TWISTED PATTERNS IN LARGE SUBSETS OF $\mathbb{Z}^N$

MICHAEL BJÖRKLUND AND KAMIL BULINSKI

Abstract. Let $E \subseteq \mathbb{Z}^N$ be a set of positive upper Banach density and let $\Gamma \subset \text{GL}_N(\mathbb{Z})$ be a finitely generated, strongly irreducible subgroup whose Zariski closure in $\text{GL}_N(\mathbb{R})$ is a Zariski connected semisimple group with no compact factors. Let $Y$ be any set and suppose that $\Psi : \mathbb{Z}^N \to Y$ is a $\Gamma$-invariant function. We prove that for every positive integer $m$, there exists a positive integer $k$ with the property that for every finite set $F \subseteq \mathbb{Z}^N$ with $|F| = m$, we have $\Psi(kF) \subseteq \Psi(E \cdot b)$ for some $b \in E$.

Furthermore, if $E$ is an aperiodic Bohr-ø-set, we can choose $k = 1$ and $b = 0$. As one of many applications of this result, we show that if $E_0 \subseteq \mathbb{Z}$ has positive upper Banach density, then, for any integer $m$, there exists an integer $k$ with the property for every finite set $F \subseteq \mathbb{Z}$, we can find $x, y, z \in E_0$ such that

$$kF \subset \{(u - x)^2 + (v - y)^2 - (w - z)^2 : u, v, w \in E_0\}.$$

In particular, if $E_0 \subseteq \mathbb{Z}$ is an aperiodic Bohr-ø-set, then every integer can be written on the form $u^2 + v^2 - w^2$ for some $u, v, w \in E_0$. Our techniques use recent results by Benoist-Quint and Bourgain-Purman-Lindenstrauss-Mozes on equidistribution of random walks on automorphism groups of tori.

1. Introduction

We begin by recalling the following classical result of Furstenberg and Katznelson [10]. The upper Banach density of a subset $E \subseteq \mathbb{Z}^N$ will be defined in Appendix I.

Theorem 1.1. Suppose that $E \subseteq \mathbb{Z}^N$ has positive upper Banach density. Then, for every finite set $F \subseteq \mathbb{Z}^N$, there exists a positive integer $k$ such that

$$kF \subseteq E - b,$$

for some $b \in E$. \hspace{1cm} (1.1)

The case $N = 1$ corresponds to Szemerédi’s celebrated theorem on arithmetic progressions.

This is an archetypical result in Arithmetic Ramsey theory. We stress the order of the quantifiers; the integer $k$ heavily depends on the finite set $F$. In this paper we shall prove a "twisted" analogue of Furstenberg-Katznelson’s Theorem, for which the dependence between the integer $k$ and the set $F$ disappears. To motivate this line of study, we begin by giving three applications.

1.1. Quadratic forms. A very influential result in Geometric Ramsey theory by Furstenberg, Katznelson and Weiss [11] asserts that if $E \subset \mathbb{R}^N$ is a Borel set with positive density in the sense that

$$\limsup_{R \to \infty} \frac{\text{Leb}(E \cap B(R))}{R^N} > 0,$$

Key words and phrases. Multiple recurrence, equidistribution, invariants.
where $\text{Leb}$ denotes the Lebesgue measure on $\mathbb{R}^N$ and $B(\mathbb{R})$ denotes the Euclidean ball of radius $R$ around the origin, then there exists $R_o > 0$ such that
\[
D(E) = \{ \|x - y\|^2 : x, y \in E \} \supset [R_o, \infty),
\]
where $\| \cdot \|$ denotes the Euclidean norm on $\mathbb{R}^N$. In other words, all sufficiently large Euclidean distances are realized within the set $E$. Recently, Magyar [13] established the following discrete analogue of this phenomenon.

**Theorem 1.2 (Theorem 1, [13]).** Fix an integer $N \geq 5$ and let
\[
Q(x_1, \ldots, x_N) = x_1^2 + \ldots + x_N^2.
\]
Then, for every subset $E \subset \mathbb{Z}^N$ of positive upper Banach density, there exist positive integers $R_o$ and $k$ such that
\[
k^2 \mathbb{Z} \cap [R_o, \infty) \subset Q(E - E).
\]

Our first application consists of an analogue of Magyar’s result for indefinite quadratic forms. Contrary to Magyar’s result, we focus here not on the values of $Q$ restricted to a difference set of a set $E \subset \mathbb{Z}^N$ of positive upper Banach density, but rather we study the values of $Q$ restricted to some translate of the set $E$. We stress that our techniques do not apply to the quadratic forms in Magyar’s Theorem as the (real points) of the symmetry group $\text{SO}(N)$ is compact. For the notion of an (aperiodic) Bohr set we refer the reader to Section 3.

**Theorem 1.3.** Let $p, q \geq 1$ and $p + q \geq 3$ and $E \subset \mathbb{Z}^{p+q}$ a set of positive upper Banach density. Let $Q$ denote the quadratic form on $\mathbb{R}^{p+q}$ defined by
\[
Q(z) = \sum_{i=1}^{p} \mu_i x_i^2 - \sum_{j=1}^{q} \lambda_j y_j^2, \quad \text{for } z = (x_1, \ldots, x_p, y_1, \ldots, y_q) \in \mathbb{R}^{p+q},
\]
where $\mu_1, \ldots, \mu_p$ and $\lambda_1, \ldots, \lambda_q$ are positive integers. Let $m$ be a positive integer. Then there exists a positive integer $k$ with the property that for every finite subset $F \subset \mathbb{Z}^{p+q}$ with $|F| = m$, we have
\[
k^2 Q(F) \subset Q(E - b), \quad \text{for some } b \in E.
\]
If $E$ is an aperiodic Bohr set, then $k$ can be chosen to be 1. In particular, if $E$ is an aperiodic Bohr$_0$-set, then $Q(E) = Q(\mathbb{Z}^{p+q})$.

Let us now explain how the application mentioned in the abstract of this paper follows from Theorem 1.3. Let $N = 3$ and consider the quadratic form (with $p = 2$, $q = 1$) given by
\[
Q(x, y, z) = x^2 + y^2 - z^2, \quad \text{for } (x, y, z) \in \mathbb{Z}^3.
\]
Since every odd integer is a difference of two consecutive squares, this form satisfies $Q(\mathbb{Z}^3) = \mathbb{Z}$. In particular, for every finite subset $F \subset \mathbb{Z}$, we can find a subset $F_0 \subset \mathbb{Z}^3$ of the same cardinality as $F$ such that $Q(F_0) = F$. We note that if $E_o \subset \mathbb{Z}$ has positive upper Banach density, then $E := E_o \times E_o \times E_o \subset \mathbb{Z}^3$ has positive upper Banach density as well. Hence, by Theorem 1.3, we conclude that for every positive integer $m$, there exists a positive integer $k$ such that for every finite set $F \subset \mathbb{Z}$ with $|F| = m$, we have
\[
k^2 F \subset Q((E_o - x) \times (E_o - y) \times (E_o - z)), \quad \text{for some } x, y, z \in E_o,
\]
Finally, if $E \subset Z$ is a Bohr$_o$-set, then $E = E \times E \times E \subset Z^3$ is again a Bohr$_o$-set, so by the second assertion of Theorem 1.3 we can in this case conclude that every integer can be written on the form $u^2 + v^2 - w^2$ for some $u, v, w \in E$.

1.2. Characteristic polynomials and their Galois groups. Our second example concerns characteristic polynomials of integer square matrices with zero trace. Let $\text{Mat}_d(Z)$ denote the additive group of integer matrices, and define the subgroup $\Lambda_d < \text{Mat}_d(Z)$ by

$$\Lambda_d = \{ a \in \text{Mat}_d(Z) : \text{tr}(a) = 0 \}.$$ 

Given a matrix $a \in \Lambda_d$, we write $\mathcal{C}(a) = \det(tI - a) \in Z[t]$ to denote its characteristic polynomial. We note that the map $\mathcal{C} : \Lambda_d \to Z[t]$ satisfies $\mathcal{C}(\gamma a \gamma^{-1}) = \mathcal{C}(a)$ for all $a \in \Lambda_d$ and $\gamma \in \text{GL}_d(Z)$.

