Abstract. Idiopathic scoliosis (IS) is a spinal 3-dimensional deformity with an unknown cause. Melatonin is secreted by the pineal body and contributes to the occurrence and progression of IS. In our previous preliminary study, it was reported that high concentrations of melatonin can induce osteoblast apoptosis, thus acting as an IS treatment, but the mechanism of action is unknown. Therefore, the present study was performed to further investigate the possible mechanism underlying the efficacy of melatonin as a treatment for IS. The present results indicated that high concentrations of melatonin mediate endoplasmic reticulum stress (ERS)-induced apoptosis in hFOB 1.19 cells, and this resulted in a significant and dose-dependent increase in the expression of Septin4, as well as the expression levels of glucose-regulated protein (GRP)78, GRP94 and cleaved caspase-3. Furthermore, osteoblasts were overexpressed with Septin4 and the mechanism via which melatonin induces osteoblast ERS was demonstrated to be via the regulation of Septin4. In addition, it was indicated that cytoskeleton destruction, cell morphology changes and the decrease in the number of cells were aggravated after osteoblasts were overexpressed with Septin4, as indicated by phalloidin and DAPI staining. Collectively, the present results suggest that the Septin4 protein may be a target of ERS in melatonin-induced osteoblast apoptosis, which is involved in bone metabolism diseases, thus providing novel evidence for clinical melatonin treatment of IS.

Introduction

Idiopathic scoliosis (IS) is defined as scoliosis with an unknown cause that presents as a spinal 3-dimensional deformity during growth and development, and has an increasing prevalence (current incidence rate, >2%) and poses a worldwide threat to human health (1-3). The most common time for the development of IS to occur is during the fastest-growing state of juveniles (age, 10-16 years), which is the most active period of bone development and osteoblast proliferation (4-7). Moreover, effective inhibition of osteoblast proliferation and induction of apoptosis contribute to the prevention and treatment of IS (8). Therefore, medication that can induce osteoblast apoptosis should be investigated as a potential therapeutic strategy for IS. Previous studies have reported that melatonin exerts an influence on the progression of IS (9‑14). Furthermore, our previous studies revealed that high concentrations of melatonin significantly inhibit osteoblast viability (15,16), thus indicating a possible clinical application of melatonin in preventing and controlling the progression of IS (17); however, the mechanism is yet to be elucidated.

The endoplasmic reticulum (ER) is a critical subcellular organelle responsible for regulation of Ca2+ homoeostasis and transmembrane protein synthesis and folding (18,19). External stimulation induces the disruption of ER physiological function, which triggers ER stress (ERS) (20,21). Moreover, ERS can reduce cell damage and restore cell function by activating the unfolded protein response (UPR) (22,23). However, excessive or prolonged ERS can induce cell apoptosis (24-26), and it has been reported that melatonin can initiate ERS-induced apoptosis in human hepatoma cells (27). In addition, excessive ERS caused by a high concentration of melatonin is a direct factor for inducing apoptosis (28). It is also speculated that these effects be due to the high concentration of melatonin caused by Ca2+ overload and the induction of osteoblastic ERS, but this is yet to be elucidated.

The ER is highly sensitive to stress; it maintains its structure and function by regulating membrane proteins, and selectively transports membrane proteins to deliver biological effects (29). However, the type of ER target protein that melatonin interacts with to export relevant membrane proteins, transfer biological information to the cell membrane, open Ca2+ channels on the cell membrane surface and induce ERS is not yet fully understood. Golgi membranes of HeLa cells using small interfering RNA screen technology and, when exposed...
to external stimuli, will rapidly redistribute on the plasma membrane, causing Ca\(^{2+}\) influx in the cell membrane (30). Furthermore, it has been reported that Septin4, a subtype of the Septin superprotein family, is a necessary component of cytoskeletal proteins and may affect vesicle trafficking, apoptosis and numerous important physiological processes (31-34). The present study hypothesized that septin4 may also be a target protein of melatonin-induced osteoblasts, activate ERS and induce apoptosis. However, the mechanism via which melatonin induces osteoblast apoptosis to regulate IS is yet to be elucidated. Therefore, the aim of the present study was to further investigate the mechanism underlying the effect of melatonin on osteoblast development and its possible target of osteoblasts, which may provide a novel insight and direction for treatment of IS.

