A class of generalized graph groups defined by balanced presentations

Johannes Cuno and Gerald Williams*

June 28, 2018

Abstract

We consider groups defined by non-empty balanced presentations with the property that each relator is of the form $R(x, y)$, where $x$ and $y$ are distinct generators and $R(\cdot, \cdot)$ is determined by some fixed cyclically reduced word $R(a, b)$ that involves both $a$ and $b$. To every such presentation we associate a directed graph whose vertices correspond to the generators and whose arcs correspond to the relators. Under the hypothesis that the girth of the underlying undirected graph is at least 4, we show that the resulting groups are non-trivial and cannot be finite of rank 3 or higher. Without the hypothesis on the girth it is well known that both the trivial group and finite groups of rank 3 can arise.

MSC2010 classes: 20F05 (Primary), 20E99 (Secondary).

1 Introduction

The groups considered in the present paper fit into the following general framework: they are defined by finite presentations with the property that each relator is of the form $R(x, y)$, where $x$ and $y$ are distinct generators and $R(\cdot, \cdot)$ is determined by some fixed cyclically reduced word $R(a, b)$ that involves both $a$ and $b$. Prominent examples of these groups are right-angled Artin groups (also known as graph groups or partially commutative groups), which arise when $R(a, b) = a^{-1}b^{-1}ab$.

Each of the above groups can be expressed in terms of a finite digraph $\Lambda$ with vertex set $V(\Lambda)$ and (directed) arc set $A(\Lambda)$. We use the convention that the arc set is an irreflexive relation on the vertex set so neither admit multiple arcs nor loops. The vertices $v \in V(\Lambda)$ correspond to the generators $x_v$ and the arcs $(u, v) \in A(\Lambda)$ correspond to the relators $R(x_u, x_v)$ so that the group $G_\Lambda(R)$ is defined by the presentation

$$P_\Lambda(R) = \langle x_v \ (v \in V(\Lambda)) \mid R(x_u, x_v) \ ((u, v) \in A(\Lambda)) \rangle.$$

Our class of groups can therefore be thought of as a class of generalized graph groups. In the case where $\Lambda$ is a directed $n$-cycle, i.e. $V(\Lambda) = \{1, 2, \ldots, n\}$ and $A(\Lambda) = \{(1, 2), (2, 3), \ldots, (n, 1)\}$, the corresponding presentation

$$P_\Lambda(R) = \langle x_1, \ldots, x_n \mid R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1) \rangle$$

is an example of a cyclic presentation (see, e.g., [13] Chapter III, §9). Cyclic presentations are special cases of balanced presentations, which are presentations with an equal number of generators and relators. Since presentations with more generators than relators necessarily define infinite groups, which can be seen by abelianizing the groups, balanced presentations represent a borderline situation where the...
corresponding groups can be finite or infinite. In our setting $P_\Lambda(R)$ is balanced precisely when $\Lambda$ has an equal number of vertices and arcs. This is the case that we shall focus on in the present work.

The rank of a group $G$, denoted by rank($G$), is the cardinality of a smallest generating set for $G$. It is not known if there exists a balanced presentation defining a finite group of rank 4 or larger (see, e.g., [9 Problem 1]) though it is known that rank 3 can be attained (see, e.g., [13, Chapter III, §8]).

It is a consequence of the Golod–Shafarevich theorem [8] that whenever a balanced presentation defines a finite nilpotent group, the latter has rank at most 3. Further, by [15 Theorem 9 (ii)], whenever a balanced presentation defines a finite group, be it nilpotent or not, the abelianization of that group must also have rank at most 3. Details can be found in [13 §3–4] and in the references therein. Let us finally record that a group has rank 0 if and only if it is the trivial group; balanced presentations of the trivial group are sought in connection with the Andrews–Curtis conjecture [2].

Both balanced presentations of finite groups of rank 3 and non-empty balanced presentations of the trivial group can be found within our class of presentations $P_\Lambda(R)$. For example, if $\Lambda$ is the directed 3-cycle and $R(a, b) = a^{-1}bab^{-n}$, we obtain Mennicke’s groups

$$M(q, q, q) = \langle x_1, x_2, x_3 \mid x_1^{-1}x_2x_1 = x_2^{-1}x_3x_2 = x_3^{-1}x_1x_3 = x_1^q \rangle,$$

which are studied in [17] and appear as $G(1, q; 1, q; 1, q)$ in [1]. For all $q \geq 3$ these groups are finite of rank 3 [17] and for $q = 2$ they are trivial [10]. If we modify this example and take the directed 2-cycle instead of the directed 3-cycle, the resulting groups will have similar properties: for all $q \geq 3$ they are finite of rank 2 and for $q = 2$ they are trivial. The essential part of the proof can be found in [4]. On the other hand, if we take a directed $n$-cycle ($n \geq 4$) and an arbitrary non-zero integer $q$, the resulting groups will always be infinite. This follows, for example, from a general curvature argument due to Pride, see Corollary 2.1. Note that for the directed 4-cycle and $q = 2$ the resulting group is Higman’s group [1].

A different example arises when $\Lambda$ is the directed 3-cycle and $R(a, b) = b^{-1}ab(ab^{-2}a^{-1}b^2+1)^{-1}$, where we obtain the groups

$$J(q, q, q) = \left\langle x_1, x_2, x_3 \mid \begin{array}{c}
x_1^{-1}x_2x_1 = x_2^{-1}x_3x_2 = x_3^{-1}x_1x_3 = x_1^q \\
x_1^{-1}x_2x_3 = x_2^{-1}x_3x_2 = x_3^{-1}x_1x_3 = x_1^q \\
x_1^{-1}x_3x_1 = x_2^{-1}x_3x_2 = x_3^{-1}x_1x_3 = x_1^q \end{array} \right\rangle,$$

considered in [12] and [13 page 70], which for all even $q \geq 2$ are finite of rank 3.

Pride showed in [15] that if $\Lambda$ is a directed $n$-cycle ($n \geq 4$) and $R(a, b)$ is a cyclically reduced word that involves both $a$ and $b$, then the resulting group $G_\Lambda(R)$ can never be finite of rank 3 or trivial. The precise statement is given in Theorem 1.1 below. The following notational convention, partially introduced by Pride, will be used throughout this paper.

**Notational convention.** Given a cyclically reduced word $R(a, b)$ that involves both $a$ and $b$, we use $\alpha$ and $-\beta$ to denote the exponent sums of $a$ and $b$ in $R(a, b)$, respectively, and $K$ to denote the group defined by the presentation $\langle a, b \mid R(a, b) \rangle$. Up to cyclic permutation the word $R(a, b)$ is of the form $a^{\alpha_1}b^{\beta_1} \cdots a^{\alpha_t}b^{\beta_t}$ with $t \geq 1$ and $\alpha_i, \beta_i \in \mathbb{Z} \setminus \{0\}$ $(1 \leq i \leq t)$. We use $\delta_a$ and $\delta_b$ to denote the greatest common divisors $(\alpha_1, \ldots, \alpha_t)$ and $(\beta_1, \ldots, \beta_t)$, respectively.

**Theorem 1.1** ([15 Theorem 3]). Let $\Lambda$ be a directed $n$-cycle ($n \geq 4$) and let $R(a, b)$ be a cyclically reduced word that involves both $a$ and $b$. Then $G_\Lambda(R)$ is finite if and only if $\alpha \neq 0$, $\beta \neq 0$, $(\alpha, \beta) = 1$, $\alpha^n - \beta^n \neq 0$, $a^a = b^b$ in $K$, in which case $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$. In particular, if $G_\Lambda(R)$ is finite, then rank($G_\Lambda(R)$) = 1.

The purpose of the present work is to generalize Theorem 1.1 from cyclic presentations to balanced presentations, i.e. to the case where the digraph $\Lambda$ has an equal number of vertices and arcs. As shown by the examples, above, if the underlying undirected graph of $\Lambda$, i.e. the undirected graph obtained from
Λ by replacing each directed edge by an undirected edge, contains a cycle of length 2 or 3, the conclusion that $G_\Lambda(R)$ is neither finite of rank 3 nor trivial cannot always be obtained. We therefore impose the hypothesis that the girth of the underlying undirected graph of Λ is at least 4. Corollary B then provides the aspired generalization of Theorem 1.1. This is a corollary to our main theorem, Theorem A, which gives tight conditions that must be satisfied if $G_\Lambda(R)$ is a finite group.

Before stating it we introduce some terminology for digraphs. By a weakly connected digraph we mean a digraph whose underlying undirected graph is connected. Vertices with positive outdegree and indegree zero are called sources, vertices with positive indegree and outdegree zero are called sinks, and vertices whose indegree and outdegree sum to one are called leaves. In particular, every leaf must be either a source or a sink. In some cases we will recursively prune all source leaves. This means that we remove the source leaves from the vertex set $V(\Lambda)$ and the arcs that are incident with these source leaves from the arc set $A(\Lambda)$. Afterwards, we consider the resulting digraph and repeat the previous step until we eventually arrive at a digraph $\Lambda_s$ without any source leaves. Because the initial digraph Λ is finite, this procedure is guaranteed to end. In the same way, recursively pruning all sink leaves yields a digraph $\Lambda_t$ without any sink leaves. To state our results we will need to refer to certain classes of digraphs. These are defined in Figure 1, below.