The following theorem is an extension of a very recent result by the first author and A. Fish in the paper [4], to which the current paper owes the initial ideas.

**Theorem 1.4.** Let $d \geq 2$ and $E \subset \Lambda_d$ a set of positive upper Banach density. Let $m$ be a positive integer. Then there exists a positive integer $k$ with the property that for every finite subset $F \subset \Lambda_d$ with $|F| = m$, we have

$$\mathcal{C}(kF) \subset \mathcal{C}(E - b), \quad \text{for some } b \in E.$$ 

If $E$ is an aperiodic Bohr set, then $k$ can be chosen to be 1. In particular, if $E$ is an aperiodic Bohr$_o$-set, then $\mathcal{C}(E) = \mathcal{C}(\Lambda_d)$.

**Remark 1.5.** During the finalization of this paper, the authors were informed by A. Fish that he had independently proved the last assertion in Theorem 1.4 (concerning aperiodic Bohr$_o$ sets); see [7].

Given $a \in \Lambda_d$, we denote by $Q_a$ the field generated by the eigenvalues of $a$, or equivalently, the splitting field of the polynomial $\mathcal{C}(a)$. We note that

$$Q_{ka} = Q_a \quad \text{and} \quad Q_{\gamma a \gamma^{-1}} = Q_a, \quad \text{for all } k \in Q^* \text{ and } \gamma \in \text{GL}_d(Z).$$

Given $P \in Z[t]$, we let $\mathcal{G}(P)$ denote the Galois group (over $Q$) of the splitting field of $P$. Thus $\mathcal{G}(\mathcal{C}(a))$ is the Galois group of the field extension $Q_a/Q$. Since each $\mathcal{C}(a)$ is a monic polynomial of degree $d$, we see that each $\mathcal{G}(\mathcal{C}(a))$ is a subgroup of the symmetric group $S_d$. Let $\mathcal{G}_d$ denote the set of all possible subgroups $\mathcal{G}(\mathcal{C}(a)) < S_d$ as $a$ ranges over $\Lambda_d$. From the relations above, we see that

$$\mathcal{G}(\mathcal{C}(ka)) = \mathcal{G}(\mathcal{C}(a)) \quad \text{and} \quad \mathcal{G}(\mathcal{C}(\gamma a \gamma^{-1})) = \mathcal{G}(\mathcal{C}(a)), \quad \text{for all } k \in N^* \text{ and } \gamma \in \text{GL}_d(Z).$$

Let $F \subset \mathbb{Z}^N$ be a finite set such that $\mathcal{G}(F) = \mathcal{G}_d$. Upon applying the map $\mathcal{G}$ to the sets $\mathcal{C}(kF)$ and $\mathcal{C}(E - b)$ in Theorem 1.4 we have established the following corollary.

**Corollary 1.6.** Let $d \geq 2$ and suppose that $E \subset \Lambda_d$ is a set of positive upper Banach density. Then there exists $b \in E$ such that $\mathcal{G}_d \subset \mathcal{G}(\mathcal{C}(E - b))$, i.e. all possible Galois groups can be found in some translate of $E$.

This result should be compared with Gallagher’s Theorem [12] which asserts that “most” irreducible monic polynomials with integer coefficients have Galois group $S_d$. 

1.3. Determinants of symmetric matrices. Our final example involves determinants of symmetric integer matrices. We let $\text{Sym}_d = \{ a \in \text{Mat}_d(\mathbb{Z}) \mid a = a^t \}$ denote the set of all symmetric $d \times d$ integer matrices.

**Theorem 1.7.** Let $d \geq 2$ and $E \subseteq \text{Sym}_d$ a set of positive upper Banach density. Let $m$ be a positive integer. Then there exists a positive integer $k$ with the property that for every finite subset $F \subseteq \text{Sym}_d$ with $|F| = m$, we have

$$k^d \det(F) \subseteq \det(E - b), \quad \text{for some } b \in E.$$

If $E$ is an aperiodic Bohr set, then $k$ can be chosen to be 1. In particular, if $E$ is an aperiodic Bohr$_o$-set, then $\det(E) = \mathbb{Z}$.

In particular, let $E_o \subseteq \mathbb{Z}$ be an aperiodic Bohr$_o$-set, and define

$$E = \{ \begin{pmatrix} x & z \\ z & y \end{pmatrix} : x, y, z \in E_o \} \subseteq \text{Sym}_2.$$

Then $E$ is a Bohr$_o$-set in $\text{Sym}_2 \cong \mathbb{Z}^2$ to which Theorem 1.7 can be applied to yield the following corollary.

**Corollary 1.8.** Suppose that $E_o \subseteq \mathbb{Z}$ is an aperiodic Bohr$_o$-set. Then,

$$\{ xy - z^2 : x, y, z \in E_o \} = \mathbb{Z}.$$

1.4. Invariant patterns in sets of positive upper Banach density. We now turn to generalizing the three examples above. The main idea is that the functions presented in those examples (the quadratic forms, the characteristic polynomial map and the determinant map) are all invariant under certain linear actions. More specifically, the quadratic form $Q$ in Theorem 1.3 is preserved by $\text{SO}(Q)(\mathbb{Z})$; the characteristic polynomial map $C$ and the Galois group map $G$ on $\Lambda_d$ are both preserved by the conjugation action of $\text{SL}_d(\mathbb{Z})$ on $\Lambda_d$; while the determinant map is preserved by the action of $\text{SL}_d(\mathbb{Z})$ on $\text{Sym}_d$ given by $\gamma \cdot a = \gamma a \gamma^t$. One of the main goals of this paper is to establish the following general result, to which the examples above apply (this will be verified in Section 6).

**Definition 1.9.** A subgroup $\Gamma \leq \text{GL}_N(\mathbb{R})$ is said to be strongly irreducible if for every finite index subgroup $\Gamma' \leq \Gamma$, the standard representation of $\Gamma'$ on $\mathbb{R}^N$ is irreducible. We say that a Zariski connected real algebraic group $G$ has no compact factors if every Zariski-continuous group homomorphism $\rho : G \to \text{GL}_r(\mathbb{R})$ with bounded image is trivial (cf. Section 2 in [2]). To avoid confusion when necessary (in Section 6), the usual Lie group theoretic compact factors will be referred to as the compact Lie group factors.

**Theorem 1.10.** Let $\Gamma \leq \text{GL}_N(\mathbb{Z})$ be a non-trivial finitely generated strongly irreducible subgroup whose Zariski closure in $\text{GL}_N(\mathbb{R})$ is a Zariski connected semisimple group with no compact factors. Let $Y$ be a set and suppose that $\Psi : \mathbb{Z}^N \to Y$ is a $\Gamma$-invariant function. For every $E \subseteq \mathbb{Z}^N$ of positive upper Banach density and $m \geq 1$, there exists a positive integer $k$ with the property that whenever $F \subseteq \mathbb{Z}^N$ is a finite set of cardinality $m$, then

$$\Psi(kF) \subseteq \Psi(E - b), \quad \text{for some } b \in E.$$

Moreover, if $E \subseteq \mathbb{Z}^N$ is an aperiodic Bohr-set, then $k$ can be chosen to be 1. In particular, if $E$ is an aperiodic Bohr$_o$-set, then $\Psi(E) = \Psi(\mathbb{Z}^N)$. 

The following result is an immediate consequence of Theorem \[1.10\] and generalizes the main result in [4].