Materials and methods

Cell culture and treatment. The clonal human fetal osteoblastic (hFOB 1.19) cell line (35) was donated by Dr Malayannan Subramaniam (Department of Biochemistry and Molecular Biology, Mayo Clinic; Rochester, USA) (36). Cells were cultured in a humidified incubator with 5% CO\(_2\) atmosphere at 37°C and in a 1:1 mixture of DMEM and F-12 medium (HyClone; GE Healthcare Life Sciences) with 10% FBS (HyClone; GE Healthcare Life Sciences) and a 100 µg/ml streptomycin and 100 U/ml penicillin solution (HyClone; GE Healthcare Life Sciences). The cell culture medium was changed every other day. The osteoblastic cells were sub-cultured using 0.25% trypsin with EDTA (HyClone; GE Healthcare Life Sciences) to replace the cells. Osteoblasts were cultured to passages 8-11 and plated at 1x10^5 cells/cm² for 24 h before treatment. Melatonin (2, 4 and 6 mM), obtained from Sigma-Aldrich (Merck KGaA), was dissolved in medium containing 0.2% DMSO and 10% FBS to treat the cells for 24 h at 37°C.

Plasmids, cell transfections. The full-length human Septin4 plasmid (Shanghai Genechem Co., Ltd.) was cloned to Flag-tagged destination vectors (Shanghai Genechem Co., Ltd.) according to the requirements of immunoblotting. Cell transfections were performed using Lipofectamine\(^\text{TM}\) 2000 (Invitrogen; Thermo Fisher Scientific, Inc.) to replace the cells. Osteoblasts were transfected for 48 h and treated with melatonin for 48 h at 37°C. The treated cells were digested with 0.25% trypsin (without EDTA), centrifuged at 300 x g for 3 min at 4°C and then washed with cold PBS twice. After the supernatant had been discarded, cells were resuspended in 500 µl binding buffer, and Annexin-V-FITC (5 µl) and PI (5 µl) were added and mixed. The suspensions were incubated in dark for 20 min at room temperature prior to flow cytometric analysis. Finally, cells were analyzed using a BD FACSDiv Image cytometer equipped with ModFit LT v3.0 (Becton, Dickinson and Company) within 1 h. Cells were classified as follows: Viable (Annexin-V-FITC-/PI-), early apoptotic (Annexin-V-FITC+/PI-), late apoptotic (Annexin-V-FITC+/PI+) or necrotic (Annexin V-FITC+/PI+). The experiment was repeated three times.

Western blotting. Monoclonal mouse anti-Septin4 (1:4,000; cat. no. ab166788; Abcam), polyclonal rabbit anti-glucose-regulated protein (GRP)78 (1:1,000; cat. no. ab2791; Abcam), GRP78 (1:1,000; cat. no. ab21685; Abcam), polyclone rabbit anti-caspase-3 (1:1,000; cat. no. 9662; Cell Signaling Technology, Inc.), monoclonal mouse anti-Flag (1:1,000; cat. no. 8146; Cell Signaling Technology, Inc.) antibodies were obtained commercially. In addition, goat anti-mouse and anti-rabbit secondary antibodies (both 1:500; cat. nos. 7076 and 4414, respectively) were purchased from Beijing Zhongshan Golden Bridge Biotechnology Co., Ltd.

