Abstract

We extend our recent results on ordinary $su(N)$ tensor product multiplicities to higher $su(N)$ tensor products. Particular emphasis is put on four-point couplings where the tensor product of four highest weight modules is considered. The number of times the singlet occurs in the decomposition is the associated multiplicity. In this framework, ordinary tensor products correspond to three-point couplings. As in that case, the four-point multiplicity may be expressed explicitly as a multiple sum measuring the discretised volume of a convex polytope. This description extends to higher-point couplings as well. We also address the problem of determining when a higher-point coupling exists, i.e., when the associated multiplicity is non-vanishing. The solution is a set of inequalities in the Dynkin labels.
1 Introduction

The decomposition of tensor products of simple Lie algebra modules has been studied for a long time now. Many elegant results have been found for the multiplicities of the decompositions, the so-called tensor product multiplicities. However, most results pertain to the decomposition of tensor products of two irreducible highest weight modules of a simple Lie algebra:

\[ M_\lambda \otimes M_\mu = \bigoplus \nu T_{\lambda,\mu,\nu} M_\nu. \]  (1)

\( M_\lambda \) is the module of highest weight \( \lambda \), while \( T_{\lambda,\mu,\nu} \) is the tensor product multiplicity. This problem is equivalent to the more symmetric one of determining the multiplicity of the singlet in the decomposition of the triple product

\[ M_\lambda \otimes M_\mu \otimes M_\nu \supset T_{\lambda,\mu,\nu} M_0. \]  (2)

Indeed, if \( \nu^+ \) denotes the weight conjugate to \( \nu \), we have \( T_{\lambda,\mu,\nu} = T_{\lambda,\mu,\nu^+} \). We will use the shorthand notation \( \lambda \otimes \mu \otimes \nu \) to represent the left hand side of (2), and refer to it as a three-point product.

The objective of the present work is to discuss higher \( su(N) \) tensor products (or higher-point \( su(N) \) couplings), and provide explicit expressions for the associated multiplicities

\[ M_\lambda \otimes M_\mu \otimes ... \otimes M_\sigma \supset T_{\lambda,\mu,...,\sigma} M_0. \]  (3)

Based on a generalisation of the Berenstein-Zelevinsky method of triangles [1], we have recently obtained very explicit expressions for \( T_{\lambda,\mu,\nu} \). The result is a multiple sum formula measuring the discretised volume of a convex polytope associated to the tensor product [2]. It is this idea which shall be extended here to cover higher-point couplings. The main focus will be on four-point couplings. Our results pertain to the \( A \)-series, \( A_r = su(r + 1) \).

We also address the problem of determining when a higher-point coupling exists, i.e., when the associated multiplicity is non-vanishing. The solution is a set of inequalities in the Dynkin labels.

2 Ordinary tensor product multiplicities

To fix notation, we review briefly our main result [2] on the computation of ordinary tensor product multiplicities, i.e., on the evaluation of three-point couplings. We refer to [2] for more details.

An \( su(r + 1) \) Berenstein-Zelevinsky (BZ) triangle, describing a particular coupling (to the singlet) associated to the triple product \( \lambda \otimes \mu \otimes \nu \), is a triangular arrangement of

\[ E_r = \frac{3}{2} r(r + 1) \]  (4)

non-negative integers, denoted entries. The entries are subject to certain constraints: the \( 3r \) outer constraints and the \( 2H_r \) hexagon identities, where

\[ H_r = \frac{1}{2} r(r - 1) \]  (5)
is the number of hexagons, see below. The case $su(3)$ provides a simple illustration:

\[
\begin{array}{cccc}
m_{13} & n_{12} & l_{23} & m_{12} \\
m_{23} & n_{13} & l_{12} & m_{23} \\
\end{array}
\]

According to the outer constraints, these $E_2 = 9$ non-negative integers are related to the Dynkin labels of the three integrable highest weights by

\[
\begin{align*}
m_{13} + n_{12} &= \lambda_1 , \\
n_{13} + l_{12} &= \mu_1 , \\
l_{13} + m_{12} &= \nu_1 , \\
m_{23} + n_{13} &= \lambda_2 , \\
n_{23} + l_{13} &= \mu_2 , \\
l_{23} + m_{13} &= \nu_2 .
\end{align*}
\]

The entries further satisfy the hexagon conditions

\[
\begin{align*}
n_{12} + m_{23} &= n_{23} + m_{12} , \\
m_{12} + l_{23} &= m_{23} + l_{12} , \\
l_{12} + n_{23} &= l_{23} + n_{12} ;
\end{align*}
\]

of which only two are independent. The number of BZ triangles is the triple tensor product multiplicity $T_{\lambda, \mu, \nu}$.

The generalisation of the BZ triangles we consider is obtained by weakening the constraint that all entries are non-negative integers to arbitrary integers, negative as well as non-negative. The hexagon identities and the outer constraints are still enforced. A triangle will be called a true BZ triangle if all its entries are non-negative.

A generalised $su(r + 1)$ BZ triangle is built out of $H_r$ hexagons and three corner points. Each hexagon corresponds to two independent constraints on the entries. This leaves

\[
E_r - (2H_r + 3r) = H_r
\]

parameters labelling the possible triangles. Thus, for a given triple product $\lambda \otimes \mu \otimes \nu$, the set of associated triangles spans an $H_r$-dimensional lattice. Among the lattice points, only a finite number correspond to true BZ triangles. As already stated, this number is precisely the tensor product multiplicity of the triple product.