**Figure 1:** Classes of digraphs referred to in the statement of Theorem A.
Theorem A. Let $\Lambda$ be a non-empty finite digraph with an equal number of vertices and arcs whose underlying undirected graph has girth $n$ ($n \geq 4$) and let $R(a,b)$ be a cyclically reduced word that involves both $a$ and $b$ with exponent sums $\alpha$ and $-\beta$ in $a$ and $b$, respectively. If $G_\Lambda(R)$ is finite, then $\alpha \neq 0$, $\beta \neq 0$, $(\alpha, \beta) = 1$, $\alpha^n - \beta^n \neq 0$, $a^\alpha = b^\beta$ in $K = \langle a, b \mid R(a,b) \rangle$, $G_\Lambda(R)$ is non-trivial, and one of the following holds:

1. $|\alpha| \geq 2$, $|\beta| \geq 2$, and in which case:

   (a) $\Lambda = \Lambda(n)$ .................................................. $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$,
   (b) $\Lambda = \Lambda(n; \frac{m}{d})$ $(m \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$,
   (c) $\Lambda = \Lambda(n; \frac{m}{e})$ $(m \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n(\alpha^n - \beta^n)|}$,
   (d) $\Lambda = \Lambda(n, 1), \delta_a = \delta_b = 1$ .......................... $G_\Lambda(R) \cong K/\langle \langle a^{\alpha(n-2) - \beta(n-2)} \rangle \rangle_K$,
                  $G_\Lambda(R)^{ab} \cong \mathbb{Z}_{|\alpha\beta(\alpha^n - \beta^n)|}$,
   (e) $\Lambda = \Lambda(n; \frac{m}{d}, \frac{1}{t})$ $(m \geq 1), \delta_a = \delta_b = 1$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$,
   (f) $\Lambda = \Lambda(n; \frac{m}{d}, \frac{1}{t})$ $(m \geq 1), \delta_a = \delta_b = 1$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n(\alpha^n - \beta^n)|}$.

2. $|\alpha| = 1$, $|\beta| \geq 2$, and after recursively pruning all source leaves the digraph $\Lambda$ becomes in which case:

   (a) $\Lambda_s = \Lambda(n)$ .................................................. $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$,
   (b) $\Lambda_s = \Lambda(n; \frac{m}{d})$ $(m \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$,
   (c) $\Lambda_s = \Lambda(n, d) (\frac{n}{d} > d \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha\beta^m(\alpha^n - \beta^n)|}$,
   (d) $\Lambda_s = \Lambda(n, d; \frac{m}{t}) (\frac{n}{d} > d \geq 1, m \geq 1)$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha\beta^m(\alpha^n - \beta^n)|}$,
   (e) $\Lambda_s = \Lambda(n; \frac{m}{d}, \frac{t}{e}) (m \geq 1, \ell \geq 1)$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$.

3. $|\alpha| \geq 2$, $|\beta| = 1$, and after recursively pruning all sink leaves the digraph $\Lambda$ becomes in which case:

   (a) $\Lambda_t = \Lambda(n)$ .................................................. $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$,
   (b) $\Lambda_t = \Lambda(n; \frac{m}{d})$ $(m \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n(\alpha^n - \beta^n)|}$,
   (c) $\Lambda_t = \Lambda(n, d) (\frac{n}{d} > d \geq 1)$ .......................... $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha\beta^m(\alpha^n - \beta^n)|}$,
   (d) $\Lambda_t = \Lambda(n, d; \frac{m}{t}) (\frac{n}{d} > d \geq 1, m \geq 1)$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha\beta^m(\alpha^n - \beta^n)|}$,
   (e) $\Lambda_t = \Lambda(n; \frac{m}{d}, \frac{t}{e}) (m \geq 1, \ell \geq 1)$ ........................ $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$.

4. $|\alpha| = |\beta| = 1$, in which case $G_\Lambda(R) \cong \mathbb{Z}_2$.

Remark 1.2. Using our terminology, Theorem A is a statement about the digraphs $\Lambda(n)$ ($n \geq 4$) and thus follows from Cases (1a), (2a), (3a), (4) of Theorem A. Note that in Case (4) the numerical restrictions imply that $|\alpha^n - \beta^n| = 2$, whence we also obtain that $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$.

Theorem A has the following immediate corollary.

Corollary B. With the notation of Theorem A if $G_\Lambda(R)$ is finite, then $\text{rank}(G_\Lambda(R)) \in \{1, 2\}$.

There exist infinitely many examples of relators $R(a,b)$ that satisfy the conditions of Cases (1d)–(1f) of Theorem A for example $R(a,b) = (ab)^q b$ $(q \geq 2)$. However, all examples that we are aware of yield abelian groups $K$, and hence $G_\Lambda(R)$ is a finite cyclic group. For this reason, we have been unable to construct any example where we cannot determine finiteness, or otherwise, of $G_\Lambda(R)$. We therefore pose:
Question 1.3. Does there exist a word \( R(a,b) = a^{\alpha_1}b^{\beta_1} \cdots a^{\alpha_t}b^{\beta_t} \) with \( t \geq 1, \alpha_i, \beta_i \in \mathbb{Z} \setminus \{0\} \) (\( 1 \leq i \leq t \)), \( \alpha = \sum_{i=1}^t \alpha_i, \beta = -\sum_{i=1}^t \beta_i, |\alpha| \geq 2, |\beta| \geq 2, (\alpha, \beta) = 1, \delta_a = (\alpha_1, \ldots, \alpha_t) = 1, \delta_b = (\beta_1, \ldots, \beta_t) = 1 \), such that \( a^\alpha = b^\beta \) in \( K = \langle a,b \mid R(a,b) \rangle \) and \( K \) is not abelian?

If Question [13] has a negative answer, then Theorem [14] provides the following nice dichotomy directly generalizing Theorem [11]. If \( \Lambda \) is a non-empty finite digraph with an equal number of vertices and arcs whose underlying undirected graph has girth at least 4 and \( R(a,b) \) is a cyclically reduced word that involves both \( a \) and \( b \), then \([16]\), the element \( w \) of the form \( a^k b^{-\ell} \) in \( K \) is equal to the identity in that group. In fact, not just Property [18], page 248], Proposition 2.2 is infinite. Hence, \( a^\alpha b^{-\ell} = 1 \) and \( b^{\ell} = 1 \) in \( K \).

Therefore, \( K \) does not have Property \( W_1 \) if and only if \( \alpha \neq 0, \beta \neq 0 \), and \( a^\alpha = b^\beta \) in \( K \). Note that the condition \( a^\alpha = b^\beta \) in \( K \) is decidable since the word problem is solvable for one-relator groups.

Excursion 1. Property \( W_1 \) is further related to one-relator groups whose Magnus subgroups have exceptional intersection; such groups are studied in [5], [6], [11], [7]. More precisely, the Magnus subgroups \( \langle a \rangle \) and \( \langle b \rangle \) of \( K \) are said to have exceptional intersection if \( \langle a \rangle \cap \langle b \rangle \cong \mathbb{Z} \) (see, e.g., [5]). The following characterization of two-generator one-relator groups whose Magnus subgroups have exceptional intersection, and the connection with Property \( W_1 \), does not seem to have been recorded explicitly before.

Lemma 2.3. The Magnus subgroups \( \langle a \rangle \) and \( \langle b \rangle \) of \( K \) have exceptional intersection if and only if \( \alpha \neq 0, \beta \neq 0 \), and \( a^\alpha = b^\beta \) in \( K \).

Proof. If \( \alpha \neq 0, \beta \neq 0 \), and \( a^\alpha = b^\beta \) in \( K \), then \( \mathbb{Z} \cong \langle a^\alpha \rangle = \langle b^\beta \rangle \leq \langle a \rangle \cap \langle b \rangle \leq \langle a \rangle \cong \mathbb{Z} \), so \( \langle a \rangle \cap \langle b \rangle \cong \mathbb{Z} \). Conversely, if \( \langle a \rangle \cap \langle b \rangle \cong \mathbb{Z} \), then an arbitrary non-trivial element of this intersection is of the form \( a^k \) for some \( k \in \mathbb{Z} \setminus \{0\} \) and simultaneously of the form \( b^\ell \) for some \( \ell \in \mathbb{Z} \setminus \{0\} \). So \( a^k = b^\ell \) in \( K \) and, by Proposition 2.2, we have that \( \alpha \neq 0, \beta \neq 0 \), and \( a^\alpha = b^\beta \) in \( K \).

