Starting from the dual Lagrangians recently obtained for (partially) massless spin-2 fields in the Stueckelberg formulation, we write the equations of motion for (partially) massless gravitons in (A)dS in the form of twisted-duality relations. In both cases, the latter admit a smooth flat limit. In the massless case, this limit reproduces the gravitational twisted-duality relations previously known for Minkowski spacetime. In the partially-massless case, our twisted-duality relations preserve the number of degrees of freedom in the flat limit, in the sense that they split into a decoupled pair of dualities for spin-1 and spin-2 fields. Our results apply to spacetimes of any dimension greater than three. In four dimensions, the twisted-duality relations for partially massless fields that appeared in the literature are recovered by gauging away the Stueckelberg field.

1 Introduction and conventions

Recently [1], manifestly covariant action principles in the Stueckelberg formulation were given for dual massless, partially massless and massive spin-2 fields in maximally symmetric spacetimes of arbitrary dimensions \( n > 3 \), such that the degrees of freedom are preserved in the flat limit. The action principles for the dual fields were also related to the standard ones for such field theories by building on the previous works [2–13], whose motivations go back to Dirac for duality in electromagnetism and to the work [14] in the context of extended supergravity. See [15] for references on earlier works.

In this Letter we focus on the massless and partially-massless cases and formulate the field equations derived from the actions of [1] in the form of twisted-duality relations. In the massless case, our twisted-duality relation — see Eq. (2.33) — generalises to (A)dS backgrounds the twisted-duality relation written in [16,17] for linearised Einstein gravity in flat spacetimes. Our duality relation actually smoothly reproduces the latter duality relation in the flat limit, thanks to the crucial role played by the Stueckelberg fields.

In the case of a partially-massless spin-2 field [18], the twisted-duality relation that we obtain — see Eq. (3.35) — has a smooth flat limit that reproduces a couple of twisted-duality relations in flat background, one for a massless spin-2 field and the other for a massless spin-1 field, thereby correctly accounting for the degrees of freedom of a partially-massless spin-2 field. Moreover, keeping the cosmological constant non-zero and setting \( n = 4 \), our twisted-duality relation reproduces the one given in [19], upon eliminating the Stueckelberg field.

Twisted-duality relations are interesting for many reasons. In particular they relate, for a pair of dual theories, the Bianchi identities of one system to the field equations of the dual one, and vice versa. In the present work, we show that the field equations of two dual theories are formulated as a twisted-duality equation, although we note that the latter is not obtained from a variational principle that is manifestly spacetime covariant. Forgoing the latter requirement, for linearised Einstein theory around flat spacetime the authors of [20] gave an action principle that yields the twisted self-duality conditions as equations of motion, keeping the graviton and its dual on equal footing. Finally, let us mention that, for the fully nonlinear Einstein-Hilbert theory, an action principle was given in [21] where both the graviton and its dual appear inside the action, albeit not on an equal footing and together with extra auxiliary fields. For recent interesting works where twisted (self) duality relations play a central role and for more references, see [22–25].

As for our conventions, we work on constant-curvature spaces with either negative or positive cosmological constant \( \Lambda \). We denote the number of spacetime dimensions by \( n \) and define the quantity \( \lambda^2 = \frac{-2\sigma \Lambda}{(n-2)(n-3)} \), \( \sigma = \pm 1 \), that is always positive. When the background is AdS\(_n\) one has \( \sigma = 1 \), while \( \sigma = -1 \) for dS\(_n\). The commutator of covariant derivatives gives \([\nabla_a, \nabla_b]V_c = -\sigma \lambda^2 (g_{ac}V_b - g_{bc}V_a)\) where \( g_{ab} \) is the background (A)dS\(_n\) metric. The symbols \( \epsilon_{a_1\cdots a_n} \) and \( \epsilon^{a_1\cdots a_n} \) denote the totally antisymmetric tensors obtained from the corresponding densities upon multiplication and division by \( \sqrt{-g} \).
2 Massless spin-2 twisted duality

2.1 Fierz-Pauli formulation

In the Fierz-Pauli formulation for a massless spin-2 field around a maximally-symmetric spacetime of dimension $n$, the Lagrangian (where we omit the factor $\sqrt{-g}$ for the sake of conciseness) is given by

\[
\mathcal{L}^{FP} = -\frac{1}{2} \nabla_a h_{bc} \nabla^a h^{bc} + \nabla_a h_{bc} \nabla^c h^{ba} + \frac{1}{2} \nabla_a h \nabla^a h - \nabla_a h \nabla_b h^{ab} - \frac{(n-1)\sigma \lambda^2}{2} (2 h_{ab} h^{ab} - h^2) .
\]  

(2.1)