**Corollary 1.11.** Let \( \Gamma \) and \( \Psi \) be as in Theorem \[1.10\] and suppose that \( E \subset \mathbb{Z}^N \) has positive upper Banach density. Then there exists a positive integer \( k \) such that

\[
\Psi(k \mathbb{Z}^N) \subset \Psi(E - E).
\]

1.5. **Twisted multiple recurrence.** Theorem \[1.10\] is derived from a "twisted" multiple recurrence result for ergodic \( \mathbb{Z}^N \)-actions which we shall now state. Let \( (X, \nu) \) be a Borel probability measure space, i.e. \( X \) is a Borel subset of a compact and second countable space \( \overline{X} \), and \( \nu \) is a probability measure on the restriction of the Borel \( \sigma \)-algebra on \( \overline{X} \) to \( X \). Suppose that \( \mathbb{Z}^N \) acts on \( X \) by Borel measurable bijections, which preserve \( \nu \). In this case we refer to \( (X, \nu) \) as a \( \mathbb{Z}^N \)-space. We say that \( (X, \nu) \) is **ergodic** if whenever \( B \subset X \) is a Borel set which is invariant under \( \mathbb{Z}^N \), then \( B \) is either a \( \nu \)-null set or a \( \nu \)-conull set.

We note that one can always associate to any \( \mathbb{Z}^N \)-space a unitary representation \( \pi_X \) of \( \mathbb{Z}^N \) on the Hilbert space \( L^2(X, \nu) \) via

\[
(\pi_X(a)f)(x) = f((-a) \cdot x), \quad \text{for } a \in \mathbb{Z}^N \text{ and } f \in L^2(X, \nu).
\]

Given a character \( \chi \) on \( \mathbb{Z}^N \), we write

\[
L^2(X, \nu)_\chi = \{ f \in L^2(X, \nu) : \pi_X(a)f = \chi(a)f \} \subset L^2(X, \nu).
\]

We say that \( \chi \) is a **rational character** if there exists a positive integer \( m \) such that \( \chi(ma) = 1 \) for all \( a \in \mathbb{Z}^N \). The set of all rational \( \chi \) for which \( L^2(X, \nu)_\chi \) is non-zero is called the **rational spectrum** of the \( \mathbb{Z}^N \)-space \( (X, \nu) \). Since the constant function 1 is fixed by \( \pi_X \), we note that the rational spectrum always contains the trivial character 1. If there are no other elements in the rational spectrum, we say that the rational spectrum is **trivial**.

**Theorem 1.12.** Let \( (X, \nu) \) be an ergodic \( \mathbb{Z}^N \)-space and suppose that \( B \) is a Borel set in \( X \). Let \( \Gamma \) be as in Theorem \[1.10\]. For every \( \varepsilon > 0 \) and integer \( m \geq 1 \), there exists a positive integer \( k \) with the property that whenever \( a_1, \ldots, a_m \) are elements in \( k \mathbb{Z}^N \), then there are \( \gamma_1, \ldots, \gamma_m \in \Gamma \) such that

\[
\nu \left( \bigcap_{j=1}^m (\gamma_j a_j) \cdot B \right) \geq \nu(B)^m - \varepsilon.
\]

If the rational spectrum of the \( \mathbb{Z}^N \)-space \( (X, \nu) \) is trivial, then \( k \) can be chosen to be 1.

In Appendix I we outline how the following result can be deduced from Theorem \[1.12\]. For the connection between trivial rational spectrum and aperiodic Bohr sets we refer the reader to Section 3.

**Corollary 1.13.** Let \( E \subset \mathbb{Z}^N \) be a set of positive upper Banach density and \( m \geq 1 \). Let \( \Gamma \) be as in Theorem \[1.10\]. For every \( \varepsilon > 0 \), there exists a positive integer \( k \) with the property that whenever \( a_1, \ldots, a_m \) are elements in \( k \mathbb{Z}^N \), then there are \( \gamma_1, \ldots, \gamma_m \in \Gamma \) such that

\[
d^*(\bigcap_{j=1}^m (E - \gamma_j a_j)) \geq d^*(E)^m - \varepsilon.
\]

If \( E \) is an aperiodic Bohr set, then \( k \) can be chosen to be 1.
1.6. Proof of Theorem 1.10 using Corollary 1.13. Let \( Y \) be a set and \( \Psi : \mathbb{Z}^N \to Y \) be a \( \Gamma \)-invariant function. Let \( E \subset \mathbb{Z}^N \) be a set of positive upper Banach density and \( \varepsilon > 0 \) and let \( m \) be a positive integer. By Corollary 1.13 we can now find a positive integer \( k \) with the property that for all \( a_1, \ldots, a_m \in k\mathbb{Z}^N \), there are \( \gamma_1, \ldots, \gamma_m \in \Gamma \) such that

\[
d^*(E \cap \bigcap_{j=1}^m (E - \gamma_j a_j)) \geq d^*(E)^{m+1} - \varepsilon,
\]

If \( \varepsilon < d^*(E)^{m+1} \), then the left hand side is positive, and we can find \( b \in E \) such that

\[
b + \gamma_j a_j \in E, \quad \text{for every } j = 1, \ldots, m.
\]

In particular, \( \Psi(a_j) = \Psi(\gamma_j a_j) = \Psi(E - b) \) for each \( j \). Since \( a_1, \ldots, a_m \in k\mathbb{Z}^N \) are arbitrary, this finishes the first part of the proof. Finally, by the second part of Corollary 1.13, if \( E \subset \mathbb{Z}^N \) is an aperiodic Bohr-\( \varepsilon \)-set, then the integer \( k \) above can be chosen to be 1.

1.7. A non-conventional mean ergodic theorem. The proof of Theorem 1.12 will use as a black box some recent deep results by Benoist and Quint from the papers [1] and [3]. The following definition will be useful.

Definition 1.14 (BQ-pair). Let \( \Gamma < \text{GL}_N(\mathbb{Z}) \) be a non-trivial finitely generated irreducible subgroup and let \( \mu \) be a finitely supported probability measure on \( \Gamma \) whose support generates \( \Gamma \) as a semigroup. We say that \( (\Gamma, \mu) \) is a BQ-pair if the Zariski closure of \( \Gamma \) is a Zariski-connected semisimple algebraic group with no compact factors.

Let \( (\mathcal{H}, \pi) \) be a unitary \( \mathbb{Z}^N \)-representation on a separable Hilbert space \( \mathcal{H} \). Given a character \( \chi \) on \( \mathbb{Z}^N \), we define

\[
\mathcal{H}_\chi = \{ v \in \mathcal{H} : \pi(a)v = \chi(a)v, \text{ for all } a \in \mathbb{Z}^N \}.
\]

The rational spectrum of \( (\mathcal{H}, \pi) \) is defined as the set of all rational characters on \( \mathbb{Z}^N \) for which \( \mathcal{H}_\chi \) is non-zero. We say that the rational spectrum is trivial if it is either empty or only consists of the character 1. Finally, we denote by \( \mathcal{H}_{\text{rat}} \) the linear span of \( \mathcal{H}_\chi \), as \( \chi \) ranges over the rational spectrum, and we write \( \mathcal{H}_G \) for the linear subspace of \( \pi(G) \)-invariant vectors in \( \mathcal{H} \).

Suppose that \( \mu \) is a probability measure on \( \Gamma \). We define

\[
\mu^{*j}(\gamma) = \sum_{\gamma_1, \ldots, \gamma_j} \mu(\gamma_1) \cdots \mu(\gamma_j), \quad \text{for } j \geq 1,
\]

where the sum is taken over all \( j \)-tuples \( (\gamma_1, \ldots, \gamma_j) \) such that \( \gamma_1 \cdots \gamma_j = \gamma \).

Our main technical result in this paper can now be stated as follows.

