HODGE GROUPS OF CERTAIN SUPERELLIPTIC JACOBIANS

II

JIANGWEI XUE

1. INTRODUCTION

Throughout this paper $\mathbb{C}$ is the field of complex numbers, $K \subseteq \mathbb{C}$ is a subfield of $\mathbb{C}$, $f(x) \in K[x]$ a polynomial without multiple roots and of degree $n \geq 4$. Let $p \in \mathbb{N}$ be a prime that does not divide $n$ and $q = p^r \in \mathbb{N}$ an integral power of $p$. We write $C_{f,q}$ for the superelliptic $K$-curve $y^q = f(x)$, and $J(C_{f,q})$ for the Jacobian of $C_{f,q}$. By definition, $C_{f,q}$ is the smooth projective model of the affine curve $y^q = f(x)$. The Jacobian $J(C_{f,q})$ is an abelian variety over $K$ of dimension

$$\dim J(C_{f,q}) = g(C_{f,q}) = \frac{(n - 1)(q - 1)}{2}.$$ 

If $q > p$, the map

$$C_{f,q} \to C_{f,q/p}, \quad (x, y) \mapsto (x, y^p)$$

induces by Albanese functoriality a surjective $K$-map between the Jacobians $J(C_{f,q}) \to J(C_{f,q/p})$. We write $J(f,q)$ for the identity component of the kernel. If $q = p$, we set $J(f,p) = J(C_{f,p})$. It is follows easily that $J(f,q)$ is an abelian variety over $K$ of dimension $(n - 1)\varphi(q)/2$, where $\varphi$ denotes the Euler $\varphi$-function. Moreover, $J(C_{f,q})$ is $K$-isogenous to the product $\prod_{i=1}^{r} J(f,p_i)$ (See [15]). Since $K \subseteq \mathbb{C}$, we may view $J(f,q)$ as a complex abelian variety. We refer to [5], [10, Sect. 6.6.1 and 6.6.2] for the definition and basic properties of the Hodge group (aka special Mumford–Tate group). In [9], assuming that $n > q$ and some other conditions on $n, q$ and $f(x)$, the authors showed that the (reductive $\mathbb{Q}$-algebraic connected) Hodge group of $J(f,q)$ coincides with the largest $\mathbb{Q}$-algebraic subgroup of $GL(H^1(J(f,q), \mathbb{Q}))$ that’s “cut out” by the induced polarization from the canonical principal polarization of $J(C_{f,q})$ and the endomorphism ring of $J(f,q)$. Notice that when $q = 2$ (i.e., in the hyperelliptic case) this group was completely determined in [12] (when $f(x)$ has “large” Galois group). In this paper, we study some additional properties of $J(f,q)$ which will allow us to extend the result to the case $n < q$ as well. This case is necessary in order to treat the infinite towers of superelliptic jacobians, which, in turn, are useful for the study of the ranks of Mordell-Weil groups in infinite towers of function fields (See [6]).

To state our main result, we make explicit the endomorphism ring and the polarization mentioned above. Let $X$ be an abelian variety over $\bar{K}$. We write $\text{End}(X)$ for the ring of all its $K$-endomorphisms and $\text{End}^0(X)$ for the endomorphism algebra $\text{End}(X) \otimes_{\mathbb{Z}} \mathbb{Q}$. In a series of papers [11, 13, 14, 15], Yuri Zarhin discussed the structure of $\text{End}^0(J(C_{f,q}))$, assuming that $n \geq 5$ and the Galois group $\text{Gal}(f)$ of $f(x)$ over $K$ is, at least, doubly transitive. Here $\text{Gal}(f) \subseteq S_n$ is viewed as a permutation group on the roots of $f(x)$. It is well known that $f(x)$ is irreducible
over $K$ if and only if $\text{Gal}(f)$ acts transitively on the roots. For the sake of simplicity let’s assume that $K$ contains a primitive $q$-th root of unity $\zeta_q$. The curve $C_{f,q} : y^q = f(x)$ admits the obvious periodic automorphism

$$\delta_q : C_{f,q} \to C_{f,q}, \quad (x, y) \mapsto (x, \zeta_q y).$$

By an abuse of notation, we also write $\delta_q$ for the induced automorphism of $J(C_{f,q})$.

The subvariety $J(f,q)$ is $\delta_q$-invariant and we have an embedding

$$\mathbb{Z}[\zeta_q] \to \text{End}(J(f,q)), \quad \zeta_q \mapsto \delta_q.$$

In particular, the $q$-th cyclotomic field $E := \mathbb{Q}(\zeta_q)$ is contained in $\text{End}^0(J(f,q))$. Zarhin showed ([11, 15, 17]) that $\text{End}(J(f,q))$ is isomorphic to $\mathbb{Z}[\zeta_q]$ if either $\text{Gal}(f)$ coincides with the full symmetric group $S_n$, $n \geq 4$ and $p \geq 3$, or $\text{Gal}(f)$ coincides with the alternating group $A_n$ (or $S_n$), and $n \geq 5$. This result has also been extended to the case $\text{Gal}(f) = S_n$ or $A_n$, $n \geq 5$ and $p \mid n$ in [7].