The $H_r$ basis vectors in the lattice correspond to so-called (basis) virtual triangles \cite{2}, denoted $V$. They are themselves triangles (i.e., points in the lattice) associated to the particular coupling $0 \otimes 0 \otimes 0$. In the case $su(4)$ the three basis virtual triangles are

\[
\begin{array}{cccccccc}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\bar{1} & \bar{1} & 0 & 0 & 0 & 0 & 0 & 0 \\
1 & \bar{1} & \bar{1} & 1 & 1 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & \bar{1} & \bar{1} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \bar{1} & \bar{1} \\
1 & \bar{1} & \bar{1} & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \bar{1} & \bar{1} \\
0 & 0 & 0 & 0 & 0 & 0 & \bar{1} & \bar{1} \\
\end{array}
\]

where $\bar{1} \equiv -1$. In general, a convenient basis for the virtual triangles is given by associating the simple distribution

\[
\begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & \bar{1} & \bar{1} & 1 \\
1 & \bar{1} & \bar{1} & 1 \\
1 & \bar{1} & \bar{1} & 1 \\
\end{array}
\]
of plus and minus ones to any given hexagon. All other entries are zero.

The lattice may now be characterised by an initial triangle $T_0$ and the basis of virtual triangles, as a generic triangle $T$ may be written

$$T = T_0 + \sum_{i,j \geq 1} v_{i,j} V_{i,j} .$$

$v_{i,j}$ are called linear coefficients, and our choice of labelling follows from

$$v_{r-1,1} \quad v_{r-2,1} \quad v_{r-2,2} \quad \ldots \quad v_{1,r-2} \quad v_{1,r-1}$$

The initial triangle corresponds to any point in the lattice. A convenient choice is based on the fact that every highest weight $\nu$ in a coupling $\lambda \otimes \mu \otimes \nu$ satisfies

$$\nu = \lambda^+ + \mu^+ - \sum_{i=1}^{r} n_i \alpha_i , \quad n_i = (\lambda^+)^i + (\mu^+)^i - \nu^i \in \mathbb{Z}_\geq ,$$

where $\alpha_i$ is the $i$-th simple root. The coefficients $n_i$ are expressed using dual Dynkin labels:

$$\lambda = \sum_{i=1}^{r} \lambda_i \Lambda_i = \sum_{i=1}^{r} \lambda_i \alpha_i^\vee ,$$

where $\{\Lambda_i\}$ and $\{\alpha_i^\vee\}$ are the sets of fundamental weights and simple co-roots, respectively. For simply-laced algebras like $su(N)$, $\alpha_i$ is identical to the co-root $\alpha_i^\vee$ (with standard normalisation $\alpha^2 = 2$, for $\alpha$ a long root). Now, it is easy to construct the unique true triangle associated to the coupling $\lambda \otimes \mu \otimes (\lambda + \mu)^+$, as well as triangles associated to the couplings $0 \otimes 0 \otimes \alpha_i$. $su(3)$ examples are

$$\begin{array}{cccc}
\lambda_1 & 0 & \mu_1 & \mu_1 \\
0 & \lambda_2 & 0 & 0 \\
0 & 0 & \lambda_2 & 0 \\
\mu_1 & 0 & 0 & 0 \\
0 & 0 & 0 & \mu_2 \\
\end{array}$$

\[1\text{The choice of labelling differs slightly from the one used in Ref. [2].}\]
Adding the triangles according to (14) results in a BZ triangle associated to \( \lambda \otimes \mu \otimes \nu \). The result for \( su(r + 1) \) is the following generalised BZ triangle:

\[
\begin{array}{cccccccc}
N'_1 & N'_{r-1} & N'_{r-2} & \ldots & N'_{r-1} & N'_{r-1} & 0 & \lambda_2 \\
0 & \mu_1 & \mu_2 & \ldots & \mu_1 & \lambda_3 & 0 & \lambda_3 \\
0 & \lambda_1 & \lambda_r & \lambda_r & \lambda_r & 0 & 0 & \lambda_r \\
& & 0 & \mu_1 & \mu_2 & \mu_3 & \ldots & \mu_1 \\
& & & 0 & \lambda_r & \lambda_r & \lambda_r & \lambda_r \\
& & & & 0 & \mu_1 & \mu_2 & \mu_3 \\
& & & & & 0 & \mu_1 & 0 \\
& & & & & & 0 & \mu_1
\end{array}
\]

The entries \( n_i, N_i \) and \( N'_i \) are defined by

\[
\begin{align*}
    n_i &= \lambda^{r-i+1} + \mu^{r-i+1} - \nu^i, \\
    N_i &= (1 - \delta_{11})n_{i-1} - n_i + \mu^{r-i+1} \\
    &= -\lambda^{r-i+1} + (1 - \delta_{11})\lambda^{r-i+2} - (1 - \delta_{1r})\mu^{r-i+1} + \mu^{r-i+1} - (1 - \delta_{11})\nu^{i-1} + \nu^i, \\
    N'_i &= \nu - N_i \\
    &= \lambda^{r-i+1} - (1 - \delta_{11})\lambda^{r-i+2} + (1 - \delta_{1r})\mu^{r-i} - \mu^{r-i+1} + \nu^i - (1 - \delta_{1r})\nu^i+1.
\end{align*}
\]

supplemented by the condition that \( n_i \), and thus also \( N_i \) and \( N'_i \), are integers (cf. (14)).