Following treatment with 4 mM melatonin for 48 h at 37°C, proteins were extracted using RIPA lysis buffer (Beyotime Institute of Biotechnology) for 30 min at 4°C and centrifuged at 2,500 x g for 20 min at 4°C. The supernatant fluid containing total cell lysate was harvested. The concentrations of protein were determined using the bicinchoninic acid protein assay (Beyotime Institute of Biotechnology). Each sample (60 µg protein/lane) was separated via 10% SDS-PAGE and transferred to 0.22 µm PVDF membranes at 80 V for 90 min at 4°C. After blocking with 5% BSA (Beyotime Institute of Biotechnology) in TBST (10% Tween 20) at room temperature for 1 h and agitation for 1 h at 4°C, PVDF membranes were incubated overnight with corresponding antibodies (GRP78, GRP94, Septin4, caspase-3, Flag and β-actin) at 4°C. Subsequently, after washing four times with TBST for 15 min each time, membranes were visualized using goat anti-mouse

Annexin V-FITC/propidium iodide (PI) double-staining for cell apoptosis analysis. Apoptotic cells were detected using an Annexin V-FITC/PI kit (Dojindo Molecular Technologies, Inc.) and quantified using a BD LSRR (BD Biosciences); data were analyzed using BD FACSDiva Software (version 6.2; BD Biosciences). hFOB 1.19 cells were seeded in 6-well plates at a density of 1x10^5 cells/well, and then the four different groups of cells were transfected for 48 h and treated with 4 mM melatonin for 48 h at 37°C. The treated cells were digested with 0.25% trypsin (without EDTA), centrifuged at 300 x g for 3 min at 4°C and then washed with cold PBS twice. After the supernatant had been discarded, cells were resuspended in 500 µl binding buffer, and Annexin-V-FITC (5 µl) and PI (5 µl) were added and mixed. The suspensions were incubated in dark for 20 min at room temperature prior to flow cytometric analysis. Finally, cells were analyzed using a BD FACSScan flow cytometer equipped with ModFit LT v3.0 (Becton, Dickinson and Company) within 1 h. Cells were classified as follows: Viable (Annexin-V-FITC-/PI-), early apoptotic (Annexin-V-FITC+/PI-), late apoptotic (Annexin-V-FITC+/PI+) or necrotic (Annexin V-FITC+/PI+). The experiment was repeated three times.

Cell viability assay. Cell viability was measured using an MTT assay (Sigma-Aldrich; Merck KGaA). hFOB 1.19 cells were seeded in 96-well plates at a density of 6x10^3 cells/well and allowed to adhere for 24 h at 37°C before being treated. Then, cells were transfected with the control plasmid or Flag-Septin4 plasmid. The time interval between transfection and subsequent experimentation was 24 h.
or goat anti-rabbit IgG antibodies conjugated with horse-radish peroxidase at 1:10,000 for 2 h at room temperature. Membranes were washed four times with TBST for 15 min, and an EC3 Imaging system (UVP LLC) was used to scan the specific bands. All of the bands were normalized to β-actin content of the same sample and ImageJ software (version 1.51; National Institutes of Health) was used to measure the protein expression.

Phalloidin staining. Phalloidin (AAT Bioquest, Inc.) was used to stain fibrillar (F)-actin. In total, 1X Phalloidin conjugate working solution was prepared according to the manufacturer’s instructions. hFOB 1.19 cells were seeded in 24-well plates at a density of 1.2x10⁴ cells/well and allowed to adhere for 24 h before being treated at 37°C. Then, the various groups of cells were transfected for 48 h and treated with 4 mM melatonin for 48 h at 37°C. Subsequently, treated cells were washed three times with PBS solution and fixed using 4% paraformaldehyde for 30 min at room temperature. After rinsing the cells three times in PBS, 0.1% Triton X-100 in PBS was added to fixed cells for 15 min at room temperature to increase permeability, and then cells were washed three times with PBS. Subsequently, cells were incubated with phalloidin-conjugate working solution (500 μl/well) at room temperature in the dark for 30 min to stain the cells. After rinsing cells gently with PBS three times to remove excess phalloidin, 10% DAPI (Beijing Solarbio Science & Technology Co., Ltd.) was used at room temperature for 30 min in the dark for nucleus staining. The cells were washed again with PBS solution three times, and then were observed and imaged via fluorescence microscopy (magnification, x20) (Olympus Corporation).