The first rational homology group $H_1(J(f,q), \mathbb{Q})$ carries a natural structure of $E$-vector space of dimension

$$\dim_E H_1(J(f,q), \mathbb{Q}) = \dim_\mathbb{Q} H_1(J(f,q), \mathbb{Q}) = \frac{2 \dim J(f,q)}{[E : \mathbb{Q}]} = \frac{(n-1)\varphi(q)}{\varphi(q)} = n - 1.$$

Notice that if $q > 2$, then $E$ is a CM field with complex conjugation $e \mapsto \bar{e}$. Let

$$E^+ = \{ e \in \mathbb{Q}(\zeta_q) \mid \bar{e} = e \}$$

be the maximal totally real subfield of $E$ and let

$$E_- = \{ e \in \mathbb{Q}(\zeta_q) \mid \bar{e} = -e \}.$$

The canonical principal polarization on $J(C_{f,q})$ induces a polarization on $J(f,q)$, which gives rise to a nondegenerate $E$-sesquilinear Hermitian form $([9])$

$$\phi_q : H_1(J(f,q), \mathbb{Q}) \times H_1(J(f,q), \mathbb{Q}) \to E.$$

We write $\text{U}(H_1(J(f,q), \mathbb{Q}), \phi_q)$ for the unitary group of $\phi_q$ of the $\mathbb{Q}(\zeta_q)$-vector space $H_1(J(f,q), \mathbb{Q})$, viewed as an $\mathbb{Q}$-algebraic subgroup of $\text{GL}(H_1(J(f,q), \mathbb{Q}))$ (via Weil’s restriction of scalars from $E^+$ to $\mathbb{Q}$ ([5])). Since the Hodge group respects the polarization and commutes with endomorphisms of $J(f,q)$,

$$\text{Hdg}(J(f,q)) \subset \text{U}(H_1(J(f,q), \mathbb{Q}), \phi_q).$$

If $\text{End}^0(J(f,q)) = E$, then $\text{U}(H_1(J(f,q), \mathbb{Q}), \phi_q)$ is the largest connected reductive $\mathbb{Q}$-algebraic subgroup of $\text{GL}(H_1(J(f,q), \mathbb{Q}))$ that both respects the polarization and commutes with endomorphisms of $J(f,q)$.

The following theorem is a natural extension of [9, Theorem 0.1].

**Theorem 1.** Suppose that $n \geq 4$ and $p$ is a prime that does not divide $n$. Let $f(x) \in \mathbb{C}[x]$ be a degree $n$ polynomial without multiple roots. Let $r$ be a positive integer and $q = p^r$. Suppose that there exists a subfield $K$ of $\mathbb{C}$ that contains all the coefficients of $f(x)$. Let us assume that $f(x)$ is irreducible over $K$ and the Galois group $\text{Gal}(f)$ of $f(x)$ over $K$ is either $S_n$ or $A_n$. Assume additionally that either $n \geq 5$ or $n = 4$ and $\text{Gal}(f) = S_4$.

Suppose that one of the following three conditions holds:

(A) $n = q + 1$;

(B) $p$ is odd and $n \not\equiv 1 \mod q$;

(C) $p = 2$, $n \not\equiv 1 \mod q$ and $n \not\equiv q - 1 \mod 2q$. 

This theorem is a natural extension of [9, Theorem 0.1].
Then $\text{Hdg}(J^{(f,q)}) = U(H_1(J^{(f,q)}, \mathbb{Q}), \phi_q)$.

**Corollary 2.** Corollary 0.3, Theorem 4.2 and Theorem 4.3 of [9] all hold without the assumption that $n > q$.

**Remark 3.** We assume that $n < q$ throughout the rest of the paper since the case $n > q$ has already been treated in [9].

**Remark 4.** Since both $\text{Hdg}(J^{(f,q)})$ and $U(H_1(J^{(f,q)}, \mathbb{Q}), \phi_q)$ are connected $\mathbb{Q}$-algebraic groups, to prove Theorem 1, it suffices to show that

$$\dim \text{Hdg}(J^{(f,q)}) \geq \dim U(H_1(J^{(f,q)}, \mathbb{Q}), \phi_q).$$

It is known that

$$\dim U(H_1(J^{(f,q)}, \mathbb{Q}), \phi_q) = \dim_{\mathbb{Q}} E^+ \cdot (\dim_{\mathbb{Q}} H_1(J^{(f,q)}, \mathbb{Q}))^2.$$

Let $\text{hdg}$ be the $\mathbb{Q}$-Lie algebra of $\text{Hdg}(J^{(f,q)})$. It is a reductive $\mathbb{Q}$-Lie subalgebra of $\text{End}_\mathbb{Q}(H_1(J^{(f,q)}, \mathbb{Q}))$, and thus splits into a direct sum

$$\text{hdg} = \mathfrak{c} \oplus \text{hdg}^{ss},$$

of its center $\mathfrak{c}$ and the semisimple part $\text{hdg}^{ss} = [\text{hdg}, \text{hdg}]$. By [8, Theorem 1.3], if $\text{Gal}(f) = S_n$ and $n \geq 4$, or $\text{Gal}(f) = A_n$ and $n \geq 5$, the center $\mathfrak{c}$ coincides with $E_-$. Notice that

$$\dim_{\mathbb{Q}} E^+ = \dim_{\mathbb{Q}} E^+ = [E : \mathbb{Q}] / 2.$$

Theorem 1 follows if we show that

$$\dim_{\mathbb{Q}} \text{hdg}^{ss} \geq \frac{1}{2}[E : \mathbb{Q}]((\dim_{\mathbb{Q}} H_1(J^{(f,q)}, \mathbb{Q}))^2 - 1).$$

The paper is organized as follows. In section 2 we study the Galois actions on certain vector spaces. In section 3 we recall some facts about the Hodge Lie algebra $\text{hdg}$. The proof of Theorem 1 is given at the end of section 3 except a key arithmetic lemma, which is proven in Section 4.

### 2. Galois Actions

Throughout this section, let $E$ be a field that is a finite Galois extension of $\mathbb{Q}$ with Galois group $G$. Let $V$ be an $E$-vector space of finite dimension. We write $V_\mathbb{Q}$ for the underlying $\mathbb{Q}$-vector space of $V$, and $V_E$ for the $E$-vector space $V \otimes \mathbb{Q} E = V_\mathbb{Q} \otimes E$ $\mathbb{Q} E$. Let $\text{Aut}(E)$ be the group of all automorphisms of $E$. It acts semilinearly on $V_E = V \otimes \mathbb{Q} E$ through the second factor. More explicitly, $\forall \kappa \in \text{Aut}(E), v \otimes z \in V \otimes E \mathbb{Q} E$, we define $\kappa(v \otimes z) := v \otimes \kappa(z)$. It follows that $\forall x \in V \otimes \mathbb{Q} E$ and $e \in E$, $\kappa(\kappa e) = \kappa(e)x$. On the other hand, $E$ acts on $V_E = V \otimes \mathbb{Q} E$ through its first factor. It follows that $V_E$ is a free $E \otimes \mathbb{Q} E$ module of rank $\dim F V$, and the action of $E = E \otimes 1 \subseteq E \otimes \mathbb{Q} E$ commutes with that of $\text{Aut}(E)$. In other words,

$$\kappa((e \otimes 1)x) = (e \otimes 1)\kappa(x), \quad \forall \kappa \in \text{Aut}(E), e \in E, \text{ and } x \in V_E.$$