It is invariant, up to a total derivative, under the gauge transformations

\[
\delta h_{ab} = 2 \nabla_{(a} \xi_{b)} .
\]  

(2.2)

The primary gauge-invariant quantity for the Fierz-Pauli theory is given by

\[
K^{ab|mn} = -\frac{1}{2} \left( \nabla^a \nabla^{|m| h^{n|b|} - \nabla^b \nabla^{|m| h^{a|n|}} + \nabla^m \nabla^{|a| h^{b|n|} - \nabla^n \nabla^{|a| h^{b|m|}} + \sigma \lambda^2 \left( g^{a|m| h^{n|b|} - g^{b|m| h^{a|n|}} \right) \right) .
\]  

(2.3)

It possesses the same symmetries as the components of the Riemann tensor,

\[
K^{[ab|c|d]} \equiv 0 ,
\]  

(2.4)

and obeys the differential Bianchi identity

\[
\nabla^{[a} K^{bc]|mn} \equiv 0 .
\]  

(2.5)

The field equations derived from the Lagrangian $\mathcal{L}^{FP}$ imply the tracelessness of the curvature:

\[
K_{mn} := g^{ab} K_{ma|nb} \approx 0 ,
\]  

(2.6)

where weak equalities are used throughout this paper to indicate equalities that hold on the surface of the solutions to the equations of motion. More precisely, defining $K = g^{ab} K_{ab}$, the left-hand side of the field equations read

\[
\frac{\delta \mathcal{L}^{FP}}{\delta h^{ab}} \equiv -2 \left( K_{ab} - \frac{1}{2} g_{ab} K \right) .
\]  

(2.7)

By virtue of the differential Bianchi identity for the curvature, one also finds that, on-shell, the curvature has vanishing divergence:

\[
\nabla^m K_{mn|ab} \approx 0 .
\]  

(2.8)

To summarise, the important equations in this section are (2.4), (2.5) and (2.6). The latter relation was derived from the Lagrangian $\mathcal{L}^{FP}$. For the purpose of deriving twisted-duality relation, we can actually forget the origin of (2.6) and focus on the three equations (2.4), (2.5) and (2.6).

---

3Indices enclosed between (square) round brackets are (anti)symmetrised, and dividing by the number of terms involved is understood (strength-one convention).
2.2 Dual formulation

We start from the dual formulation of the massless spin-2 theory as given by the Lagrangian $L_\text{d}(\hat{Y}, W)$ in Eq. (20) of [1]:

$$L_\text{d}(\hat{Y}, W) = \frac{1}{2}\,\epsilon \left[ \frac{1}{2} \nabla^c W^{abc|d} \nabla_c W^{d|e}_a + \lambda \hat{Y}^{abc|d} \nabla^e W^{c|e}_a ight] + \frac{\sigma}{2(n-2)} \nabla^c \hat{Y}^{abc|d} \nabla^d \hat{Y}_{cd|a} + \lambda^2 \hat{Y}^{abc|d} \hat{Y}_c^d|a|b].$$

(2.9)

This Lagrangian describes the propagation of the same degrees of freedom as the Fierz-Pauli one in (2.1). We now define the following quantities

$$R_{a|b}^{cd} := 2 \nabla_{[a} \left( \nabla_c W^{cde}_{|b]} + \lambda \hat{Y}^{cde}_{|b]} \right),$$

(2.10)

$$K_{a|b}^{cd} := 2 \nabla_{[a} \nabla_c \hat{Y}^{cde}_{|b]} + 2\sigma(n-2)\lambda \left( \nabla_c W^{cde}_{|a|b]} + \lambda \hat{Y}^{cde}_{|a|b]} \right),$$

(2.11)

together with their various non-vanishing traces

$$R_{a}^{c} = R_{a|b}^{cb}, \quad K_{a} = K_{a|b}^{b}.$$  

(2.12)

Further introducing the traceless tensor $V_{a|b}^{cd}$ encoding the traceless projection of $R_{a|b}^{cd}$,

$$V_{a|b}^{cd} = R_{a|b}^{cd} - \frac{4}{n-2} \delta_{[a}^{e|b|} R^{d]}_{a|b|},$$

(2.13)

we find that $V_{a|b}^{cd}$ is invariant under the following gauge transformations:

$$\delta \hat{Y}^{abc|}_{a} = \nabla_{d} \theta^{bcd|}_{a} + \nabla_{a} \Lambda^{bc} + \frac{2}{n-1} \delta_{[a}^{b} \nabla_{d} \Lambda^{c]d} + (n-3)\sigma \lambda \chi_{a}^{bc},$$

(2.14)

$$\delta W^{bde|}_{a} = \nabla_{e} \theta^{bde|}_{a} + \nabla_{a} \chi^{bcd} - \frac{3}{n-2} \delta_{[a}^{b} \nabla_{e} \chi^{cde]e} - \lambda \zeta^{bcd|}_{a}.$$  

(2.15)

Finally, the traceless tensor

$$X_{a|b}^{c} := K_{a|b}^{c} + \frac{2}{n-1} \delta^{c}_{[a} K_{b]}$$

(2.16)

is also found to be gauge invariant.