Theorem 1.15. Let \( (\Gamma, \mu) \) be a BQ-pair and let \( (\mathcal{H}, \pi) \) be a unitary \( \mathbb{Z}^N \)-representation. For every \( a \in \mathbb{Z}^N \) and \( v \in \mathcal{H} \), the limit

\[
Q_a v := \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^n \left( \sum_{\gamma \in \Gamma} \mu^{*j}(\gamma) \pi(\gamma a) v \right),
\]

exists in the norm topology on \( \mathcal{H} \). Furthermore, for every \( \varepsilon > 0 \) and \( v \in \mathcal{H} \), there exists a positive integer \( k \) with the property that whenever \( a \in k\mathbb{Z}^N \), then

\[
\|Q_a v - P_{ma} v\| < \varepsilon,
\]
where $P_{\text{rat}}$ denotes the orthogonal projection onto $\mathcal{H}_{\text{rat}}$. If the rational spectrum of $(\mathcal{H}, \pi)$ is trivial, then $Q_a$ coincides with the orthogonal projection onto the space of $\pi$-invariant vectors, for all $a \in \mathbb{Z}^N \setminus \{0\}$.

1.8. Proof of Theorem 1.12 using Theorem 1.15. Let $(X, \nu)$ be an ergodic $\mathbb{Z}^N$-space and let $(L^2(X, \nu, \tau_X))$ be the associated $\mathbb{Z}^N$-representation as in Subsection 1.5. Since $(X, \nu)$ is ergodic, we see that all $\tau_X$-invariant elements are $(\nu$-essentially) constant functions. Let $f \in L^2(X\nu)$ be a measurable function such that 0 ≤ $f$ ≤ 1, and define

$$(Q_a^{(n)} f)(x) = \frac{1}{n} \sum_{j=1}^{n} \left( \sum_{\gamma \in \Gamma} \mu^s(\gamma)(\tau_X(\gamma a) f)(x) \right), \text{ for } a \in \mathbb{Z}^N.$$ 

Let $f_{\text{rat}} = P_{\text{rat}} f$ and fix $m \in \mathbb{N}$ and $\varepsilon > 0$. By Theorem 1.12 and the fact that $P_{\text{rat}}$ can be expressed as a conditional expectation (see §7.4 in [4]), we know that:

- There exists a positive integer $k$ such that for all $a \in k\mathbb{Z}^N \setminus \{0\}$, and sufficiently large $n$, we have
  $$\|Q_a^{(n)} f\|_{\infty} \leq 1 \text{ and } \|Q_a^{(n)} f - f_{\text{rat}}\| < \frac{\varepsilon}{m}.$$ 

- We have
  $$0 \leq f_{\text{rat}} \leq 1 \text{ and } \int_X f_{\text{rat}} \, d\nu = \int_X f \, d\nu.$$ 

- If the rational spectrum of $(X, \nu)$ is trivial, then $Q_a = P_{\text{rat}}$ and $Q_a f = \int_X f \, d\nu$ for all non-zero $a \in \mathbb{Z}^N$. In particular, the integer $k$ above can be chosen to be one.

Now fix $a_1, \ldots, a_m \in k\mathbb{Z}^N$. Hence, for some sufficiently large $n$, we have that

$$\int_X Q_{a_1}^{(n)} f(x) \cdot \ldots \cdot Q_{a_m}^{(n)} f(x) \, d\nu(x) \geq \int_X f_{\text{rat}}^{m-s} f^s \, d\nu - \varepsilon,$$

where $s$ denotes the number of $a_i$’s equal to zero (note that $Q_0 f = f$). If $s > 0$ then, since $f_{\text{rat}}^{m-s} \in \mathcal{H}_{\text{rat}}$, we have that

$$\int_X f_{\text{rat}}^{m-s} f^s \, d\nu = \int_X f_{\text{rat}}^{m-s} f \, d\nu = \int_X f_{\text{rat}}^{m-s+1} \, d\nu \geq \int_X f_{\text{rat}}^m \, d\nu.$$ 

Hence in either case we have that

$$\int_X Q_{a_1}^{(n)} f(x) \cdot \ldots \cdot Q_{a_m}^{(n)} f(x) \, d\nu(x) \geq \int_X f_{\text{rat}}^m \, d\nu - \varepsilon \geq \left( \int_X f_{\text{rat}} \, d\nu \right)^m - \varepsilon,$$

where in the last step we used Hölder’s inequality. In particular, for all $a_1, \ldots, a_m \in k\mathbb{Z}^N$, we can find $\gamma_1, \ldots, \gamma_m \in \Gamma$ such that

$$\int_X f((-\gamma_1 a_1) \cdot x) \cdot \ldots \cdot f((-\gamma_m a_m) \cdot x) \, d\nu(x) \geq \left( \int_X f \, d\nu \right)^m - \varepsilon,$$

which gives Theorem 1.12.
2. Proof of Theorem 1.15

Let $\mathbb{T}^N$ denote the set of all homomorphisms from $\mathbb{Z}^N$ into $S^1 = \{ z \in \mathbb{C}^* : |z| = 1 \}$, and note that $\text{GL}_N(\mathbb{Z})$ acts on $\mathbb{T}^N$ by

$$(\gamma^* \chi)(a) = \chi(\gamma^{-1} a), \quad \text{for } \chi \in \mathbb{T}^N \text{ and } \gamma \in \text{GL}_N(\mathbb{Z}).$$

Given $\chi \in \mathbb{T}^N$ and $\Gamma < \text{GL}_N(\mathbb{Z})$, we define

$$\Gamma \chi = \{ \gamma \in \Gamma : \gamma^* \chi = \chi \} \subset \Gamma.$$

We recall that an element $\chi \in \mathbb{T}^N$ is called rational if there exists a positive integer $m$ such that $\chi(ma) = 1$ for all $a \in \mathbb{Z}^N$.

Lemma 2.1. Suppose that $\Gamma < \text{GL}_N(\mathbb{Z})$ is infinite\(^1\) and strongly irreducible and $\chi \in \mathbb{T}^N$. Then the index $|\Gamma : \Gamma \chi|$ is finite if and only if $\chi$ is rational.

Proof. Suppose that $|\Gamma : \Gamma \chi|$ is finite, hence $\Gamma \chi$ is non-trivial as $\Gamma$ is infinite. Then $\Lambda = \ker \chi < \mathbb{Z}^N$ is a non-trivial $\Gamma \chi$-invariant subgroup, and thus $V = \Lambda \otimes \mathbb{R} < \mathbb{R}^N$ is a non-trivial $\Gamma \chi$-invariant linear subspace. By strong irreducibility of $\Gamma$, we have $V = \mathbb{R}^N$, and thus $\Lambda$ must have finite index in $\mathbb{Z}^N$. Let $m$ be the order of $\mathbb{Z}^N/\Lambda$. Then we have $\chi^m = 1$, and thus $\chi$ is rational.

Suppose that $\chi$ is rational. Then $\Lambda = \ker \chi < \mathbb{Z}^N$ has finite index, and $\Gamma$ acts on the finite set $\text{Im} \chi \cong \mathbb{Z}^N/\Lambda$, which shows that $\Gamma \chi = \text{Stab}_\Gamma \Lambda$ has finite index in $\Gamma$. \hfill $\square$

The main technical ingredient in the proof of Theorem 1.15 is the following deep result by Benoist and Quint; see Théorème 1.3 in [1] and Corollary 1.10b) in [3]. If $\Gamma$ in addition contains an element with a dominant eigenvalue of multiplicity one, then this result was established earlier by Bourgain, Furman, Lindenstrauss and Mozes; see Theorem B in [5].

Theorem 2.2. Let $(\Gamma, \mu)$ be a BQ-pair. For every $\chi \in \mathbb{T}^N$ and $a \in \mathbb{Z}^N\setminus\{0\}$, we have

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^n \left( \sum_{\gamma \in \Gamma} \chi(\gamma a) \mu^j(\gamma) \right) = 0,$$

if $|\Gamma : \Gamma \chi| = \infty$, and

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^n \left( \sum_{\gamma \in \Gamma} \chi(\gamma a) \mu^j(\gamma) \right) = \frac{1}{|\Gamma : \Gamma \chi|} \sum_{\gamma \in \Gamma \chi/\Gamma} \chi(\gamma a),$$

if $|\Gamma : \Gamma \chi| < \infty$.

