Search for the Light Charged Higgs in CMS

M. Hashemi
IPM, P.O.Box 19395-5531, Tehran, Iran

In this report the CMS potential for the light charged Higgs boson discovery in the Minimal Supersymmetric Standard Model is presented. First the latest results of the Tevatron and LEP experiments on the light charged Higgs search are reminded. In the rest of the report the perspectives of CMS for the light charged Higgs search are presented with description of some details of the analysis. The results are based on the full simulation and reconstruction of the CMS detector including the systematic uncertainties on the background determination. Finally the $5\sigma$ discovery contour for an integrated luminosity of $30fb^{-1}$ is shown.

1. Introduction

The Minimal Supersymmetric extension to the Standard Model (MSSM) requires the introduction of two Higgs doublets in order to preserve the supersymmetry. Five physical Higgs particles are predicted, two CP-even ($h,H$), one CP-odd ($A$) and two charged ones ($H^\pm$). All couplings and masses of the MSSM Higgs sector are determined at the lowest order by two independent parameters, which are generally chosen as $\tan\beta = v_2/v_1$, the ratio of the vacuum expectation values of the two Higgs doublets, and the pseudo–scalar Higgs boson mass $m_A$. Since the charged Higgs boson is a crucial signature of the MSSM, it is presently considered as one of the most interesting particles in the MSSM Higgs sector.

The latest results from the LEP Higgs working group concerning the indirect search for neutral MSSM Higgs bosons provide a lower mass limit of $125 \text{ GeV}/c^2$ for $m_H^+$ at $\tan\beta > 10$ [2]. Results from direct searches at LEP give instead a lower limit on the charged Higgs boson mass of $\sim 90 \text{ GeV}/c^2$ for $\mathrm{BR}(H^+ \to \tau\nu) \simeq 1$ [3]. Figure 1 shows the excluded region obtained in 2006 by the LEP Higgs working group. Direct and indirect searches performed at the Tevatron lead to some exclusion region in the parameter space for $\tan\beta > 50$ and $\tan\beta < 1$ [4, 5]. Figure 2 shows the excluded region obtained by Tevatron in the D0 and CDF experiments.

![Figure 1: The excluded region at 99.7% C.L. (Dark Green) obtained by the LEP Higgs working group.](image)

![Figure 2: The excluded region at 95% C.L. obtained by D0 and CDF at Tevatron.](image)

The study presented in this report the light charged Higgs ($m_{H^\pm} < m_t - m_b$) is searched for in the channel $H_{\text{MSSM}}^\pm \rightarrow \tau^\pm \nu_\tau \rightarrow \mu \tau$ and $H_{\text{MSSM}}^\pm \rightarrow \tau^\pm \nu_\tau \rightarrow \tau \nu$ in the mass range $125 < m_{H^\pm} < 170 \text{ GeV}/c^2$ [6]. The mass range chosen is the most critical since for Higgs boson masses close to the top mass the signal rate is low. Proving that the discovery is attainable in this mass range would imply that the light charged Higgs boson can be discovered also at lower masses. All results are obtained according to the LEP $m_{h^0} - \text{max benchmark scenario}$ [2] with the following choice of the MSSM parameters: $SU(2)$ gaugino mass $M_2 = 200 \text{ GeV}/c^2$, $\mu = +200 \text{ GeV}/c^2$, gluino mass $M_3 = 800 \text{ GeV}/c^2$, SUSY breaking mass parameter $M_{\text{SUSY}} = 1 \text{ TeV}/c^2$ and stop mixing parameter $X_t = \sqrt{6} M_{\text{SUSY}}$ ($X_t = A_t + \mu \cot\beta$). The $m_{h^0} - \text{max scenario}$ is one of the LEP benchmark scenarios designed to maximize the upper limit on $m_{h^0}$ by non-zero stop mixing parameter thus providing a wider available parameter space compared to the case of $\text{no}-\text{mixing}$ scenario in which the stop mixing parameter is set to zero and the available parameter space is smaller. The top quark mass is set to $175 \text{ GeV}/c^2$. 