Statistical analysis. Quantitative data from ≥3 independent experiment were analyzed using GraphPad Prism 5 software (GraphPad Software, Inc.). Differences in data between two experiment were analyzed using GraphPad Prism 5 software.

Results

High concentration of melatonin promotes ERS and ERS-induced apoptosis, and decreases the viability of hFOB 1.19 cells. To determine the effect of different concentrations of melatonin on the viability of osteoblasts, an MTT assay was performed. Firstly, 0, 2, 4 and 6 mM melatonin were used to treat osteoblasts for 48 h, and it was revealed that the viability of osteoblasts decreased in association with increased melatonin concentration (Fig. 1A). In addition, compared with the control group, cells treated with high concentrations of melatonin exhibited significantly enhanced apoptosis (Fig. 1B). Moreover, the expression levels of ERS-related genes (GRP78 and GRP94) and apoptosis-related genes (cleaved caspase-3) were significantly increased in a dose-dependent manner following a rise in melatonin concentration (Fig. 1C). Therefore, the results indicated that a high concentration of melatonin promoted ERS, which induced apoptosis and decreased the viability of osteoblasts.

Septin4 expression affects ERS and apoptosis and decreases the viability of hFOB 1.19 cells treated with a high concentration of melatonin. The present study also assessed the importance of Septin4 in bone metabolic diseases. It was demonstrated that, compared with the control group, the expression of Septin4 in osteoblasts treated with a high concentration of melatonin was significantly increased. Moreover, the expression of Septin4 was significantly increased in a dose-dependent manner in association with melatonin concentration (Fig. 1C). Thus, the results suggested that Septin4 may be associated with melatonin-induced osteoblast apoptosis via ERS (Fig. 1).

Overexpression of Septin4 promotes apoptosis in hFOB 1.19 cells induced by treatment with a high concentration of melatonin. To further examine the effect of Septin4 on high concentration of melatonin-induced osteoblasts apoptosis, cells were transfected with control plasmid or Flag-Septin4 plasmid for 48 h and treated with 0, 2, 4 and 6 mM melatonin for 48 h. It was identified that overexpression of Septin4 further inhibited osteoblast viability compared with the control plasmid (Fig. 2A). Furthermore, the results indicated that overexpression of Septin4 resulted in a significantly higher rate of apoptosis (NC with melatonin 18.43%; P<0.001; Fig. 2B); however, this effect was not observed in the absence of melatonin. Collectively, the results demonstrated that Septin4 significantly decreased cell viability and promoted apoptosis, following induction using a high concentration of melatonin (Fig. 2).

Overexpression of Septin4 increases ERS in hFOB 1.19 cells ERS and apoptosis pathway-associated genes expression levels induced by treatment with high concentration of melatonin. In addition, the effect of overexpressing Septin4 on the expression levels of ERS- and apoptosis-associated pathway genes were assessed, as well as the effects induced by a high concentration of melatonin in osteoblasts. Cells were transfected with either the Flag-Septin4 plasmid or control plasmid for 48 h and treated with 0 or 4 mM melatonin for 48 h. It was identified that both the expression levels of ERS-associated genes (GRP78 and GRP94) and apoptosis-associated genes (cleaved caspase-3) were increased in the cells transfected with the Flag-Septin4 plasmid and treated with melatonin, compared with cells transfected with the control plasmid and administered melatonin (Fig. 3). However, in the absence of melatonin treatment, the expression levels of these genes were not significantly different between the Flag-Septin4 plasmid and the control plasmid. Therefore, the results indicated that Septin4 mediates ERS and osteoblast apoptosis, and its effect was dependent on treatment with melatonin (Fig. 3).