Remark 2.3. We stress that Theorem 2.2 is not explicited in neither of the papers [1] or [3]. Under the assumption that $(\Gamma, \mu)$ is a BQ-pair, Corollary 1.10b) in [3] asserts that for every $\chi \in \mathbb{T}^N$, there exists a $\Gamma$-invariant Borel probability measure on $\gamma_\chi$ on $\mathbb{T}^N$, supported on the closure of the $\Gamma$-orbit of $\chi$, such that for every continuous function $f : \mathbb{T}^N \to \mathbb{C}$, we have

$$\frac{1}{n} \sum_{k=1}^n \left( \sum_{\gamma \in \Gamma} f((\gamma^*)^{-1} \chi) \mu^j(\gamma) \right) = \int_{\mathbb{T}^N} f \ d\nu_\chi.$$

\(^1\)This is satisfied for $\Gamma$ coming from a BQ pair: If $\Gamma$ is non-trivial and has Zariski connected Zariski closure, then it must be infinite.
By Théoremé 1.3 in [1], \( \nu_\chi \) is either the counting probability measure on a the (finite) \( \Gamma \)-orbit of \( \chi \) in \( \mathbb{T}^N \) (in which case the index \([\Gamma : \Gamma_\chi]\) is finite), or it is equal to the Haar probability measure on \( \mathbb{T}^N \). We get Theorem 2.2 by letting \( f(\chi) = \chi(a) \) for \( a \in \mathbb{Z}^N \).

Let \((\mathcal{H}, \pi)\) be a unitary \( \mathbb{Z}^N \)-representation on a separable Hilbert space \( \mathcal{H} \). Given \( \chi \in \mathbb{T}^N \), we define

\[
\mathcal{H}_\chi = \{ \nu \in \mathcal{H} : \pi(\alpha) \nu \equiv \chi(\alpha) \nu, \text{ for all } \alpha \in \mathbb{Z}^N \}.
\]

One readily verifies that if \( \chi_1 \) and \( \chi_2 \) are distinct elements in \( \mathbb{T}^N \), then \( \mathcal{H}_{\chi_1} \) and \( \mathcal{H}_{\chi_2} \) are orthogonal subspaces in \( \mathcal{H} \). Since \( \mathcal{H} \) is separable, we conclude that there is a possibly empty, but at most countable, set \( \Omega \subset \mathbb{T}^N \) such that \( \mathcal{H}_\chi \) is a non-trivial subspace for \( \chi \in \Omega \). The set of rational elements in \( \Omega \) will be denoted by \( \mathcal{R}_N \), which we shall refer to as the rational spectrum of \((\mathcal{H}, \pi)\), and we write

\[
\mathcal{H}_{\text{rat}} = \bigoplus_{\chi \in \mathcal{R}_N} \mathcal{H}_\chi \subset \mathcal{H},
\]

where the direct sum is taken in the Hilbert space sense. The following lemma is an immediate consequence of the definitions above and the second assertion in Theorem 2.2, so we omit the proof.

**Lemma 2.4.** For every \( \nu \in \mathcal{H}_{\text{rat}} \) and \( a \in \mathbb{Z}^N \), we have

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \left( \sum_{\gamma \in \Gamma} \mu^j(\gamma) \pi(\gamma a) \nu \right) = \sum_{\chi \in \mathcal{R}_N} \left( \frac{1}{|\Gamma : \Gamma_\chi|} \sum_{\gamma \in \Gamma \chi \Gamma} \chi(\gamma a) \right) \nu_\chi
\]

where \( \nu = \sum \nu_\chi \) and \( \nu_\chi \in \mathcal{H}_\chi \).

The full force of Theorem 2.2 is released in the proof of the following lemma.

**Lemma 2.5.** For every \( \nu \in \mathcal{H}_{\text{rat}} \) and \( a \in \mathbb{Z}^N \setminus \{0\} \), we have

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \left( \sum_{\gamma \in \Gamma} \mu^j(\gamma) \pi(\gamma a) \nu \right) = 0.
\]

**Proof.** Let \( \nu \in \mathcal{H}_{\text{rat}} \) with \( |\nu| = 1 \). By Bochner’s Theorem, there exists a Borel probability measure \( \eta \) on \( \mathbb{T}^N \) such that

\[
\langle \pi(\alpha) \nu, \nu \rangle = \int_{\mathbb{T}^N} \chi(a) \, d\eta(\chi), \quad \text{for all } \alpha \in \mathbb{Z}^N.
\]

We observe that, by an application of von-Neumann’s mean ergodic theorem to the unitary \( \mathbb{Z}^N \)-representation \((\mathcal{H}, \pi_\chi)\) given by

\[
\pi_\chi(\alpha) \nu = \chi(\alpha)^{-1} \nu \quad \text{for } \alpha \in \mathbb{Z}^N \text{ and } \nu \in \mathcal{H},
\]

we have that \( \eta(\{\chi\}) = 0 \) for every rational \( \chi \in \mathbb{T}^N \). We note that

\[
\left| \frac{1}{n} \sum_{j=1}^{n} \left( \sum_{\gamma \in \Gamma} \mu^j(\gamma) \pi(\gamma a) \nu \right) \right|^2 = \int_{\mathbb{T}^N} \left| \frac{1}{n} \sum_{j=1}^{n} \left( \sum_{\gamma \in \Gamma} \mu^j(\gamma) \chi(\gamma a) \right) \right|^2 \, d\eta(\chi),
\]

for all \( n \). By Lemma 2.1, we have \([\Gamma : \Gamma_\chi] = \infty \) for every irrational \( \chi \) and \([\Gamma : \Gamma_\chi] < \infty \) for every rational \( \chi \). Hence, by Theorem 2.2, we conclude that the right-hand side above converges to

\[
\sum_{\chi \in \mathcal{R}_N} \left| \frac{1}{[\Gamma : \Gamma_\chi]} \sum_{\gamma \in \Gamma \chi \Gamma} \chi(\gamma a) \right|^2 \eta(\{\chi\}) = 0,
\]
with dense image. Let $U$ and a non-empty open set $U$ group $K$ be connected, we say that $E$ is aperiodic if there exist a compact and second countable abelian group $K$ with Haar probability measure $m_K$, a homomorphism $\tau : \mathbb{Z}^N \to K$ with dense image, and a non-empty open set $U \subset K$ with $m_K(U) = m_K(\mathbb{U})$ such that $E = \tau^{-1}(U)$. If $K$ is connected, we say that $E$ is aperiodic, and if $U$ contains the identity element of $K$, we say that $E$ is an aperiodic Bohr set. We note that if $E \subset \mathbb{Z}^N$ is any aperiodic Bohr set, then one can always find another Bohr set $C$ such that $C - C \subset B$.

Example. We give here an example of an aperiodic Bohr set in $\mathbb{Z}$. Let $K = \mathbb{R}/\mathbb{Z}$ and suppose that $\alpha$ is an irrational number. Then $\tau(\alpha) = a \cdot \alpha \mod 1$ is a homomorphism from $\mathbb{Z}$ into $K$ with dense image. Let $U \subset K$ be an open subset, e.g. an open interval. Then

$$B = \tau^{-1}(U) = \{ a \in \mathbb{Z} : a \cdot \alpha \mod 1 \in U \} \subset \mathbb{Z}$$
is an aperiodic Bohr set in $\mathbb{Z}$. More generally, for every integer $N$, we can form the homomorphism $\tau_N : \mathbb{Z}^N \to K^N$ defined by
$$
\tau(a_1, \ldots, a_N) = (\tau(a_1), \ldots, \tau(a_N)), \quad \text{for} \ (a_1, \ldots, a_N) \in \mathbb{Z}^N.
$$
One can readily check that $\tau_N$ has dense image in $K^N$, and thus
$$
B \times \cdots \times B = \tau_N^{-1}(U \times \cdots \times U) \subset \mathbb{Z}^N
$$
is an aperiodic Bohr$_o$-set in $\mathbb{Z}^N$.