A true BZ triangle associated to the product \( \lambda \otimes \mu \otimes \nu \) has the additional property that all its entries are non-negative integers. From (14) it then follows that the set of true BZ triangles may be characterised by a set of inequalities in the linear coefficients. It is easily seen that these inequalities define a convex polytope embedded in \( \mathbb{R}^H \), whose discretised volume is the tensor product multiplicity \( T_{\lambda, \mu, \nu} \). As discussed in Ref. [2], this volume may be measured explicitly and calculated by a multiple sum:

\[
T_{\lambda, \mu, \nu} = \left( \sum_{v_{1,1}} \right) \left( \sum_{v_{1,2}} \sum_{v_{2,1}} \right) \ldots \left( \sum_{v_{r-2,1}} \sum_{v_{1,r-2}} \right) \left( \sum_{v_{r-1,1}} \sum_{v_{1,r-1}} \right) 1. \tag{19}
\]

Here the summation variables are bounded according to

\[
\begin{align*}
    \max\{-N_1, v_{1, r-2} - N'_1 + v_{2, r-2} - \mu_{r-2} + v_{1, r-2} - v_{2, r-3} + v_{2, r-2}\} \\
    \leq v_{1, r-1} \leq \min\{n_1, \mu_{r-1} + v_{1, r-2} - v_{1, r-2} - \mu_{r-2} + v_{1, r-2} + v_{2, r-2}, \\
    n_2 + v_{1, r-2} - v_{2, r-2} - N'_1, N_2 + v_{2, r-2}\}, \\
    \max\{|v_{l-1, r-l} - v_{l-1, r-l-2} + v_{l, r-l-1} - N'_{l+1} + v_{l, r-l-1}, \\
    -\mu_{r-l-1} + v_{l+1, r-l-1} - (1 - \delta_{r-2})v_{l+1, r-l-2} + v_{l, r-l-1}\}.
\end{align*}
\]
be the decomposition polytope, and then to express the volume explicitly as a multiple sum. Our starting point will focus first on four-point products:

\[ T \]

Due to the freedom in choosing the initial triangle, this is just one out of an infinite class of multiple sum representations of \( T_{\lambda,\mu,\nu} \). Its asymmetry in the weights merely reflects the symmetry-breaking choice of initial triangle, and the choice of an order of summation.

### 3 Four-point products

We focus first on four-point products:

\[ M_\lambda \otimes M_\mu \otimes M_\nu \otimes M_\sigma \supset T_{\lambda,\mu,\nu,\sigma} M_0 \, . \] (21)

The objective is to characterise the multiplicity \( T_{\lambda,\mu,\nu,\sigma} \) as the discretised volume of a convex polytope, and then to express the volume explicitly as a multiple sum. Our starting point will be the decomposition

\[ T_{\lambda,\mu,\nu,\sigma} = \sum_\rho T_{\lambda,\mu,\rho} T_{\rho,\nu,\sigma} \] (22)

which may be represented graphically by

\[ \begin{array}{c}
\lambda \\
\uparrow \\
\mu \\
\downarrow \\
\nu \\
\downarrow \\
\sigma
\end{array}
\]

\[ = \sum_\rho 
\begin{array}{c}
\lambda \\
\uparrow \\
\rho \\
\downarrow \\
\mu \\
\downarrow \\
\nu \\
\downarrow \\
\sigma
\end{array}
\] (23)

The arrow indicates that the third weight associated to the coupling involving \( \lambda \) and \( \mu \) is \( \rho \), while its conjugate, \( \rho^\dagger \), takes part in the second coupling. Due to the \( S_4 \) symmetry of \( T_{\lambda,\mu,\nu,\sigma} \) there are many possible decompositions in terms of three-point couplings, associated to different channels. As in the case of the three-point couplings, we are not seeking a symmetric representation of the multiplicity, but merely an explicit multiple sum formula. The decomposition is itself a representation but less explicit than our goal. The former corresponds to considering a sum over products of discretised volumes of convex polytopes embedded in \( H_r \)-dimensional euclidean spaces. The sum is over the \( r \) Dynkin labels of the interior weight \( \rho \). Our goal is to represent the multiplicity as the discretised volume of a single convex polytope embedded in a \((2H_r + r)\)-dimensional euclidean space, and eventually to measure explicitly the volume in terms of a multiple sum. The number of parameters is of course conserved.
Our approach does not admit an immediate and simple modification in order to obtain a result which is manifestly $S_4$ symmetric. Taking an average over the possible (symmetry-breaking) channels would provide a straightforward symmetrisation but result in a much more complicated expression. One should rather look for an approach which respects the four-coupling nature, and thus does not rely on breaking the coupling up into three-point couplings.

Let

\[
\begin{array}{c}
\begin{array}{c}
\triangle
\end{array}
\end{array}
\tag{24}
\]

denote a BZ triangle whose entries have not been specified explicitly. This offers an alternative illustration of the channel \eqref{23}:

\[
\begin{array}{c}
\begin{array}{c}
\triangle
\end{array}
\end{array}
\tag{25}
\]

The dotted lines indicate a gluing of the triangles. These composite objects may be regarded as a generalisation of the BZ triangles to diagrams associated to particular choices of four-point channels; governed by a gluing of triangles representing three-point couplings. Disregarding this origin of \eqref{24}, the configuration is merely an arrangement of $2E_r$ (non-)negative integers subject to certain constraints: $4H_r$ hexagon identities, $4r$ outer constraints representing the four weights, and $r$ gluing constraints. Along the dotted lines, the original $2r$ outer constraints are substituted by the $r$ gluing constraints requiring opposite weights to be identical. A four-point diagram is called true if all entries are non-negative integers. Explicit examples of four-point diagrams are provided below.

The number of parameters labelling the possible four-point diagrams is

\[
2E_r - (4H_r + 4r + r) = 2H_r + r. \tag{26}
\]

As in the three-point case, this reflects the existence of $2H_r + r$ basis virtual diagrams that correspond to the basis vectors in the $(2H_r + r)$-dimensional lattice associated to any given four-point product $\lambda \otimes \mu \otimes \nu \otimes \sigma$. The points in the lattice are the four-point diagrams.