As in [1], one can also express the fields $W$ and $\hat{Y}$ in terms of their Hodge duals, that we denote by $C$ and $T$:

$$W^{abc|}_{d} = -\frac{1}{(n-3)!} \epsilon^{[n-3]abc} C^{c|n-3|d}, \quad \hat{Y}^{abc|}_{d} = -\frac{1}{(n-2)!} \epsilon^{[n-2]abc} T^{c|n-2|d}. $$

(2.17)

The corresponding curvatures are obtained from the previous gauge-invariant tensors $V$ and $X$ as follows:

$$K^{C}_{a|n-2||bc} = \frac{1}{2n} \epsilon_{a[n-2]|de} V^{d|e}_b c, \quad K^{T}_{a|n-1||bc} = \epsilon_{a[n-1]|d} X_{bc|d}.$$  

(2.18)

\footnote{We substitute groups of antisymmetrised indices with a label denoting the total number of indices, e.g., $\epsilon_{a_1\ldots a_n} \equiv \epsilon_{[a_1[a}$. Moreover, repeated indices denote an antisymmetrisation, e.g., $A_a B_a \equiv A_{[a_1} B_{a_2]}$.}
In components, the curvature tensors read

\[ K_{a[n-2]|bc}^C = 2(n-2)(-1)^{n-1} \nabla^{[b} \nabla_a C_{a[n-3]|c]} + 2\lambda \nabla^{[b} T_{a[n-2]|c]} + \ldots , \tag{2.19} \]

\[ K_{a[n-1]|bc}^T = 2(n-1)(-1)^n \nabla^{[b} \nabla_a T_{a[n-2]|c]} - 2\sigma \lambda(n-1)(n-2)^2 \delta^{[b}_a \nabla_a C_{a[n-3]|c]} + 2\sigma \lambda^2(n-1)(n-2) T_{a[n-2]|[b]c] + \ldots , \tag{2.20} \]

where the ellipses denote terms that are necessary to ensure \( GL(n) \)-irreducibility of the curvatures \( K_{a[n-2]|bc}^C \) and \( K_{a[n-1]|bc}^T \) on the two-column Young tableaux of types \([n-2, 2]\) and \([n-1, 2]\), respectively. Pictorially, they are represented by

\[
\begin{array}{c|c}
  a_1 & b \\
  a_2 & c \\
  \vdots & \vdots \\
  a_{n-2} & \\
\end{array}
\text{ and } \begin{array}{c|c}
  a_1 & b \\
  a_2 & c \\
  \vdots & \vdots \\
  a_{n-2} & \\
\end{array}
\]

Indeed, tracelessness of \( V_{bc}^{de} \) and \( X_{ab}^c \) implies that the Hodge dual tensors \( K_{a[n-2]|bc}^C \) and \( K_{a[n-1]|bc}^T \) obey the following algebraic Bianchi identities:

\[ K_{a[n-2]|ac}^C \equiv 0 , \quad K_{a[n-1]|ac}^T \equiv 0 . \tag{2.21} \]

The two curvatures are linked via the following differential Bianchi identities:

\[ \nabla_a K_{a[n-2]|bc}^C = \lambda \frac{(-1)^n(n-3)}{(n-1)(n-2)} K_{a[n-1]|bc}^T , \tag{2.22} \]

\[ \nabla^{[b} K_{a[n-2]|cd]}^C = \lambda \frac{1}{n-2} K_{a[n-2]|[b]cd}^T . \tag{2.23} \]

These are equivalent to the following two identities:

\[ \nabla_d V_{ab}^{cd} \equiv -\lambda \frac{n-3}{n-2} X_{ab}^c , \quad \nabla_{[b} V_{cd]}^{ij} \equiv \lambda \frac{2}{n-2} \delta_{[b}^{[i} X_{cd]}^{j]} . \tag{2.24} \]