We can make $(K, m_K)$ into a $\mathbb{Z}^N$-space with the $\mathbb{Z}^N$-action defined by
$$
a \cdot x = x - \tau(a), \quad \text{for} \ x \in K \text{ and } a \in \mathbb{Z}^N.
$$
We denote by $\pi_K$ the regular representation of $\mathbb{Z}^N$ on $L^2(K, m_K)$ and given $\chi \in \mathcal{T}^N$, we define
$$
L^2(K, m_K)_\chi = \{ f \in L^2(K, m_K) : \pi_K(a)f = \chi(a)f \}.
$$
Let $\hat{K}$ denote the dual of $K$. We can view $\eta \in \hat{K}$ as an element in $L^2(K, m_K)$ with the property that $\pi_K(a)\eta = \eta(\tau(a))\eta$ for all $a \in \mathbb{Z}^N$. Note that if $\eta_1, \eta_2 \in \hat{K}$ satisfy $\eta_1 \circ \tau = \eta_2 \circ \tau$, then $\eta_1 = \eta_2$ since the image of $\tau$ is dense. In particular, for every $\chi \in \mathcal{T}^N$ of the form $\chi = \eta \circ \tau$, we have
$$
L^2(K, m_K)_\chi = \mathbb{C} \cdot \eta.
$$
Since all $\eta$ are orthogonal to each other in $L^2(K, m_K)$, and together span $L^2(K, m_K)$, we conclude that
$$
L^2(K, m_K) = \bigoplus_{\eta \in \hat{K}} L^2(K, m_K)_{\eta \circ \tau},
$$
where the direct sum is taken in the Hilbert space sense. Suppose that $\chi = \eta \circ \tau$ is rational, i.e. assume that there exists a positive integer $m$ such that $\chi^m = 1$. Then,
$$
\chi(a)^m = \eta(m\tau(a)) = \eta(\tau(ma)) = 1, \quad \text{for all} \ a \in \mathbb{Z}^N,
$$
and thus $\eta(k) = 1$ for all $k \in L$, where $L := \overline{\tau(m\mathbb{Z}^N)} < K$, by continuity of $\eta$. One readily shows that $L$ has finite index in $K$ and thus is an open subgroup of $K$. In particular, if $K$ is connected, then $L = K$, and $\eta = 1$, which establishes the following lemma.

**Lemma 3.1.** Let $K$ be a compact and connected abelian group and suppose that $\tau : \mathbb{Z}^N \to K$ is a homomorphism with dense image. Then the associated $\mathbb{Z}^N$-space $(K, m_K)$ has trivial rational spectrum.

### 4. Acknowledgements

The authors have greatly benefited from discussions with Alexander Fish, Peter Hegarty and Jean-François Quint. This work was carried out during the second author's visit to Chalmers University in September and October of 2015 funded by the University of Sydney's Philipp Hofflin International Research Travel Scholarship, for which he is very grateful for. He would like to also thank the Department of Mathematical Sciences at Chalmers University for their hospitality.
5. Appendix I: Correspondence Principle

We shall now explain how one can deduce Corollary 1.13 from Theorem 1.12. The arguments in this section are nowadays rather standard, and can be traced back to the seminal paper [9] by Furstenberg.

Suppose that \( E \subset \mathbb{Z}^N \). We may view \( E \) as an element in the compact and second countable space \( \mathcal{P} Z_N \) of all subsets of \( \mathbb{Z}^N \) equipped with the product topology, on which \( \mathbb{Z}^N \) acts by homeomorphisms via

\[
 a \cdot A = A - a, \quad \text{for } A \in \mathbb{Z}^N \text{ and } a \in \mathbb{Z}^N.
\]

Let \( X \) denote the closure of \( \mathbb{Z}^N \cdot E \) in \( \mathcal{P} Z_N \). Then \( X \) is again a compact and second countable space, and

\[
 V = \{ A \in X : 0 \in A \} \subset X,
\]

is a clopen (closed and open) subset of \( X \). We note that \( E = \{ a \in \mathbb{Z}^N : a \cdot E \in V \} \). In other words, \( E \) can be realized as the "hitting times" of the set \( V \) of the \( \mathbb{Z}^N \)-orbit of \( E \) in \( X \).

More generally, let \( X \) be a compact and second space, equipped with an action of \( \mathbb{Z}^N \) by homeomorphisms. Given a subset \( U \subset X \) and \( x \in X \), we define

\[
 U_x = \{ a \in \mathbb{Z}^N : a \cdot x \in U \} \subset \mathbb{Z}^N.
\]

For instance, if \( K \) is a compact and connected second countable group, \( \tau : \mathbb{Z}^N \to K \) is a homomorphism with dense image and \( (K, m_K) \) denotes the associated \( \mathbb{Z}^N \)-space defined in Section 3, then for any non-empty open subset \( U \subset K \), we see that

\[
 U_0 = \{ a \in \mathbb{Z}^N : \tau(a) \in -U \} = \tau^{-1}(-U) \subset \mathbb{Z}^N
\]

is an aperiodic Bohr set. Since \( K \) is connected, the \( \mathbb{Z}^N \)-space \( (K, m_K) \) has trivial rational spectrum by Lemma 3.1.

Let \( F_n = [-n, n]^N \subset \mathbb{Z}^N \) and define the upper Banach density of a subset \( E \subset \mathbb{Z}^N \) by

\[
 d^*(E) = \sup \left\{ \limsup_{n} \frac{|E \cap (F_n + a_n)|}{|F_n|} : (a_n) \text{ is a sequence in } \mathbb{Z}^N \right\}.
\]

In particular,

\[
 d^*(E) \geq \limsup_{n} \frac{|E \cap F_n|}{|F_n|}, \quad \text{for all } E \subset \mathbb{Z}^N.
\]

Let \( \mathcal{P}_{\mathbb{Z}^N}(X) \) denote the (non-empty) convex set of \( \mathbb{Z}^N \)-invariant Borel probability measures on the compact and second countable space \( X \). The following proposition can now be deduced from Theorem 1.1 in [9].

**Proposition 5.1.** Suppose that \( U \subset X \) is open and \( x_o \in X \) has a dense \( \mathbb{Z}^N \)-orbit in \( X \). Then,

\[
 d^* \left( \bigcap_{a \in F} (U_{x_o} - a) \right) \geq \nu \left( \bigcap_{a \in F} a \cdot U \right),
\]

for every finite set \( F \subset \mathbb{Z}^N \) and \( \nu \in \mathcal{P}_{\mathbb{Z}^N}(X) \). Furthermore, if \( \nu(U) = \nu(U) \) for all \( \nu \in \mathcal{P}_{\mathbb{Z}^N} \), then

\[
 d^*(U_{x_o}) = \nu(U), \quad \text{for some ergodic } \nu \in \mathcal{P}_{\mathbb{Z}^N}(X).
\]
5.1. **Proof of Corollary 1.13.** Suppose that \((X, \nu)\) is a compact and second countable \(\mathbb{Z}^N\)-space, and let \(U \subset X\) be a non-empty open set such that \(\nu(U) = \nu(U)\) for all \(\nu \in \mathcal{P}_{\mathbb{Z}^N}(X)\). For instance, we could choose:

- \(X\) to be the orbit closure of the set \(E \subset \mathbb{Z}^N\) and \(U = V\) as in (6.1). In this case, \(U\) is a non-empty clopen set, and there exists an ergodic \(\nu \in \mathcal{P}_{\mathbb{Z}^N}(X)\) such that
  \[
  d^*(E) = d^*(U_E) = \nu(U).
  \]
- \(K\) to be a compact, connected and second countable group, \(\tau : \mathbb{Z}^N \to K\) a homomorphism with dense image and \((X, \nu) = (K, m_K)\) the \(\mathbb{Z}^N\)-space associated to \((K, \tau)\) as in Section 3. In this case, \(m_K\) is the unique \(\mathbb{Z}^N\)-invariant Borel probability measure on \(K\). In particular, for any open subset such that \(m_K(U) = m_K(U)\), we have \(d^*(\tau^{-1}(U)) = m_K(U)\), and \(\nu = \tau^{-1}(U)\) is an aperiodic Bohr set.

