Abstract: Model continuity plays an important role in applications like system identification, adaptive control, and machine learning. This paper provides sufficient conditions under which input-output systems represented by locally convergent Chen-Fliess series are jointly continuous with respect to their generating series and as operators mapping a ball in an $L_p$-space to a ball in an $L_q$-space, where $p$ and $q$ are conjugate exponents. The starting point is to introduce a class of topological vector spaces known as Silva spaces to frame the problem and then to employ the concept of a direct limit to describe convergence. The proof of the main continuity result combines elements of proofs for other forms of continuity appearing in the literature to produce the desired conclusion.

Keywords: nonlinear systems, Chen-Fliess series, topological vector spaces, system identification, machine learning

1. INTRODUCTION

In applications involving system identification, adaptive control, and machine learning, a stream of input-output data is continually processed over time to produce a sequence of parameter/weight estimates so that an assumed model’s behavior matches that of the data source. In the context of control, for example, this usually means that the dynamics of the model should asymptotically approach those of the plant. This can fail to happen when the model is incompatible with the plant or the data stream contains insufficient information. A more subtle mode of failure is one where the model’s dynamics do not depend continuously on the parameters. In which case, it is possible for the sequence of parameter estimates to converge to some limit, while the corresponding sequence of approximations of the model’s dynamics fail to converge in any sense.

The earliest work on the continuity of input-output systems was that of Hazewinkel (Hazewinkel, 1980). The focus there was on one parameter families of linear time-invariant systems and certain degeneration phenomena. Continuity of the same class of systems was later addressed from the behavioral point of view in Nieuwenhuis and Willems (1988, 1992). Continuity of one parameter families of input-output systems with Chen-Fliess series representations (Fliess, 1981) was first characterized by Wang (1990). In this same work it was also shown that under certain growth conditions on the generating series such system are continuous as maps from $L_1[0,T]$ into $C[0,T]$ with the $L_\infty$-norm for $T > 0$ sufficiently small. More stringent growth conditions can even render an output function which is well defined and continuous on $[0,\infty)$ (Gray and Wang, 2002). Various improvements and generalizations of these results have appeared in Duffaut Espinosa (2009); Winter Arboleda (2019). In parallel with this development, continuity properties regarding control affine nonlinear state space models have appeared in Azhmyakov et al. (2009). The primary aim there was to characterize the continuity of flows with respect to the input and initial condition. Continuity with respect to the vector fields of the realization was not considered. As the coefficients of the corresponding Chen-Fliess depend explicitly on these vector fields and the initial condition, that analysis will not directly apply to the problems considered in this paper.

The main objective of this paper is provide sufficient conditions under which input-output systems represented by locally convergent Chen-Fliess series are jointly continuous with respect to their generating series and as operators mapping a ball in an $L_p$-space to a ball in an $L_q$-space, where $p$ and $q$ are conjugate exponents. Of course, continuity and convergence are ultimately topological concepts, so this phenomenon can only be understood precisely in a topological framework. The starting point is to introduce a class of topological vector spaces known as Silva spaces to frame the problem and then to employ the concept of a direct limit to describe convergence. The proof of the main continuity result combines elements of proofs for weaker forms of continuity appearing in Wang (1990), Gray and

* The second author was supported by the National Science Foundation under grant CMMI-1839378.
Wang (2002), and Duffaut-Espinosa (2009) to produce the desired conclusion.

The paper is organized as follows. The next section gives a brief summary of the Chen-Fließ series mainly to establish the notation. The subsequent section describes the topological concepts used throughout the paper. The main continuity results appear in Section 4 along with some examples to illustrate their application. The final section summarizes the paper’s main conclusions.

2. CHEN-FLIEß SERIES

An alphabet $X = \{x_0, x_1, \ldots, x_m\}$ is any nonempty and finite set of noncommuting symbols referred to as letters. A word $\eta = x_{i_1} \cdots x_{i_k}$ is a finite sequence of letters from $X$. The number of letters in a word $\eta$, written as $|\eta|$, is called its length. The empty word, $\emptyset$, is taken to have length zero.

The collection of all words having length $k$ is denoted by $X^k$. Define $X^* = \bigcup_{k \geq 0} X^k$ and $X^{\leq J} = \bigcup_{j=0}^J X^k$. The former is a monoid under the concatenation product. Any mapping $c : X^* \to \mathbb{R}^\ell$ is called a formal power series. Often $c$ is written as the formal sum $c = \sum_{\eta \in X^*} c(\eta) \eta$, where the coefficient $(c, \eta)$ is the image of $\eta \in X^*$ under $c$. The support of $c$, supp$(c)$, is the set of all words having nonzero coefficients. The set of all noncommutative formal power series over the alphabet $X$ is denoted by $\mathbb{R}^\ell(\langle X \rangle)$.

The subset of series with finite support, if possible, is represented by $\mathbb{R}_f^\ell(\langle X \rangle)$. Each set is an associative $\mathbb{R}$-algebra under the concatenation product and an associative and commutative $\mathbb{R}$-algebra under the shuffle product, that is, the bilinear product uniquely specified by the shuffle product of two words

$(x_1 \eta) \shuffle (x_2 \xi) = x_1(x_2 \eta (x_1 \xi)) + x_2((x_1 \eta) \shuffle \xi)$,

where $x_1, x_2 \in X$, $\eta, \xi \in X^*$ and with $\eta \shuffle \emptyset = \emptyset \shuffle \eta = \eta$ (Fließ, 1981).