Let’s fix an embedding $E \hookrightarrow \mathbb{C}$. This allows us to identify each Galois automorphism $\sigma : E \to E$ with the embedding $\sigma : E \to E \subset \mathbb{C}$ of $E$ into $\mathbb{C}$. It is well known that

$$E \mathbb{C} := E \otimes \mathbb{Q} E = \bigoplus_{\sigma \in G} E \otimes_{E, \sigma} \mathbb{C} = \bigoplus_{\sigma \in G} \mathbb{C}_{\sigma}, \text{ where } C_\sigma := E \otimes_{E, \sigma} \mathbb{C}.$$
So every $E_C$ module $W$ splits as a direct sum $W = \oplus_{\sigma \in G} W_{\sigma}$, where

$$W_{\sigma} := C_{\sigma} W = \{ w \in W \mid (\epsilon \otimes 1)w = \sigma(\epsilon)w, \forall \epsilon \in E \}.$$  

In particular, $V_{C} = \oplus_{\sigma \in G} V_{\sigma}$, and each $V_{\sigma}$ is a $C$-vector space of dimension $\dim_{E} V_{\sigma}$.

For each $\sigma \in G$, let $P_\sigma : V_{C} \to V_{\sigma}$ be the $C$-linear projection map from $V_{C}$ to the summand $V_{\sigma}$. Similarly, for each pair $\sigma \neq \tau$, we write $P_{\sigma,\tau} = P_{\sigma} \oplus P_{\tau} : V_{C} \to V_{\sigma} \oplus V_{\tau}$ for the projection map onto this pair of summands.

We claim that $\text{Aut}(C)$ permutes the set $\{V_{\sigma} \mid \sigma \in G\}$, and the action factors through the canonical restriction

$$\text{Aut}(C) \to G, \quad \kappa \mapsto \kappa \mid_{E}.$$  

Indeed, for all $\kappa \in \text{Aut}(C)$, $e \in E$ and $x_\sigma \in V_\sigma$,

$$(e \otimes 1) \kappa(x_\sigma) = \kappa((e \otimes 1)x_\sigma) = \kappa(\sigma(e)x_\sigma) = \kappa(\sigma(e)) \kappa(x_\sigma) = \kappa(e) \kappa(x_\sigma).$$

Clearly $\kappa \sigma(e) = ((\kappa \mid_{E}) \sigma)(e)$. By an abuse of notation, we write $\kappa$ for the restriction $\kappa \mid_{G}$. So it follows that $\kappa(x_\sigma) \in V_{\kappa \sigma}$, and thus $V_{\kappa}$ for all $\kappa \in \text{Aut}(C)$ and $\sigma \in G$.

Let us define an action of $\text{Aut}(C)$ on the set of projection $P = \{ P_\sigma \mid \sigma \in G \}$ by

$$\kappa_* P_\sigma := \kappa \circ P_\sigma \circ \kappa^{-1}.$$  

Then for any element $\sum x_\sigma \in \oplus_{\sigma \in G} V_\sigma = V_{C}$ and $P_\tau \in P$,

$$(\kappa_* P_\tau)(\sum x_\sigma) = \kappa \circ P_\tau \left( \sum \kappa^{-1}(x_\sigma) \right) = \kappa(\kappa^{-1}(x_\kappa)) = x_\kappa,$$

where all summations runs through $\sigma \in G$, and we used the fact that $\kappa^{-1}(x_\sigma)$ belongs to $V_{\tau}$ if and only if $\sigma = \kappa \tau$. Therefore,

$$\kappa_* P_\sigma = P_{\kappa \sigma}.$$  

Clearly $\text{Aut}(C)$ acts transitively on $P$. Since $P_{\sigma,\tau} = P_\sigma \oplus P_\tau$, we have similarly an action of $\text{Aut}(C)$ on the set $\mathcal{PP} := \{ P_{\sigma,\tau} \mid (\sigma, \tau) \in G^2, \sigma \neq \tau \}$ by

$$\kappa_* P_{\sigma,\tau} = \kappa \circ P_{\sigma,\tau} \circ \kappa^{-1} = P_{\kappa \sigma,\kappa \tau}.$$  

The $\text{Aut}(C)$-orbit $O_{\sigma,\tau}$ of each $P_{\sigma,\tau} \in \mathcal{PP}$ consists of all elements of the form $P_{\kappa \sigma,\kappa \tau}$ with $\kappa \in G$.

**Lemma 5.** Let $W_Q \subseteq V_Q$ be any $Q$-subspace of $V_Q$, and $W_C := W_Q \otimes_Q C \subseteq V_C$ be its complexification.

(i) If there exists $\sigma_0 \in G$ such that $P_{\sigma_0}(W_C) = V_{\sigma_0}$, then $P_{\sigma}(W_C) = V_{\sigma}$ for all $\sigma \in G$.

(ii) If there exists a pair $(\sigma_0, \tau_0) \in G^2$ with $\sigma_0 \neq \tau_0$ such that $P_{\sigma_0,\tau_0}(W_C) = V_{\sigma_0} \oplus V_{\tau_0}$, then $P_{\sigma,\tau}(W_C) = V_{\sigma} \oplus V_{\tau}$ for all $P_{\sigma,\tau} \in O_{\sigma_0,\tau_0}$.