The equations of motion for the dual gauge fields \( C_{a[n-3]|b} \) and \( T_{a[n-2]|b} \) derived from the Lagrangian \( \mathcal{L}_0(C, T) \) — obtained by substituting (2.17) in (2.9) and given in Eq. (23) of [1] — can be written in terms of the traces of the gauge-invariant curvatures \( K_{a[n-2]|b[2]}^C \) and \( K_{a[n-1]|b[2]}^T \). Explicitly, one has

\[ \frac{\delta \mathcal{L}_0}{\delta C_{a[n-3]|b}} \equiv \frac{1}{\lambda^2(n-3)!} \left( K_{C_{a[n-3]|c]}^{a[n-3]|c} b + \frac{n-2}{2} K_{C_{a[n-4]cd}}^{a[n-4]cd} g^{ab} \right) \approx 0 , \tag{2.25} \]

\[ \frac{\delta \mathcal{L}_0}{\delta T_{a[n-2]|b}} \equiv \frac{\sigma}{\lambda^2(n-2)^2(n-3)!} \left( K_{T_{a[n-2]|c]}^{a[n-2]|c} b + \frac{n-2}{2} K_{T_{a[n-3]cd}}^{a[n-3]cd} g^{ab} \right) \approx 0 . \tag{2.26} \]
The field equations (2.25) and (2.26) can easily be obtained by starting from the field equations of the Lagrangian $L_0(W, \hat{Y})$ and then expressing the fields $W^{abc|d}$ and $\hat{Y}^{ab|c}$ in terms of their Hodge duals $C^{a[n-3]|b}$ and $T^{a[n-2]|b}$, respectively. More in details, the left-hand sides of the field equations derived from $L_0(W, \hat{Y})$ read

$$\delta L_0(W, \hat{Y}) \delta W^{abc|d} = \frac{1}{2\lambda^2} V^{[abc]|d}, \quad \delta L_0(W, \hat{Y}) \delta \hat{Y}^{ab|c} = -\frac{\sigma}{2(n-2)\lambda^2} X_{ab|c}^d,$$

(2.27)

and the gauge invariant tensors $X$ and $V$ can be expressed as

$$X_{ab|d} = -\frac{1}{(n-1)!} \epsilon^{[n-1]d} K^{T|c[n-1]|ab}, \quad V_{ab|cd} = -\frac{1}{(n-2)!} \epsilon^{[n-2]cd} K^{C|c[n-2]|ab}. \quad (2.28)$$

The field equations (2.25) and (2.26) imply the tracelessness of the curvatures:

$$K^{C|a[n-3]|b|c} \approx 0, \quad K^{T|a[n-2]|b|c} \approx 0. \quad (2.29)$$

In fact, from a result in representation theory of the orthogonal group — see the theorem on p. 394 of [26] —, the second equation above implies that

$$K^{T|a[n-1]|b|c} \approx 0. \quad (2.30)$$

The curvature for the field $T$ thus vanishes on shell, consistently with the observation that this field does not propagate any degrees of freedom in the flat limit [13,1].

Upon using the first and second differential Bianchi identities (2.22) and (2.23), we also find the following two relations that are true on shell:

$$\nabla_a K^{C|a[n-2]|b|c} \approx 0, \quad \nabla^{[b} K^{C|a[n-2]|c|d]} \approx 0. \quad (2.31)$$

These equations, together with (2.29), imply that the divergences of the curvature $K^C$ vanish on shell:

$$\nabla^a K^{C|a[n-3]|b|c} \approx 0, \quad \nabla^b K^{C|a[n-2]|b|c} \approx 0. \quad (2.32)$$

To summarise, the important equations of this section are the equations of motion (2.29) and the Bianchi identities (2.21), (2.22) and (2.23). In the following section we will relate them to the field equations and the Bianchi identities of the Fierz-Pauli formulation via a twisted-duality relation.

### 2.3 Massless twisted duality

The twisted-duality relations for the massless spin-2 theory around (A)dS backgrounds are

$$K^{C|a[n-2]|b|c} \approx \frac{1}{2} \epsilon^{a[n-2]|ij} K^{ij|b|c}. \quad (2.33)$$

6
As usual for twisted-duality relations, the Bianchi identities in a formulation of the theory are mapped to the field equations of the dual formulation, and vice versa, as we now explain in details.

First, the algebraic Bianchi identity (2.21) for the left-hand side of the twisted-duality relation (2.33) implies that the trace of $K_{ab|cd}$ vanishes on-shell, which is the field equation (2.6) in the metric formulation. The converse is true: If one takes the trace of the relation (2.33), the right-hand side vanishes by virtue of the algebraic Bianchi identity (2.4). This implies that the trace of the left-hand side of (2.33) vanishes, which enforces the field equation (2.29) in the dual formulation.