Given any $c \in \mathbb{R}_f^\ell(\langle X \rangle)$ one can associate a causal $m$-input, $\ell$-output operator, $F_c$, in the following manner. Let $p \geq 1$ and $t_0 < t_1$ be given. For a Lebesgue measurable function $u : [t_0, t_1] \to \mathbb{R}^{m}$, define $\|u\|_p = \max\{\|u_i\|_p : 1 \leq i \leq m\}$, where $\|u_i\|_p$ is the usual $L_p$-norm for a measurable real-valued function, $u_i$, defined on $[t_0, t_1]$. Let $L^p_\infty[t_0, t_1]$ denote the set of all measurable functions defined on $[t_0, t_1]$ having a finite $\|\cdot\|_p$ norm and $B^p_\infty(R_u)[t_0, t_1] := \{u \in L^p_\infty[t_0, t_1] : \|u\|_p \leq R_u\}$. Assume $C[t_0, t_1]$ is the subset of continuous functions in $L^1_\infty[t_0, t_1]$. Define inductively for each $\eta \in X^*$ the map $E_{\eta} : L^m_\infty[t_0, t_1] \to C[t_0, t_1]$ by setting $E_{\eta}[u] = 1$ and letting

$E_{x, \eta}[u](t, t_0) = \int_{t_0}^{t} u_i(\tau) E_{\eta}[u](\tau, t_0) d\tau,$

where $x_i \in X$, $\eta \in X^*$, and $u_0 = 1$. The Chen-Fließ series corresponding to $c$ is

$y(t) = F_c[u](t) = \sum_{\eta \in X^*} (c, \eta) E_{\eta}[u](t, t_0)$

(Fließ, 1981, 1983). It can be shown that if there exists real numbers $K, M \geq 0$ such that

$|(c, \eta)| \leq K M^{\|\eta\|}$, \hspace{1cm} \forall \eta \in X^*$

$|\eta| := \max \{ |z| \} \text{ when } z \in \mathbb{R}^\ell$ then the series (1) converges absolutely and uniformly for sufficiently small $R, T > 0$ and constitutes a well defined mapping from $B^m_\infty(R)[t_0, t_0 + T]$ into $B^q_\infty(S)[t_0, t_0 + T]$, where the numbers $p, q \in [1, +\infty]$ are conjugate exponents, i.e., $1/p + 1/q = 1$ (Gray and Wang, 2002). Any such mapping is called a locally convergent Fließ operator.

A more refined convergence analysis of Chen-Fließ series appears in Winter Arboleda (2019) utilizing the notion of Grevy order. A series $c \in \mathbb{R}_f^\ell(\langle X \rangle)$ is said to have Grevy order $s \in [0, \infty)$ if there exists constants $K, M > 0$ such that

$\|(c, \eta)\| \leq K M^{\|\eta\|}$, \hspace{1cm} \forall \eta \in X^*$ \hspace{1cm} (3)

Clearly, if $c$ has Grevy order $s$ then it is also has Grevy order $s'$, where $s' > s$. Define for a given $c$ the real number $\gamma_c = \min\{s \in [0, \infty) : s \text{ satisfies (3)}\}$ and the set of all generating series with minimum Grevy order $\gamma$ as $\mathbb{R}_f^\ell(\langle X \rangle)$. In this context, the set of all generating series for locally convergent Fließ operators as described above is

$\mathbb{R}_f^\ell(\langle X \rangle) := \bigcup_{0 \leq s_1 \leq 1} \mathbb{R}_{s_1}(\langle X \rangle)$

while a subset of series (note the upper bound on $\gamma$)

$\mathbb{R}^\ell_{s_1}(\langle X \rangle) := \bigcup_{0 \leq \gamma \leq 1} \mathbb{R}_f^\ell(\langle X \rangle)$

can be shown to yield a type of global convergence on the extended space $L^m_{p, c}(t_0) \to C(t_0, \infty)$, where

$L^\infty_{p, c}(t_0) := \bigcup_{T > 0} L^m_{p, c}(t_0, t_0 + T)$

(Winter Arboleda et al., 2015). Interestingly, this latter set of generating series does not constitute all of those that provide a globally defined Fließ operator as shown by example in Winter Arboleda (2019).

Finally, a Fließ operator $F_c$, defined on $B^m_\infty(R)[t_0, t_0 + T]$, is said to be realizable when there exists a state space model

$\dot{z}(t) = g_0(z(t)) + \sum_{i=1}^{m} g_i(z(t)) u_i(t), \hspace{1cm} z(t_0) = z_0$ \hspace{1cm} (4a)

$y_j(t) = h_j(z(t)), \hspace{1cm} j = 1, 2, \ldots, \ell$ \hspace{1cm} (4b)

where each $g_i$ is an analytic vector field expressed in local coordinates on some neighborhood $W$ of $z_0$, and each output function $h_j$ is an analytic function on $W$ such that (4a) has a well defined solution $z(t)$, $t \in [t_0, t_0 + T]$ for any given input $u \in B^m_\infty(R)[t_0, t_0 + T]$, and $y_j(t) = F_{c_j}[u](t) = h_j(z(t)), t \in [t_0, t_0 + T], j = 1, 2, \ldots, \ell$. It can be shown that for any word $\eta = x_{i1} \cdots x_{i_k} \in X^*$

$(c_j, \eta) = L_{g_{i1}} h_j(z_0) = L_{g_{i1}} \cdots L_{g_{i_k}} h_j(z_0)$ \hspace{1cm} (5)

where $L_{g_{i1}} h_j$ is the Lie derivative of $h_j$ with respect to $g_{i1}$.