A triangle consisting of zeros alone is called a zero-triangle. It is then obvious that $2H_r$ of the basis virtual diagrams are made up of a basis virtual triangle glued together with a zero-triangle, while the remaining $r$ virtual diagrams are associated to the gluing. We shall denote virtual diagrams of the first kind by $V_{i,j}^{(1)}$ or $V_{i,j}^{(2)}$ (depending on which triangle includes the non-trivial part) and call them extended (basis) virtual triangles, and virtual diagrams of the second kind by $G_i$ and call them “simple gluing roots”. It follows from \eqref{14} that the latter

\footnote{The lower indices $i$ and $j$ refer to any chosen labelling of the $H_r$ hexagons and, thus, of the associated virtual triangles. \eqref{13} is a merely a convenient choice.}
indeed correspond to pairs of simple roots, as illustrated by this \( su(3) \) example (cf. \( (16) \)):

\[
\begin{align*}
G_1 & = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
0 & \bar{1} & \bar{1} & 0 & 0 \\
0 & 1 & \bar{1} & 1 & 0 \\
0 & 0 & \bar{1} & 1 & 0 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix} \\
G_2 & = \begin{bmatrix}
1 & 1 & \bar{1} & 0 & 0 \\
\bar{1} & \bar{1} & \bar{1} & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{align*}
\]

(27)

A natural generalisation of conventional notation allows us to represent graphically the gluing roots as tree-graphs:

\[
G_1 \sim \begin{array}{c}
\alpha_1
\end{array} \quad G_2 \sim \begin{array}{c}
\alpha_2
\end{array}
\]

(28)

These graphs, of course, represent couplings that do not exist (i.e., they have vanishing multiplicities) but nevertheless serve to illustrate the power of virtual diagrams. One may even extend the summation range in \( (23) \) to include them, since the associated algebraic expressions \( (22) \) merely contribute zeros whenever non-true diagrams are encountered.

As in the three-point case, we may now characterise any diagram \( D \) in the lattice by specifying an initial diagram \( D_0 \):

\[
D = D_0 + \sum_{a=1,2} \sum_{i,j \geq 1} v_{i,j}^{(a)} \nu_{i,j}^{(a)} - \sum_{i=1}^r g_i G_i.
\]

(29)

\( v_{i,j}^{(a)} \) and \( g_i \) are integers, denoted linear coefficients. Note that we have chosen a convention with a minus sign in front of the last sum \( (29) \). This reflects the intimate relationship between a simple gluing root and (our convention \( [11] \) for) a basis virtual triangle:

\[
\begin{align*}
\bar{1} & \quad \bar{1} \\
\bar{1} & \quad 1 & \bar{1} & \bar{1} & \bar{1} \\
-\nu & = 1 & 1 \\
\bar{1} & \quad 1 & \bar{1} & \bar{1} & \bar{1} \\
\bar{1} & \quad \bar{1} & \bar{1} & \bar{1} & \bar{1}
\end{align*}
\]

(30)

One may of course choose to substitute the gluing roots with virtual triangles. However, that would introduce redundant parameters that cannot be fixed. This is because such extended
gluing roots have the same number of entries as virtual triangles but fewer constraints. \( su(2) \) offers a simple illustration of that where the single gluing root is substituted by a single hexagon:

![Hexagon Diagram](image-url)

The redundancy occurs since the hexagon identities allow us to fix only a relation between the two extra entries \( e \) and \( e' \). This “uniformisation” makes possible relations between higher-point \( su(N') \) couplings and lower-point \( su(N) \) couplings, when \( N \) is sufficiently larger than \( N' \). The four-point \( su(2) \) diagram above may thus be embedded in a three-point \( su(N \geq 4) \) diagram. We hope to discuss such relations in the future. Here, however, we refrain from replacing the gluing roots.

Now we turn to the construction of a convenient initial diagram \( D_0 \). Referring to (22) we know that

\[
\begin{align*}
\rho &= \lambda^+ + \mu^+ - \sum_{i=1}^{r} n^{(1)}_i \alpha_i, \quad n^{(1)}_i = (\lambda^+)^i + (\mu^+)^i - \rho^i \in \mathbb{Z}_\geq, \\
\rho^+ &= \nu^+ + \sigma^+ - \sum_{i=1}^{r} n^{(2)}_i \alpha_i, \quad n^{(2)}_i = (\nu^+)^i + (\sigma^+)^i - (\rho^+)^i \in \mathbb{Z}_\geq.
\end{align*}
\]

(32)

It follows that

\[
\lambda + \mu + \nu + \sigma = \sum_{i=1}^{r} m_i \alpha_i, \quad m_i \in \mathbb{Z}_\geq,
\]

(33)

ensuring the integer nature of the entries. This invites us to choose

\[
D_0 \sim
\]

as the initial diagram. This \( D_0 \) is easily constructed explicitly as it corresponds to gluing together our original initial triangles \( T_0 \) (17) associated to the couplings \( \lambda \otimes \mu \otimes (\nu + \sigma) \) and \( \nu \otimes \sigma \otimes (\nu + \sigma)^+ \), respectively.
Now, requiring that $D$ in (29) is a true diagram leads to a set of inequalities in the linear coefficients $v$ and $g$. It follows from the structure of the virtual diagrams that this set defines a convex polytope in the euclidean space $\mathbb{R}^{2H_r+r} = \mathbb{R}^{r^2}$. The discretised volume of the polytope is by construction the tensor product multiplicity $T_{\lambda,\mu,\nu,\sigma}$. This characterisation of the four-point tensor product multiplicity is our first main result.

To measure the volume in a straightforward manner, we should organise the inequalities such that a multiple sum expressing the volume may be written down without having to evaluate intersections of polytope faces. This corresponds to choosing an “appropriate” order of summation, as discussed in Ref. [2]. Anticipating the extension to higher tensor products to be discussed below, we propose the following procedure.