Question [13] therefore concerns groups \( K \) where \( \langle a \rangle \) and \( \langle b \rangle \) have exceptional intersection.
3 Proving Theorem [A]

3.1 Strategy

Before giving the actual proof of Theorem [A] we sketch the strategy and discuss some lemmas. Lemma 3.1 below, is the first of these and will serve as a general tool to simplify the presentations that arise in the subsequent parts of the paper. (Recall that we can always suppose that \( \alpha \neq 0 \), \( \beta \neq 0 \), and \( \alpha^\alpha = b^\beta \) in \( K \) for otherwise, by Corollary 2.1 and Proposition 2.2 the group \( K \) has Property \( W_1 \) and thus \( G_\Lambda(R) \) is infinite.) In Section 3.2 we turn to the setting of Theorem [A] and suppose that both \( |\alpha| \geq 2 \) and \( |\beta| \geq 2 \). The strategy is to obtain conditions that must be satisfied if \( G_\Lambda(R) \) is a finite group. We then analyse \( G_\Lambda(R) \) under these conditions. In some cases we are able to show that \( G_\Lambda(R) \) is a finite cyclic group, in others at least that rank(\( G_\Lambda(R) \)) \( \in \{1, 2\} \). Then, in Sections 3.3 and 3.4 we consider the remaining cases and suppose without loss of generality that \( |\alpha| = 1 \) and \( |\beta| \) is an arbitrary positive integer. The fact that \( |\alpha| = 1 \) enables us to recursively prune the digraphs without changing the isomorphism types of the resulting groups.

Lemma 3.1. Let \( R(a, b) \) be a word such that \( \alpha^\alpha = b^\beta \) in \( K \) and let \( G \) be a group defined by a presentation \( \langle \mathcal{R} \mid \mathcal{S} \rangle \). Further suppose that there are distinct generators \( x_i, x_j \in \mathcal{R} \) such that \( R(x_i, x_j) \in \mathcal{S} \). Then the following hold:

(a) If \( x_i^\gamma \in \mathcal{S} \) for some \( \gamma \in \mathbb{Z} \) with \( (\alpha, \gamma) = 1 \), then every \( p \in \mathbb{Z} \) with \( p \alpha \equiv 1 \pmod{\gamma} \) yields a new presentation \( \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{S} \rangle \) of \( G \). The relators \( \mathcal{S} \) are obtained from \( \mathcal{R} \) by removing \( R(x_i, x_j) \) and \( x_i^\gamma \), replacing all remaining occurrences of \( x_i \) by \( x_j^\beta \), and adjoining \( x_j^{\beta \gamma} \).

(b) If \( x_j^\gamma \in \mathcal{S} \) for some \( \gamma \in \mathbb{Z} \) with \( (\beta, \gamma) = 1 \), then every \( p \in \mathbb{Z} \) with \( p \beta \equiv 1 \pmod{\gamma} \) yields a new presentation \( \langle \mathcal{R} \backslash \{x_j\} \mid \mathcal{S} \rangle \) of \( G \). The relators \( \mathcal{S} \) are obtained from \( \mathcal{R} \) by removing \( R(x_i, x_j) \) and \( x_j^\gamma \), replacing all remaining occurrences of \( x_j \) by \( x_i^{\alpha \beta} \), and adjoining \( x_i^{\alpha \beta \gamma} \).

Proof. The proofs of the two parts are similar and one only needs to switch the roles of \( x_i \) and \( x_j \) and the roles of \( \alpha \) and \( \beta \) (wherever necessary). We therefore prove Part (a) only. For simplicity of notation let \( \mathcal{R}_1 \) be obtained from \( \mathcal{R} \) by removing \( R(x_i, x_j) \) and \( x_i^\gamma \). Further, let \( \mathcal{R}_2 \) be obtained from \( \mathcal{R}_1 \) by removing all occurrences of \( x_i \) by \( x_j^\beta \) so that \( \mathcal{S} \) is obtained from \( \mathcal{R}_2 \) by adjoining \( x_j^{\beta \gamma} \). Note that

\[
G = \langle \mathcal{R} \mid \mathcal{S} \rangle = \langle \mathcal{R} \mid \mathcal{R}_1, R(x_i, x_j), x_i^\alpha \rangle = \langle \mathcal{R} \mid \mathcal{R}_1, R(x_i, x_j), x_i^\alpha = x_j^\beta, x_i^\gamma \rangle.
\]

Since \( p \alpha \equiv 1 \pmod{\gamma} \), there is an integer \( q \in \mathbb{Z} \) such that \( p \alpha + q \gamma = 1 \). Moreover, \( p \alpha \equiv 1 \pmod{\gamma} \) implies that \( x_i = x_i^{p \alpha} = x_j^{p \beta} \) in \( G \). This allows us to adjoin the relation \( x_i = x_j^{p \beta} \) and to eliminate the generator \( x_i \) as follows:

\[
G = \langle \mathcal{R} \mid \mathcal{R}_1, R(x_i, x_j), x_i^\alpha = x_j^\beta, x_i^\gamma \rangle = \langle \mathcal{R} \mid \mathcal{R}_2, R(x_j^{p \beta}, x_j), x_j^{p \alpha \beta} = x_j^{\beta}, x_j^{p \beta \gamma}, x_i = x_j^{p \beta} \rangle = \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{R}_2, R(x_j^{p \beta}, x_j), x_j^{p \beta \gamma} = x_j^\beta, x_j^{p \gamma} \rangle = \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{R}_2, x_j^{p \alpha \beta}, x_j^{p \beta \gamma} \rangle = \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{R}_2, x_j^{p \beta \gamma}, x_j^{p \beta} \rangle.
\]

The last two relators can be subsumed to a single one of the form \( x_j^\gamma \) where \( r \) is the greatest common divisor of \( p \beta \gamma \) and \( q \beta \gamma \). Recall that \( p \alpha + q \gamma = 1 \), so \( (p, q) = 1 \) and \( r = (p \beta \gamma, q \beta \gamma) = (p, q) \beta \gamma = \beta \gamma \). Therefore,

\[
G = \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{R}_2, x_j^{p \beta \gamma} \rangle = \langle \mathcal{R} \backslash \{x_i\} \mid \mathcal{S} \rangle.
\]

\( \square \)
Let us address two applications of this lemma to presentations of the form $P_\Lambda(R)$. First, suppose that $|\alpha| = 1$. If $i \in V(\Lambda)$ is a source leaf and $(i, j) \in A(\Lambda)$ is the only arc incident with it, then $R(x_i, x_j) \in \mathcal{R}$, and this is the only relator of $\mathcal{R}$ involving $x_i$. We can always assume that $x_i^\gamma \in \mathcal{R}$ for $\gamma = 0$ because adjoining or removing the empty relator does not change $G_\Lambda(R)$. Further, $(\alpha, \gamma) = 1$. By Lemma 3.1(a), we can now remove the generator $x_i$ together with the relators $R(x_i, x_j)$ and $x_i^\gamma$. Since $R(x_i, x_j)$ is the only relator of $\mathcal{R}$ involving $x_i$, it is not necessary to replace any further occurrence of $x_i$. Moreover, as mentioned above, it is not necessary to adjoin the empty relator $x_i^{\beta\gamma}$. In other words, if we prune the source leaf $i$, i.e. consider the digraph $\Lambda'$ obtained from $\Lambda$ by removing $i \in V(\Lambda)$ and $(i, j) \in A(\Lambda)$, then $G_{\Lambda'}(R) \cong G_\Lambda(R)$. Analogously, if $|\beta| = 1$, then Lemma 3.1(b) allows us to prune any sink leaf without changing the isomorphism type of the resulting group.

A second application neither requires $|\alpha| = 1$ nor $|\beta| = 1$. As soon as $(\alpha, \beta) = 1$, we can iterate the procedure. For example, if there are relators $R(x_{i_1}, x_{i_2}), R(x_{i_2}, x_{i_3}), \ldots, R(x_{i_{n-1}}, x_{i_n}) \in \mathcal{R}$, say arising from a directed path in $\Lambda$, and $x_{i_1}^\gamma \in \mathcal{R}$ for some $\gamma \in \mathbb{Z}$ with $(\alpha, \gamma) = 1$, then we can apply Lemma 3.1(a) to remove the generator $x_{i_1}$, under suitable modifications of the remaining relators. Since $(\alpha, \beta) = 1$ and $(\alpha, \gamma) = 1$, we have that $(\alpha, \beta) = 1$. So the presence of the adjoined relator $x_{i_2}^{\beta\gamma}$ allows us to apply Lemma 3.1(a) again to remove the generator $x_{i_2}$. Inductively, we can remove all the generators $x_{i_1}, \ldots, x_{i_{n-1}}$.

**Remark 3.2.** We will occasionally make use of a reflection principle: if $\Lambda$ is any digraph and $R(a, b)$ is any word, then we may consider the digraph $\Lambda'$ that is obtained from $\Lambda$ by reversing the direction of each arc and the word $R'(a, b)$ that is obtained from $R(a, b)$ by interchanging $a$ and $b$ and further replacing every letter by its inverse so that also $\alpha$ and $\beta$ are interchanged (without any change of sign). Then, by definition, $G_\Lambda(R) \cong G_{\Lambda'}(R')$.

**3.2 Cases where both $|\alpha| \geq 2$ and $|\beta| \geq 2$**

The proof of the following lemma uses the notion of killing. When we are given a group $G = \langle \mathcal{X} \mid \mathcal{R} \rangle$ and kill a generator $x \in \mathcal{X}$, we simply adjoin the relator $x$. The generator $x$ can then be removed by a Tietze transformation. It is clear that $G$ maps onto the resulting group. We note that, unlike all later lemmas, Lemma 3.3 does not require the hypothesis that $a^\alpha = b^\beta$ in $K$, and so it can be applied independently of Corollary 2.1 and Proposition 2.2.