3. TOPOLOGICAL SUBSPACES OF $\mathbb{R}^\ell(\langle X \rangle)$

Suppose a sequence of generating series $\{c_j\}_{j \geq 1}$ is produced in real-time by processing a stream of input-output data in some manner. The corresponding sequence of Chen-Fließ series is taken to be $\{F_{c_j}\}_{j \geq 1}$. If the estimation or learning algorithm producing these generating series ensures that $c_j \to c$ in some sense, then it is desirable that $F_{c_j} \to F_c$ in some fashion as well. Perhaps the most obvious way in which one series can approach another is in the ultrametric sense. Specifically, for any fixed real number $\sigma$ such that $0 < \sigma < 1$, consider the mapping

$\text{dist} : \mathbb{R}(\langle X \rangle) \times \mathbb{R}(\langle X \rangle) \to \mathbb{R}$,
Example 1. Let $X = \{x_1\}$ and consider the sequence of polynomials

$$c_j = x_1 + (2!)^2 x_1^2 + (3!)^2 x_1^3 + \cdots + (j!)^2 x_1^j, \quad j \geq 1.$$  

Clearly, each polynomial $c_j$ is locally convergent. Thus, each Fiess operator $F_{c_j}$ is well defined on some ball of input functions in $L^m_{[t_0, t_1]}$. Furthermore, the sequence $(c_j)_j$ converges to $c = \sum_{k=1}^{\infty} (k!)^2 x_1^k$ in the ultrametric topology. But the limiting Chien-Fiess series $F_c$ is not well defined in any obvious sense.

This example motivates the following fundamental problem: On what topological subspaces of $\mathbb{R}^\ell((X))$ does $c_j \to c$ imply that $F_{c_j} \to F_c$ in some sense with the limit point $F_c$ being a well defined operator? The following subsections lay the foundation for addressing this problem by presenting what subspaces are available for consideration.

3.1 Fixed $M > 0$ (Banach Spaces)

As a first step, consider the following interpretation of condition (2). Fix $M > 0$ and define

$$\|c\|_{\ell^\infty, M} := \sup \left\{ \frac{|c(\eta)|}{M^|\eta|} : \eta \in X^*, M \geq 0, \|\eta\| \leq 1 \right\} \in [0, \infty)$$

for each $c \in \mathbb{R}^\ell((X))$. The set of all $c$ with $\|c\|_{\ell^\infty, M} < \infty$ is denoted by $\ell^\infty, M((X), \mathbb{R})$. It is straightforward to check that $\ell^\infty, M((X), \mathbb{R})$ is a vector subspace of $\mathbb{R}^\ell((X))$. The function $\|\cdot\|_{\ell^\infty, M}$ is a norm on $\ell^\infty, M((X), \mathbb{R})$. The following assignment is an isometry of normed spaces:

$$\ell^\infty, M((X), \mathbb{R}) \to \ell^\infty, (X), \mathbb{R}) : c \mapsto \frac{c}{M^|\eta|}$$

where $\ell^\infty, M((X), \mathbb{R}) := \{c : X^* \to \mathbb{R}^\ell : \sup_{|\eta|} |c(\eta)| < \infty\}$ is the Banach space of all bounded functions from $X^*$ to $\mathbb{R}^\ell$. This shows that for each fixed $M > 0$ the space $\ell^\infty, M((X), \mathbb{R})$ is a Banach space. A sequence $c \in \mathbb{R}^\ell((X))$ belongs to $\ell^\infty, M((X), \mathbb{R})$ if and only if the bound (2) holds for some $K \geq 0$ and the fixed number $M$. In fact, the norm $\|c\|_{\ell^\infty, M}$ is the smallest number $K \geq 0$ such that (2) is satisfied.

As $\ell^\infty, M((X), \mathbb{R})$ is a Banach space, and, in particular, a metric space, the topology of $\ell^\infty, M((X), \mathbb{R})$ can be recovered from convergent sequences, where a sequence $(c_j)_j$ in $\ell^\infty, M((X), \mathbb{R})$ converges to $c \in \ell^\infty, M((X), \mathbb{R})$ if and only if

$$\lim_{j \to \infty} \|c_j - c\|_{\ell^\infty, M} = 0.$$  

Given that $\ell^\infty, M((X), \mathbb{R})$ is an infinite dimensional Banach space, the Bolzano-Weierstrass theorem fails to hold, i.e., not every $\|\cdot\|_{\ell^\infty, M}$-bounded sequence has a $\|\cdot\|_{\ell^\infty, M}$-convergent subsequence (Werner, 2000, Satz 1.2.7). Furthermore, the space is not separable, i.e., there is no countable dense subset. Given $M_1$ and $M_2$ such that $M_1 \leq M_2$, it is clear that $\|\cdot\|_{\ell^\infty, M_1} \geq \|\cdot\|_{\ell^\infty, M_2}$, and thus the inclusion (as vector spaces)

$$\ell^\infty, M_1((X), \mathbb{R}^\ell) \subseteq \ell^\infty, M_2((X), \mathbb{R}^\ell)$$

holds. This inclusion is not a topological embedding as the topology induced by $\ell^\infty, M_2((X), \mathbb{R}^\ell)$ is coarser than the one induced by $\ell^\infty, M_1((X), \mathbb{R}^\ell)$. It turns out for $M_1 < M_2$ that the inclusion map

$$\ell^\infty, M_1((X), \mathbb{R}^\ell) \to \ell^\infty, M_2((X), \mathbb{R}^\ell)$$

is a compact operator (Dahmen and Schmeding, 2018, Lemma B.6), i.e., it maps bounded sets to relatively compact sets. In particular, this shows for $M_1 < M_2$ that every sequence which is bounded in the $\|\cdot\|_{\ell^\infty, M_1}$-norm has a subsequence which converges in the coarser $\|\cdot\|_{\ell^\infty, M_2}$-topology.

