ANALYSIS OF FUNCTIONAL CAPACITY IN INDIVIDUALS WITH AND WITHOUT CHRONIC LOWER BACK PAIN

Claudiane Pedro Rodrigues, Rubens Alexandre da Silva, Elias Nasrala Neto, Rodrigo Antonio Carvalho Andraus, Marcos Tadeu Parron Fernandes, Karen Barros Parron Fernandes

ABSTRACT

Objective: The objective of this study was to analyze the functional status of adult and older adult individuals with lower back pain. Methods: Eighty-three individuals were recruited, 42 older adults (20 with lower back pain and 22 control group) and 41 younger adults (21 with lower back pain and 20 control group). Functional capacity was assessed using the following tests: Timed Up and Go (TUG), Five Times Sit-to-Stand (FTSTS), six-minute walking test (SMWT), and sitting-rising test (SRT). Results: In the younger adults, there was no difference in functional capacity between the groups (p > 0.05). On the other hand, when statistical analysis was adjusted using body mass index (BMI) as a covariate, the lower back pain group performed more poorly on the SRT (p < 0.004). Furthermore, poorer physical capacity was seen in the older adults with back pain via the SRT test (p = 0.001), and when the BMI was adjusted, a statistical difference was seen in the SRT as well as the SMWT (p < 0.05). Conclusion: Older individuals with lower back pain have poorer physical performance, and the sitting-rising test is the most discerning for assessment of functional status in individuals with lower back pain. Level of Evidence III, Retrospective Comparative Study.

Keywords: Low back pain. Aged. Reproducibility of results.

INTRODUCTION

Like a number of other developing countries, Brazil is undergoing a demographic shift, which is more evident in recent decades; the Brazilian population has been aging quickly since the early 1960s. According to data from the Brazilian Institute of Geography and Statistics (IBGE), an increase in the population aged 65 years or over has been observed in this country, and it is estimated that by 2025 the elderly population could comprise 15% of the entire population. This fact is attributed to the chronic nature of diseases that lead to an increase in physical disabilities such as decline in health, decreased strength, reduced muscle endurance, flexibility, and mobility, as well as deterioration in motor control, causing postural instability in a variety of situations in daily life. The incidence of chronic degenerative diseases, namely chronic musculoskeletal pain, particularly in the lumbar region, is one of the most common complaints in individuals over age 60, and leads to functional limitation and greater physical dependence. Some of the tests used to evaluate functional capacity include the sitting-rising test (SRT), the Timed Up and Go (TUG) test, the six-minute walking test (SMWT) and the Five Times Sit-to-Stand.
by assessing the pressure pain threshold using a EGM Systems
lumbar pain with or without irradiation limited to the knees, measured
The eligibility criteria for the groups with pain were: presence of
chronic lumbar pain (G4, n=20). Chronic lumbar pain determined
young adults with chronic lumbar pain (G2, n=21); 3) healthy older adults (G3 n=22); 4) older adults with
regional, and found that pain affects these individuals in relation to
risk of falls, mainly in elderly women. Although different studies have applied functional tests, few address
population of individuals with chronic lumbar pain. Considering the high prevalence and functional disability in different age groups resulting from chronic lumbar pain, new proposals to assess functional capacity are expected to help health professionals develop preventive programs and intervention, thus promoting an improvement in life expectancy and quality of life during the aging process. Functional capacity assessments can provide important information on the population with lumbar pain; this requires the use of instruments that assess motor function, muscle strength and aerobic resistance, flexibility, coordination, agility, and dynamic balance. These activities aim to ensure muscular and skeletal integrity in individuals, particularly in the elderly population, helping to reduce the risk of falls and functional disability, and in individuals recovering from chronic conditions.

Therefore, the objective of this study was to evaluate the functionality of elderly and younger individuals with chronic lower back pain, and to identify which tests are most discerning in analyzing the functional status of these individuals.

MATERIALS AND METHODS
This study is part of a multicenter research project (UNOPAR/UNIC), which was approved by the UNIC institutional review board (CEP n° 273,376). All participants signed a document indicating free and informed consent before tests were performed.

This study was observational, cross-sectional, descriptive, and used a quantitative approach. The Bioestat 5.0 program was used to calculate the sample, using the data obtained from the study of Champagné et al. as parameters. The confidence interval was set at 95%, alpha level at 5% and consequently a minimum sample of 16 individuals per group was required to test the null hypothesis that there is no difference between the sensory-motor properties of individuals with and without chronic lumbar pain. Considering possible losses, we recruited a 20% larger sample (20 subjects in each group).

