuals belonging to the Taygetis laches species were captured that has greater preference for more urbanly impacted environments (Silva et al. 2007).

_Eurema albula_ and _Eurema elathea_, also registered in this site, have cosmopolitan habits and great adaptatations for disturbed areas (Isehard et al. 2007, Bogiani et al. 2012). It is important to mention that _Morpho helenor_, which was well sampled – 51 individuals (Table 1), disappears quickly when severe disturbances and size reduction of forests occur (Santana 2005). These data demonstrate that the region could be severely impacted at some sites.

_Morpho helenor_, _Siproeta stelenes_, _Heliconius erato_, and _Heliconius ethilla_ coincided with the study realized at the University Campus Darcy Ribeiro, in an urbanized area in the Federal District (Pinheiro et al. 2008). These are typical species of riparian areas, a characteristic of the sample site. _Euptychoides castrensiss_ is found in abundance in tropical rain forest environments, being registered in the states of São Paulo, Rio Grande do Sul, and Minas Gerais Pedrotti et al. (2011); this study obtained the same high record, a fact that corroborates with the presence of Atlantic Forest patches of vegetation in the studied sites.

There are no records of inventories for the Espinhaço mountain range within the state of Minas Gerais: this is the first published inventory for the region. This study and the only study in the Serra do Espinhaço about butterflies, conducted in Chapada Diamantina in Bahia - Brazil by Zacca and Bravo (2012) had similar predominance of species belonging to the family Nymphalidae. The species shared among these two studies are: _Adelpha pleasure_, _Archaeopena demophon_, _Ascia monuste_, _Callicore sorana_, _Colobura dirce_, _Dryas iulia_, _Eresia lansdorfi_, _Eryphanis reevesii_, _Eurema albula_, _Eurema elathea_, _Hamadryas amphimone_, _Hamadryas februa_, _Hamadryas feronia_, _Heliconius erato_, _Heliconius ethilla_, _Junonia evarete_, _Leptotes cassius_, _Pareuptychia ocirrhoe_, _Pyrgus orcus_, _Prepona laertes_, _Siproeta stelenes_, _Smyrna blomfildia_, _Taygetis laches_, _Temenis laothoe_, _Zaretis itty_, and _Yphthimoides straminea._

It is emphasized that in this study the majority of butterflies species captured are typical of Cerrado and Atlantic Forest (Emery et al. 2006, Brown Jr. and Freitas 2000b).

Further investigation on biodiversity should be conducted and motivated in this region. The group of Lepidoptera showed great research and conservation potential for the Serra do Intendente State Park. The biodiversity information should be made available for decision
makers, specially for regions such as the one studied, which is currently threatened by mining, tourism, and housing developments.

Acknowledgements

The authors thank the biologists André Freitas and Ana Beatriz Borges for their attention and help in the determination of genera and species of butterflies, Diogo França for his help and contributions in the field work, and Miguel Andrade for his attention and for providing workplace, the members of the Invertebrates Laboratory of PUC Minas – Alex Souza, Isabela Rocha and Nathalia Melgaço for their assistance in the execution stages of this study and PROBIC – FAPEMIG and IEF for the opportunity to accomplish this study and for collecting permits. We thanks José Apezteguia for the mapping of the area. We also would like to thank Dr. Tadeu Guerra for putting together essential parts for the realization of this research and files assistance as well.