**Proof.** Clearly, $W_C$ is $\text{Aut}(C)$-invariant. For each $\sigma \in G$, let us choose $\kappa \in \text{Aut}(C)$ such that $\sigma = \kappa \sigma_0$. Then

$$P_{\sigma}(W_C) = (\kappa_* P_{\sigma})(W_C) = \kappa \circ P_{\sigma_0} \circ \kappa^{-1}(W_C) = \kappa \circ P_{\sigma_0}(W_C) = \kappa(V_{\sigma_0}) = V_{\sigma}.$$  

This proves part (i). Similarly, suppose that $P_{\sigma_0,\tau_0}(W_C) = V_{\sigma_0} \oplus V_{\tau_0}$. For all $P_{\sigma,\tau} \in O_{\sigma_0,\tau_0}$, there exists $\kappa \in \text{Aut}(C)$ such that $\sigma = \kappa \sigma_0$ and $\tau = \kappa \tau_0$. So we have

$$P_{\sigma,\tau}(W_C) = (\kappa_* P_{\sigma,\tau})(W_C) = \kappa \circ P_{\sigma_0,\tau_0} \circ \kappa^{-1}(W_C) = \kappa \circ P_{\sigma_0,\tau_0}(W_C) = \kappa(V_{\sigma_0} \oplus V_{\tau_0}) = \kappa(V_{\sigma_0}) \oplus \kappa(V_{\tau_0}) = V_{\sigma} \oplus V_{\tau},$$

and part (ii) follows. 

\qed
Let $R$ be a commutative ring with unity, and $N$ be a free $R$-module of finite rank. We write $\text{Tr}_R : \text{End}_R(N) \to R$ for the trace map, and

$$\mathfrak{s}_R(N) := \{ g \in \text{End}_R(N) \mid \text{Tr}_R(g) = 0 \}$$

for the $R$-Lie algebra of traceless endomorphisms of $N$. It is well-known that

$$\mathfrak{s}_E(V) \otimes \mathbb{Q} C = \mathfrak{s}_E C(VC) = \mathfrak{s}_E C(\oplus_{\sigma \in G} V_\sigma) = \bigoplus_{\sigma \in G} \mathfrak{s}_C(V_\sigma).$$

We will denote the projection map $\mathfrak{s}_E(V) \otimes \mathbb{Q} C \to \mathfrak{s}_C(V_\sigma)$ again by $P_\sigma$, and similarly for $P_{\sigma,\tau}$.

For the rest of the section, we assume additionally that $E$ is a CM-field. For any $\sigma \in G$, let $\bar{\sigma} : E \to E$ be the complex conjugation of $\sigma$. In other words, $\bar{\sigma}$ is the composition $E \xrightarrow{\sigma} E \xrightarrow{\sigma} E$, where the second arrow stands for the complex conjugation map $e \mapsto \bar{e}$.

**Lemma 6.** Let $\mathfrak{k}$ be a semisimple $\mathbb{Q}$-Lie subalgebra of $\mathfrak{s}_E(V)$, and $\mathfrak{k}_C := \mathfrak{k} \otimes \mathbb{Q} C$ be its complexification. Suppose that the following two conditions hold:

1. There exists $\sigma_0 \in G$ such that $P_{\sigma_0}(\mathfrak{k}_C) = \mathfrak{s}_C(V_{\sigma_0})$;
2. For each pair $(\sigma, \tau) \in G^2$ with $\sigma \neq \tau$ and $\sigma \neq \bar{\tau}$, there exists $P_{\sigma,\tau} \in O_{\sigma,\tau}$ such that $P_{\sigma,\tau}(\mathfrak{k}_C) = \mathfrak{s}_C(V_{\sigma}) \oplus \mathfrak{s}_C(V_{\tau})$.

Then

$$\dim_{\mathbb{Q}} \mathfrak{k} \geq \frac{1}{2} [E : \mathbb{Q}] ((\dim_E V)^2 - 1).$$

**Proof.** Applying Lemma 5 with $\mathfrak{k}$ in place of $W$ and $\mathfrak{s}_E(V)$ in place of $V$, we see that

$$P_\sigma(\mathfrak{k}_C) = \mathfrak{s}_C(V_\sigma), \quad \forall \sigma \in G;$$

$$P_{\sigma,\tau}(\mathfrak{k}_C) = \mathfrak{s}_C(V_\sigma) \oplus \mathfrak{s}_C(V_\tau), \quad \forall (\sigma, \tau) \in G^2 \text{ with } \sigma \neq \tau \text{ and } \sigma \neq \bar{\tau}. $$

Let us fix a CM-type $\Phi$ of $E$. By definition, $\Phi$ is a maximal subset of $G = \text{Hom}(E, \mathbb{C})$ such that no two elements of $\Phi$ are complex conjugate to each other. Clearly, $|\Phi| = [E : \mathbb{Q}]/2$, and

$$\dim_C \left( \bigoplus_{\sigma \in \Phi} \mathfrak{s}_C(V_\sigma) \right) = \frac{1}{2} [E : \mathbb{Q}] ((\dim_E V)^2 - 1).$$

Let $\mathfrak{k}'_C$ be the projection of $\mathfrak{k}_C$ on $\bigoplus_{\sigma \in \Phi} \mathfrak{s}_C(V_\sigma)$. It follows that the projection $\mathfrak{k}'_C \to \mathfrak{s}_C(V_\sigma)$ is surjective for all $\sigma \in \Phi$, and $\mathfrak{k}'_C$ also projects surjectively onto $\mathfrak{s}_C(V_\sigma) \oplus \mathfrak{s}_C(V_\tau)$ for all distinct pairs $\sigma, \tau \in \Phi$. Therefore, $\mathfrak{k}'_C = \bigoplus_{\sigma \in \Phi} \mathfrak{s}_C(V_\sigma)$ by the Lemma on pp.790-791 of [4]. In particular, we get

$$\dim_{\mathbb{Q}} \mathfrak{k} = \dim_C \mathfrak{k}_C \geq \dim_C \mathfrak{k}'_C = \frac{1}{2} [E : \mathbb{Q}] ((\dim_E V)^2 - 1).$$