Second, starting again from the twisted-duality equation (2.33), the differential Bianchi identity (2.23) on the second column of $K^C$ combined with the Bianchi differential identity (2.5) imply the on-shell vanishing of $K^T$, that is, (2.30). Using this result, the differential Bianchi identity (2.22) on the first column of $K^C$ gives the first equation of (2.31) that implies in its turn, via (2.33), the field equation (2.8) in the metric formulation of the massless spin-2 theory. The converse is also true: acting on the twisted-duality (2.33) relation with $\nabla^a$ gives identically zero, from the right-hand side and as a consequence of the differential Bianchi identity (2.5) for the curvature in the metric formulation of linearised gravity around (A)dS. This implies the first field equation (2.32) for the dual graviton. Moreover, acting on (2.33) with $\nabla_d$ and antisymmetrising over the three indices $\{b, c, d\}$ gives identically zero from the right-hand side of (2.33), as a consequence of (2.5). That implies the field equation (2.30) (and therefore the second field equation (2.31)) by virtue of the identity (2.23). Finally, the field equation (2.8) is mapped to the second field equation in (2.32).

Third, the twisted-duality relation (2.33) exactly reproduces, in the limit where the cosmological constant goes to zero, the twisted-duality relations given by Hull in [17] for linearised gravity in flat spacetime, see also section 4 of [27].

3 Partially-massless spin-2 twisted duality

3.1 Standard Stueckelberg formulation

We consider the Stueckelberg Lagrangian for a partially-massless, symmetric spin-2 field in which both signatures are allowed (making AdS manifestly non-unitary at the classical level):

$$
\mathcal{L}_{PM} = -\frac{1}{2} \nabla_a h_{bc} \nabla^a h^{bc} + \nabla_a h_{bc} \nabla^c h^{ba} + \frac{1}{2} \nabla_a h \nabla^a h - \nabla_a h \nabla_b h^{ab} - \frac{(n-1)\sigma\lambda^2}{2} (2h_{ab}h^{ab} - h^2) \\
+ \sigma \nabla_{[a} A_{b]} \nabla^{[a} A^{b]} + (n - 1)\lambda^2 A_a A^a - 2\tilde{m} A_a \left( \nabla^a h - \nabla_b h^{ab} \right) \\
+ \sigma \tilde{m}^2 \left( h_{ab}h^{ab} - h^2 \right),
$$

(3.1)
where the partially massless theory really appears in the limit
\[
\tilde{m}^2 \longrightarrow \frac{(n-2)\lambda^2}{2}.
\]

The last two lines in the expression (3.1) are new terms in comparison with the Lagrangian for a strictly massless spin-2 field in (A)dS, see (2.1). In the limit (3.2), the Lagrangian \( \mathcal{L}_{PM} \) is invariant, up to total derivatives, under the gauge transformations
\[
\delta h_{ab} = 2 \nabla (a) \xi_b + \frac{2\tilde{m}}{n-2} g_{ab} \epsilon, \quad \delta A_a = \nabla_a \epsilon + 2 \sigma \tilde{m} \xi_a.
\]

The quantity
\[
H_{ab} = h_{ab} - \sigma \tilde{m} \nabla (a) A_b
\]
is invariant under the gauge transformations with parameter \( \xi_a \), but not under the gauge transformations with parameter \( \epsilon \). A fully gauge-invariant quantity is provided by the antisymmetrised curl of \( H_{ab} \). Indeed, defining
\[
K_{ab|cd} := 2 \nabla_c \nabla_{[a} \xi_{b]} - 4\sigma \lambda^2 g_{c[a} A_{b]} - 4\sigma \tilde{m} \nabla_{[a} h_{b]c} \equiv -4\sigma \tilde{m} \nabla_{[a} H_{b]c},
\]
we have that \( K_{ab|cd} \) is fully gauge invariant in the partially massless limit (3.2), hence so is \( \nabla_{[a} H_{b]c} \). We further define the derived quantity \( Q^{ab|mn} \) as follows:
\[
Q^{ab|mn} = -\frac{1}{2} (\nabla^a \nabla^[m] H^{n]b} - \nabla^b \nabla^[m] H^{n]a} + \nabla^m \nabla^[a] H^{b]n} - \nabla^n \nabla^[a] H^{b]m})
+ (1 - \frac{2\tilde{m}^2}{(n-2)\lambda^2}) \sigma \lambda^2 (g^a[m] H^{n]b} - g^b[m] H^{n]a}) .
\]

It possesses the symmetries of the components of the Riemann tensor, like \( K_{ab|cd} \) in the massless case. The second line of the above expression is identically vanishing in the limit (3.2), so that \( Q^{ab|mn} \) is indeed a composite object purely built out of the gauge-invariant curl of \( H_{ab} \). The writing that we adopted in (3.6) facilitates the relation between \( K_{ab|cd} \) and \( Q^{ab|cd} \). The interest in defining (3.6) rests in the fact that the field equations for \( h_{ab} \) read
\[
\frac{\delta \mathcal{L}_{PM}}{\delta h^{ab}} \equiv -2 G_{ab}, \quad \text{where} \quad G_{ab} := (Q_{ac|b}^\epsilon - \frac{1}{2} g_{ab} Q^{cd|} cd). \tag{3.7}
\]

As a consequence, the field equations for \( h_{ab} \) imply that the curvature \( Q_{ab|cd} \) is traceless on-shell, as it was for \( K_{ab|cd} \) in the strictly massless case.