2. Signal and background simulation, cross sections and branching ratios

The MSSM charged Higgs boson can be produced in top quark decays, \( t \to H^+b\), if \( m_{H^\pm} < m_t - m_b \). In this report the case of \( W^\pm \) leptonic decay (e or \( \mu \)) is described. The background channels consist of \( t\bar{t} \) events with at least a single lepton (e or \( \mu \)) and \( \tau\) jets or jets which could fake \( \tau \) jets, \( W^\pm + 3 \) jets events and also single top events which have, however, a small contribution. A total NLO \( t\bar{t} \) cross section of 850 \( \text{pb} \) is used in this report \([8]\) for calculating the cross sections and branching ratios.

Table I shows the cross section times branching ratio of \( \beta \) MadEvent generator \([9]\) with some preselection cuts: \( \sigma \times \text{BR} \) of the different final states. The cross section of \( W^\pm \) events is obtained with the MadEvent generator \([9]\) with some preselection cuts: \( \sigma \times \text{BR} \) of the different final states. The cross section and branching ratios

\[
\begin{array}{cccc}
 m_{H^\pm} (\text{GeV}/c^2) & 140 & 150 & 160 & 170 \\
 \text{Cross section (pb)} & 10.70 & 5.06 & 1.83 & 0.157 \\
\end{array}
\]

Table II shows the cross section times branching ratio of \( t\bar{t} \to H^+W^\mp b\bar{b} \to \tau\nu\ell\nu\ell\ell b\bar{b}, \tau \to \text{hadrons} \) for \( \tan \beta = 20 \)

\[
\begin{array}{cccc}
 m_{H^\pm} (\text{GeV}/c^2) & 140 & 150 & 160 \\
 \text{Cross section (pb)} & 0.91 & 0.19 & 0.02 \\
\end{array}
\]

Table III shows the cross section times branching ratio of \( t\bar{t} \to H^+W^- b\bar{b} \) events for \( \tan \beta = 20 \). Due to the small cross section of \( t\bar{t} \to H^+H^- b\bar{b} \) as shown in Table II only \( t\bar{t} \to H^+W^- b\bar{b} \) events were generated and simulated as signal events for \( m_{H^\pm} < 170 \text{ GeV}/c^2 \). For \( m_{H^\pm} = 170 \text{ GeV}/c^2 \) both \( t\bar{t} + gb \) and \( gg \to tbH^\pm \) are used for comparison. The NLO cross section times branching ratio of signal events with \( m_{H^\pm} \simeq m_t \) is listed in Table III. Finally the cross section of the main background channels are shown in Table IV.

3. Event selection

Full simulation of the detector response was achieved with CMSIM \([10]\) or OSCAR \([11]\) including pile-up events corresponding to a luminosity of \( 2 \times 10^{35} \text{cm}^{-2}\text{s}^{-1} \). The full reconstruction of the detector response and event analysis was performed with the ORCA package \([12]\). The event selection is as the following:

- **Event trigger**
  Events are triggered if there is a muon with \( p_T > 14 \text{ GeV}, |\eta| < 2.1 \) or an electron with \( p_T > 29 \text{ GeV}, |\eta| < 2.4 \). At HLT harder cuts are applied such as \( p_T > 19 \text{ GeV} \) and isolation requirements for muons \([13]\).