In the next section, we will show that our semisimple part of Hodge Lie algebra $\text{hdg}^{ss} = [\text{hdg, hdg}]$ satisfies (I) and (II) of Lemma 6 and thus prove our Main Theorem.
We keep all notation and assumptions of the previous sections. More specifically, \( \zeta_q \) is a primitive \( q \)-th root of unity, \( E = \mathbb{Q}(\zeta_q) \) and \( G = \text{Gal}(E/\mathbb{Q}) = (\mathbb{Z}/q\mathbb{Z})^* \), where each \( a \in (\mathbb{Z}/q\mathbb{Z})^* \) maps \( \zeta_q \) to \( \zeta_q^a \). In order to simplify the notation, we write \( X \) for the abelian variety \( J^{(f, \phi)} \), and \( V \) for its first rational homology group \( H_1(X, \mathbb{Q}) \). In addition, we assume that \( \text{End}^0(X) = E \).

Recall that \( E_C = E \otimes_{\mathbb{Q}} \mathbb{C} \). Let \( \text{Lie}(X) \) be the complex tangent space to the origin of \( X \). By functoriality, \( E \) acts on \( \text{Lie}(X) \) and provides \( \text{Lie}(X) \) with a natural structure of \( E_C \)-module. Therefore, \( \text{Lie}(X) \) splits into a direct sum

\[
\text{Lie}(X) = \oplus_{a \in \mathbb{G}} \text{Lie}(X)_a.
\]

where \( \text{Lie}(X)_a := \{ x \in \text{Lie}(X) \mid (\zeta_q \otimes 1)x = \zeta_q^a x \} \). Let us put \( n_a = \dim \text{Lie}(X)_a \).

It is known that \( n_a = \lceil na/q \rceil \) (see [15, 16]), where \( \lceil x \rceil \) is the maximal integer that’s less or equal to \( x \), and we take the representative \( 1 \leq a \leq q - 1 \).

**Remark 7.** By [9, Proposition 2.1, 2.2], the assumptions \((A)(B)(C)\) of Theorem 1 guarantee that there exists an integer \( a \) such that

\[
1 \leq a \leq q - 1, \quad \text{gcd}(a, p) = 1
\]

and the integers \( \lceil na/q \rceil \) and \( \dim_E V = n - 1 \) are relative prime. We note that the conditions \((A)(B)(C)\) of Theorem 1 are equivalent to the conditions \((A)(B)(C)\) of [9, Theorem 0.1].

Since \( V = H_1(X, \mathbb{Q}) \) carries a natural structure of \( E \)-vector space, the first complex homology group \( V_C = H_1(X, \mathbb{C}) = H_1(X, \mathbb{Q}) \otimes_{\mathbb{Q}} \mathbb{C} \) carries a structure of \( E_C \)-module, and therefore splits into a direct sum

\[
V_C = \oplus_{a \in \mathbb{G}} V_a.
\]

Each \( V_a \) is a \( \mathbb{C} \)-vector space of dimension \( \dim_F V = n - 1 \).

There is a canonical Hodge decomposition ([3, chapter 1], [1, pp. 52–53])

\[
V_C = H_1(X, \mathbb{C}) = H^{-1,0}(X) \oplus H^{0,-1}(X)
\]

where \( H^{-1,0}(X) \) and \( H^{0,-1}(X) \) are mutually “complex conjugate” \( \dim(X) \)-dimensional complex vector spaces. This splitting is \( E \)-invariant, and \( H^{-1,0}(X) \) and \( \text{Lie}(X) \) are canonically isomorphic as \( E_C \)-modules. In particular,

\[
\dim_C H^{-1,0}(X)_a = \dim_C \text{Lie}(X)_a = n_a.
\]

Let \( f_H^0 = f_{H,Z}^0 : V_C \to V_C \) be the \( \mathbb{C} \)-linear operator such that

\[
f_H(x) = -x/2 \quad \forall x \in H^{-1,0}(X); \quad f_H^0(x) = x/2 \quad \forall x \in H^{0,-1}(X).
\]

Since the Hodge decomposition is \( E \)-invariant, \( f_H^0 \) commutes with \( E \). Therefore, each \( V_a \) is \( f_H^0 \)-invariant. It follows that the linear operator \( f_H^0 : V_a \to V_a \) is semisimple and its spectrum lies in the two-element set \( \{-1/2, 1/2\} \). The multiplicity of eigenvalue \(-1/2\) is \( n_\bar{a} = \dim_C H^{-1,0}(X)_a \), while the multiplicity of eigenvalue \( 1/2 \) is \( \dim_E V - n_\bar{a} \). Clearly, the complex conjugate of \( a \in \text{Gal}(E/\mathbb{Q}) = (\mathbb{Z}/q\mathbb{Z})^* \) is \( \bar{a} = q - a \). It is known ([1], [2]) that

\[
n_a + n_\bar{a} = \dim_E V.
\]

This implies that the multiplicity of the eigenvalue \( 1/2 \) is \( n_{\bar{a}} \).
The Hodge Lie algebra \( \text{hdg} \) of \( X \) is a reductive \( \mathbb{Q} \)-Lie subalgebra of \( \text{End}_\mathbb{Q}(V) \). Its natural representation in \( V \) is completely reducible and its centralizer in \( \text{End}_\mathbb{Q}(V) \) coincides with \( \text{End}_\mathbb{Q}^0(X) = E \). Moreover, its complexification
\[
\text{hdg} \otimes \mathbb{C} = \text{hdg} \otimes \mathbb{Q} \subset \text{End}_\mathbb{Q}(V) \otimes \mathbb{Q} \mathbb{C} = \text{End}_\mathbb{C}(V \mathbb{C})
\]
contains \( f_H \) [8, Sect. 3.4]. Recall that \( \text{hdg} = c \oplus \text{hdg}^{ss} \), with \( c \) being the center of \( \text{hdg} \) and \( \text{hdg}^{ss} = [\text{hdg}, \text{hdg}] \) the semisimple part. Let \( \mathfrak{c} \mathbb{C} := c \otimes \mathbb{C} \) be the complexification of \( c \) and \( \text{hdg}_C^{ss} := \text{hdg}^{ss} \otimes \mathbb{C} \) the complexification of \( \text{hdg}^{ss} \). Clearly, \( \text{hdg}^{ss} \subset \mathfrak{sl}(V) \), and thus
\[
\text{hdg}_C^{ss} \subset \mathfrak{sl}_E(V \mathbb{C}) = \oplus_{a \in G} \mathfrak{sl}_C(V_a).
\]
We write \( \text{hdg}_a^{ss} \) for the image of projection \( P_a : \text{hdg}_C^{ss} \to \mathfrak{sl}_C(V_a) \). Clearly, each \( \text{hdg}_a^{ss} \) is a semisimple complex Lie subalgebra of \( \mathfrak{sl}_C(V_a) \).