Let the left (or lower) triangle in (25) correspond initially to the product $\lambda \otimes \mu \otimes (\nu + \sigma)$ such that the right triangle initially corresponds to the product $\nu \otimes \sigma \otimes (\nu + \sigma)^\dagger$. These couplings are of course altered by the gluing process, adding linear combinations of roots to the third weights. Denoting the linear coefficients of the virtual triangles $v^{(1)}_{i,j}$ and $v^{(2)}_{i,j}$, respectively, we may choose the labelling indicated in the following diagram (cf. (13))

$$\begin{align}
T_{\lambda,\mu,\nu,\sigma} &= \left( \sum_{v^{(1)}_{1,1}} \right) \left( \sum_{v^{(1)}_{2,1}} \sum_{v^{(1)}_{1,2}} \right) \cdots \left( \sum_{v^{(1)}_{r-1,1}} \sum_{v^{(1)}_{1,r-1}} \right) \left( \sum_{g_r} \cdots \sum_{g_1} \right) \\
&\times \left( \sum_{v^{(2)}_{1,r-1}} \right) \cdots \left( \sum_{v^{(2)}_{r-1,1}} \right) \cdots \left( \sum_{v^{(2)}_{1,2}} \sum_{v^{(2)}_{2,1}} \right) \sum_{v^{(2)}_{1,1}} \right) \sum_{v^{(2)}_{2,1}} \right) 1 .
\end{align}$$

(36)

An appropriate order of summation is then obtained by starting with the right-most variable, $v^{(2)}_{1,1}$, and moving systematically towards left:

$$\max \{0, -\sigma_2 + v^{(2)}_{1,2}, v^{(2)}_{1,2} - v^{(2)}_{2,2} + v^{(2)}_{2,1}, -\nu_{r-1} + v^{(2)}_{2,1}\} \leq v^{(2)}_{1,1} \leq \min \{\sigma_1, v^{(2)}_{1,2}, \nu_r - v^{(2)}_{1,2} + v^{(2)}_{2,1}, \sigma_1 + v^{(2)}_{1,2} - v^{(2)}_{2,1}, v^{(2)}_{2,1}, \nu_r\} ,$$

9
\[
\begin{align*}
\text{max}\{ & -\sigma_2 + v_{i-1,2}^{(2)} - v_{i-1,3}^{(2)} + v_{i,2}^{(2)} , \\
& v_{i,2}^{(2)} - (1 - \delta_{i,r-2})v_{i+1,2}^{(2)} - \delta_{i,r-2}g_2 + v_{i+1,1}^{(2)}, -v_{i+1} + v_{i,1}^{(2)} \} \\
\leq v_{i,1}^{(2)} \leq \min\{ & \nu_{i-1,i+1} + v_{i-1,2}^{(2)} - v_{i-1,1}^{(2)} + v_{i,1}^{(2)}, \\
& \sigma_1 + v_{i,2}^{(2)} - v_{i+1,1}^{(2)}, v_{i+1,1}^{(2)} \}, \quad \text{for } 2 \leq i \leq r - 2 , \\
\text{max}\{ & v_{i+1,j}^{(2)} + v_{i,j+1}^{(2)} - (1 - \delta_{i,j,r-1})v_{i+1,j+1}^{(2)} - \delta_{i,j,r-1}g_{j+1}, \\
& -\sigma_{j+1} + v_{i-1,j+1}^{(2)} - v_{i-1,j+2}^{(2)} + v_{i,j+1}^{(2)} \} \\
\leq v_{i,j}^{(2)} \leq \nu_{i-1,j+1} + v_{i-1,j+1}^{(2)} - v_{i,j+1}^{(2)} , \quad \text{for } 2 \leq i, j, i + j \leq r - 1 , \\
\text{max}\{ & -\sigma_{j+1} + v_{i,j+1}^{(2)}, v_{i,j+1}^{(2)} + v_{i,j+1}^{(2)} - (1 - \delta_{j,r-2})v_{j+1,j+1}^{(2)} - \delta_{j,r-2}g_{r-1} \} \\
\leq v_{i,j}^{(2)} \leq \min\{ & v_{i,j+1}^{(2)}, \nu_r - v_{i,j+1}^{(2)} + v_{i,j+1}^{(2)} \}, \quad \text{for } 2 \leq j \leq r - 2 , \\
\text{max}\{ & -\nu_1 + g_1, -\sigma_2 + v_{r-2,2}^{(2)} + g_2 - g_3 \} \\
\leq v_{r-1,1}^{(2)} \leq \min\{ & \sigma_1 - g_1 + g_2, \nu_2 + v_{r-2,2}^{(2)} + g_1 - g_2, g_1 \} , \\
-\sigma_{l+1} + v_{r-l,l+1}^{(2)} + g_{l+1} - g_{l+2} \\
\leq v_{r-l,l}^{(2)} \leq \nu_{r-l+1} - v_{r-l+1,l+1}^{(2)} + g_l - g_{l+1} , \quad \text{for } 2 \leq l \leq r - 2 , \\
-\sigma_r + g_r \leq v_{r-1}^{(2)} \leq \min\{ & g_r, \nu_r + g_{r-1} - g_r \} , \\
\text{max}\{ & -n_1 + v_{i,r-1}^{(1)}, -N_2 + v_{i-1}^{(1)} - v_{i-2}^{(2)} + g_2 \} \\
\leq g_1 \leq \min\{ & N_1 + v_{i-1}^{(1)}, N_1' - v_{i-1}^{(1)} + g_2 \} , \\
\text{max}\{ & -n_i + v_{i-1,i-r+1}^{(1)}, v_{i,r-i}^{(1)} - v_{i-1,i-r-i}^{(1)}, -N_i + v_{i,r-i}^{(1)} - (1 - \delta_{i,r-1})v_{i+1,i-r-i}^{(1)} + g_{i+1} \} \\
\leq g_i \leq N_i' + v_{i-1,i-r-1}^{(1)} - v_{i-1,i-r+i}^{(1)} + g_{i+1} \} , \quad \text{for } 2 \leq i \leq r - 1 , \\
n_r + v_{r-1}^{(1)} \leq g_r \leq N_r' + v_{r-1}^{(1)} , \\
\text{max}\{ & v_{1,j-1}^{(1)}, -\mu_{j-1} + v_{1,j-1}^{(1)} + v_{2,j-1}^{(1)} - (1 - \delta_{j,2})v_{2,j-2}^{(1)} \} \\
\leq v_{1,j}^{(1)} \leq \min\{ & \mu_j + v_{1,j-1}^{(1)}, \lambda_r - v_{1,j-1}^{(1)} + v_{2,j-1}^{(1)} \}, \quad \text{for } 2 \leq j \leq r - 1 , \\
\text{max}\{ & v_{i,j-1}^{(1)} + v_{i-1,j}^{(1)} - v_{i-1,j-1}^{(1)}, -\mu_{i,j-1} + v_{i,j-1}^{(1)} + v_{i,j-1}^{(1)} - (1 - \delta_{j,2})v_{i+1,j-2}^{(1)} \} \\
\leq v_{i,j}^{(1)} \leq \lambda_r - v_{i,j-1}^{(1)} - v_{i,j-1}^{(1)} + v_{i,j-1}^{(1)} , \quad \text{for } 2 \leq i, j, i + j \leq r , \\
v_{i-1,1}^{(1)} \leq v_{i,1}^{(1)} \leq \lambda_{r-i+1} + v_{i-1,1}^{(1)} , \quad \text{for } 2 \leq i \leq r - 1 , \\
0 \leq v_{1,1}^{(1)} \leq \min\{ & \mu_1, \lambda_r \} ,
\end{align*}
\]