3.2 The projective limit $M \to 0$ (Fréchet–Schwartz Spaces)

Consider next those $c \in \mathbb{R}^\ell((X))$ for which $\|c\|_{\ell^\infty, M}$ is finite for all $M > 0$. This means that for each $M > 0$ there is a $K = \|c\|_{\ell^\infty, M} \geq 0$ satisfying (2). Algebraically, this corresponds to the intersection of all vector spaces $\ell^\infty, M((X), \mathbb{R}^\ell)$, namely,

$$\ell^\infty, \left((X), \mathbb{R}^\ell \right) := \bigcap_{M > 0} \ell^\infty, M((X), \mathbb{R}^\ell).$$

On spaces like these, there is a natural topology which turns this space into a locally convex topological vector space. In the functional analysis literature, this object is called the projective limit (or inverse limit or categorical limit) of the system $\ell^\infty, M((X), \mathbb{R}^\ell)$ of system $\ell^\infty, M((X), \mathbb{R}^\ell)$, and denoted also by

$$\ell^\infty, \left((X), \mathbb{R}^\ell \right) := \lim_{M \to 0} \ell^\infty, M((X), \mathbb{R}^\ell) = \bigcap_{M > 0} \ell^\infty, M((X), \mathbb{R}^\ell).$$

For a given $c \in \mathbb{R}^\ell((X))$, one can check whether it belongs to this space in the following way:

$$c \in \ell^\infty, \left((X), \mathbb{R}^\ell \right) \iff \|c\|_{\ell^\infty, M} < \infty, \forall M > 0. \quad (6)$$

The sequence $M_k = 1/k, k \in \mathbb{N}$, hence it suffices to check (6) only for $M$ of the form $M_k$.

Now $\ell^\infty, \left((X), \mathbb{R}^\ell \right)$ is the projective limit of countably many Banach spaces. Thus it becomes a Fréchet space, i.e., a complete metrisable space. Fréchet spaces share many nice properties with Banach spaces. For example, their topology is determined by sequences, where a sequence $(c_j)_j$ in $\ell^\infty, \left((X), \mathbb{R}^\ell \right)$ converges to $c \in \ell^\infty, \left((X), \mathbb{R}^\ell \right)$ if and only if

$$\lim_{j \to \infty} \|c_j - c\|_{\ell^\infty, M} = 0, \forall M > 0.$$  

(Again it suffices to check this only for all $M = 1/k$, $k \in \mathbb{N}$.) Since the inclusion maps are all compact operators, $\ell^\infty, \left((X), \mathbb{R}^\ell \right)$ is even a Fréchet–Schwartz space, (Pérez Carreras, Bonet, 1987, Definition 8.5.2). Hence, it behaves much more nicely than the Banach spaces from which it was built. In particular, the space $\ell^\infty, \left((X), \mathbb{R}^\ell \right)$ satisfies a version of the Bolzano–Weierstrass theorem, namely, every $\ell^\infty, \cdot$-bounded sequence has a $\ell^\infty, \cdot$-convergent subsequence. Here, a sequence $(c_j)_j$ is called $\ell^\infty, \cdot$-bounded if

$$\sup_{j} \|c_j\|_{\ell^\infty, M} < \infty \text{ for all } M > 0.$$  

This follows from
(Pérez Carreras and Bonet, 1987, Proposition 8.5.9), which furthermore implies that \( \ell_{\infty,-}(X^*, \mathbb{R}^\ell) \) is separable, i.e., there is countable dense subset. In (Winter Arboleda, 2019, Theorem 3.4.5) it is shown that

\[
\ell_{\infty,-}(X^*, \mathbb{R}^\ell) = \overline{\mathcal{GC}}^\ast\langle \langle X \rangle \rangle,
\]

where the closure on the right is taken with respect to the \( \ell_{\infty,-} \)-topology (called the semi-norm topology in loc. cit.). In other words, there are some generating series with direct limit inclusion maps. Direct limit spaces like these are called \( \ell^\infty \) which the sequence is Cauchy.

Let \( c \in \mathbb{R}^\ell \) (called the topology (called the \( \ell^\infty \), or \( \mathbb{R}^\ell \)), i.e., one can check whether it belongs to \( \ell^\infty, M > 0 \) has to work \( \mathbb{R}^\ell \), \( \mathbb{R}^\ell \) or \( \mathbb{R}^\ell \) according to the system

\[
\ell_{\infty,M}(X^*, \mathbb{R}^\ell) \}
\]

\[
\ell_{\infty,M}(X^*, \mathbb{R}^\ell) \}
\]

\[
\ell_{\infty,-}(X^*, \mathbb{R}^\ell) := \bigcup_{M > 0} \ell_{\infty,M}(X^*, \mathbb{R}^\ell).
\]

As with the intersection, there is also a natural topology turning this space into a locally convex topological vector space. This object is called the direct limit (or inductive limit or categorical colimit) of the system \( \{ \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \}_{M > 0} \) and denoted by

\[
\ell_{\infty,-}(X^*, \mathbb{R}^\ell) := \lim_{M \to \infty} \ell_{\infty,M}(X^*, \mathbb{R}^\ell) = \bigcup_{M > 0} \ell_{\infty,M}(X^*, \mathbb{R}^\ell).
\]

This construction can also be found in Bogfjellmo and Schmeding (2016; Dahmen and Schmeding (2018). For a given \( c \in \mathbb{R}^\ell \langle \langle X \rangle \rangle \), one can check whether it belongs to this space in the following way:

\[
c \in \ell_{\infty,-}(X^*, \mathbb{R}^\ell) \iff \exists M > 0 \text{ such that } \|c\|_{\ell_{\infty,M}} < \infty.
\]

Since the sequence \( M_k = k, k \in \mathbb{N} \) is cofinal, there exists an \( M \in \mathbb{N} \) for which \( \|c\|_{\ell_{\infty,M}} < \infty \). Thus, one could equivalently work only with \( M \in \mathbb{N} \). In general, direct limits are more difficult to work with than projective limits. Fortunately, this particular direct limit is a countable direct limit of Banach spaces with compact operators as inclusion maps. Direct limit spaces like these are called Silva spaces.