**Lemma 3.3.** Let $\Lambda$ and $R(a, b)$ be as in Theorem 4. Further suppose that $\Lambda$ is weakly connected and that both $|\alpha| \geq 2$ and $|\beta| \geq 2$. If $G_\Lambda(R)$ is finite, then $(\alpha, \beta) = 1$ and $\Lambda$ is one of the following digraphs:

- (a) $\Lambda(n)$,
- (b) $\Lambda(n; m \gamma)$ ($m \geq 1$),
- (c) $\Lambda(n; m \gamma)$ ($m \geq 1$),
- (d) $\Lambda(n, 1)$,
- (e) $\Lambda(n; m, \frac{1}{\gamma})$ ($m \geq 1$),
- (f) $\Lambda(n; m, \frac{1}{\gamma})$ ($m \geq 1$).

**Proof.** Suppose that $G_\Lambda(R)$ is finite. Because $\Lambda$ is a non-empty finite digraph with an equal number of vertices and arcs that is weakly connected, the underlying undirected graph of $\Lambda$ has precisely one cycle. By the hypothesis on the girth, this cycle must have length $n$ ($n \geq 4$), whence there exist two distinct vertices $u, w \in V(\Lambda)$ that are not connected by an arc. Consider the presentation $P_\Lambda(R)$. Killing all generators $x_v$ ($v \in V(\Lambda) \setminus \{u, w\}$) yields a presentation $\langle x_u, x_w \mid \mathcal{R} \rangle$ where

$$\mathcal{R} \subseteq \{ R(u_1, 1), R(1, u), R(x_u, 1), R(1, x_w) \} = \{ x^\alpha_u, x^\beta_u, x^\alpha_w, x^\beta_w \}.$$ 

Further adjoining the relators $x^{(\alpha, \beta)}_u$ and $x^{(\alpha, \beta)}_w$ gives that $G_\Lambda(R)$ maps onto

$$\langle x_u, x_w \mid \mathcal{R}, x^{(\alpha, \beta)}_u, x^{(\alpha, \beta)}_w \rangle \cong \langle x_u, x_w \mid x^{(\alpha, \beta)}_u, x^{(\alpha, \beta)}_w \rangle \cong \mathbb{Z}(\alpha, \beta) \ast \mathbb{Z}(\alpha, \beta),$$

which is infinite if $(\alpha, \beta) \neq 1$. Since $G_\Lambda(R)$ is finite, we have that $(\alpha, \beta) = 1$. This is the first statement of the lemma. For the second one we make two observations of similar flavour.
Suppose that there are a source \( u \in V(\Lambda) \) and a sink \( w \in V(\Lambda) \) that are not connected by an arc. Killing all generators \( x_v \ (v \in V(\Lambda) \setminus \{u, w\}) \) gives that \( G_\Lambda(R) \) maps onto \( \mathbb{Z}_{|\alpha|} * \mathbb{Z}_{|\beta|} \), which is infinite since \(|\alpha| \geq 2\) and \(|\beta| \geq 2\). Thus, we can assume that there is an arc between every source and every sink. Next, suppose that there are distinct vertices \( u, w \in V(\Lambda) \) that are both sources (resp. both sinks). Clearly, these vertices cannot be connected by an arc. Killing all generators \( x_v \ (v \in V(\Lambda) \setminus \{u, w\}) \) gives that \( G_\Lambda(R) \) maps onto \( \mathbb{Z}_{|\alpha|} * \mathbb{Z}_{|\alpha|} \) (resp. \( \mathbb{Z}_{|\beta|} * \mathbb{Z}_{|\beta|} \)), which is infinite. Thus, we can assume that \( \Lambda \) has at most one source and at most one sink. With these two restrictions in mind we can investigate the possible digraphs \( \Lambda \). Let \( \sigma \) and \( \tau \) be the numbers of sources and sinks, respectively. Moreover, let \( \sigma_1 \) be the number of source leaves and let \( \tau_1 \) be the number of sink leaves. Then \( 0 \leq \sigma_1 \leq \sigma \leq 1 \) and \( 0 \leq \tau_1 \leq \tau \leq 1 \).

If \( \sigma = \tau = 0 \), then \( \sigma_1 = \tau_1 = 0 \) and \( \Lambda \) is the directed \( n \)-cycle, i.e. the digraph \( \Lambda(n) \) of Figure 1. If \( \sigma = 0 \) and \( \tau = 1 \), then \( \sigma_1 = 0 \) and \( \tau_1 \in \{0,1\} \). If \( \tau = 0 \), then the underlying undirected graph of \( \Lambda \) is a cycle, which is impossible because \( \Lambda \) has fewer sources than sinks. Therefore, \( \tau_1 = 1 \) and \( \Lambda = \Lambda(n; \overleftarrow{m}, \overrightarrow{1}) \ (m \geq 1) \).

Suppose then that \( \sigma = \tau = 1 \) and so either \( \sigma_1 = \tau_1 = 0 \) or \( \sigma_1 = 1 \), \( \tau_1 = 0 \) or \( \sigma_1 = 0 \), \( \tau_1 = 1 \). The case \( \sigma_1 = \tau_1 = 1 \) cannot occur for otherwise the restriction that there is an arc between every source and every sink implies that \( \Lambda \) is the digraph consisting of two vertices and one arc between them, and thus has more vertices than arcs. The restriction further yields that if \( \sigma_1 = \tau_1 = 0 \), then \( \Lambda = \Lambda(n, 1) \). In a similar way, if \( \sigma_1 = 0 \), \( \tau_1 = 1 \) or \( \sigma_1 = 1 \), \( \tau_1 = 0 \), we have that \( \Lambda = \Lambda(n; \overrightarrow{m}, \overleftarrow{1}) \ (m \geq 1) \) or \( \Lambda = \Lambda(n; \overleftarrow{m}, \overrightarrow{1}) \ (m \geq 1) \), respectively.

Excursion II. The statement of Lemma 3.3 remains valid when we replace the hypothesis “\( n \geq 4 \)” by “\( n \geq 3 \)” and the underlying undirected graph of \( \Lambda \) is not a triangle”. However, for triangles the conclusion that \( (\alpha, \beta) = 1 \) does not hold; the group \( J(2, 2, 2) \) given in the introduction is finite and serves as a counterexample.

Despite this we cannot make the same replacement of hypotheses in Corollary 3.3. If we did, then the trivial group could arise. For example, let \( \Lambda = \Lambda(3; \overleftarrow{1}) \) and \( R(a, b) = a^{-1}bab^{-2} \). In \( G_\Lambda(R) \) the three generators corresponding to the vertices of the directed 3-cycle are trivial by [10], as mentioned in the introduction, which implies that the fourth generator must be trivial, too. It would be interesting to see whether all finite groups \( G_\Lambda(R) \) arising when \( n = 3 \) and the underlying undirected graph of \( \Lambda \) is not a triangle satisfy \( \text{rank}(G_\Lambda(R)) \in \{0, 1, 2\} \).

We shall now consider the group \( G_\Lambda(R) \), and in some cases also the abelianization \( G_\Lambda(R)^{ab} \), for each of the digraphs \( \Lambda \) in Lemma 3.3(a)–(f) under its conclusion that \( (\alpha, \beta) = 1 \) and the further hypothesis that \( a^\alpha = b^\beta \) in \( K \). The following lemma was stated without proof in [18] page 248 and the omitted argument was given in [3] Lemma 3.4. Nevertheless, we include a proof here as a showcase for the methods and for further reference.

**Lemma 3.4** ([18] page 248), [3] Lemma 3.4). Let \( R(a, b) \) be as in Theorem A. Further suppose that \( (\alpha, \beta) = 1 \) and \( a^\alpha = b^\beta \) in \( K \). If \( \Lambda = \Lambda(n) \ (n \geq 2) \), then \( G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|} \).