where the parameters \( n_i, N_i \) and \( N_i' \) are defined as in (18), with \( \nu \) replaced by \( \nu + \sigma \):

\[
\begin{align*}
n_i &= \lambda^{r-i+1} + \mu^{r-i+1} - (\nu + \sigma)^i , \\
N_i &= (1 - \delta_{i})n_{i-1} - n_i + \mu_{r-i+1} \\
&= -\lambda^{r-i+1} + (1 - \delta_{i})\lambda^{r-i+2} - (1 - \delta_{ir})\mu^{r-i} + \mu^{r-i+1} - (1 - \delta_{i})((\nu + \sigma)^{i-1} + (\nu + \sigma)^i) , \\
N_i' &= (\nu + \sigma)_i - N_i \\
&= \lambda^{r-i+1} - (1 - \delta_{i})\lambda^{r-i+2} + (1 - \delta_{ir})\mu^{r-i} - \mu^{r-i+1} + (\nu + \sigma)^i - (1 - \delta_{ir})(\nu + \sigma)^{i+1} \quad (38)
\end{align*}
\]
This multiple sum formula is our second main result. For $su(2)$, $su(3)$ and $su(4)$ the explicit multiple sum formulas are provided in Section 5.

4 Higher point couplings

We shall now indicate how one may extend our results on four-point couplings to any higher $\mathcal{N}$-point coupling, in straightforward fashion.

It is well-known that higher-point couplings may be decomposed into three-point couplings along the lines of (22). The various tree-graph channels all have diagram counterparts as illustrated by the following two examples:

\begin{equation}
\begin{array}{c}
\begin{array}{c}
\includegraphics[width=0.3\textwidth]{example1}
\end{array}
\end{array}
\end{equation}

and

\begin{equation}
\begin{array}{c}
\begin{array}{c}
\includegraphics[width=0.3\textwidth]{example2}
\end{array}
\end{array}
\end{equation}

Since we may choose the channel freely, we can avoid complicated configurations like the “rocket” of (40) and concentrate on the “string-like” ones, like (39) and the following nine-point coupling:

\begin{equation}
\begin{array}{c}
\begin{array}{c}
\includegraphics[width=0.3\textwidth]{example3}
\end{array}
\end{array}
\end{equation}
Thus, an $N$-point coupling may conveniently be represented by an $N$-point diagram consisting of $N-2$ triangles glued together along $N-3$ pairs of faces to form a string-like configuration. An $N$-point diagram is therefore a geometrical arrangement of $(N - 2)E_r$ (non-)negative integers subject to $2(N - 2)H_r$, hexagon identities, $N r$ outer constraints, and $(N-3)r$ gluing constraints. (This is also true for the more complicated diagrams, such as (40)). This leaves

$$(N - 2)E_r - ((N - 2)H_r + N r + (N - 3)r) = (N - 2)H_r + (N - 3)r$$

parameters labelling the possible diagrams. As it should be, this is equal to the total number of virtual triangles and simple gluing roots.

Thus, from the point of view of the $N$-point diagram, we have two types of virtual diagrams: extended (basis) virtual triangles $V$, and simple gluing roots $G$, exactly as for four-point couplings.