**Remark 8.** Let us decompose \( f_H^0 \) as \( f \oplus f' \) with \( f' \in \mathfrak{c} \) and \( f \in \text{hdg}_C^{ss} \). By [9, Remark 3.2], the natural representation \( V_a \) of \( \text{hdg}_a^{ss} \) is simple for all \( a \in G \). It follows from Schur’s Lemma that when restricted to each \( V_a \), \( f' \) coincides with multiplication by scalar \( c_a \in \mathbb{C} \). Therefore, \( \text{hdg}_C^{ss} \) contains an operator (namely, \( f \)) whose restriction on each \( V_a \) is diagonalizable with at most two eigenvalues: \( -1/2 - c_a \) of multiplicity \( n_a \) and \( 1/2 - c_a \) of multiplicity \( n_a = \dim_E V - n_a \).

**Lemma 9.** Let the assumptions be the same as in Theorem 1. There exists an \( a \in G = (\mathbb{Z}/q\mathbb{Z})^* \) such that \( \text{hdg}_a^{ss} = P_a(\text{hdg}_C^{ss}) \) coincides with \( \mathfrak{sl}_C(V_a) \).

**Proof.** The idea is to combine Remark 7, 8 together with Lemma 3.3 of [9]. This result is already contained in the proof of [9, Theorem 3.4], where we note that the assumption \( n > q \) in [9, Theorem 3.4] is not used for this particular step of the proof.

Notice that this is the place where assumptions (A)(B)(C) in Theorem 1 are used, since we need to make sure that there exists \( a \in G \) such that \( n_a \) and \( \dim_E V \) are relatively prime in order to apply Lemma 3.3 of [9].

Let \( h : (\mathbb{Z}/q\mathbb{Z})^* \to \mathbb{R} \) be the function such that for all \( 1 \leq a \leq q - 1 \) with \( \gcd(a, q) = 1 \),
\[
(3) \quad h(a) = \left( \frac{\dim_E V}{2} - n_a \right)^2 = \left( \frac{n - 1}{2} - \frac{na}{q} \right)^2.
\]
By (2), \( n_a + n_a = \dim_E V \), so \( h(a) = h(a) = h(q - a) \), which is also easy to check directly from (3). The function \( h \) is non-increasing on the set of integers \( [1, q/2] \mathbb{Z} := \{ a \mid 1 \leq a \leq q/2, \gcd(a, p) = 1 \} \).

By Remark 3, we have \( 4 \leq n < q \). In particular, \( [n/q] = 0 \). On the other hand, let \( t \) be the maximal element of \( [1, q/2] \mathbb{Z} \). Then \( t \neq 1 \) and \( [nt/q] \neq 0 \). It follows that \( h \) is not a constant function.

**Lemma 10.** Let the assumption be the same as Theorem 1. Let \((a, b) \in G^2 \) be a pair such that \( h(a) \neq h(b) \). Then \( P_{a,b}(\text{hdg}_C^{ss}) = \mathfrak{sl}_C(V_a) \oplus \mathfrak{sl}_C(V_b) \).

**Proof.** By (3),
\[
h(a) - h(b) = (n_a - n_b)(\dim_E V - n_a - n_b).
\]
So \( h(a) \neq h(b) \) if and only if \( n_a \neq n_b \) and \( n_a \neq \dim_E V - n_b \). Let \( \mathfrak{t}^{ss} = P_{a,b}(\text{hdg}_C^{ss}) \). By Lemma 9 and part (i) of Lemma 5, both projections \( \mathfrak{t}^{ss} \to \mathfrak{sl}_C(V_a) \) and \( \mathfrak{t}^{ss} \to \mathfrak{sl}_C(V_b) \).
\textbf{Proof of Theorem 1.} As remarked at the end of Section 2, Theorem 1 follows if we show that the conditions (I) and (II) of Lemma 6 holds for \( \mathfrak{t} = \text{hdg}^{ss} \). Condition (I) holds by Lemma 9. To show that Condition (II) holds, by Lemma 10 it is enough to prove that for each \((a, b) \in G^2 \) with \( a \neq b \) and \( a \neq b \), there exists \( x \in G \) such that \( h(xa) \neq h(xb) \). Suppose that this is not the case, then there exists a pair \((a, b)\) such that \( h(xa) = h(xb) \) for all \( x \in G \). Without loss of generality, we may and will assume that \( b = 1 \in (\mathbb{Z}/q\mathbb{Z})^* \), thus \( a \neq \pm 1 \). It follows that \( h(xa) = h(x) \) for all \( x \in (\mathbb{Z}/q\mathbb{Z})^* \). Since \( h \) is not a constant function, such an \( a \) does not exists by Lemma 11 of next section. Contradiction. \( \square \)

4. Arithmetical Results

Throughout this section, \( G = (\mathbb{Z}/q\mathbb{Z})^* \). For each \( a \in G \), let \( \theta_a : G \to G \) be the translation map: \( b \mapsto ab \). A function \( h : G \to \mathbb{R} \) is said to be \textit{even} if \( h \circ \theta_{-1} = h \). For any \( x \leq y \in \mathbb{R} \), we write \( |x, y|_\mathbb{Z} \) for the set of integers \( \{i \mid x \leq i \leq y, \gcd(i, p) = 1\} \).