**Proof.** Let \( V(\Lambda) = \{1, \ldots, n\} \) and \( A(\Lambda) = \{(1, 2), (2, 3), \ldots, (n, 1)\} \), whence the group \( G_\Lambda(R) \) is defined by the presentation

\[
\langle x_1, \ldots, x_n \mid R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1) \rangle.
\]

Because \( a^\alpha = b^\beta \) in \( K \), we know that whenever the relator \( R(x_i, x_j) \) appears in the above list, the respective equation \( x_i^\alpha = x_j^\beta \) holds in \( G_\Lambda(R) \). Therefore,

\[
x_1^{\alpha^n} = x_2^{\alpha^{n-1}} = x_3^{\alpha^{n-2}}\beta^2 = \cdots = x_n^{\alpha^{n-1}} = x_1^\beta.
\]
We set $\gamma = \alpha^n - \beta^n$ and obtain that $x_1^\gamma = 1$ in $G_\Lambda(R)$. Adjoining the relator $x_1^\gamma$ yields

$$G_\Lambda(R) = \langle x_1, \ldots, x_n \mid x_1^\gamma, R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1) \rangle.$$  

Since $(\alpha, \beta) = 1$, also $(\alpha, \gamma) = 1$. We can thus apply Lemma 3.1(a) to simplify the presentation. Before doing so let us observe that also $(\alpha, \gamma) = 1$. By choosing an integer $p \in \mathbb{Z}$ such that $p\alpha \equiv 1 \pmod{\beta^{n-2}\gamma}$, the congruence $p\alpha \equiv 1$ simultaneously holds modulo $\gamma$, $\beta$, $\alpha$, $\beta$, $\delta$. Now, an iterated application of Lemma 3.1(a) yields

$$G_\Lambda(R) = \langle x_1, \ldots, x_n \mid x_1^\gamma, R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1) \rangle$$

$$= \langle x_2, \ldots, x_n \mid x_2^{\beta\gamma}, R(x_2, x_3), R(x_3, x_4), \ldots, R(x_n, x_2^{\beta\gamma}) \rangle$$

$$= \langle x_3, \ldots, x_n \mid x_3^{\beta^2\gamma}, R(x_3, x_4), \ldots, R(x_n, x_3^{\beta^2\gamma}) \rangle$$

$$= \ldots = \langle x_n \mid x_n^{\beta^{n-1}\gamma}, R(x_n, x_n^{\beta^{n-1}\gamma-1}) \rangle$$

The two relators can be subsumed to a single one of the form $x_n^\gamma$ where $r$ is the greatest common divisor of $\beta^{n-1}\gamma$ and $\alpha - \beta^{p-1}\beta^{n-1}$. That is,

$$r = (\beta^{n-1}\gamma, \alpha - \beta^{p-1}\beta^{n-1}) = (\gamma, \alpha - \beta^{p-1}\beta^{n-1}).$$

In order to evaluate the rightmost term, observe that

$$p^{n-1}\beta^n \equiv (p\alpha)^{p^{n-1}\beta^n} = \alpha^n p^{n-1}\beta^n = \alpha^n \gamma = \alpha^n (\alpha - \beta^n) \equiv \alpha^n = \alpha \pmod{\gamma}.$$  

So $\gamma$ divides $\alpha - \beta^n$, which implies that $r = \gamma$ or $\alpha - \beta^n$. Therefore,

$$G_\Lambda(R) = \langle x_n \mid x_n^{\alpha^n - \beta^n} \rangle \cong \mathbb{Z}_{|\alpha^n - \beta^n|}.$$

**Lemma 3.5.** Let $\Lambda(a, b)$ be as in Theorem A. Further suppose that $(\alpha, \beta) = 1$ and $a^n = b^\beta$ in $K$. Then the following hold:

(a) If $\Lambda = \Lambda(n; \frac{m}{r})$ ($n \geq 2$, $m \geq 1$), then $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$.

(b) If $\Lambda = \Lambda(n; \frac{m}{r})$ ($n \geq 2$, $m \geq 1$), then $G_\Lambda(R) \cong \mathbb{Z}_{|\alpha^n - \beta^n|}$.

**Proof.** We prove Part (a) only. Part (b) can either be proved similarly or it can be deduced from Part (a) using the reflection principle addressed in Remark 3.2. The group $G_\Lambda(R)$ is defined by the presentation

$$\left\langle x_1, \ldots, x_n, y_1, \ldots, y_m \mid R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1), R(x_n, y_1), R(y_1, y_2), \ldots, R(y_{m-1}, y_m) \right\rangle.$$  

We set $\gamma = \alpha^n - \beta^n$ and apply precisely the same transformations as in the proof of Lemma 3.4. The fact that there are further generators and relators does not affect the validity of the transformations. What remains is

$$G_\Lambda(R) = \langle x_n, y_1, \ldots, y_m \mid x_n^\gamma, R(x_n, y_1), R(y_1, y_2), \ldots, R(y_{m-1}, y_m) \rangle.$$  

We continue simplifying this presentation. Choose an integer $p \in \mathbb{Z}$ such that $p\alpha \equiv 1 \pmod{\beta^{m-1}\gamma}$. Hence, the congruence $p\alpha \equiv 1$ simultaneously holds modulo $\gamma$, $\beta$, $\gamma$, $\beta$, $\gamma$. Now, an iterated application of Lemma 3.1(a) yields

$$G_\Lambda(R) = \langle x_n, y_1, \ldots, y_m \mid x_n^\gamma, R(x_n, y_1), R(y_1, y_2), \ldots, R(y_{m-1}, y_m) \rangle$$

$$= \langle y_1, \ldots, y_m \mid y_1^{\beta^1\gamma}, R(y_1, y_2), R(y_2, y_3), \ldots, R(y_{m-1}, y_m) \rangle$$

$$= \langle y_2, \ldots, y_m \mid y_2^{\beta^2\gamma}, R(y_2, y_3), \ldots, R(y_{m-1}, y_m) \rangle$$

$$= \ldots = \langle y_{m-1}, y_m \mid y_{m-1}^{\beta^{m-1}\gamma}, R(y_{m-1}, y_m) \rangle = \langle y_m \mid y_m^{\beta^m\gamma} \rangle.$$  

Therefore, $G_\Lambda(R) \cong \mathbb{Z}_{|\beta^m\gamma|} = \mathbb{Z}_{|\beta^m(\alpha^n - \beta^n)|}$.

\[\square\]
Lemma 3.6. Let \( R(a, b) \) be as in Theorem A. Further suppose that \((\alpha, \beta) = 1 \) and \( a^\alpha = b^\beta \) in \( K \). If \( \Lambda = \Lambda(n, 1) \) \((n \geq 3)\), then
\[
G_\Lambda(R) \cong K/\langle a^{\alpha(n^2 - \beta n - 2)} \rangle^K \quad \text{and} \quad G_\Lambda(R)^{ab} \cong \mathbb{Z}[\alpha, \beta]/\langle \alpha(n^2 - \beta n - 2) \rangle.
\]
If, in addition, \(|\alpha| \neq \beta \neq 1\), and \( G_\Lambda(R) \) is finite, then \( \delta_a = \delta_b = 1 \).

Proof. Let \( V(\Lambda) = \{1, \ldots, n\} \). Without loss of generality let \( n \) be the source and \( n - 1 \) be the sink so that the group \( G_\Lambda(R) \) is defined by the presentation
\[
\langle x_1, \ldots, x_n \mid R(x_1, x_2), R(x_2, x_3), \ldots, R(x_{n-2}, x_{n-1}), R(x_n, x_{n-1}), R(x_n, x_1) \rangle.
\]
Because \( a^\alpha = b^\beta \) in \( K \), we know that whenever the relator \( R(x_i, x_j) \) appears in the above list, the respective equation \( x_i^{\alpha} = x_j^{\beta} \) holds in \( G_\Lambda(R) \). Therefore,
\[
x_1^{\alpha n^2 - \beta n - 2} = x_2^{\alpha n^2 - \beta n - 2} = x_3^{\alpha n^2 - \beta n - 2} = \ldots = x_{n-2}^{\alpha n^2 - \beta n - 2} = x_{n-1}^{\alpha n^2 - \beta n - 2} = x_n^{\alpha n^2 - \beta n - 2}.
\]
We set \( \gamma = \alpha n^2 - \beta n - 2 \) and obtain that \( x_1^{\gamma} = 1 \) in \( G_\Lambda(R) \). Adjoining this relator yields
\[
G_\Lambda(R) = \langle x_1, \ldots, x_n \mid x_1^{\gamma}, R(x_1, x_2), R(x_2, x_3), \ldots, R(x_{n-2}, x_{n-1}), R(x_n, x_{n-1}), R(x_n, x_1) \rangle.
\]
As in the previous proofs, choose an integer \( p \in \mathbb{Z} \) such that \( p\alpha \equiv 1 \pmod{\beta n^2 - \gamma} \). Hence, the congruence \( p\alpha \equiv 1 \) simultaneously holds modulo \( \gamma, \beta \gamma, \ldots, \beta^m \gamma \). Now, an iterated application of Lemma 3.1(a) yields
\[
G_\Lambda(R) = \langle x_1, \ldots, x_n \mid x_1^{\gamma}, R(x_1, x_2), R(x_2, x_3), \ldots, R(x_{n-2}, x_{n-1}), R(x_n, x_{n-1}), R(x_n, x_1) \rangle.
\]
We set \( a = x_n \) and \( b = x_{n-1} \) to obtain that
\[
G_\Lambda(R) = \langle a, b \mid b^{\gamma n^2 - \gamma}, R(a, b), R(a, b^{\gamma n^2 - \gamma}) \rangle.
\]
Since \( a^\alpha = b^\beta \) in \( K \), we can replace each occurrence of \( b^\beta \) in the first and third relator by \( a^\alpha \). Afterwards, we simplify the third relator, which has become a word in the generator \( a \). This yields
\[
G_\Lambda(R) = \langle a, b \mid a^{\alpha n^2 - \gamma}, R(a, b), a^{\alpha n^2 - \gamma} \rangle.
\]
The first and third relator can be subsumed to a single one of the form \( a^r \) where \( r \) is the greatest common divisor of \( \alpha n^2 - \gamma \) and \( \alpha - \beta (p^{n-2} \alpha \beta n^2) \). That is,
\[
r = (\alpha n^2 - \gamma, \alpha - \beta (p^{n-2} \alpha \beta n^2)) = \alpha(\gamma, 1 - p^{n-2} \beta n^2).
\]
In order to evaluate the rightmost term, observe that
\[
p^{n-2} \beta n^2 - 1 \equiv p^{n-2} (\alpha n^2 - \gamma) \equiv p^{n-2} \alpha n^2 = (pa)^{n-2} \equiv 1 \pmod{\gamma}.
\]
So \( \gamma \) divides \( 1 - p^{n-2} \beta n^2 \). Therefore, \( r = \alpha \gamma = \alpha(\alpha n^2 - \beta n^2) \), which proves the first conclusion. Thus, the group \( G_\Lambda(R) \) is given by the presentation \( \langle a, b \mid R(a, b), a^{\alpha \gamma} \rangle \), whose relation matrix is
\[
A = \begin{pmatrix} \alpha & -\beta \\ \alpha \gamma & 0 \end{pmatrix}.
\]
The diagonal entries of the Smith Normal Form of \( A \) are the greatest common divisor \( (\alpha, -\beta, \alpha \gamma, 0) = 1 \) and the quotient \( |\det(A)|/(\alpha, -\beta, \alpha \gamma, 0) = |\alpha \beta \gamma| \), whence \( G_\Lambda(R)^{ab} \cong \mathbb{Z} \langle \alpha \beta \rangle \cong \mathbb{Z}[\alpha, \beta]/\langle (\alpha n^2 - \beta n - 2) \rangle \).