The extension of (29) is therefore obvious:

$$D = D_0 + \sum_{a=1}^{N-2} \sum_{i,j \geq 1} v_{i,j}^{(a)} V_{i,j}^{(a)} - \sum_{a=1}^{N-3} \sum_{i=1}^{r} g_{i}^{(a)} G_{i}^{(a)} .$$

The initial diagram $D_0$ is likewise easy to describe, as it may be constructed by gluing $N - 2$ initial triangles together. Labelling the $N$ weights according to (in this example $N$ is assumed odd)

$$\lambda^{((N-1)/2)} \otimes \lambda^{((N+3)/2)} \otimes (\lambda^{((N+1)/2)} + \lambda^{((N+3)/2)})^+, \quad (\lambda^{((N+1)/2)} + \lambda^{((N+3)/2)}) \otimes \lambda^{((N+5)/2)} \otimes (\lambda^{((N+1)/2)} + \lambda^{((N+3)/2)} + \lambda^{((N+5)/2)})^+, \quad \vdots \quad (\lambda^{(3)} + \ldots + \lambda^{(N-1)}) \otimes \lambda^{(N)} \otimes (\lambda^{(3)} + \ldots + \lambda^{(N)})^+, \quad \lambda^{(1)} \otimes \lambda^{(2)} \otimes (\lambda^{(3)} + \ldots + \lambda^{(N)}) .$$

The weights are subject to the consistency condition (cf. (43))

$$\lambda^{(1)} + \ldots + \lambda^{(N)} = \sum_{i=1}^{r} m_i \alpha_i , \quad m_i \in \mathbb{Z}. $$

The characterisation of the associated tensor product multiplicity in terms of a convex polytope, is materialised by requiring that the diagram should be a true diagram, i.e., all
entries must be non-negative integers. As before, its discretised volume is the multiplicity by construction. That volume can be expressed explicitly as a multiple sum. An appropriate order of summation is indicated here:

\[
T_{\lambda(1),\lambda(2),\ldots,\lambda(N)} = \{ \sum_{v(1)} \} \{ \sum_{g(1)} \} \ldots \{ \sum_{v(N-3)} \} \{ \sum_{g(N-3)} \} \{ \sum_{v(N-2)} \} 1 .
\] (47)

This generalisation of our main results on three- and four-point couplings, concludes the extension to general higher-point couplings.

5 Examples and an application

It is of interest to know whether or not an \( N \)-point coupling \( \lambda \otimes \mu \otimes \cdots \otimes \sigma \) exists, without having to work out the tensor product multiplicity. Based on our multiple sum formulas (36) and (47), one may derive a set of inequalities in the dual and ordinary Dynkin labels of the \( N \) weights, determining when the associated tensor product multiplicity is non-vanishing. The method is an immediate extension of the one employed in Ref. [2] when discussing three-point couplings (19). We work out the inequalities for \( su(2) \) and \( su(3) \) four-point couplings. In principle, it is possible to repeat the procedure for higher rank and higher \( N \) than four, though it rapidly becomes cumbersome.

To the best of our knowledge, similar results only exist for three-point products where, besides our work [4], the works [3, 4] provide recent results and extensive lists of references. For \( su(2) \) the BZ triangle representing the product \( \lambda \otimes \mu \otimes \nu \) is unique \( (H_1 = 0) \):

\[
\frac{1}{2}(\lambda_1 - \mu_1 + \nu_1)
\]

\[
\frac{1}{2}(\lambda_1 + \mu_1 - \nu_1) \quad \frac{1}{2}(-\lambda_1 + \mu_1 + \nu_1)
\]

(48)

Nevertheless, gluing two triangles together leaves one free parameter \( g \). We have

\[
\mathcal{D} = \mathcal{D}_0 - g\mathcal{G}
\] (49)

where

\[
\sigma_1 \\
\vdots \\
\sigma_1
\]

\[
\mathcal{D}_0 = \begin{bmatrix}
\frac{1}{2}(\lambda_1 - \mu_1 + \nu_1 + \sigma_1) \\
\frac{1}{2}(\lambda_1 + \mu_1 - \nu_1 - \sigma_1) \\
\vdots \\
\frac{1}{2}(\lambda_1 + \mu_1 - \nu_1 - \sigma_1)
\end{bmatrix}
\]

(50)
and

\[
G = \begin{pmatrix}
\ddots & 1 & \ddots & \ddots \\
1 & \ddots & 1 & \ddots \\
\ddots & 1 & \ddots & \ddots
\end{pmatrix}
\]

\[(51)\]

Requiring \(D\) to be a true diagram results in a set of inequalities defining a one-dimensional convex polytope - a line segment. Its discretised volume (or length) is the sought multiplicity:

\[
T_{\lambda,\mu,\nu,\sigma} = \min_{g=\max\{0, S-\lambda-\mu\}} \{S, -\lambda, -\mu, \nu, \sigma\} \in \mathbb{Z}_+.
\]

\[(52)\]

The summation, and thus the multiplicity, is non-vanishing if and only if the upper bound is greater than or equal to the lower bound. This requirement defines a four-dimensional cone:

\[
0 \leq \lambda, \mu, \nu, \sigma, S-\lambda, S-\mu, S-\nu, S-\sigma.
\]

\[(53)\]

It is easily verified that (52) and (53) are in accordance with well-known results.

For \(su(3)\) the four-point coupling may be characterised by a convex polytope in a four-dimensional euclidean space. Its discretised volume is the tensor product multiplicity which we find may be expressed as the following multiple sum:

\[
T_{\lambda,\mu,\nu,\sigma} = \min\{\lambda_2, \mu_1\} \sum_{v(1)=0}^{N_2+\nu(1)} \sum_{g_2=-n_2+\nu(1)}^{g_1=\max\{-N_2+\nu(1)+g_2, -n_1+\nu(1)\}} \sum_{\nu_1=\min\{\nu_1, \sigma_1, g_1, g_2, \nu_1+g_1-g_2, \sigma_1-g_1+g_2\}}^{\nu(1)+g_1} 1,
\]

\[(54)\]

where the weights are subject to

\[
S_i = \lambda^i + \mu^i + \nu^i + \sigma^i \in \mathbb{Z}_+, \quad i = 1, 2
\]

\[(55)\]

and where

\[
n_1 = \lambda^2 + \mu^2 - \nu^1 - \sigma^1,
n_2 = \lambda^1 + \mu^1 - \nu^2 - \sigma^2,
N_1 = -\lambda^2 - \mu^1 + \nu^1 + \sigma^1,
N_2 = -\lambda^1 - \mu^2 + \nu^1 + \nu^2 - \sigma^1 + \sigma^2,
N_1' = \lambda^2 + \mu^1 - \mu^2 + \nu^1 - \nu^2 + \sigma^1 - \sigma^2,
N_2' = \lambda^1 - \lambda^2 - \mu^1 + \nu^2 + \sigma^2.
\]

\[(56)\]