Let \(\Gamma < \text{GL}_N(\mathbb{Z})\) and \(a_1, \ldots, a_m \in \mathbb{Z}^N\). In the first case above, Proposition 5.1 guarantees that
\[
d^*(E) = \nu(V) \quad \text{and} \quad d^*(\bigcap_{j=1}^m (E - \gamma_j a_j)) \geq \nu\left(\bigcap_{j=1}^m (\gamma_j a_j) \cdot V\right),
\]
for all \(\gamma_1, \ldots, \gamma_m\), and in the second case above, Proposition 5.1 asserts that
\[
d^*(E) = m_K(U) \quad \text{and} \quad d^*(\bigcap_{j=1}^m (\tau^{-1}(U) - \gamma_j a_j)) \geq m_K\left(\bigcap_{j=1}^m (\gamma_j a_j) \cdot U\right),
\]
for all \(\gamma_1, \ldots, \gamma_m\).

Let \(\Gamma\) be as in Theorem 1.10 and suppose that \((X, \nu)\) and \(U\) are as in one of the two examples above. Let \(\varepsilon > 0\) and let \(m\) be a positive integer. By Theorem 1.12 there exist a positive integer \(k\) with the property that whenever \(a_1, \ldots, a_m \in \mathbb{Z}^N\), then
\[
\nu\left(\bigcap_{j=1}^m (\gamma_j a_j) \cdot U\right) \geq \nu(U)^m - \varepsilon, \quad \text{for some } \gamma_1, \ldots, \gamma_m \in \Gamma. \tag{5.3}
\]
Furthermore, if \((X, \nu)\) has trivial spectrum, as in the second example above (by Lemma 3.1), then \(k\) can be chosen to be 1.

Upon combining the bounds above, we conclude that for all \(a_1, \ldots, a_m \in \mathbb{Z}^N\), we have
\[
d^*\left(\bigcap_{j=1}^m (E - \gamma_j a_j)\right) \geq d^*(E)^m - \varepsilon, \quad \text{for some } \gamma_1, \ldots, \gamma_m \in \Gamma.
\]
In the case when \((X, \nu) = (K, m_K)\), the integer \(k\) can be chosen to be 1.

6. **Appendix II: Verifying the conditions for a BQ-pair.**

We now verify that our examples satisfy the conditions of a BQ-pair. Note that in each of our examples we have a polynomial group homomorphism \(\rho : G \to \text{SL}_N(\mathbb{R})\) for some Zariski closed subgroup \(G \leq \text{SL}_d(\mathbb{R})\), which then defines an action of \(G\) on \(\mathbb{R}^N\) given by \(g \cdot \nu = \rho(g)\nu\). For example, in Theorem 1.4 we consider the adjoint representation \(\text{Ad} : \text{SL}_d(\mathbb{R}) \to \text{GL}(\text{sL}_d(\mathbb{R}))\), given by
\[
\text{Ad}(g)\nu = g\nu g^{-1} \quad \text{for } g \in \text{SL}_d(\mathbb{R}) \text{ and } \nu \in \text{sL}_d(\mathbb{R}),
\]
where $\mathfrak{sL}_d(\mathbb{R})$ is the real vector space of real $d \times d$ traceless matrices. In other words, Theorem 1.4 is obtained from Theorem 1.10 by setting $\Gamma = \text{Ad}(\mathfrak{sl}_d(\mathbb{Z}))$ (and identifying $\Lambda_d$ with $\mathbb{Z}^{d^2-1}$). The following Proposition ensures that such a representation $\rho$ preserves certain algebraic conditions in the definition of a BQ-pair.

**Proposition 6.1.** Let $\rho : G \to \mathfrak{SL}_N(\mathbb{R})$ be a polynomial homomorphism, where $G \subset \mathfrak{SL}_d(\mathbb{R})$ is a Zariski connected semisimple Lie group with no compact algebraic factors. Then for $\Gamma \leq G$ Zariski dense, we have that the Zariski closure of $\rho(\Gamma)$ is a Zariski connected semisimple Lie group with no compact algebraic factors.

**Proof.** By Zariski-continuity, $\rho(G) \leq \overline{\rho(\Gamma)^Z}$ and in fact it is classical that $[\rho(G) : \overline{\rho(\Gamma)^Z}]$ is finite (see for example Corollary 4.6.5 [16]). Hence $\rho(G)$ being semisimple implies that $\overline{\rho(\Gamma)^Z}$ also is. Again by Zariski continuity of $\rho$, we have that $\overline{\rho(\Gamma)^Z}$ is Zariski connected. Finally, suppose that $\kappa : \overline{\rho(\Gamma)^Z} \to \text{GL}_d(\mathbb{R})$ is a bounded algebraic group homomorphism (for some $D$), then so is $\kappa \circ \rho$ and so $\kappa(\rho(G))$ is the trivial subgroup. Thus $\rho(G) \leq \text{ker} \kappa \leq \overline{\rho(\Gamma)^Z}$. But since $\text{ker} \kappa$ is Zariski closed we have that it is equal to $\overline{\rho(\Gamma)^Z}$, so there are no compact factors. □

### 6.1. Algebro-geometric properties

We now turn to determining the Zariski closures of $\mathfrak{SL}_d(\mathbb{Z})$ and $\text{SO}(Q)(\mathbb{Z})$ and verifying the required algebro-geometric properties (In this appendix, $Q$ will always denote a quadratic form as in Theorem 1.3). We first note the crucial fact that the groups $\mathfrak{SL}_d(\mathbb{Z})$ and $\text{SO}(Q)(\mathbb{Z})$ are, respectively, lattices in $\mathfrak{SL}_d(\mathbb{R})$ and $\text{SO}(Q)(\mathbb{R})$ (See Theorem 5.1.11 and Example 5.1.12 in [15]). We also note that, as required by our main theorems, these lattices are finitely generated (See Theorem 4.7.10 in [15] or Chapter IX in [14]). We will demonstrate below, via Borel’s density theorem, that these lattices are Zariski dense. We remark the technicality that we use the following formulation of Borel’s density theorem (not explicated in [8] as it demands that $G$ is connected), which follows immediately from a combination of (4.5.1) in [15] and (4.5.2) in [16].

**Theorem 6.2** (Borel’s density theorem). Let $G \leq \mathfrak{SL}_N(\mathbb{R})$ be a Zariski connected semisimple Lie group (in particular, it has finitely many connected components) with no compact Lie group factors. Then any lattice in $G$ is Zariski dense.

**Lemma 6.3.** The group $\mathfrak{SL}_d(\mathbb{R})$ is the Zariski closure of $\mathfrak{SL}_d(\mathbb{Z})$ and is a Zariski-connected semisimple Lie group with no compact factors.

**Proof.** Zariski connectedness follows from the fact that $\mathfrak{SL}_d(\mathbb{R})$ is connected in the Euclidean topology. The lack of compact factors follows from the much stronger classical fact that the only proper non-trivial normal (abstract) subgroup of $\mathfrak{SL}_d(\mathbb{R})$ is its center (in particular, this also shows semisimplicity). Thus Borel’s density theorem may be applied. □

From now on, we identify $\text{SO}(Q)(\mathbb{R})$ with $\text{SO}(p,q)(\mathbb{R})$, as can be done via a linear change of coordinates.