- **Jet reconstruction, selection and b-tagging**
  Jets were reconstructed with the Iterative Cone algorithm \([13]\) with a cone size \( R = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} = 0.5 \) for all pairs of final state jets. The branching ratio of top decay to charged Higgs depends on both \( m_{H^\pm} \) and tan\( \beta \). Figure 4 shows the H\(^{\pm}\) decay branching ratio in different final states for tan\( \beta = 20 \).}

- **Offline \( \tau \) tagging**
  The \( \tau \) reconstruction and selection is performed offline starting from the Level 1 \( \tau \)-like energy deposits in the calorimeters \([13]\). A regional jet reconstruction is performed around the direction of the Level 1 \( \tau \) objects; the raw jet transverse energy is required to be \( E_T^{\text{jet}} > 20 \text{ GeV} \). The contribution from electrons faking \( \tau \)-jets can be reduced by requiring the hottest HCAL tower \( E_T \) to be larger than 2 GeV (only towers belonging to jets are considered). In the next step a matching cone with \( \Delta R = 0.1 \) is defined around the jet axis. Tracks with \( p_T > 1 \text{ GeV}/c \) are searched for within the matching cone and the largest \( p_T \) track is identified and a signal cone with \( \Delta R = 0.07 \) is defined around its direction. The signal vertex is considered as the vertex from which the leading track originates. Then an isolation cone with \( \Delta R = 0.4 \) is defined around the leading track to check the tracker isolation requirement. If no track from the signal vertex is found with \( p_T > 1 \text{ GeV}/c \) in the isolation cone except for those falling in the signal cone, the isolation is satisfactory. The electromagnetic isolation parameter (Eq. 1) is used to suppress the contamination arising from quark
Figure 3: a) Branching ratio of top decay to $H^\pm$ vs $\tan\beta$, b) Branching ratio of top decay to $W^\pm$ vs $\tan\beta$

Table III Cross section times branching ratio of signal events for $m_{H^\pm} \simeq m_t$ according to NLO calculations in [7] for $\tan\beta = 20$.

| Channel | Cross section [pb] |
|---------|-------------------|
| $gb \rightarrow tH^\pm \rightarrow \ell\nu tb\tau\nu$ ($\tau \rightarrow$ hadrons) $m_{H^\pm} = 170$ GeV/c$^2$ | 0.14 |
| $gg \rightarrow t\bar{b}H^\pm \rightarrow \ell\nu b\bar{b}\tau\nu$ ($\tau \rightarrow$ hadrons) $m_{H^\pm} = 170$ GeV/c$^2$ | 0.297 |

Figure 4: Branching ratio of $H^\pm$ decays for different $m_{H^\pm}$ at $\tan\beta = 20$

and gluon jets [14]:

$$P_{\text{isol.}} = \sum_{\text{crystals}, \Delta R_{\text{crystal}}, \tau - \text{jet < 0.4}} \frac{E_{T\text{crystal}}}{\sum_{\text{crystals}, \Delta R_{\text{crystal}}, \tau - \text{jet < 0.13}} E_{T\text{crystal}}} < 5.6 \text{ GeV}$$

When a jet satisfies all requirements mentioned above, it is identified as a $\tau$-jet candidate. A cut on the transverse energy of the $\tau$ jet, $E_T > 40$ GeV, can be applied to suppress the background. Since the leading track in the jet is more energetic in signal events than in background events, a cut on the $\tau$ energy carried by the leading track in the signal cone is applied by requiring $p_{\text{leading track}}/E_T > 0.8$. The total charge of all tracks contained in the signal cone of an identified $\tau$-jet gives an estimate of the $\tau$-lepton charge. The sum of the charges of the event trigger lepton (e or $\mu$) and of the $\tau$-lepton is hence required to be $Q(\ell) + Q(\tau) = 0$, since they originate from mother particles of opposite charges ($H^\pm, W^\mp$).

- **Missing $E_T$ reconstruction**
  The missing transverse energy reconstruction is performed by summing all the Ecal deposits plus the Hcal towers and correcting for muons (if any in the event). The raw energy of jets involved in the $E_T^{\text{miss}}$ reconstruction are corrected to improve their energy resolution. Only jets with raw jet $E_T > 30$ GeV are used; this cut is optimized to improve the $E_T^{\text{miss}}$ resolution. A cut at $E_T^{\text{miss}} > 70$ GeV is applied to increase the signal to background ratio.