Although Silva spaces are not metrizable, they are always sequential (Yoshinaga, 1957, Proposition 6). This means that as in the Banach space case, the topology is determined by sequences, i.e., sets are closed if and only if they are sequentially closed. A sequence \( \{c_j\} \) in \( \ell_{\infty,-}(X^*, \mathbb{R}^\ell) \) converges to \( c \in \ell_{\infty,-}(X^*, \mathbb{R}^\ell) \) if and only if

\[
\lim_{j \to \infty} \|c_j - c\|_{\ell_{\infty,M}} = 0 \text{ for one fixed } M > 0.
\]

In other words, a sequence in a Silva space converges if there exists one fixed \( M > 0 \) for the whole sequence such that \( \{c_j\} \) converges in the Banach space \( \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \) (Yoshinaga, 1957, Theorem 1). In particular, note that for a sequence to converge, all terms must lie in one of the spaces \( \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \), i.e., one \( M > 0 \) has to work for the whole sequence. The sequence in Example 1 fails to converge in the Silva topology since there is no \( M \) for which the sequence is Cauchy.

Using again the compactness of the inclusion maps, it follows that a sequence which is bounded in one \( \|\| \ell_{\infty,M} \|-\)norm (for a given \( M > 0 \)) has a subsequence which converges in the coarsest \( \|\| \ell_{\infty,M} \|-\)topology for all \( M_2 > M_1 \). As earlier, there is a version of the Bolzano-Weierstrass theorem, namely, every \( \ell_{\infty,-} \)-bounded sequence has a \( \ell_{\infty,-} \)-convergent subsequence. In this case, a sequence \( \{c_j\} \) is called \( \ell_{\infty,-} \)-bounded if there is at least one \( M > 0 \) with \( \sup \|c_j\|_{\ell_{\infty,M}} < \infty \). Therefore, a Silva space has better topological properties than the Banach spaces from which it is constructed. Furthermore, every Silva space is separable. Finally, it is shown in (Winter Arboleda, 2019, Theorem 3.2.7) that

\[
\ell_{\infty,-}(X^*, \mathbb{R}^\ell) = \overline{\mathcal{GC}}^\ast\langle \langle X \rangle \rangle
\]

In the continuity theorems presented in the next section, every sequences \( \{c_j\} \) will be assumed a priori to be entirely contained in some Banach space \( \ell_{\infty,M}(X^*, \mathbb{R}) \), \( M > 0 \), thus avoiding the phenomenon shown in the previous example. Therefore, only a Banach topology is really needed. However, for applications such as the interconnection of Chen-Fliss series, the Silva topology is more applicable in the corresponding continuity analysis. For example, one can define for generating series \( c,d \in \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \) a product \( c \circ d \) such that the composition satisfies \( F_c \circ F_d = F_{cd} \). It is known that in general \( c \circ d \) will not be contained in \( \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \) (Thitsa and Gray, 2012). However, there does exist a \( K(M, N, R) < \infty \) for all \( M, N, R \in [0, \infty] \) such that for \( B_{\infty,N}(R) : = \{ c \in \ell_{\infty,N}(X^*, \mathbb{R}^\ell) : \|c\|_{\ell_{\infty,N}} < R \} \) the map

\[
\circ : \ell_{\infty,M}(X^*, \mathbb{R}^\ell) \times B_{\infty,N}(R) \to \ell_{\infty,K(M, N, R)}(X^*, \mathbb{R}^\ell)
\]

is well defined (Gray et al., 2021, Lemma 3.4). Using these estimates, the interconnection of Chen-Fliss series induces a continuous product on the Silva space \( \ell_{\infty,-}(X^*, \mathbb{R}^\ell) \). Hence, the Silva topology is the natural topology for describing the continuity of such interconnections. This is investigated further in Gray et al. (2021).

4. MAIN CONTINUITY THEOREMS

The continuity problem for a Chen-Fliss series \( F_c[u] \) is approached incrementally. It is first assumed that the input \( u \) is fixed and the generating series \( c \) is variable (series to output continuity). Then the case where \( c \) is

\footnote{Sequence A000108 in OEIS (2021).}
fixed and $u$ is variable is presented (input-output operator continuity). Finally, the two cases are combined. For notational convenience, define the space of $L^p$-germs $L^m_p(t_0) := \{[u] \mid u \in L^m_p(t_0, t_1)\}$ for some $t_1 > t_0$, where the class $[u]$ contains all functions equal to $u$ in some neighborhood of $t_0$. Note that this space can not be endowed with any useful topology making the inclusion $L^m_p(t_0, t_1)$ continuous (as this would automatically be non-Hausdorff).

**Theorem 4.** (series to output continuity). The map

$$L^m_{\ell}((0) \times \mathbb{R}_c((X)) \to L^m_{\ell}(0), \quad (u, c) \mapsto y = F_c[u]$$

is well defined. Moreover, for every $M > 0$ and fixed $u \in L^m_{\ell}(0)$, there exists a $T > 0$ such that

$$\ell_{\infty, M}(X^c, \mathbb{R}^c) \to L^m_{\ell}(0, T), \quad c \mapsto y = F_c[u]$$

is continuous.

The following two lemmas are needed for the proof (Duf-faut Espinosa, 2009).