The Noether identities associated with the gauge parameter \( \xi_a \) give the left-hand side of the field equations for the vector \( A_a \):
\[
\frac{\delta \mathcal{L}_{PM}}{\delta A^a} \equiv -\frac{2\sigma}{\tilde{m}} \nabla^b G_{ab} . \tag{3.8}
\]

The non-vanishing of the covariant divergence of \( G_{ab} \) is also related to the Bianchi identity
\[
\nabla^[a Q^{bc]|}_m \equiv -\frac{\tilde{m}}{n-2} \delta^[a |m K^{bc]|}_n), \tag{3.9}
\]
where the gauge-invariant quantity $K_{abc}$ was defined above in (3.5) and satisfies the identity $K_{[abc]} \equiv 0$. In terms of $K_{abc}$, the left-hand side of the field equations for $A_a$ reads

$$\frac{\delta \mathcal{L}_{PM}}{\delta A^a} \equiv \sigma K_{ab}^b, \quad (3.10)$$

so that the field equations for $A_a$ implies that the curvature $K_{abc}$ is traceless on-shell.

### 3.2 Dual formulation

Starting from the dual formulation of partially-massless spin-2 theory that is described by the Lagrangian $\mathcal{L}_{PM}(W, U)$, Eq. (39) in [1]:

$$\mathcal{L}_{PM}(W, U) = -\frac{1}{2\kappa} \nabla_d W^{bcd|a} \nabla^e W_{a|b} + \frac{\sigma}{m} U_{abc} \nabla_d W^{abcd|c} - \frac{\lambda^2}{2m^2} U^{abc} U_{abc}, \quad (3.11)$$

one can define the following quantities

$$R_{ab|cd} := 2 \nabla_{[a} \left( \nabla_e W^{cde|b] - \frac{\sigma\lambda^2}{m} U_{[b]^{|cd}} \right), \quad (3.12)$$

$$K^{U|abc} := 2 \nabla_{[a} \nabla_e U_{b|c]} e + 2(n-2)\bar{m} \left( \nabla_e W^{e|b[|a} - \frac{\sigma\lambda^2}{m} U_{abc} \right), \quad (3.13)$$

together with the successive traces

$$R_{a|c} = R_{ab|cb}, \quad R = R_{a|a} \equiv 0, \quad K^{U^b|a} = K^{U|abc} \equiv 0. \quad (3.14)$$

In a similar manner to the massless case, we introduce the traceless tensor $V_{ab|cd}$ according to

$$V_{ab|cd} = R_{ab|cd} - 4(n-2)\delta^{[c|a} R_{b|d]}, \quad (3.15)$$

and we find that the tensors $V_{ab|cd}$ and $K^{U|abc}$ are invariant under the following gauge transformations:

$$\delta W^{abcd|}_a = \nabla_e W^{e|bced|}_a + \nabla_a W^{bced} - \frac{3}{n-2} \delta^{[b} \nabla_e W^{cde]}_a e - \frac{\sigma\lambda^2}{m} \rho^{bcd} a, \quad (3.16)$$

$$\delta U^{abc} = \nabla_d U^{abcd} - (n-3)\bar{m} \chi^{abc}. \quad (3.17)$$

Also in this case, we then express $W$ and $U$ in terms of their Hodge duals

$$W^{abc|}_d = -\frac{1}{(n-3)!} \epsilon^{[n-3|abc} C^{e|n-3]|d}, \quad U^{abc} = -\frac{1}{(n-3)!} \epsilon^{[n-3|abc} A_{d|n-3]} \quad (3.18)$$

The curvature tensor for $C$ is defined, as in the massless case, by

$$K_{a|n-2|bc} = \frac{1}{2!} \epsilon_{a|n-2|de} V_{bc}^{\,de}. \quad (3.19)$$
We also define the curvature $\tilde{K}_{a[n-2]} b$ via

$$K^U_{ab|c} = (-1)^{n-1} \frac{2}{(n-2)!} \epsilon_{d[n-2]|a}^c \tilde{K}^{d[n-2]|b}.$$

(3.20)

In order to invert this relation, we first compute

$$\frac{(-1)^n}{2} \epsilon^{d[n-2]ab} K^U_{ab|c} = \tilde{K}^{d[n-2]|c} - (n-2)\delta^d_c \tilde{K}^{d[n-3]|e}$$

(3.21)

and take the trace of the above relation, which produces

$$\tilde{K}^{a[n-3]|a} = \frac{1}{4} \epsilon^{b[n-3|de} K^U_{cd|e}.$$

(3.22)