4. Signal and background selection efficiencies

The summary of all event selection requirements together with the corresponding efficiencies is given in Tables VII (signal) and Table VIII (background). As mentioned in Section 2 the number of signal events from $t\bar{t}$ and gb fusion for $m_{H^\pm} = 170$ GeV/c$^2$ should
Table IV Cross section times branching ratio of background events

| Channel | $tt \to W^+W^-bb$ | $tt \to W^+W^-bb$ | $tt \to W^+W^-bb$ | $WW^\pm + 3$ jets |
|---------|------------------|------------------|------------------|------------------|
|         | $(\tau \to hadrons)$ | $(\tau \to e\mu)$ | $(\tau \to e\mu)$ |                  |
| Cross section [pb] | 25.8 | 39.7 | 245.6 | 840 |

actually be added together and then compared to gg fusion process. No significant difference is seen between $tt+gb$ and gg. The one b-jet requirement mentioned in Section 3.2 is decomposed into two different steps: firstly events with at least one b-jet are accepted, secondly events with more than one b-jet are rejected. The first requirement has a higher selection efficiency for background events, however, the second cut rejects background events reasonably (more than $\sim 30\%$) at the expense of losing $\sim 5 - 20\%$ of signal events. The efficiency of the second cut for signal events increases with larger $m_H$, i.e. with lower signal cross section. Hence there is little loss where the signal rate is low.

Results can be extrapolated to other $\tan\beta$ values by using the branching ratios of Figs. [3], [1] and [2]. The effect of a larger $\tan\beta$ appears only as some increase in the signal rate and no kinematic effect is expected. Selection efficiencies are then expected to be independent from $\tan\beta$. Different $\tan\beta$ values were investigated in this study for different masses of charged Higgs. In the next sections the results are presented and the final conclusions are drawn.

5. Contribution of other signal and background final states

Contribution of other signal final states is estimated to be an additional factor of $\sim 2\%$ to the number of signal events [1]. The single top background produces about 60 events after all selection cuts and is taken into account in all calculations. The contribution of other background events such as $W^\pm b\bar{b}$ with $W^\pm \to e\nu\ell\nu$ and $\mu\nu\ell\nu$ and Zbb followed by the decay $Z \to e\ell$ or $\tau\tau$ are also estimated to be negligible.

6. Results with systematic uncertainties

Since the number of background events after all selection cuts is large enough (more than 1000 events), the significance can be defined as

$$S = \frac{N_{obs}^{SM} - (N_{W+3\, jets}^{SM} + N_{tb}^{SM})}{\sqrt{N_{W+3\, jets}^{SM} + N_{tb}^{SM} + (\Delta N_{W+3\, jets}^{SM})^2 + (\Delta N_{tb}^{SM})^2}}$$

(2)

The approach for including systematic uncertainties in the signal statistical significance calculation have been described in detail in [2]. Therefore here only the sources of uncertainties and how they are taken into account are presented.

The total systematic uncertainty on the $tt$ background can be expressed as

$$\Delta_{sys}^{tt} = \Delta_{lepton\, reconstruction} \oplus \Delta_{b\,-jet\, selection} \oplus \Delta_{1\, b\,-jet\, tagging} \oplus \Delta_{1\, \tau\, tagging} \oplus \Delta_{lumi} \oplus \Delta_{theo}$$

(3)

The $W^\pm + 3$ jets background uncertainty is estimated as the following

$$\Delta_{sys}^{W^\pm + 3\, jets} = \Delta_{stat} \oplus \frac{N_{W^\pm + 3\, jets}^{tt}}{N_{W^\pm + 3\, jets}^{tt}} \oplus \Delta_{b\,-jet\, mistagging} \oplus \Delta_{\tau\, mistagging}$$

(4)

In Eq. (4) $\Delta N_{B}^{tt}$ is the uncertainty of the number of $tt$ events in the background area and $N_{W^\pm + 3\, jets}^{B}$ is the number of $W^\pm + 3$ jets events in the background area. Table [VIII] shows the values of individual uncertainties which were used in the signal significance calculation for $30\, fb^{-1}$. These are the minimum values of uncertainties in the duration of an integrated luminosity of $30\, fb^{-1}$ which would be reached at the end of this period.