\textbf{Lemma 11.} Let \( h : (\mathbb{Z}/q\mathbb{Z})^* \to \mathbb{R} \) be an even function that’s monotonic on \([1, q/2]_\mathbb{Z} \). If \( h \circ \theta_a = h \) for some \( a \in (\mathbb{Z}/q\mathbb{Z})^* \) and \( a \neq \pm 1 \), then \( h \) is a constant function.

\textit{Proof.} We prove the Lemma in seven steps.

\textbf{Step 1.} Let \langle \pm a \rangle be the subgroup of \((\mathbb{Z}/q\mathbb{Z})^* \) generated by \( a \) and \(-1\). Clearly \( h \circ \theta_b = h \) for any \( b \in \langle \pm a \rangle \) since \( h \circ \theta_a = h \) and \( h \) is even. In particular, this holds true for the maximal element \( b_{\text{max}} \) in the set in \( \langle \pm a \rangle \cap [1, q/2]_\mathbb{Z} \). If \( b_{\text{max}} = 1 \), the group \( \langle \pm a \rangle \) is necessarily \( \{\pm 1\} \). Therefore, it is enough to prove that \( h \) being nonconstant implies that \( b_{\text{max}} = 1 \). So with out lose of generality, we assume that \( a = b_{\text{max}} \) throughout the rest of the proof. Notice that if \( a \neq 1 \), then \( 2a^2 > q \), for otherwise it contradicts the maximality of \( a \).

\textbf{Step 2.} Lemma 11 holds if \( p = 2 \).

Every even function on \((\mathbb{Z}/q\mathbb{Z})^* \) is constant if \( q \) is 2 or 4 so we assume that \( q = 2^r \geq 8 \). The group \((\mathbb{Z}/2^r\mathbb{Z})^* \) is isomorphic to \( \mathbb{Z}/2^r\mathbb{Z} \times \mathbb{Z}/2^{r-2}\mathbb{Z} \), where the factor \( \mathbb{Z}/2^r\mathbb{Z} \) is generated by \(-1\). Let us assume that \langle \pm a \rangle has order \( 2^r \). Since \( \langle \pm a \rangle \cong \langle \pm 1 \rangle \), it follows that \( \langle \pm a \rangle \cong \mathbb{Z}/2^r\mathbb{Z} \times \mathbb{Z}/2^{r-1}\mathbb{Z} \). In particular, if \( \langle \pm a \rangle = \langle \pm 1 \rangle \), then \( \mathbb{Z}/2^{r-1}\mathbb{Z} \) is nontrivial, therefore \( \langle \pm a \rangle \) contains 3 elements of order two. But there are exactly 3 elements of order two in \((\mathbb{Z}/q\mathbb{Z})^* : -1, 2^{r-1}-1, 2^{r-1}+1 \). Hence \( \langle \pm a \rangle \) contains all the above elements of order 2. So \( a = 2^{r-1}-1 \) since it is the largest element in \([1, q/2]_\mathbb{Z} \). Therefore,

\[ h(q/2-1) = h(2^{r-1}-1) = h(a) = (h \circ \theta_a)(1) = h(1). \]

Since \( h \) is monotonic on \([1, q/2]_\mathbb{Z} \), the above equality implies that \( h \) is constant on \([1, q/2]_\mathbb{Z} \) and therefore a constant function.
Step 3. Let $p$ be an odd prime. Lemma 11 holds if either $a$ is even, or $a$ is odd and $3a \geq q$.

It is enough to prove that if $a \neq 1$, then $h(1) = h((q - 1)/2)$. Since $h(1) = (h \circ \theta_a)(1) = h(a)$, by monotonicity $h$ is constant on $[1, a]_Z$. Therefore it is enough to find $b$ such that $h((q - 1)/2) = h(b)$ and $b \in [1, a]_Z$.

First, let’s assume that $a = 2b$ is even. Then

$$a \cdot \frac{q - 1}{2} = (q - 1)b \equiv -b \mod q.$$  

So $h((q - 1)/2) = h(a(q - 1)/2) = h(-b) = h(b)$. Clearly $b = a/2$ lies in $[1, a]_Z$.

Next, assume that $a$ is odd. Then

$$a \cdot \frac{q - 1}{2} = \frac{qa - a}{2} \equiv \frac{q - a}{2} \pmod{(mod q)}.$$  

So $h((q - 1)/2) = h((q - a)/2)$. Let $b = (q - a)/2$. When $3a \geq q$, we have $b = (q - a)/2 \leq a$ hence $b$ lies in $[1, a]_Z$ as desired.

Step 4. Lemma 11 holds if $p = 3$.

When $p$ is odd, $(Z/p^rZ)^*$ is cyclic of order $\varphi(p^r) = (p - 1)p^{r - 1}$. For $p = 3$,

$$(Z/3^rZ)^* \cong Z/(2 \cdot 3^{r - 1})Z \cong Z/2Z \times Z/3^{r - 1}Z.$$  

In particular, if $q \geq 9$, $(Z/qZ)^*$ contains a unique subgroup of order 3 which is generated by $3^{r - 1} + 1$. If the order of $\langle \pm a \rangle$ is coprime to 3, then $\langle \pm a \rangle$ is necessarily $\{\pm 1\}$, which leads to a contradiction. If the order of $\langle \pm a \rangle$ is divisible by 3, then $q \geq 9$ and $\langle \pm a \rangle$ contains $3^{r - 1} + 1$. By assumption on the maximality of $a$ we must have $a \geq 3^{r - 1} + 1$ and hence $3a > q$.

Step 5. Assume that both $p$ and $a$ are odd, $p \neq 3$ and $3a < q$. Lemma 11 holds if $7a \geq q$.