Overexpression of Septin4 increases cytoskeleton destruction induced by treatment with a high concentration of melatonin in hFOB 1.19 cells. To determine whether a high concentration of melatonin can induce cytoskeleton destruction, phalloidin was used to stain F-actin and DAPI was used for nuclei staining. Then, fluorescence microscopy was performed to analyze the staining profiles and it was revealed that F-actin was well aligned along the axis of hFOB cells in control groups (Fig. 4). However, when hFOB cells were treated with 4 mM
melatonin for 48 h, actin microfilament staining was blurry or non-existent. Moreover, the size of the cells increased, and the cell count decreased in the melatonin treatment groups. In addition, statistical analysis demonstrated that this event had a 1.39-fold increase (P<0.01) in cells with the overexpression Flag-Septin4 plasmid compared with those that expressed the control plasmid. Collectively, the results demonstrated that overexpression of Septin4 increased cytoskeleton destruction,
which was induced by treatment with a high concentration of melatonin in hFob 1.19 cells. (Fig. 4).

Discussion

It has been reported that the level of melatonin is associated with IS (37), and the clinical application of melatonin can also be used to treat patients with partial IS, which may be associated with melatonin-induced proliferation and apoptosis in osteoblasts (38). However, the optimal effective concentration and mechanism of action are yet to be elucidated. The present results are in line with those from previous studies, which have reported that low concentrations of melatonin (1 nM-100 µM) promote osteoblast proliferation, while high concentrations of melatonin (>1 mM) significantly inhibit osteoblast viability (15,16,39). In order to provide more accurate results, various high concentrations of melatonin (2, 4 and 6 mM) were selected in the present study, and 48 h was selected as the most suitable observation time to examine melatonin function in osteoblasts, which was based on our previous studies (40,41). In the present study, it was demonstrated that a decrease in

Figure 2. Overexpression of Septin4 promotes apoptosis in hFob 1.19 cells treated with a high melatonin concentration. (A) hFob cells were transfected with NC plasmid or Flag-Septin4 plasmid for 48 h and treated with 0, 2, 4 and 6 mmol/l of melatonin for 48 h. Cell viability was assessed via the MTT assay. (B) hFob cells were transfected with NC plasmid or Flag-Septin4 plasmid for 48 h and treated with 0 or 4 mmol/l of melatonin for 48 h. Flow cytometry was performed to analysis cell apoptosis (Q4 region). *P<0.05, **P<0.01, ***P<0.001, vs. NC group. GRP, glucose-regulated protein; NC, negative control; Con, control; PI, propidium iodide.

Figure 3. Overexpression of Septin4 increases ERS- and apoptosis pathway-related gene expression levels in hFob 1.19 cells treated with a high melatonin concentration. hFob 1.19 cells were transfected with Flag-Septin4 plasmid or NC plasmid for 48 h and treated with 0 or 4 mmol/l of melatonin for 48 h and western blotting was performed to detect the expression levels of Flag, Septin4, GRP78, GRP94 and cleaved caspase-3. *P<0.05, **P<0.01, ***P<0.001, vs. NC group. viability of osteoblasts was associated with an increase in melatonin concentration. Furthermore, it was revealed that melatonin induced osteoblast apoptosis via regulation of Septin4, resulting in the promotion of ERS-mediated apoptosis mechanisms involving the GRP94/caspase-3 pathways. This indicates a possible clinical application for melatonin in the prevention and reversal of IS progression.