6.1. Final result and the $5\sigma$ discovery contour with systematic uncertainties

Equation [2] is used to calculate the signal statistical significance at $30\, fb^{-1}$ for different $\tan\beta$ values. Table [IX] shows the signal significance for different $m_H$ and $\tan\beta$ values at $30\, fb^{-1}$. The extrapolation to large $\tan\beta$ values shows that a $5\sigma$ significance for $m_H = 170$ GeV/c$^2$ is obtained only for $\tan\beta \geq 100$.

The results listed in Table [IX] are shown in the form of a $5\sigma$ discovery contour in Fig. [6]. The result of introducing the systematic uncertainties in calculation of the signal significance reduces the observability of $m_H$ for $\tan\beta < 50$. For $\tan\beta > 50$ the signal cross section increases and the effect of the uncertainties becomes small. The light charged Higgs discovery potential of CMS was presented in the $tt \to H^\pm W^\mp b\bar{b} \to \ell\nu\ell\nu b\bar{b}$ ($\tau \to hadrons$) channel. Results correspond to an integrated luminosity of $30\, fb^{-1}$ including low luminosity pile-up events. The
Table V List of selection cuts and their efficiencies for signal events with $m_{H^\pm} < 170$ GeV/$c^2$ for $\tan\beta = 20$. Numbers in each row show the remaining cross section after applying the corresponding cut. Numbers in parentheses are relative efficiencies in percent.

| Cut Parameters | $tt \rightarrow H^\pm W^\mp bb$ | $tt \rightarrow H^\pm W^\mp b\bar{b}$ |

| $E_T^{\text{miss}} > 70$ GeV | 51.0(58.0) | 25.4(59.9) | 9.2(63.3) |
| Expected Number of events after 10 fb$^{-1}$ | 510 | 254 | 92 |

Figure 5: The 5$\sigma$ contour in ($m_{H^+}$, $\tan\beta$) plane for the light charged Higgs discovery including the effect of systematic uncertainties.

It was shown that the effect of the systematic uncertainties is a decrease of 5-10 GeV/$c^2$ the observable charged Higgs mass for $\tan\beta < 50$. Since for $m_{H^\pm} > 160$ GeV/$c^2$ the signal rate becomes small the 5$\sigma$ discovery contour shows a small growth for $m_{H^\pm} \geq 160$ GeV/$c^2$ and the charged Higgs mass of 170 GeV/$c^2$ is observable at $\tan\beta \simeq 100$.

### 7. Acknowledgement

I would like to thank the IPM conference organizers especially Dr. Farzan who provided this opportunity for me to have a talk there and report my recent results in the CMS collaboration.

| $E^{miss}_{T} > 70$ GeV                                 | 0.8(61.7)                 | 1.0(65.2)                 | 1.6(55.3)                 |
| Expected Number of events after 10 fb$^{-1}$             | 8                         | 10                        | 16                        |
Table VII List of selection cuts and their efficiencies for background events. Numbers in each row show the remaining cross section after applying the corresponding cut. Numbers in parentheses are relative efficiencies in percent.