Since $p \neq 3$, $(q - 3)/2$ lies in $[1, q/2]_Z$. It is enough to prove that $a \neq 1$ implies that $h(1) = h((q - 3)/2)$. Indeed, it follows from the proof of Step 3 that $h((q - 1)/2) = h((q - a)/2)$. But if $a \neq 1$ then $a \geq 3$ so $(q - a)/2 \leq (q - 3)/2$. If we prove that $h$ is constant on $[1, (q - 3)/2]_Z$, then $h((q - 1)/2) = h((q - a)/2) = h(1)$ and it follows that $h$ is a constant function.

By our assumption $3a < q$, so $(q - 3a)/2$ lies in $[1, q/2]_Z$. Notice that

$$a \cdot \frac{q - 3}{2} = \frac{q - 3a}{2} \pmod{q}.$$  

We see that $h((q - 3)/2) = h((q - 3a)/2)$. Since $h$ is constant on $[1, a]_Z$, the inequality $h(1) \neq h((q - 3)/2)$ would imply that $a < (q - 3a)/2$, or equivalently $5a < q$. In particular, $2a < q/2$. But $2 \in [1, a]_Z$ since $p$ is odd and $a \geq 3$. So $h(2) = h(1)$, therefore $h(2a) = h(1)$ and $h$ is constant on $[1, 2a]_Z$. But now by our assumption $7a \geq q$, or equivalently $2a \geq (q - 3a)/2$, it follows that

$$h \left( \frac{q - 3}{2} \right) = h \left( \frac{q - 3a}{2} \right) = h(1).$$

Step 6. Assume that both $p$ and $a$ are odd, $p \neq 3, 5$ and $7a < q$. Lemma 11 holds.
Since $7a < q$ and $p \neq 5$, $(q - 5a)/2$ lies in $[1, q/2] \mathbb{Z}$. By similar argument as in Step 5, $h((q - 5)/2) = h((q - 5\alpha)/2)$. We claim that now it is enough to show that $h(1) = h((q - 5)/2)$. Indeed, by the proof of the Step 5, all we need to show is that $h(1) = h((q - 3)/2)$, but since $a \geq 3$, then $(q - 3a)/2 < (q - 5)/2$. So $h$ being constant on $[1, (q - 5)/2] \mathbb{Z}$ implies that $h(1) = h((q - 3)/2) = h((q - 3)/2)$.

Let $S$ be the set of all integers

$$S = \{b \mid b \geq 1, p \nmid b, (2b + 1)a < q\}.$$ 

Clearly $1 \in S$ so $S$ is not empty. Let $x$ be the maximal element of $S$. By Step 1, $2a^2 > q$ so necessarily $x < a$. Since $h$ is constant on $[1, a] \mathbb{Z}$, we must have $h(1) = h(x)$. Notice that $ax < q/2$ by assumption. So $h(ax) = h(x) = h(1)$ and it follows that $h$ is constant on $[1, ax] \mathbb{Z}$. Assume that $h(1) \neq h((q - 5)/2)$. It is necessary that $ax < (q - 5a)/2$, or equivalently, $(2x + 5)a < q$. But we can choose $x'$ from the two elements set $\{x + 1, x + 2\}$ such that $x'$ is coprime to $p$. It follows that $x' \in S$. This contradicts the maximality of $x$.

**Step 7.** Lemma 11 holds if $p = 5$.

If the order of $(\pm a)$ is divisible by 5, then $(\pm a)$ contains the unique subgroup of order 5 in $(\mathbb{Z}/5^r\mathbb{Z})^\times$. In particular, $2 \cdot 5^r - 1 + 1 \in (\pm a)$. It follows that $a > 2 \cdot 5^r - 1 + 1$ and therefore $3a > 5^r$. The Lemma holds by Step 3. If the order of $(\pm a)$ is coprime to 5. Then from the isomorphism

$$\mathbb{Z}/5^r\mathbb{Z} \cong \mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/5^r-1\mathbb{Z},$$

we see that $(\pm a)$ is has either order 2 or 4. If $(\pm a)$ has order 2, then $(\pm a)$ is necessarily $(\pm 1)$ and this leads to a contradiction. So we assume that $(\pm a)$ has order 4 and $a$ is the unique element such that $1 < a < 5^r/2$ and $a^2 \equiv -1 \mod 5^r$. In particular, $a^2 + 1 \geq 5^r$. If $a$ is even then the Lemma holds by Step 3. In particular, this works for $q = p = 5$ since $a = 2$ in this case. We assume that $q \geq 25$ and $a$ is odd throughout the rest of the proof. First we claim that $a \geq 7$. Indeed, if $q = 25$, then $a = 7$ by direct calculation; if $q > 25$, then $a > 7$ since $a^2 + 1 \geq q$. This implies that $(q - a)/2 \leq (q - 7)/2$. Therefore, it is enough to prove that $h((q - 7)/2) = h(1)$ since it then follows that $h((q - 1)/2) = h((q - a)/2) = h(1)$. By Step 5 we may also assume that $7a < q$. It follows that $(q - 7a)/2 \in [1, q/2] \mathbb{Z}$ and $h((q - 7)/2) = h((q - 7a)/2)$.

Let $c = [q/a]$. Since $a^2 + 1 \geq q$ and $a < q/2$ we see that $2 \leq c \leq a$. Let $x = [c/2]$ if $[c/2]$ is not divisible by 5, and $x = [c/2] - 1$ otherwise. Notice that $a > x \geq \max\{1, (c - 3)/2\}$ and $xa \leq q/2$ by our choice of $x$. It follows that $x \in [1, a] \mathbb{Z}$ therefore $h(x) = h(1)$, and therefore $h(ax) = h(x) = h(1)$. So $h$ is constant on $[1, ax] \mathbb{Z}$. If $h(1) \neq h((q - 7)/2)$, we must have $xa < (q - 7a)/2$, or equivalently, $(2x + 7)a < q$. Then it follows that

$$\frac{q}{a} > 2x + 7 \geq 2\left(\frac{c - 3}{2}\right) + 7 = c + 4 = \left\lfloor\frac{q}{a}\right\rfloor + 4,$$

which is absurd.

Lemma 11 is proved by combining all the above steps. \qed