Finally, by adjoining the relator \( a^{\delta n \gamma} \) we see that the group \( G_\Lambda(R) = \langle a, b \mid R(a, b), a^{\alpha \gamma} \rangle \) maps onto \( \langle a, b \mid a^{\delta n \gamma}, b^{\beta} \rangle \cong \mathbb{Z}[\delta n] \ast \mathbb{Z}[\beta] \) and by adjoining the relator \( b^{\delta n \gamma} \) that it maps onto \( \langle a, b \mid a^{\alpha}, b^{\beta} \rangle \cong \mathbb{Z}[\alpha] \ast \mathbb{Z}[\beta] \). If \( G_\Lambda(R) \) is finite, then these images must be finite, too, from where the last conclusion follows.
Lemma 3.7. Let \( R(a, b) \) be as in Theorem \([4]\). Further suppose that \((\alpha, \beta) = 1\) and \(a^\alpha = b^\beta \) in \( K\). Then the following hold:

(a) If \( \Lambda = \Lambda(n; \frac{m}{\alpha}, \frac{1}{\beta}) \) \((n \geq 2, m \geq 1)\), then

\[
G_\Lambda(R) \cong K / \langle b^{m(\alpha^n - \beta^n)} \rangle^K \quad \text{and} \quad G_\Lambda(R)^{ab} \cong \mathbb{Z}[\alpha^{m(\alpha^n - \beta^n)}].
\]

(b) If \( \Lambda = \Lambda(n; \frac{m}{\alpha}, \frac{1}{\beta}) \) \((n \geq 2, m \geq 1)\), then

\[
G_\Lambda(R) \cong K / \langle a^{m(\alpha^n - \beta^n)} \rangle^K \quad \text{and} \quad G_\Lambda(R)^{ab} \cong \mathbb{Z}[\alpha^{m(\alpha^n - \beta^n)}].
\]

If, in addition, \(|\alpha| \neq 1\), \(|\beta| \neq 1\), and \(G_\Lambda(R)\) is finite, then \(\delta_a = \delta_b = 1\).

Proof. The proof is essentially the same as the one of Lemma 3.3. Again, we prove Part (a) only. Part (b) can either be proved similarly or it can be deduced from Part (a) using the reflection principle addressed in Remark 3.2. The group \(G_\Lambda(R)\) is defined by the presentation

\[
\left\langle x_1, \ldots, x_n, y_1, \ldots, y_m, z \mid R(x_1, x_2), R(x_2, x_3), \ldots, R(x_n, x_1), R(x_n, y_1), R(y_1, y_2), \ldots, R(y_m-1, y_m), R(z, y_m) \right\rangle.
\]

We set \(\gamma = \alpha^n - \beta^n\) and apply precisely the same transformations as in the proof of Lemma 3.3. What remains is \(G_\Lambda(R) = \langle y_m, z \mid R(z, y_m), y_m^{\beta^n \gamma} \rangle\). Next, we set \(a = z\) and \(b = y_m\) to obtain that

\[
G_\Lambda(R) = \langle a, b \mid R(a, b), b^{\beta^n \gamma} \rangle.
\]

The relation matrix of this presentation is

\[
A = \begin{pmatrix} \alpha & -\beta \\ 0 & \beta^n \gamma \end{pmatrix}.
\]

The diagonal entries of the Smith Normal Form of \(A\) are the greatest common divisor \((\alpha, -\beta, 0, \beta^n \gamma) = 1\) and the quotient \(|\det(A)|/(\alpha, -\beta, 0, \beta^n \gamma) = |\alpha| \beta^n \gamma|\), whence \(G_\Lambda(R)^{ab} \cong \mathbb{Z}[\alpha^{m(\alpha^n - \beta^n)}] = \mathbb{Z}[\alpha^{m(\alpha^n - \beta^n)}]\).

Finally, by adjoining the relator \(a^\delta_a\) we see that the group \(G_\Lambda(R) = \langle a, b \mid R(a, b), b^{\beta^n \gamma} \rangle\) maps onto \(\langle a, b \mid a^{\delta_a}, b^{\beta^n} \rangle \cong \mathbb{Z}_{\beta^n} \ast \mathbb{Z}_{\beta^n}\) and by adjoining the relator \(b^\delta_b\) that it maps onto \(\langle a, b \mid a^{\alpha^n}, b^{\beta^n} \rangle \cong \mathbb{Z}_{\alpha^n} \ast \mathbb{Z}_{\beta^n}\). If \(G_\Lambda(R)\) is finite, then these images must be finite, too, from where the last conclusion follows.

3.3 Cases where \(|\alpha| = 1\) and \(|\beta| \geq 2\)

Lemma 3.8. Let \(\Lambda\) and \(R(a, b)\) be as in Theorem \([4]\). Further suppose that \(\Lambda\) is weakly connected and that \(|\alpha| = 1\), \(|\beta| \geq 2\), and \(a^\alpha = b^\beta \) in \( K\). If \(G_\Lambda(R)\) is finite, then after recursively pruning all source leaves \(\Lambda\) becomes one of the following digraphs:

(a) \(\Lambda_s = \Lambda(n)\),

(b) \(\Lambda_s = \Lambda(n; \frac{m}{\alpha}, \frac{1}{\beta}) \) \((m \geq 1)\),

(c) \(\Lambda_s = \Lambda(n; \frac{m}{\alpha}, \frac{1}{\beta}) \) \((m \geq 1, \ell \geq 1)\),

(d) \(\Lambda_s = \Lambda(n, d; \frac{m}{\beta}) \) \((\frac{m}{\beta} \geq d \geq 1, m \geq 1)\),

(e) \(\Lambda_s = \Lambda(n; \frac{m}{\alpha}, \frac{1}{\beta}) \) \((m \geq 1, \ell \geq 1)\).

Proof. Suppose that \(G_\Lambda(R)\) is finite. After recursively pruning all source leaves we obtain a digraph \(\Lambda_s\) that is still non-empty and finite, has an equal number of vertices and arcs, and is weakly connected. Therefore, the underlying undirected graph of \(\Lambda_s\) has precisely one cycle. Moreover, as explained after proving Lemma 3.1 since \(|\alpha| = 1\), pruning a source leaf does not change the isomorphism type of the resulting group, whence \(G_{\Lambda_s}(R)\) is finite, too. Suppose that there are distinct vertices \(u, w \in V(\Lambda_s)\) that are both sinks. Killing all generators \(x_v \) \((v \in V(\Lambda_s) \setminus \{u, w\})\) gives that \(G_{\Lambda_s}(R)\) maps onto \(\mathbb{Z}_{|\beta|} \ast \mathbb{Z}_{|\beta|}\), which is infinite. Thus, we can assume that \(\Lambda_s\) has at most one sink. As in the proof of Lemma 3.3 let
σ and τ be the numbers of sources and sinks, respectively. By construction of Λs, there are no source leaves. Let τ1 be the number of sink leaves (which is the number of all leaves). Then 0 ≤ τ1 ≤ τ ≤ 1. If τ = 0, then τ1 = 0 and the underlying undirected graph of Λs is the n-cycle. In this situation τ = 0 implies that σ = τ = 0, whence Λs = Λ(n). On the other hand, if τ = 1, then τ1 ∈ {0, 1}. If τ1 = 0, the same argument shows that σ = τ = 1 and Λs = Λ(n, d) (μ ≠ d ≥ 1). If τ1 = 1, the underlying undirected graph of Λs is a tadpole, i.e. a graph that consists of a cycle C and a path P joined by a bridge B, see Figure 2. Because the leaf is the only sink of Λs, there can be at most one source on P and at most one source on C.