| Cut Description | $t\bar{t} \rightarrow W^+W^-b\bar{b}$ | $t\bar{t} \rightarrow W^+W^-b\bar{b}$ | $t\bar{t} \rightarrow W^+W^-b\bar{b}$ | $W^\pm + 3$ jets |
|-----------------|---------------------------------|---------------------------------|---------------------------------|-----------------|
| $\sigma \times BR$(fb) | $25.8 \times 10^3$ | $39.8 \times 10^3$ | $245.6 \times 10^3$ | $840. \times 10^3$ |
| $\ell\nu\tau\nu\tau b\bar{b}$ | | | | |
| $\ell\nu\ell'\nu' b\bar{b}$ | | | | |
| $W^\pm$ $+$ $3$ jets | $12101.2(46.9)$ | $28429.1(71.4)$ | $99506.6(40.5)$ | $287280(34.2)$ |
| $L1 + HLT$ | $5105.2(42.2)$ | $11306.6(39.8)$ | $66038.6(66.4)$ | $114050(34.2)$ |
| $\geq 1$ b jets | $3428.3(67.1)$ | $76220.6(67.4)$ | $43433.0(65.8)$ | $24292.7(21.3)$ |
| $< 2$ b jets | $2325.7(67.8)$ | $5262.7(69.0)$ | $29003.4(66.8)$ | $114050(39.7)$ |
| Having $L1$ $\tau$ | $2310.7(99.3)$ | $5233.7(99.4)$ | $28698.8(98.9)$ | $20613.7(97.2)$ |
| $\tau$-jet reconstruction | $2303.6(99.7)$ | $5224.4(99.8)$ | $28465.0(99.2)$ | $19438.7(94.3)$ |
| Hottest HCAL tower $E_T > 2$ GeV | $2034.1(88.3)$ | $3850.6(73.7)$ | $26635.1(93.6)$ | $17125.5(88.1)$ |
| Tracker isolation | $798.7(39.3)$ | $1120.6(25.0)$ | $6653.3(25.0)$ | $5412.7(31.6)$ |
| Ecal isolation | $545.6(68.3)$ | $519.5(46.3)$ | $2952.8(44.4)$ | $2554.3(47.2)$ |
| $\tau$ $E_T > 40$ GeV | $405.8(74.4)$ | $341.8(65.8)$ | $1946.8(65.9)$ | $1312.9(51.4)$ |
| $p_{\text{leading track}}/E_{\tau} > 0.8$ | $123.5(30.4)$ | $131.9(38.6)$ | $377.9(19.4)$ | $224.5(17.1)$ |
| $Q(\ell) + Q(\tau) = 0$ | $95.7(77.5)$ | $56.7(43.0)$ | $78.8(20.9)$ | $27.1(12.1)$ |
| $E_T^{\text{miss}} > 70$ GeV | $51.6(53.9)$ | $29.3(51.8)$ | $36.6(46.4)$ | $10.7(39.3)$ |
| Expected Number of events after 10 fb$^{-1}$ | 516 | 293 | 366 | 107 |

Table VIII The values of different experimental and theoretical uncertainties used for $t\bar{t}$ and $W^\pm + 3$ jets background events at 30 fb$^{-1}$.

| Uncertainty Description | Value |
|--------------------------|-------|
| Scale uncertainty of $t\bar{t}$ cross section | 5% |
| PDF uncertainty of $t\bar{t}$ cross section | 2.5% |
| b-tagging | 5% |
| $\tau$-tagging | 4% |
| Lepton identification | 2% |
| Jet energy scale | 3% |
| Mistagging a non-b-jet as a b-jet | 5% |
| Mistagging a jet as a $\tau$-jet | 2% |
| Non-b-jet identification (anti-b-tagging) | 5% |
| Luminosity uncertainty | 5% |

Table IX The signal significance for different $m_{H^+}$ and $\tan\beta$ values at 30 fb$^{-1}$ including systematic uncertainties.

| $m_{H^+}$ in GeV/c$^2$ | $\tan\beta = 10$ | $\tan\beta = 20$ | $\tan\beta = 30$ | $\tan\beta = 40$ | $\tan\beta = 50$ |
|-------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| 140                     | 1.60            | 5.02            | 9.43            | 15.00           | 20.17           |
| 150                     | 0.96            | 2.50            | 4.70            | 8.61            | 12.71           |
| 160                     | 0.33            | 0.93            | 1.66            | 3.76            | 5.98            |
| 170                     | 0.07            | 0.21            | 0.46            | 0.75            | 1.19            |