**Lemma 5.** Let $X = \{x_0, x_1, \ldots, x_m\}$. For any $k \in \mathbb{N}$, the characteristic polynomial char($X^k$) of $X^k$, i.e. the sum of all words of length $k$, satisfies

$$\text{char}(X^k) = \sum_{r_0, r_1, \ldots, r_m \geq 0, \ r_0 + r_1 + \cdots + r_m = k} x_0^{r_0} x_1^{r_1} \cdots x_m^{r_m},$$

where $\omega$ denotes the shuffle product.

**Lemma 6.** Let $X = \{x_0, x_1, \ldots, x_m\}$. For any $u \in L^m_X[0, T]$ and $\eta \in X^c$

$$\|E_\eta[u](t)\| \leq E_\eta[|u|(t)], \quad 0 \leq t \leq T,$$

where $\eta \in L^m_X[0, T]$ has components $\eta_j := |u_j|, j = 1, 2, \ldots, m$. Furthermore, for any integers $r_j \geq 0$ it follows that

$$\|E_\eta[u](t)\| \leq \left| \prod_{r_j = 0}^m u_j(\tau) \right| \leq \left| \prod_{r_j = 0}^m u_j(\tau) \right|,$$

where $U_j(\tau) := \int_0^\tau u_j(\tau) \, d\tau$. In particular, if $0 \leq t \leq T$ it is assumed that $\max\{\|u\|_1, T\} \leq R$ then

$$\|E_\eta[u](t)\| \leq \frac{R^k}{r_0! r_1! \cdots r_m!}, \quad 0 \leq t \leq T,$$

where $k = \sum j r_j$.

Now the proof of Theorem 4.

**Proof:**

If $c \in \mathbb{R}^{\ell_c}((X))$, then there exists $K, M \geq 0$ satisfying (2). Fix $u \in L^m_X(0)$ without loss of generality $p = 1$ and $t_0 = 0$ so that for some $T > 0, u \in L^m_X(0, T)$. Define $R = \max\{\|u\|_1, T\}$. Applying Lemmas 5 and 6 it then follows that:

$$\|y(t)\| \leq \sum_{\eta \in X^c} \|c, \eta\| E_\eta[u](t)$$

$$\leq \sum_{k=0}^\infty \sum_{\eta \in X^c} \|c, \eta\| E_\eta[u](t)$$

$$\leq \sum_{k=0}^\infty K M^k k! \sum_{r_0, r_1, \ldots, r_m \geq 0, \ r_0 + r_1 + \cdots + r_m = k} E^{r_0}_{x_0} x_1^{r_1} \cdots x_m^{r_m}[u](t)$$

$$\leq \sum_{k=0}^\infty K M^k k! \sum_{r_0, r_1, \ldots, r_m \geq 0, \ r_0 + r_1 + \cdots + r_m = k} \frac{R^k}{r_0! r_1! \cdots r_m!}.$$
\[ \|y_j - y\|_\infty = \sup_{t \in [0, T]} \left\| \frac{(M_j - M_b)E_{x_i}[u(t)]}{(1 - M_j E_{x_i}[u(t)])(1 - M_b E_{x_i}[u(t)])} \right\| \]

so that \( y_j \xrightarrow{j \to \infty} y \) in the \( L_\infty \) norm sense. The specific example where \( M_a = 1 \), \( M_b = 7 \), and \( u(t) = \cos(10t) \) with \( t \in [0, 0.2\pi] \) is shown in Figure 1. Here \( T = 0.6283 \), \( \|u\|_1 = 0.4 \) and \( 1/\max(M_a, M_b) = 0.1429 \) (note \( m + 1 = 1 \) as \( X \) has only one letter), which shows that condition (8) is conservative in this instance.

Input-output operator continuity is addressed in the next theorem. The proof is inspired by results appearing in Wang (1990) except that certain details have to be handled differently in order to use the result in the proof of the final continuity theorem.

**Theorem 8.** (input-output operator continuity) Suppose \( c \in \mathbb{R}_+^{\ell C}(\langle X \rangle) \) and select any pair of conjugate exponents \( p, q \in [1, \infty) \). If \( 0 < T \leq R < 1/(M(m + 1)) \) such that \( c \in \ell_{\infty, M}(X^*, \mathbb{R}^L) \), then the operator

\[ F_c : B^p_p(R)[t_0, t_0 + T] \to B^q_q(S)[t_0, t_0 + T] \]

for some \( S > 0 \) is continuous with respect to the \( L_p \) and \( L_q \) norms.

**Proof:** It needs to be shown for any \( \epsilon > 0 \) that there exists a \( \delta > 0 \) such that if \( v, u \in B^p_p(R)[t_0, t_0 + T] \) satisfy \( \|v - u\|_p < \delta \), then \( \|F_c[v] - F_c[u]\|_q < \epsilon \). It is first proved by induction on the length of the word \( \eta \in X^* \) that the mapping

\[ E_\eta : B^p_p(R)[t_0, t_0 + T] \to B^q_q(S)[t_0, t_0 + T] \]

has the desired continuity property. The focus is on the case where \( p, q \in (1, \infty) \) (the remaining case is handled similarly). Without loss of generality, assume \( t_0 = 0 \). The claim is trivial when \( \eta \) is the empty word. If \( \eta = x_r \), then

\[ \|E_{x_r}[v] - E_{x_r}[u]\|_q = \left( \int_{0}^{T} |v(t) - u(t)|^q dt \right)^{\frac{1}{q}} \]

\[ \leq \left( \int_{0}^{T} \left( \int_{0}^{T} |v(\tau) - u(\tau)| d\tau \right)^q d\tau \right)^{\frac{1}{q}} \]

\[ = \int_{0}^{T} |v(\tau) - u(\tau)| d\tau T^{1/q} \]

\[ \leq \|v - u\|_p T^{2/q} \]

\[ \leq \|v - u\|_p T^{2/q} \]

where Hölder’s inequality has been used in the second to the last step above. Thus, if \( \|v - u\|_p < \delta_v := \epsilon/T^{2/q} \), then clearly

\[ \|E_{x_r}[v] - E_{x_r}[u]\|_q < \epsilon \]

