We study gravitational waves to first and second order in amplitude in vacuum asymptotically flat spacetimes. The Einstein equations are solved to first order and these solutions are superposed to form a time-symmetric ingoing and then outgoing pulse regular everywhere. The waves are assumed to have odd-parity and a non-vanishing angular momentum which keeps them away from the axis at all times. The averaged energy of the waves is evaluated. The relevant Einstein equation is then solved to second order in the amplitude. The influence of the angular momentum of the waves on the rotation of local inertial frames with respect to the frames at great distances is analyzed. The rotation of the frames occurs even in the region around the origin where spacetime is almost flat. The rotation is without time delay as it follows from the constraint equation.

The results are illustrated graphically for various values of the “harmonic index $m$” corresponding to azimuthal rotation and the “harmonic index $l$” describing the latitudinal rotation of the waves. The apparent motions of the fixed stars on the celestial sphere as seen through rotating waves from the local inertial frame are calculated and displayed.

I. INTRODUCTION

It was just 100 years ago in Prague when Einstein wrote the paper [1] in which he, for the first time, expressed his understanding of Mach’s Principle. Within his pre-general relativity theory in which there was only one metric function he considered a mass point inside a shell accelerated “upwards” and found that the mass point is dragged along by the shell.

Many formulations and studies of Mach’s Principle have appeared during the last 100 years, most of them were analyzed in the Tübingen conference in 1993 which led to the remarkable volume [2] containing lectures as well as valuable discussions. We studied Machian effects in various contexts, both in asymptotically flat spacetimes and within cosmological perturbation theory – see, e.g., [3] and number of references therein; later, cf. Schmid [4].

More recently, we investigated the subtle question whether dragging of inertial frames should also be attributed also to gravitational waves. After the discovery of binary pulsars losing energy and angular momentum as a consequence of emitting gravitational radiation it would be surprising if gravitational waves did not have an influence on local inertial frames. However, there are still doubts about the status of gravitational stress-energy as compared with stress-energy tensor $T_{\mu\nu}$ of matter in relation to Machian ideas (see, e.g., [5], p. 83).

In [5] and [6], we studied gravitational waves with translational symmetry that rotate about the axis of cylindrical polar coordinates. We solved the Einstein equations to first order in the wave amplitude and formed a pulse. By solving the relevant Einstein equation to second order we calculated and illustrated graphically the rotation of a local inertial frame at the axis which is caused by the rotating wave pulse.

In the present work we investigate the effects of rotating gravitational waves in a more general, asymptotically flat setting, without assuming any symmetry. We again start out from linearized theory and construct an ingoing rotating pulse of radiation which later transforms into an outgoing pulse. While in the translational symmetric case our waves were characterized by just one harmonic index $m$ governing the number of wave crests in $\varphi$, now the situation becomes considerably richer involving both spherical harmonic indices $l$ and $m$.

Our problem now resembles, in some respects, the study by Lindblom and Brill [2] of the gravitational collapse of a slowly rotating, massive spherical shell freely falling under its own gravity. We reconsidered and extended their analysis in [8]. The construction of our waves starts out from (the linearized version of) a Bonnor-Weber-Wheeler time-symmetric, ingoing and outgoing pulse of a typical width $a$ and a typical amplitude $C$. One can make a pulse that is rotating, but still localized in the radial direction so that it resembles a falling and rotating shell. Although we do not find the complete metric up to the second order in the amplitude, the resulting spacetime will be asymptotically flat at spatial infinity since the first-order perturbations decay as $h_{\mu\nu}^{(1)} \sim r^{-(l+1)}$ there, $l$ being the multipolar index. Hence, one can define “fixed stars” at infinity at rest in an asymptotically Minkowski system given in asymp-
The angular velocity $\omega_0$ of rotation of the local inertial frames at the origin, whose neighborhood remains as flat as we wish for all times by choosing very high $l$, is found by solving a simple linear elliptic equation for the second-order dipole odd-parity perturbation with a complicated source term given by the averaged component, $\langle R_{\mu\nu}^{(2)}(h^{(1)}, h^{(1)}) \rangle$, of the Ricci tensor, quadratic in $h^{(1)}$ and its derivatives.