1. If there is no source on P, the bridge B must point away from the cycle C and we distinguish between two cases. If there is no source on C, then Λs = Λ(n; m) (m ≥ 1). If there is a source on C, then Λs = Λ(n, d; m) (μ ≥ d ≥ 1, m ≥ 1).

2. If there is one source on P, then the bridge B must point towards the cycle C and the fact that there cannot be a sink on C implies that Λs = Λ(n; m, ℓ) (m ≥ 1, ℓ ≥ 1).

The groups arising in Cases (a)–(e) of Lemma 3.8 can be analysed by an iterated application of Lemma 3.1(a). In fact, the first two cases are already covered by Lemmas 3.4 and 3.5(a), respectively. The following lemmas therefore address the remaining three cases. Roughly speaking, since |α| = 1, there is no need to verify the coprimality of α and some exponent γ. Instead, we can simply apply Lemma 3.1(a) with γ = 0, or any other suitable value, and p = α until a one-generator presentation of the group is obtained.

We use the convention that Z0 = Z. In Cases (c) and (d) of Lemma 3.8, it will turn out that we could even have claimed that 2n ≥ d ≥ 1 because GΛs(R), which is isomorphic to GΛ(R), is infinite if and only if d = 2n.

Lemma 3.9. Let R(a, b) be as in Theorem [A] Further suppose that |α| = 1, |β| ≥ 2, and αa = bβ in K. If Λs = Λ(n, d) (n ≥ 3, 2n ≥ d ≥ 1), then GΛs(R) ≅ Z[(αβ)n−d−(αβ)d]. In particular, GΛs(R) is infinite if and only if d = 2n.

Proof. Let V(Λ) = {1, . . . , n}. Without loss of generality let n be the source and d be the sink so that the group GΛs(R) is defined by the presentation

\[
\left\langle x_1, \ldots, x_n \mid R(x_1, x_2), \ldots, R(x_d, x_{d-1}), R(x_{d+1}, x_d) \right\rangle.
\]

We simplify this presentation in two steps. An iterated application of Lemma 3.1(a) with γ = 0 and p = α allows us to remove the generators x1, x2, . . . , xd−1 and thus yields

\[
GΛs(R) = \langle x_1, \ldots, x_{n-1} \mid R(x_1, x_2), \ldots, R(x_{d-1}, x_d), R(x_{d+1}, x_d) \rangle = \langle x_2, \ldots, x_{n-1} \mid R(x_2, x_3), \ldots, R(x_{d-1}, x_d), R(x_{d+1}, x_d) \rangle = \cdots = \langle x_d, \ldots, x_{n-1} \mid R(x_d^{(αβ)^d}, x_{n-1}) \rangle.
\]
Next, we introduce a new generator \( y \) to simplify the first relator, which enables us to proceed as above and to remove the generators \( y, x_{n-1}, x_{n-2}, \ldots, x_{d+1} \). More precisely,

\[
G_\Lambda(R) = \langle x_d, \ldots, x_{n-1}, y \mid R(y, x_{n-1}), R(x_{n-1}, x_{n-2}), \ldots, R(x_{d+1}, x_d), y = x_d^{(\alpha \beta)^d} \rangle
\]

\[
= \langle x_d, \ldots, x_{n-1} \mid R(x_{n-1}, x_{n-2}), \ldots, R(x_{d+1}, x_d), x_d^{\alpha \beta} = x_d^{(\alpha \beta)^d} \rangle
\]

\[
= \langle x_d, \ldots, x_{n-2} \mid R(x_{n-2}, x_{n-3}), \ldots, R(x_{d+1}, x_d), x_d^{(\alpha \beta)^d} = x_d^{(\alpha \beta)^d} \rangle
\]

\[
= \ldots = \langle x_d \mid x_d^{(\alpha \beta)^{n-d}} = x_d^{(\alpha \beta)^d} \rangle.
\]

Therefore, \( G_\Lambda(R) \cong \mathbb{Z}_{(\alpha \beta)^{n-d}-n(\alpha \beta)^d} \).

**Lemma 3.10.** Let \( R(a, b) \) be as in Theorem [A]. Further suppose that \( |\alpha| = 1, |\beta| \geq 2, \) and \( a^\alpha = b^\beta \) in \( K \).

If \( \Lambda_s = \Lambda(n, d; \frac{m}{n}) \) \( (n \geq 3, \frac{n}{2} \geq d \geq 1, m \geq 1) \), then \( G_\Lambda_s(R) \cong \mathbb{Z}_{|\beta^m((\alpha \beta)^{n-d}-(\alpha \beta)^d)|} \). In particular, \( G_\Lambda_s(R) \) is infinite if and only if \( d = \frac{n}{2} \).

**Proof.** The group \( G_\Lambda_s(R) \) is defined by the presentation

\[
\begin{align*}
G_\Lambda_s(R) &= \langle x_d, y_1, \ldots, y_m \mid x_d^{\gamma}, R(x_d, y_1), \ldots, R(y_m, y_{m-1}) \rangle
\end{align*}
\]

where \( \gamma = (\alpha \beta)^{n-d} - (\alpha \beta)^d \). An iterated application of Lemma 3.1(a) then yields

\[
G_\Lambda_s(R) = \langle y_1, \ldots, y_m \mid y_1^{\beta \gamma}, R(y_1, y_2), \ldots, R(y_{m-1}, y_{m}) \rangle
\]

\[
= \langle y_2, \ldots, y_m \mid y_2^{\beta^2 \gamma}, R(y_2, y_3), \ldots, R(y_{m-1}, y_{m}) \rangle
\]

\[
= \ldots = \langle y_m \mid y_m^{\beta^m \gamma} \rangle.
\]

Therefore, \( G_\Lambda_s(R) \cong \mathbb{Z}_{(\beta^m n - (\alpha \beta)^d)} \).

**Lemma 3.11.** Let \( R(a, b) \) be as in Theorem [A]. Further suppose that \( |\alpha| = 1, |\beta| \geq 2, \) and \( a^\alpha = b^\beta \) in \( K \).

If \( \Lambda_s = \Lambda(n; \frac{m}{n}, \ell) \) \( (n \geq 2, m \geq 1, \ell \geq 1) \), then \( G_\Lambda_s(R) \cong \mathbb{Z}_{|\beta^\ell((\alpha \beta)^{n-d}-(\alpha \beta)^d)|} \).

**Proof.** The group \( G_\Lambda_s(R) \) is defined by the presentation

\[
\begin{align*}
G_\Lambda_s(R) &= \langle x_d, y_1, \ldots, y_m, z_1, \ldots, z_\ell \mid R(x_{n-1}, x_1), R(y_m, y_{m-1}), \ldots, R(y_2, y_1), R(y_1, x_n), R(y_{m-1}, z_1), R(z_1, z_2), \ldots, R(z_{\ell-1}, z_\ell) \rangle
\end{align*}
\]

We apply precisely the same transformations as in the proof of Lemma 3.1 to obtain that

\[
G_\Lambda_s(R) = \langle x_d, y_1, \ldots, y_m, z_1, \ldots, z_\ell \mid x_n^{(\alpha \beta)^{n-d}}, R(y_m, y_{m-1}), \ldots, R(y_2, y_1), R(y_1, x_n), R(y_{m-1}, z_1), R(z_1, z_2), \ldots, R(z_{\ell-1}, z_\ell) \rangle
\]

Now, an iterated application of Lemma 3.1(a) with \( \gamma = 0 \) and \( p = \alpha \) allows us to remove the generators \( y_m, y_{m-1}, \ldots, y_1 \) together with the relators in the second row. This eventually results in

\[
G_\Lambda_s(R) = \langle x_n, z_1, \ldots, z_\ell \mid x_n^{(\alpha \beta)^{n-d}}, R(x_n^{(\alpha \beta)^m}, z_1), \ldots, R(z_{\ell-1}, z_\ell) \rangle
\]

\[
= \langle x_n, y, z_1, \ldots, z_\ell \mid x_n^{(\alpha \beta)^{n-d}}, R(y, z_1), R(z_1, z_2), \ldots, R(z_{\ell-1}, z_\ell) \rangle.
\]
Since the exponents \( r = \alpha^n - \beta^n \) and \( s = (\alpha\beta)^m \) are coprime, we can remove the generator \( x_n \). Indeed, choose an integer \( t \in \mathbb{Z} \) such that \( st \equiv 1 \pmod{r} \). Starting from \( \langle x_n, y, \ldots | x_n^r, y = x_n^t, \ldots \rangle \), we modify the set of relators by first adjoining \( y^r \) and \( x_n = y^t \) and then removing \( x_n^r \) and \( y = x_n^t \), which eventually allows us to remove the generator \( x_n \) together with the relation \( x_n = y^t \). An iterated application of Lemma 3.1(b) then yields

\[
G_\Lambda(R) = \langle y, z_1, \ldots, z_{\ell} | y^r, R(y, z_1), R(z_1, z_2), \ldots, R(z_{\ell-1}, z_{\ell}) \rangle \\
= \langle z_1, \ldots, z_{\ell} | z_1^{\beta r}, R(z_1, z_2), \ldots, R(z_{\ell-1}, z_{\ell}) \rangle \\
= \langle z_2, \ldots, z_{\ell} | z_2^{\beta r}, R(z_2, z_3), \ldots, R(z_{\ell-1}, z_{\ell}) \rangle \\
= \ldots = \langle z_\ell | z_\ell^{\beta r} \rangle
\]

Therefore, \( G_\Lambda(R) \cong \mathbb{Z}_{|\beta r|} = \mathbb{Z}_{|\beta (\alpha^n - \beta^n)|} \). \( \square \)

### 3.4 Cases where \(|\alpha| = |\beta| = 1\)

In the cases where \(|\alpha| = |\beta| = 1\) we can use Lemma 3.1(a) and (b) to recursively prune all source and all sink leaves, which leaves a digraph whose underlying undirected graph is the \( n \)-cycle.