We evaluated 83 individuals of both sexes in the local community of Londrina, Paraná, Brazil: 41 younger adults and 42 older adults. The participants were divided into four groups for analysis: 1) healthy young adults (G1 n=20); 2) young adults with chronic lumbar pain (G2, n=21); 3) healthy older adults (G3 n=22); 4) older adults with chronic lumbar pain (G4, n=20). Chronic lumbar pain determined via self-report and was defined as being of unknown mechanical origin and persisting for more than 3 months. We used data on the pressure pain threshold to confirm the presence of low back pain. The eligibility criteria for the groups with pain were: presence of lumbar pain with or without irradiation limited to the knees, measured by assessing the pressure pain threshold using a EGM Systems brand device; presence of chronic pain, defined as pain every day or nearly every day over the previous three months; lower back pain of unknown mechanical origin (muscle or passive structures); non-participation in rehabilitation programs, such as conventional physiotherapy, Pilates, or global postural re-education.

Inclusion criteria for the control group were lack of any lumbago or lower back pain radiating to the lower limbs; non-participation in physical activity programs more than three days per week in accordance with the recommendations of the American College of Sports Medicine, good overall health; be physically independent and voluntarily opt to participate in the study. The young adult participants were between 18 and 50 years of age and the older participants were 60 years or over.

Exclusion criteria for all groups were presence of any kind of neurological, respiratory, metabolic, and/or orthopedic disorder, rheumatic disease with bone or muscular impairment; vestibular disease or acute attacks of labyrinthitis; mental problems, attention and speech disorders; having undergone any type of surgery of the locomotor system; non-volunteer.

This study was conducted at the Universidade Norte do Paraná (UNOPAR) from August to December 2014. The assessments were conducted in just one day, always in the afternoon. Initially we collected sociodemographic and anthropometric data such as weight and height, and calculated body mass index (BMI).

Evaluation of pain to pressure threshold (PPT)
An EGM Systems brand device was used to measure PPT. The device measures pressure in kgf and has a rod at one end with a 1 cm² flat circular end surface which applies constant and increasing pressure perpendicular to anatomic pressure points.

The sitting-rising test
The sitting-rising test evaluates the functional mobility of older adults. In this test, the individual rises from the floor using as little support as possible, without concern for speed. Total score ranges from zero to 10, with five points attributed to sitting and five points to rising from the floor. One point is subtracted for each support used; these can be the hands, knee, or the side of the leg, and half a point is deducted for loss of balance.

Five Times Sit-to-Stand Test (FTSTS)
This test is easy to administer and assesses leg strength, balance, and risk of falls. The patient is directed to cross his arms over his chest and sit with his back against the chair (43 cm high, 47.5 cm deep). The examiner gives the following instructions according to the standard protocol: “I want you to stand up and sit down five times, as fast as you can, when I say ‘Go.’” Timing begins when the examiner says “Go” and ends when the buttocks touch the chair after the fifth repetition.

Timed Up and Go Test (TUG)
This test assesses fall risk. Transfer from a seated position to standing is evaluated along with stability and gait changes without using compensatory strategies. The assessor asks the individual to get up from a chair where she/he was fully supported, walk three meters, turn around, return by the same route, and sit back down in the chair with his or her back supported; performance is measured as the time (in seconds) required to perform the test.

Six-Minute Walk Test (SMWT)
According to the recommendations of the American Thoracic Society (ATS), this self-paced test assesses the sub-maximal level of functional capacity on a 30-meter course marked by two cones at each end. This test measures the distance an individual can walk as quickly as possible without running on a flat, firm, covered surface
for a period of six minutes. The individual is allowed to pause or rest during the test if necessary, but the timer does not stop. The assessments were performed on the same day, always in the afternoon. The better score for each test was considered, except for the SMWT, which according to the ATS uses a 30-minute rest interval. All tests were applied twice, with a rest period of 1 minute between tests. The tests were applied in the following order: sitting-rising test, then Five Times Sit-to-Stand test, then the Timed Up and Go test, and last the six-minute walk test.

**Statistical analysis**

The data were analyzed descriptively and analytically using Statistical Package for Social Sciences software (SPSS) version 18.0. A confidence interval of 95% was established, along with a 5% significance level (P<0.05) for all tests. The Shapiro-Wilk test was used to test the normality of the data. To compare the four groups we used the t test for independent samples, considering normal distribution in the comparable subgroups. Finally, the ANCOVA test was used to compare the groups in order to reduce the variance of the error and adjust the means of the covariate “body mass index” (BMI) for all subjects to a fixed value.