Inserting this relation back in (3.21) gives

$$\tilde{K}_{a[n-2]|b} = (-1)^{n-1} \frac{n}{2} \epsilon^{a[n-3|cd} \left( \delta^c_d K^U_{cd|b} - \frac{n^2}{2} \delta^a_b K^U_{cd|e} \right).$$

(3.23)

Explicitly, we have

$$\tilde{K}_{a[n-2]|b} = (n-2) \left( \nabla^b \nabla^a A^{a[n-3]} + (n-2)\tilde{m} \nabla^a C^{a[n-3]|b} - \sigma(n-2)\lambda^2 g^{ab} A^{a[n-3]} \right),$$

(3.24)

which is gauge invariant under [1]

$$\delta C_{a[n-3]|b} = (-1)^{n-1}(n-3) \left( \nabla_a \tilde{v}_{a[n-4]|b} - \frac{\sigma\lambda^2}{\tilde{m}} g_{ba} \tilde{p}_{a[n-4]} \right) + \frac{n-3}{n-2} \left( \nabla_b \tilde{x}_{a[n-3]} + (-1)^n \nabla_a \tilde{x}_{a[n-4]|b} \right),$$

(3.25)

$$\delta A_{a[n-3]} = (n-3) \left( (-1)^{n-1} \nabla_a \tilde{p}_{a[n-4]} - \tilde{m} \tilde{x}_{a[n-3]} \right).$$

(3.26)

The curvatures obey the following algebraic Bianchi identities

$$\tilde{K}^C_{a[n-2]|ab} \equiv 0, \quad \tilde{K}_{a[n-2]|a} \equiv 0,$$

(3.27)

which means that $K^C_{a[n-2]|bc}$ and $\tilde{K}_{a[n-2]|b}$ are projected on the following $GL(n)$-irreducible Young tableaux

![Young tableaux](image)

and

![Young tableaux](image)

The left-hand sides of the equations of motion derived from the Lagrangian (3.11) are given by

$$\frac{\delta \mathcal{L}_{PM}}{\delta W_{abc|d}} = \frac{1}{2\lambda^2} \mathcal{V}^{abc|d}, \quad \frac{\delta \mathcal{L}_{PM}}{\delta U_{abc}} = \frac{\sigma}{2(n-2)\tilde{m}^2} K_{U}^{abc|d}.$$

(3.28)
Combining with what we obtained above, the field equations therefore imply
\[ \tilde{K}_{a[n-3]b}^b \approx 0 , \quad K_{a[n-3]b}^{bc} \approx 0 . \]  
(3.29)

The Bianchi identities read
\[ \nabla_a \nabla^a \tilde{V}^{ab} \equiv -\sigma \lambda^2 \frac{(n-3)}{(n-2)m} \tilde{K}^{a[n-3]}_{\phantom{a[n-3]}b} , \quad \nabla_a \nabla^a \tilde{V}_{bc} \equiv \frac{2\sigma \lambda^2}{m(n-2)} \delta^d_{[a} \tilde{K}^{bc]}_{\phantom{bc]}d} . \]  
(3.30)

In terms of the curvatures \( K^C \) and \( \tilde{K} \), they become
\[ \nabla_a K^C_{a[n-2]} \equiv (-1)^n \frac{2\sigma \lambda^2 (n-3)}{m(n-2)} \delta^b_{[a} \tilde{K}_{a[n-2]}^{c]b} , \]  
(3.31)
\[ \nabla^a K^C_{[a}^{[d[n-2]} \equiv -\frac{2\sigma \lambda^2}{m} \tilde{K}^c_{[a}^{[b} \delta_{d]}^c d} . \]  
(3.32)

By taking a trace of the Bianchi identity and using the field equations, one therefore deduces that
\[ \nabla^b K^C_{a[n-2]} \approx (-1)^n \frac{(n-3)\sigma \lambda^2}{(n-2)m} \tilde{K}_{a[n-2]}^c , \]  
(3.33)
\[ \nabla^b K^C_{a[n-3]b} \approx -\frac{2\sigma \lambda^2}{(n-2)m} \tilde{K}^c_{a[n-3]} d . \]  
(3.34)

### 3.3 Partially-massless twisted duality

The twisted duality that mixes the field equations and Bianchi identities of the two dual theories, the one for \( \mathcal{L}_{PM}(h_{ab}, A_a) \) on the one hand, and the one for \( \mathcal{L}_{PM}(C_{a[n-3]b}, A_{a[n-3]}) \) on the other hand, is
\[ K^C_{a[n-2]} \approx \frac{1}{2} \epsilon_{a[n-2]ij} Q^{ij} \]  
(3.35)

This equation plays the same role as (2.33) in the strictly massless case.