A lengthy, complicated form of $\langle R_{\mu\nu}^{(2)} \rangle$ allows us to find $\omega_0$ explicitly in a useful form only at particular values of time. However, by using computer algebra system we produce nice “bell-shaped” curves showing how $\omega_0$ increases as the waves approach the origin and decreases as the waves recede back to infinity. From $\omega_0$ plotted for different azimuthal harmonic index $m$, with $l$ fixed, it is easily seen how an increase of the azimuthal angular momentum of the waves implies a stronger dragging of inertial frames (gyroscopes) in nearly flat regions surrounded by the waves.

We also calculate how the celestial sphere will look when observed from the inertial frame at the origin. This is influenced both by the passage of the stellar light through gravitational waves and by the dragging of the inertial frame due to their rotation. The resulting figures describing the apparent motion of fixed stars on the celestial sphere nicely illustrate the role of the multipolar harmonic indices $l$ and $m$ on the pattern of the motion.

The paper is organized as follows. Since odd-parity perturbations follow from a function satisfying the wave equation, in the next Sections II and III we study rotating scalar-field waves in Minkowski space. We evaluate their energy density and angular momentum density averaged over the azimuth $\varphi$ and in every direction, after averaging also over the latitude $\theta$. We turn to rotating linearized gravitational waves in Sections IV and V. Recalling some basic properties of the Regge-Wheeler formalism and tensor harmonics, and fixing our convention, we calculate the averaged energy density of the rotating linearized gravitational waves and compare it with that of scalar waves. We find that for “rapidly rotating” waves with $m \sim l$ the scalar field part dominates.

The core of the paper lies in Sections VI and VII. Here we consider the second-order perturbations. After expanding in tensor spherical harmonics, and taking the axially symmetric part, we find the second-order Einstein equations for the radial parts of the second-order odd-parity metric components in the Regge-Wheeler gauge. For general $l$ we get linear wave-type equations with source terms given by combinations of averaged components $\langle R_{\mu\nu}^{(2)}(h^{(1)}, h^{(1)}) \rangle$. For the dipole perturbations we obtain an elliptic equation which we solve by variation of constants. The angular velocity $\omega_0$ of an inertial frame near the origin is determined and analyzed both analytically and numerically in Section VII. Here also the figures demonstrating the dragging of inertial frames by...
Bičák et al.

the waves and the apparent motion of fixed stars as seen from the inertial frame at the origin are presented. In the concluding remarks we discuss the global, instantaneous character of the dragging of inertial frames as it follows from our results and show how it can be seen in diverse situations, including cosmological perturbations. We also indicate some open questions. Some lengthy expressions are written down in Appendices. There, also various integrals over products of Legendre functions and non-trivial radial integrals are evaluated.

II. ROTATING SCALAR WAVES

In linearized Einstein theory the basic Regge-Wheeler equation [13] for odd parity waves becomes the usual flat-space 1-dimensional wave equation for the radial part. It is thus natural to first present rotating waves in Minkowski space.

Consider the wave equation

\[ -\frac{\partial^2 \psi}{\partial t^2} + \Delta \psi = 0 \]  

in spherical coordinates. Assume

\[ \psi_{lm} = \frac{1}{2} \left[ Q_l(t, r) Y_{lm}(\theta, \phi) + \overline{Q}_l(t, r) \overline{Y}_{lm}(\theta, \phi) \right], \]

\[ Y_{lm} = \sqrt{\frac{2l + 1}{4\pi}} \frac{(l + m)!}{(l - m)!} \]  

The angular part of Eq. (2.1) then separates and the radial part satisfies

\[ -\ddot{Q}_l + Q''_l + \frac{2}{r} Q'_l - \frac{l(l + 1)}{r^2} Q_l = 0. \]

Hereafter the dot denotes \( \partial_t \), the prime \( \partial_r \).