**Lemma 6.4.** For $p, q \geq 1$ with $p + q \geq 3$, the group $\text{SO}(p,q)(\mathbb{R})$ is a Zariski-connected semisimple Lie group with no compact factors. Moreover, the Zariski closure of $\text{SO}(Q)(\mathbb{Z})$ is $\text{SO}(Q)(\mathbb{R}) \cong \text{SO}(p,q)(\mathbb{R})$. 
Proof. Let \( G = SO(p, q)(\mathbb{R}) \) and let \( G^o \) denote the connected (in the Euclidean topology) component of \( SO(p, q) \). It follows from Problems 9 and 10 of Section 3 in Chapter 1 of [17] that \( [G : G^o] = 2 \) and that \( G^o \) is not Zariski closed. This implies that \( G \) is the Zariski closure of \( G^o \) and thus is Zariski connected. For \( (p, q) \neq (2, 2) \) it is well known (see for instance Appendix A in [15]) that \( G^o \) is simple as a Lie group and hence has no compact Lie group factors, while for \( (p, q) \neq (2, 2) \) we have that \( G \) is a finite index quotient of \( SL_2(\mathbb{R}) \times SL_2(\mathbb{R}) \) (see Appendix B in [18]) and thus is semisimple with no compact Lie group factors. In either case, we have that \( G^o \) is contained in the kernel of all compact (algebraic) factors of \( G \). Hence, since \( SO^o(p, q)(\mathbb{R}) \) is not Zariski closed, there are no non-trivial compact (algebraic) factors. Moreover, we may apply Borel’s density theorem to obtain that all lattices (and hence \( SO(Q)(\mathbb{Z}) \)) are Zariski dense in \( SO(Q)(\mathbb{R}) \cong G \). \( \square \)

6.2. Irreducibility. It now remains to check the strong irreducibility of the subgroups in our examples. Our first lemma shows that in fact it is enough to check the irreducibility of its Zariski closure.

Lemma 6.5 (Irreducibility implies strong irreducibility). Suppose that \( \Gamma \leq \text{GL}_N(\mathbb{Z}) \) is a subgroup such that its Zariski closure \( G = \overline{\Gamma}^Z \leq \text{GL}_N(\mathbb{R}) \) is Zariski connected and irreducible. Then \( \Gamma \) is a strongly irreducible subgroup of \( \text{GL}_N(\mathbb{R}) \).

Proof. Let \( V \leq \mathbb{R}^N \) be a non-trivial subspace invariant under a finite index subgroup \( \Gamma_0 \leq \Gamma \). Then \( \overline{\Gamma_0}^Z \) also preserves \( V \) and is a finite index Zariski closed subgroup of \( G \), hence \( G = \overline{\Gamma_0}^Z \) by Zariski connectedness of \( G \). So \( G \) preserves \( V \) and so \( V = \mathbb{R}^N \), as required. \( \square \)

Lemma 6.6. The adjoint action (i.e. action by conjugation) of \( \text{SL}_d(\mathbb{R}) \) on \( s_l_d(\mathbb{R}) \) is irreducible.

Proof. Let \( W \leq s_l_d(\mathbb{R}) \) by a subspace that is invariant under the adjoint action. By differentiating, we see that \( [s_l_d(\mathbb{R}), W] = W \), i.e. \( W \) is an ideal. But it is well known that \( s_l_d(\mathbb{R}) \) is simple. \( \square \)

For a representation \( G \rightharpoonup V \) and \( v \in V \), we let \( \mathbb{R}[G]v \) denote the smallest \( G \)-invariant subspace containing \( v \).

Lemma 6.7. The action of \( \text{SL}_d(\mathbb{R}) \) on \( \text{Sym}_d \) given by \( gA = gAg^t \) is irreducible.

Proof. Since each non-zero element of \( \text{Sym}_d \) is in the \( G \)-orbit of some diagonal matrix, it is enough to show that \( \mathbb{R}[G]A = \text{Sym}_d \) for each non-zero diagonal matrix \( A \). All positive diagonal matrices (i.e. diagonal matrices with positive diagonal entries) are in the \( G \)-orbit of some positive constant multiple of the identity matrix, but the positive diagonal matrices span the space of all diagonal matrices. Thus it remains to show that if we fix a non-zero diagonal matrix \( A = \text{diag}(a_1, a_2, \ldots, a_d) \), then the space \( \mathbb{R}[G]A \) contains a positive diagonal matrix. Note that the \( G \)-orbit of \( A \) contains

\[
\text{diag}(Ka_1, K^{-1/(d-1)}a_2, \ldots, K^{-1/(d-1)}a_d)
\]

for all \( K > 0 \)

and also

\[
\text{diag}(a_{\sigma(1)}, \ldots, a_{\sigma(n)})
\]

for all \( \sigma \in S_n \).
which can be seen from the identity

\[
\begin{pmatrix}
0 & 1 \\
-1 & 0
\end{pmatrix}
\begin{pmatrix}
d_1 & 0 \\
0 & d_2
\end{pmatrix}
\begin{pmatrix}
0 & -1 \\
1 & 0
\end{pmatrix}
= \begin{pmatrix}
d_2 & 0 \\
0 & d_1
\end{pmatrix}.
\]

Assuming (without loss of generality) that \(a_1 > 0\), we see (by taking \(K\) large enough) that the \(G\)-orbit of \(A\) contains an element of the form \(B_1 = \text{diag}(b_1, \ldots, b_n)\) where \(b_1 > d\) and \(|b_k| < 1\) for \(k = 2, \ldots, d\). The \(G\)-orbit of \(A\) also contains \(B_r = (b_{\sigma(1)}, \ldots, b_{\sigma(n)})\) where \(\sigma\) is the transposition \((1r)\). Thus \(B_1 + \cdots + B_d \in \mathbb{R}[G]\) is a diagonal matrix with positive diagonal entries.

\[\square\]

**Lemma 6.8.** For \(p, q \geq 1\) with \(p + q \geq 3\), the action of \(SO(p, q)\) on \(\mathbb{R}^{p+q}\) is irreducible.

This will be deduced from the following general observation.

**Lemma 6.9.** Let \(V\) and \(W\) be vector spaces with \(\dim W > 1\) and let \(H \leq GL(V), K \leq GL(W)\) be subgroups acting irreducibly on \(V\) and \(W\) respectively. Now suppose that \(H \times K \leq G \leq GL(V \oplus W)\) is a subgroup such that \(V \times \{0\}\) and \(\{0\} \times W\) are not \(G\)-invariant. Then \(G\) acts irreducibly on \(V \oplus W\).

**Proof.** Choose \(x_0 = (v_0, w_0) \in V \oplus W \setminus \{(0, 0)\}\) and let \(\mathbb{R}[G]x_0\) denote the smallest \(G\)-invariant subspace containing \(x_0\). There exists \(x_1 = (v_1, w_1) \in \mathbb{R}[G]x_0\) such that \(w_1 \neq 0\) (by non-invariance of \(V \times \{0\}\)). Now since \(\dim W > 1\) and \(K\) acts irreducibly, there exists \(k_1 \in K\) such that \(k_1.w_1 \neq w_1\). Hence

\[x_2 := x_1 - (1, k_1).x_1 = (0, w_2) \in \mathbb{R}[G]x_0\]

with \(w_2 = w_1 - k_1.w_1 \neq 0\). Since the action of \(K\) is irreducible, we have \(\{0\} \times W \leq \mathbb{R}[G]x_0\). But since \(\{0\} \times W\) is not \(G\)-invariant, there exists \((v_3, w_3) \in \mathbb{R}[G]x_0\) such that \(v_3 \neq 0\). But \((v_3, 0) = (v_3, w_3) - (0, w_3) \in \mathbb{R}[G]x_0\). So by irreducibility of \(H\) we have that \(V \times \{0\} \subset \mathbb{R}[G]x_0\).

The lemma applies (assuming \(q \geq 2\)) with \(V = \mathbb{R}^p, W = \mathbb{R}^q, H = SO(p), K = SO(q)\) and \(G = SO(p, q)\). The non-invariance of \(V\) and \(W\) follow from considering a natural embedding \(SO(1, 1) \hookrightarrow SO(p, q)\) and using the fact that \(SO(1, 1)\) acts irreducibly on \(\mathbb{R}^2\) (this can be seen by considering hyperbolic rotations).