What is new in the partially massless case compared to the massless case is that the flat limit of (3.35) is not enough to describe the degrees of freedom of a partially massless field in the flat limit. In fact, the twisted-duality relation (3.35) also induces a duality relation between the curvatures \( \tilde{K}_{a[n-2]}^b \) and \( K_{ab}^c \). This can be viewed by acting on (3.35) with \( \nabla_a \) and contracting the result with \( \epsilon^{a[n-1]d} \). One then uses (3.31) and the trace of (3.9), taking into account that, on shell, the traces of the four curvatures \( \tilde{K}_{a[n-2]}^b , K^C_{a[n-2]} , Q_{ab}^{cd} \) and \( K_{ab}^c \) vanish. We obtain
\[ \tilde{K}_{a[n-2]}^b \approx (-1)^{n-1} \frac{\sigma \lambda^2}{2 \lambda} \epsilon_{a[n-2]cd} K^C_{ab} \]  
(3.36)
where we stress that (3.35) and (3.36) are equivalent for non-zero cosmological constant.

Now, taking the flat limit of both (3.35) and (3.36), we obtain two decoupled twisted-duality relations for the two decoupled pairs of fields \( (C_{a[n-3]b}, h_{ab}) \) and \( (A_{a[n-3]}, A_a) \).
Both together, they propagate the correct degrees of freedom for a partially massless spin-2 field in the flat limit, as was found and discussed in section 4.3 of [1]. The flat limit of (3.36) gives

$$\partial_b \tilde{F}_{a[n-2]} \approx (-1)^n \frac{(n-2)\lambda}{8} \epsilon_{a[n-2]cd} \partial_b F^{cd},$$

(3.37)

where $\tilde{F}_{a[n-2]} = (n-2) \partial_b A_{a[n-3]}$ and $F_{ab} = 2 \partial_{[a} A_{b]}$ are the field strengths for $A_{a[n-3]}$ and $A_b$, respectively. In the flat limit, these latter quantities are gauge invariant, therefore the gradient $\partial_b$ on both sides of the above relation (3.37) can be stripped off to give, up to an unessential coefficient that can be absorbed into a redefinition of $A_{a[n-3]}$, the usual electric-magnetic duality between a 1-form and its dual $(n-3)$-form in dimension $n$.

As a consistency check for the second duality relation (3.36), one can start from the twisted-duality relation (3.35) and this time take the curl of $K^C$ on its second column of indices, which yields

$$\nabla^b K^C_{a[n-2]]cd} \approx \frac{1}{2} \epsilon_{a[n-2]ij} \nabla^b Q^{cd]}_{ij}.$$

(3.38)

We then use the Bianchi identities (3.32) and (3.9) and take a trace, taking into account the field equations (3.29), which allows us to obtain the relation

$$\tilde{K}^C_{a[n-3]|b|c} \approx (-1)^{n-1} \frac{\sigma}{4\lambda^2} \epsilon_{a[n-3]ij} [b \tilde{K}^C_{ij}|c],$$

(3.39)

which is fully consistent with (3.36).

Finally, we come back to twisted-duality relation (3.36) and gauge fix to zero both $A_a$ and $A_{a[n-3]}$ since they are Stueckelberg fields as long as $\lambda$ is different from zero. In these gauges for the dual formulations, our second twisted-duality relation (3.36) becomes

$$(n-2) \nabla^a C^{a[n-3]|b} \approx (-1)^n \frac{\sigma}{2} \epsilon_{a[n-2]cd} \nabla_c h^{db},$$

(3.40)

while the first twisted-duality relation (3.35) is just its curl, as one can readily check. This duality relation makes immediate contact with the one proposed for the specific case $n = 4$ in Eq. (2.3) of [19]. Relation (3.40) identifies the dual curvature $\tilde{F}_{ab|c}$ in [19] with $4 \nabla_{[a} C_{b]|c}$, the curl of the dual potential $C_{b|c} = C_{c|b}$. Note that, once the Stueckelberg fields $A_a$ and $A_{a[n-3]}$ have been set to zero, one cannot take a smooth flat limit any longer in the sense that physical degrees of freedom are lost in the flat limit.

The advantage of our Stueckelberg formulation for the twisted-duality relation is that the identification of the helicity degrees of freedom is manifest and does not require any specific system of coordinates to be seen. In the original Stueckelberg formulation, $h_{ab}$ and $A_a$ carry the helicity two and one degrees of freedom, and the twisted-duality relations (3.35) and (3.36) identify these degrees of freedom with the dual fields $C_{a[n-2]|b}$ and $A_{a[n-3]}$, respectively, in a manifestly covariant way.
Acknowledgments

We performed or checked several computations with the package xTras [28] of the suite of Mathematica packages xAct.