**Lemma 3.12.** Let \( \Lambda \) and \( R(a, b) \) be as in Theorem A. Further suppose that \( \Lambda \) is weakly connected and that \(|\alpha| = |\beta| = 1\) and \( a^n = b^\beta \) in \( K \). If \( G_\Lambda(R) \) is finite, then \( \alpha\beta = -1 \), \( n \) is odd, and \( G_\Lambda(R) \cong \mathbb{Z}_2 \).

**Proof.** Suppose that \( G_\Lambda(R) \) is finite. After recursively pruning all source and all sink leaves we obtain a digraph \( \Lambda_m \) whose underlying undirected graph is the \( n \)-cycle. As explained after the proof of Lemma 3.1 since \(|\alpha| = |\beta| = 1\), pruning any leaf does not change the isomorphism type of the resulting group, whence we can assume without loss of generality that

\[
G_\Lambda(R) \cong G_{\Lambda, m}(R) = \langle x_1, \ldots, x_n | g_1, \ldots, g_{n-1}, R(x_n, x_1) \rangle
\]

where each relator \( g_i \in \{ R(x_i, x_{i+1}), R(x_{i+1}, x_i) \} \) (1 \( \leq i \leq n - 1 \)). Now, observe that if \( g_i = R(x_i, x_{i+1}) \) (resp. \( g_i = R(x_{i+1}, x_i) \)), then application of Lemma 3.1(a) with \( \gamma = 0 \) and \( p = \alpha \) (resp. application of Lemma 3.1(b) with \( \gamma = 0 \) and \( p = \beta \)) allows us to remove the generator \( x_i \) together with the relator \( g_i \). All occurrences of \( x_i \) in the remaining relators are replaced by \( x_i^{\alpha \beta} \). This yields

\[
G_\Lambda(R) = \langle x_1, \ldots, x_n | g_1, \ldots, g_{n-1}, R(x_n, x_1) \rangle = \langle x_2, \ldots, x_n | g_2, \ldots, g_{n-1}, R(x_n, x_2^{\alpha \beta}) \rangle \\
= \langle x_3, \ldots, x_n | g_3, \ldots, g_{n-1}, R(x_n, x_3^{(\alpha \beta)^2}) \rangle = \ldots = \langle x_n | R(x_n, x_n^{(\alpha \beta)^n - 1}) \rangle
\]

Therefore, we have that \( G_\Lambda(R) \cong \mathbb{Z}_{(\alpha \beta)^n - 1} \). In particular, \( G_\Lambda(R) \) is finite if and only if \( (\alpha \beta)^n \neq 1 \). Since \(|\alpha| = |\beta| = 1\), this happens if and only if \( \alpha\beta = -1 \) and \( n \) is odd, in which case \( G_\Lambda(R) \cong \mathbb{Z}_2 \). \( \square \)

### 3.5 Proof of Theorem A

We first restrict ourselves to the case where the digraph \( \Lambda \) is weakly connected. The conclusion that \( G_\Lambda(R) \) is non-trivial will then allow us to deal with the case where \( \Lambda \) is not weakly connected. So suppose that \( \Lambda \) is weakly connected and that \( G_\Lambda(R) \) is finite. By Corollary 2.4 we can assume that \( K \) does not have Property \( W_1 \). Then, by Proposition 2.2 we have that \( \alpha \neq 0, \beta \neq 0, \) and \( a^\alpha = b^\beta \) in \( K \). If both \(|\alpha| \geq 2 \) and \(|\beta| \geq 2 \), then Lemma 3.3 implies that \( (\alpha, \beta) = 1 \), whence \( a^n - \beta^n \neq 0 \), and that \( \Lambda \) is one of the following digraphs:

- (a) \( \Lambda(n) \)
- (b) \( \Lambda(n; \frac{m}{\gamma}) \) (\( m \geq 1 \))
- (c) \( \Lambda(n; \frac{m}{\gamma}) \) (\( m \geq 1 \))
- (d) \( \Lambda(n, 1) \)
- (e) \( \Lambda(n; \frac{m}{\gamma}, \frac{1}{\gamma}) \) (\( m \geq 1 \))
- (f) \( \Lambda(n; \frac{m}{\gamma}, \frac{1}{\gamma}) \) (\( m \geq 1 \))
The result then follows from Lemmas 3.4, 3.5, 3.6, 3.7. Note that in each case $G_{\Lambda}(R)$ is non-trivial. Indeed, in Cases (a)–(c) this can be deduced directly from the lemmas. In Cases (d)–(f) observe that the abelianization $G_{\Lambda}(R)^{ab}$ is non-trivial, and so is $G_{\Lambda}(R)$. If $|\alpha| = 1$ and $|\beta| \geq 2$, then $(\alpha, \beta) = 1$ and $\alpha^n - \beta^n \neq 0$ are obviously satisfied. Lemma 3.8 implies that after recursively pruning all source leaves $\Lambda$ becomes one of the following digraphs:

- $(a) \Lambda_{\alpha} = \Lambda(n)$,
- $(b) \Lambda_{\alpha} = \Lambda(n; m_{\alpha}) (m \geq 1)$,
- $(c) \Lambda_{\alpha} = \Lambda(n, d) \left( \frac{\alpha}{\beta} \geq d \geq 1 \right)$,
- $(d) \Lambda_{\alpha} = \Lambda(n, d; m_{\alpha}) \left( \frac{\alpha}{\beta} \geq d \geq 1, m \geq 1 \right)$,
- $(e) \Lambda_{\alpha} = \Lambda(n; \frac{m_{\alpha}}{\beta}, \frac{\alpha}{\beta}) (m \geq 1, \ell \geq 1)$.

The result then follows from Lemmas 3.2, 3.3, 3.4, 3.5, 3.6, 3.7. Again, it turns out that in each case $G_{\Lambda}(R)$ is non-trivial. If $|\alpha| \geq 2$ and $|\beta| = 1$, then we have a mere reflection of the previous situation. More precisely, due to the reflection principle addressed in Remark 3.2, there is a one-to-one correspondence between the two situations: starting off from a digraph $\Lambda$ and a word $R(a, b)$ with $|\alpha| \geq 2$ and $|\beta| = 1$, we reverse the direction of each arc, interchange $a$ and $b$, and further replace every letter by its inverse so that also $\alpha$ and $\beta$ are interchanged (without any change of sign), to obtain a digraph $\Lambda'$ and a word $R'(a, b)$ with $|\alpha| = 1$ and $|\beta| \geq 2$. Since the resulting groups are isomorphic, we can translate the classification of finite groups from one situation to the other. Note that we now have to consider the digraph $\Lambda$ obtained from $\Lambda$ by recursively pruning all sink leaves.

If $|\alpha| = |\beta| = 1$, then $(\alpha, \beta) = 1$ is obviously satisfied. Moreover, Lemma 3.12 implies that $\alpha \beta = -1$ and $n$ is odd, whence $|\alpha^n - \beta^n| = 2$ and, in particular, $\alpha^n - \beta^n \neq 0$. The lemma further implies that $G_{\Lambda}(R) \cong \mathbb{Z}_2$, which is non-trivial. This completes the proof for the case where the digraph $\Lambda$ is weakly connected and, in particular, shows that in this case $G_{\Lambda}(R)$ is non-trivial.

What remains is to consider the case where $\Lambda$ is not weakly connected, for which we claim that $G_{\Lambda}(R)$ cannot be finite. Indeed, if $\Lambda$ has weakly connected components $\Lambda_1, \ldots, \Lambda_k$ with $k \geq 2$, then $G_{\Lambda}(R)$ is isomorphic to the free product $G_{\Lambda_1}(R) * \cdots * G_{\Lambda_k}(R)$. If for some $1 \leq i \leq k$ the weakly connected component $\Lambda_i$ has more vertices than arcs, then $P_{\Lambda_i}(R)$ has more generators than relations. Hence, $G_{\Lambda_i}(R)$ is infinite, and so is $G_{\Lambda}(R)$. Because of this we can assume that each $\Lambda_i$ has at most as many vertices as arcs. If any $\Lambda_i$ has fewer vertices than arcs, then $\Lambda$ has fewer vertices than arcs, which contradicts the hypothesis of Theorem A. Therefore, each $\Lambda_i$ has an equal number of vertices and arcs. But then, by the above, each $G_{\Lambda_i}(R)$ is non-trivial and thus $G_{\Lambda}(R) \cong G_{\Lambda_1}(R) * \cdots * G_{\Lambda_k}(R)$ is infinite.