**RESULTS**

Eighth-three individuals participated in the study. The anthropometric characteristics were similar between the groups with regard to age, weight, height, BMI, and pain pressure threshold. (Table 1) As for the presence of multiple morbidities and medication use in the population studied, the older adults exhibited a higher prevalence for these variables than the younger adults. (Table 2)

**DISCUSSION**

In this present study no difference was seen between the control and pain groups in younger adults in terms of the relationship between functional capacity and lower back pain. However, the older adults with chronic lower back pain performed more poorly on functional tests than the older adults without lower back pain.

### Table 1. Characteristics of the study population.

| Variable | Control Mean ± SD | Lower back pain Mean ± SD | Independent t test (P)* |
|----------|-------------------|---------------------------|-------------------------|
| Age (years) | 30.75 ± 10.86 | 27.23 ± 5.14 | 0.002* |
| Weight (kg) | 70.32 ± 18.82 | 27.23 ± 5.14 | 53.84 |
| Height (m) | 1.67 ± 0.73 | 27.23 ± 5.14 | 0.45 |
| BMI (kg/m²) Pressure pain threshold (kgf) | 24.73 ± 5.14 | 27.23 ± 5.14 | 0.002* |

### Table 2. Characteristics of medication use and presence of multiple morbidities in the study population.

| Young adults | Control | Lower back pain |
|--------------|---------|-----------------|
| Sex | Female | 14 | 46.67% |
| | Male | 6 | 54.54% |
| Medication use | 0 | 2 | 9.5% |
| Multiple morbidities | 0 | 0 | 0 |

| Older adults | Control | Lower back pain |
|--------------|---------|-----------------|
| Sex | Female | 18 | 48.65% |
| | Male | 4 | 80% |
| Medication use | 3 | 13 | 61.9% |
| Multiple morbidities | 9 | 15 | 71.4% |

P<0.05*, SD = standard deviation, kg = kilogram, m = meters, BMI = body mass index, kgf = kilogram force.
Studies on aging have emphasized the search for strategies that can mitigate the deleterious consequences of the aging process on quality of life; aging is a physiological process and functional capacity in the elderly may be affected by several factors, since these individuals have more chronic health problems than younger peers.

Although elderly patients with lumbar pain can use medications that act centrally or peripherally for pain control, we found that the vast majority of this sample did not use medication for pain on a continuous basis. These data agree with the study by Figureirado et al., who reported that elderly individuals with lumbar pain only used medication when pain was acute. When we assessed the physical function and capacity of individuals with lower back pain, we found that lumbar pain in young people has no significant clinical repercussions, except in cases where the participant was also overweight or obese. Lira et al. evaluated the acute effect of increased body weight on performance in the sitting-rising test among young, active adults and found that overweight status had a negative impact on test performance, and concluded that active overweight individuals performed worse in the activities performed (sitting down and standing up), in agreement with our findings.

This present study demonstrated that older adults with chronic lumbar pain performed more poorly on functional tests than the older adults without lower back pain. It can be assumed that the aging process, associated with incorrect posture and excess burden on the spine, are significant factors in triggering serious injury to the discs of the vertebrae and mechanical or degenerative changes.

The presence of pain has been described by some authors as a limiting factor in elderly individuals during performance of daily activities. In assessing functional capacity, we highlight the use of some functional evaluations such as the sitting-rise test (SRT), the six-minute walk test (SMWT), the Five Times Sit-to-Stand test (FTSTS), and the Timed Up and Go test.

In terms of performance in the SRT and SMWT, older individuals in both groups had much poorer performance compared to the younger adults, which is consistent with a study conducted by Lee et al., who found that individuals with chronic lower back pain tend to walk more slowly in the SMWT. Mascarenhas and Santos assessed the perception and intensity of pain and functional capacity in young and elderly people with chronic low back pain and found that pain in the lumbar region was not seen as a limiting factor in relation to daily activities, especially in younger individuals, which was also found by Bento et al. This latter finding explains that it is unusual for chronic lumbar pain to completely incapacitate an individual in terms of performing everyday activities, but this pain can partially and temporarily affect individuals, at times on a recurring basis, when individuals are economically active.

Camara et al. stated that the ability to rise from a chair or bed, even though it may be considered a simple task, is considered a complex action which may be related to musculoskeletal and neuromotor disorders which make significant demands of elderly individuals. For Silva et al. this is because of the exposure of the body when there is an extra load that the musculoskeletal system must support, and consequently may cause alterations to the biomechanical balance of the body.

**CONCLUSION**

The findings of this study provide evidence about the best strategy to evaluate the function of older adults with chronic lower back pain in order to reproduce the functional tests in daily clinical practice, being the SRT the most discerning for this population.