This explicit result is believed to be new.
Analysing when the tensor product multiplicity is non-vanishing, leads to the following definition of a cone in the eight-dimensional Dynkin label space:

\[
0 \leq \lambda_i, \mu_i, \nu_i, \sigma_i , \quad i = 1, 2 \\
0 \leq S_i - \lambda_1 - \lambda_2, S_i - \mu_1 - \mu_2, S_i - \nu_1 - \nu_2, S_i - \sigma_1 - \sigma_2 , \quad i = 1, 2 \\
0 \leq S_i - \lambda_i - \mu_i, S_i - \lambda_i - \nu_i, S_i - \lambda_i - \sigma_i , \
S_i - \mu_i - \nu_i, S_i - \mu_i - \sigma_i, S_i - \nu_i - \sigma_i , \quad i = 1, 2 
\]

(57)

This explicit characterisation is also believed to be new. It is verified immediately that for one weight equal to zero, (57) reduces to the result for the three-point product discussed in Ref. 2, i.e., \( T_{\lambda,\mu,\nu} > 0 \) if and only if \( T_{\lambda,\mu,\nu} > 0 \).

For ease of use of the formula (34) expressing the tensor product multiplicity \( T_{\lambda,\mu,\nu,\sigma} \) as a multiple sum, we conclude this section by writing down explicitly the result for \( su(4) \):

\[
T_{\lambda,\mu,\nu,\sigma} = \min\{\lambda_1, \mu_1\} \sum_{v_1,1=0}^{\lambda_2+v_1^{(1)}} \sum_{v_2,1=v_1,1}^{\lambda_3+v_2^{(1)}-v_1^{(1)}} \sum_{v_3,1}^{\mu_2+v_3^{(1)}-v_2^{(1)}} \sum_{v_4,1}^{N_1+v_4^{(1)}-v_3^{(1)}} \\
\times \left( \sum_{v_5,2,1=-v_1^{(1)}} g_2=v_2^{(1)} \sum_{v_6,2,1}^{N_2+g_2-v_1^{(1)}-v_2^{(1)}} \right) \min\{N_1^{(1)}+v_2^{(1)}-v_1^{(1)}-v_2^{(1)}, N_1^{(1)}+v_2^{(1)}\} \\
\times \sum_{v_7,2,1}^{\sigma_1-g_1+g_2-g_3, g_3} \sum_{v_8,2,1}^{\nu_1+g_2-g_3, g_3} \sum_{v_9,2,1}^{\nu_2+g_1-g_2, g_1} \sum_{v_10,2,1}^{\nu_3+g_1-g_2-g_3, g_3} \sum_{v_11,2,1}^{\nu_4+g_1-g_2-g_3, g_3} \\
\times \sum_{v_12,2,1}^{\nu_5+g_1-g_2-g_3, g_3} \sum_{v_13,2,1}^{\nu_6+g_1-g_2-g_3, g_3} \sum_{v_14,2,1}^{\nu_7+g_1-g_2-g_3, g_3} \sum_{v_15,2,1}^{\nu_8+g_1-g_2-g_3, g_3} \\
\times 1 . 
\]

(58)

The parameters \( n_i, N_i \) and \( N_i^{(1)} \) are defined in (58), while the weights are subject to the condition

\[
\lambda^i + \mu^i + \nu^i + \sigma^i \in \mathbb{Z}_{\geq} , \quad i = 1, 2, 3 . 
\]

(59)

6 Conclusion

We have generalised our recent work on three-point products [2] to cover general \( N \)-point products. That is, we have characterised the associated higher tensor product multiplicities by certain convex polytopes, and measured explicitly their discretised volumes. The latter are the multiplicities and are expressed as multiple sums.

The characterisation of the multiplicity as the number of integer points in a convex polytope is an example of a polyhedral combinatorial expression. Alternative polyhedral combinatorial expressions for three-point products (including other simple Lie algebras as well) may be found in [3, 7]. To the best of our knowledge, our result for higher-point products is the first of its kind.
As an application we have also addressed the problem of determining when a tensor product multiplicity is non-vanishing, and as an illustration of the general resolution provided explicit characterisations for $su(2)$ and $su(3)$. The result for $su(3)$ is believed to be new.

We are currently extending our work (presented here and in Ref. [2]) on tensor product multiplicities to fusion multiplicities. The latter are relevant to the representation theory of affine extensions of the Lie algebra, the so-called affine Kac-Moody algebras. They have found prominent applications to conformal field theory with affine Lie group symmetry, the so-called WZW theories. Since tensor product multiplicities correspond to the infinite-level limit of fusion multiplicities, our current efforts are concentrated on incorporating the finite-level dependence into the characterisation of the multiplicities in terms of convex polytopes and their discretised volumes. That again relies on our recent studies of three-point correlation functions in WZW theory [6, 8]. We intend to report more on this in the future.

Related in spirit to our approach is the recent work Ref. [9] on fusion rules in $SU(N)$ WZW theory. For lower ranks the authors discuss a combinatorial relation between three-point fusion multiplicities and numbers of certain group theoretical orbits. It would be interesting to understand how the results of Ref. [9] are related to ours.