GRP94 is a member of the HSP90 family and is primarily localized in the ER. GRP94 serves as a molecular chaperone involved in the folding, transport and secretion of proteins, and regulates apoptosis and antigen presentation (42). Furthermore, glucose regulated protein 78 (GRP78) is a core regulator of UPR (43). GRP78 expression is upregulated in ERS, which inhibits protein synthesis and decreases cellular stress in the early stage of ERS. However, prolonged ERS activates the CHOP and caspase-12 pathways, which induce cell apoptosis and result in upregulation of the apoptosis marker protein caspase-3 (44). The present results suggest that

Figure 4. Overexpression of Septin4 increases cytoskeleton destruction in hFOB 1.19 cells treated with a high melatonin concentration. hFOB 1.19 cells were untreated or treated with 4 mmol/l melatonin for 48 h. F-actin was visualized using phallolidin and the nucleus was stained using DAPI. The images were captured using fluorescence microscopy (x20) and an image of the two stains merged was shown. The yellow arrow represents the F-actin cytoskeleton and the red arrow depicts the destroyed cytoskeleton. The histogram indicates the percentage of cytoskeleton-destroyed cells among the total cells. **P<0.01, vs. NC group. GRP, glucose-regulated protein; NC, negative control; F-actin, fibrillar actin.
a high concentration of melatonin induced osteoblast ERs, which was positively associated with melatonin concentration. Furthermore, both of the expression levels of pathway-related genes of ERs (GRP78 and GRP94) and apoptosis (cleaved caspase-3) were significantly increased in a dose-dependent manner of melatonin concentration, which indicates that ERs may serve an important role in cell apoptosis induced by high concentrations of melatonin. However, the target protein by which melatonin induces ERs and cell apoptosis has not been elucidated.

It has been revealed that Septin4, an ER membrane protein and a receptor associated with ERs, inhibits hepatocellular carcinoma via the regulation of hepatoma cell apoptosis (32). Moreover, previous studies have reported that Septin4 aggravates cell apoptosis induced by transforming growth factor-β, etoposide and staurosporine, and Septin4 affects the regulation of myofibroblast transformation and hepatic fibrosis induced by chemokine ligands 4 (32,45). Thus, these findings reveal the important role of Septin4 in apoptosis. Furthermore, the present results indicate that increasing melatonin concentrations are associated with an increase in the expression levels of Septin4 and ERs-related proteins (GRP78 and GRP94). It was also identified that the expression of the apoptosis-associated protein caspase-3 was positively associated with Septin4 expression, which suggests that Septin4 may regulate bone metabolism via apoptotic pathways. Subsequently, Septin4 was overexpressed and it was demonstrated that melatonin-induced osteoblast injury was further exacerbated, which was indicated by the further decrease in cell viability, apoptotic exacerbations and a significant increase in GRP78, GRP94 and caspase-3 expression levels.

In addition, Septin4 is an important component of the cytoskeleton; thus, phalloidin was used to stain F-actin and DAPI in the nucleus. The present results demonstrated that cytoskeleton destruction, cell morphology changes and the reduction in the number of cells were increased after osteoblasts had overexpressed Septin4 and were treated with melatonin; however, Septin4 did not serve this role independently of melatonin treatment. It was originally speculated that the expression of Septin4 should be increased with 6 mM melatonin; however, after the repeated experiments, the expression of Septin4 was decreased; this effect may due to the excessive concentration of melatonin, which resulted in enhanced apoptosis and destruction of the cell structure and Septin4 is a cytoskeletal protein, and could not be identified. However, these effects should be investigated in future research. A limitation of the present study was that a Z-VAD-FMK/pan-caspase inhibitor was not used to prevent melatonin-induced Septin4 expression levels. Therefore, further studies are required to investigate the association between Septin4 and apoptosis.

In conclusion, the present results indicated that high concentrations of melatonin may result in ERS and induce osteoblast apoptosis, and that Septin4 is a membrane protein associated with ER Ca²⁺ ion regulation and a target for high-concentration melatonin to act on osteoblasts. The present results may provide a novel direction for the treatment of abnormal proliferation of osteoblasts and indicated that suppressing Septin4 may be a novel target for the prevention of IS.