Now suppose the claim holds for all words up to some fixed length \( k \geq 0 \). Then for any \( x_i \in X \) and \( \eta \in X^k \) observe

\[ \|E_{x_i,\eta}[v] - E_{x_i,\eta}[u]\|_q \]

\[ = \left\| \left( E_{x_i,\eta}[v] - \int_{0}^{T} u_i(\tau) E_{\eta}[v](\tau) d\tau \right) + \left( \int_{0}^{T} u_i(\tau) E_{\eta}[v](\tau) d\tau - E_{x_i,\eta}[u] \right) \right\|_q \]

\[ \leq \left\| E_{x_i,\eta}[v] - \int_{0}^{T} u_i(\tau) E_{\eta}[v](\tau) d\tau \right\|_q + \left\| \int_{0}^{T} u_i(\tau) E_{\eta}[v](\tau) d\tau - E_{x_i,\eta}[u] \right\|_q \]

\[ \leq \left( \int_{0}^{T} \left( \int_{0}^{T} |v(\tau) - u(\tau)| |E_{\eta}[v](\tau)| d\tau \right)^q d\tau \right)^{\frac{1}{q}} + \left( \int_{0}^{T} \left( \int_{0}^{T} |u_i(\tau)| |E_{\eta}[v](\tau) - E_{\eta}[u](\tau)| d\tau \right)^q d\tau \right)^{\frac{1}{q}} \]

\[ \leq \left( \int_{0}^{T} \left( \int_{0}^{T} |v(\tau) - u(\tau)| |E_{\eta}[v](\tau)| d\tau \right)^q d\tau \right)^{\frac{1}{q}} \]

\[ + \left( \int_{0}^{T} \left( \int_{0}^{T} |u_i(\tau)| |E_{\eta}[v](\tau) - E_{\eta}[u](\tau)| d\tau \right)^q d\tau \right)^{\frac{1}{q}} \]

\[ \leq \|v - u\|_p T^{1/q} + \|u\|_p \|E_{\eta}[v] - E_{\eta}[u]\| T^{1/q} \]

\[ \leq \|v - u\|_p \|E_{\eta}[v] - E_{\eta}[u]\| T^{1/q} < \epsilon/2 \]

for all \( v \) in a ball centered at \( u \) of radius \( \delta_v > 0 \). In which case, choose

\[ \delta_{x_i,\eta} = \min \left\{ \delta_v \left( \|E_{\eta}[v]\|_q + 1 \right)^{1/q} \right\} \]

so that if \( \|v - u\|_p < \delta_{x_i,\eta} \), then

\[ \|E_{x_i,\eta}[v] - E_{x_i,\eta}[u]\|_q < \epsilon \]

Hence, by induction, \( E_\eta \) is continuous with respect to the \( L_p \) and \( L_q \) norms for every \( \eta \in X^* \).

To show that \( F_c \) is also continuous in the desired sense, observe that for any integer \( N > 0 \)

\[ \|F_c[v] - F_c[u]\|_q = \left\| \sum_{k=0}^{N} \sum_{\eta \in \Theta} (c, \eta)(E_{\eta}[v] - E_{\eta}[u]) \right\|_q \]

\[ \leq \sum_{k=0}^{N} \sum_{\eta \in \Theta} (c, \eta)(E_{\eta}[v] - E_{\eta}[u]) \| \]

\[ \leq \sum_{k=N}^{\infty} \sum_{\eta \in \Theta} (c, \eta)(E_{\eta}[v] - E_{\eta}[u]) \| \]

\[ \leq \sum_{k=0}^{N} \sum_{\eta \in \Theta} (c, \eta)(E_{\eta}[v] - E_{\eta}[u]) \| \]

\[ \leq 2 \sum_{k=N}^{\infty} K(MR(m + 1))^k \]

where \( c \in \ell_{\infty, M}(X^*, \mathbb{R}^L) \) and \( K = \|c\|_{\ell_{\infty, M}} > 0 \). Clearly the second term above can be bounded by \( \epsilon/2 \) by selecting \( N \) to be sufficiently large. Having done this, take \( \delta := \min_{|\eta| \leq N} \delta_{\eta} \), where the \( \delta_{\eta} \) have been chosen as above to bound the first term by \( \epsilon/2 \). This establishes the continuity of the map to \( L_q^R(t_0, t_0 + T) \). Moreover, in light of (7), it follows that \( \|F_c[u]\|_q \leq \|c\|_{\ell_{\infty, M}} \sum_{\eta \in \Theta} (M(m + 1))^\eta \)

where the series is a convergent geometric series. Hence,

\[ 3 \text{ Of course, } \delta_{\eta} \text{ must be selected so that this ball is contained inside } B^p_p(R)[0, T]. \]
there exists a constant $S > 0$ depending only on $\|c\|_{\ell_{\infty,M}}$ bounding the $L_q$-norm of $F_c[u]$. \hfill \blacksquare

Now the stronger property of joint continuity is derived using some of concepts developed for the previous two theorems. First recall that for Banach spaces $V,W$ and $U \subseteq V$ open, the following spaces are Banach spaces:

- $BC(U,W)$ the space of bounded continuous functions with the sup norm $\| \cdot \|_\infty$.
- $L(V,W)$ the space of bounded linear functions with the operator norm $\| \cdot \|_{op}$.

**Theorem 9.** (joint continuity) Let $M \in \mathbb{R}^+, p, q$ be conjugate exponents, and $0 < T \leq R < 1/(M(m + 1))$. The maps

$$
\Phi : \ell_{\infty,M}(X^*, \mathbb{R}^k) \to BC(B^m_p(R)[t_0, t_0 + T], L^q_p(t_0, t_0 + T)),
$$

$$
c \mapsto F_c
$$

and

$$
\Psi : B^m_p(R)[t_0, t_0 + T] \to L(\ell_{\infty,M}(X^*, \mathbb{R}^k), L^q_p(t_0, t_0 + T)),
$$

$$
u \mapsto (c \mapsto F_c[u])
$$

are well defined and continuous. Therefore, the joint map

$$
\ell_{\infty,M}(X^*, \mathbb{R}^k) \times B^m_p(R)[t_0, t_0 + T] \to \mathcal{L}^q_p(t_0, t_0 + T),
$$

$$(c, u) \mapsto F_c[u]
$$

(9)

is also continuous.

**Proof:** First observe from Theorem 8 that for every $c \in \ell_{\infty,M}(X^*, \mathbb{R}^k)$, $F_c$ is bounded and continuous on $B^m_p(R)[t_0, t_0 + T]$. Hence, $\Phi$ is well defined and clearly linear. Furthermore, from (7),

$$
\|\Phi(c)\|_{\infty} = \sup_{u \in B^m_p(R)[t_0, t_0 + T]} \|F_c[u]\|_q
\leq \sum_{k=0}^{\infty} \|c\|_{\ell_{\infty,M}} (MR(m+1))^k.
$$

Suitably choosing $R$, the right-hand side will be bounded by a finite constant times the factor $\|c\|_{\ell_{\infty,M}}$. Hence, $\|\Phi\|_{op} < \infty$, and $\Phi$ is continuous.

In light of Theorem 4, $\Psi$ is also well defined. To see that $\Psi$ is continuous, let $\epsilon > 0$ and fix $u, v \in B^m_p(R)[t_0, t_0 + T]$. Then the estimate in the proof of Theorem 8 yields

$$
\|\Psi(u) - \Psi(v)\|_{op} = \sup_{\|c\|_{\ell_{\infty,M}}=1} \|F_c[u] - F_c[v]\|_q
\leq \sum_{k=0}^{N-1} \sum_{\eta \in X^k} \sum_{\|mL(k)\| \leq M} \|E_{\eta}[v] - E_{\eta}[u]\|_q + 2 \sum_{k=N}^{\infty} (MR(m+1))^k.
$$

Choosing $N$ sufficiently large, the second term is smaller than $\epsilon/2$. It is known from the proof of Theorem 8 that every $E_\theta$ is continuous, hence one can choose $\delta > 0$ such that the first term is less than $\epsilon/2$ if $v$ is in the $\delta$-ball around $u$. Therefore, $\Psi$ is continuous.

The continuity of the joint map (9) follows directly from the continuity of $\Psi$ by (Lang, 1999, I, §3 Proposition 3.10). However, it can also be easily derived from the continuity of $\Phi$ as shown next. Select $c_1, c_2 \in \ell_{\infty,M}(X^*, \mathbb{R}^k)$ and $u, v \in B^m_p(R)[t_0, t_0 + T]$. Applying the triangle inequality, observe that $\|F_{c_1}[u] - F_{c_2}[v]\|_q$ is dominated by

$$
\|F_{c_1}[u] - F_{c_2}[v]\|_q + \|F_{c_1}[u] - F_{c_2}[v]\|_q
\leq \|\Phi_{c_1-c_2}(u)\|_{op} + \|F_{c_1}[u] - F_{c_2}[v]\|_q.
$$

Finally, Theorem 8 shows that (10) converges to 0 as $c_2$ tends to $c_2$ and $u$ to $v$, hence (9) is continuous.

**Example 10.** A nonlinear system identification problem is solved in Gray et al. (2020) by truncating (1) up to words of length $J$ and then applying a recursive least-squares algorithm to identify the coefficients of the generating polynomial $p := \sum_{\eta \in X^j} c(\eta)\eta$. In this case, Theorem 9 applies directly to the sequence of estimates $(\hat{\eta}_j)_j$ with, for example, $M = 1$.

**Example 11.** Cuchiero et al. (2019) describe a model for deep neural networks using (4) with parameter dependent vector fields $g_j(z, \theta)$. Here $\theta$ is assumed to be the set of fixed parameters of the network, while the inputs $u_i$ correspond to the trainable parameters. In light of (5), if these vector fields are analytic in the state, such networks constitute a family of Chen-Flies series $C = \{c_\theta \in \mathbb{R}^{LC}(\langle X \rangle) : \theta \in \Theta\}$. In which case, each generating series would have a $\theta$ dependent growth parameter $M(\theta)$. For a fixed $\theta \in \Theta$, Theorem 8 ensures that the output of the network is a continuous function of the trainable parameters. In addition, if $sup_{\theta \in \Theta} M(\theta)$ is finite, then Theorem 9 guarantees joint continuity in both the trainable parameters and over the set of design parameters $\Theta$.

5. CONCLUSIONS

Sufficient conditions were given under which input-output systems represented by locally convergent Chen-Flies series are jointly continuous with respect to their generating series and as operators mapping a ball in an $L_p$-space to a ball in an $L_q$-space, while $\mathbf{p}$ and $\mathbf{q}$ are conjugate exponents. Continuity with respect to the generating series was characterized using Banach topologies on subsets of $\mathbb{R}^k(\langle X \rangle)$. These results were then combined with elements of proofs for other forms of continuity appearing in the literature to produce the desired joint continuity result.