Assume that \( Q_l(t, r) = Q_l(\omega, r) e^{i\omega t} \) and substitute

\[ Q_l(\omega, r) = \frac{1}{\sqrt{r}} u_l(\omega, r). \]

Equation (2.5) is then transformed into

\[ u''_l + \frac{1}{r} u'_l - \frac{(l + \frac{1}{2})^2}{r^2} u_l + \omega^2 u_l = 0, \]

which is the Bessel equation with index \( \nu = l + \frac{1}{2} \). The independent solutions of (2.7) are given in terms of spherical Bessel and Hankel functions \( j_l(\omega r), n_l(\omega r) \) and \( h_l(\omega r) \). We want solutions regular at the origin, so we construct our radial waves as superpositions of

\[ j_l(\omega r) = \sqrt{\frac{\pi}{2\omega r}} J_{l + \frac{1}{2}}(\omega r), \]

\( J_l \) is a Bessel function of the first kind. Inspired by the example of the Bonnor [15], Weber-Wheeler [16] cylindrical pulse and by our recent work [5], [6], in which time symmetric incoming and outgoing rotating waves are smooth and finite everywhere at all time, we consider, in spheri-
cal polar coordinates, the superposition

\[ Q_l(t, r) = B_l \sqrt{\frac{\pi a^3}{2r}} \int_0^\infty \frac{e^{-\alpha^2}}{r} \sin^l \omega J_{l+1}(\omega r) d\omega, \]

(2.9)

where the real amplitude \( B_l \) and the characteristic width of the pulse \( a \) are constant. It is convenient to introduce

\[ \alpha = \alpha(t) = a + it. \]  

(2.10)

Employing then formula (8.6.5) in [17] (see also formula 6.623 in [18]), we find the integral in (2.9) to yield

\[ Q_l(t, r) = B_l 2^l l! \frac{(r/a)^l}{[(a^2 + r^2)^{l+1}]} \]  

(11.11)

To construct rotating waves coming in and then going out in a time-symmetric manner we just multiply by \( Y_{lm}(\theta, \varphi) \) containing the factor \( e^{im\varphi} \). Clearly, the field is the superposition of rotating waves: it is apparent that for each \( \omega \) the wave contains the factor

\[ e^{im\varphi} e^{-i\omega t} = e^{im(\varphi - \frac{\omega}{a})} \]

(2.12)

so that the wave pattern rotates with the rate \( \Omega_p = \omega / m \).

The rotation and the pulse character of the wave as well as its regularity is easily seen when \( \psi_{lm} \) is written explicitly in real terms:

\[ \psi_{lm} = \frac{B_l 2^l l! N_l m P_l m (\cos \theta) \tilde{\varphi}^l}{\sqrt{(1 + \tilde{r}^2 - t^2)^2 + 4t^2l(l+1)/2}} \cos (m\varphi - \lambda(t, r)), \]

(2.13)

where

\[ \tilde{r} = \frac{r}{a}, \quad \tilde{t} = \frac{t}{a} \]

(2.14)

and

\[ \lambda(t, r) = (l + 1) \arctan \frac{2\tilde{t}}{1 + \tilde{r}^2 - t^2} \]

(2.15)

\[ = \arg \left[ \tilde{r}^2 + (1 + i\tilde{t})^2 \right]^{(l+1)}. \]

Some snapshots of the rotating waves profiles are illustrated in Figure [1].

III. ENERGY AND ANGULAR MOMENTUM IN ROTATING SCALAR WAVES

We start with some simple properties of scalar fields. The energy density of the scalar field can be derived from the scalar field Lagrangian density

\[ \mathcal{L} = -\frac{1}{\sqrt{-\bar{g}}} \bar{g}^{\mu
u} \partial_\mu \bar{\psi} \partial^\nu \psi, \]

(3.1)

where we use the background Minkowski metric in spherical coordinates

\[ \bar{g}_{\mu\nu} = \{1, -\bar{\eta}_{kl}\} = \{1, -1, -r^2, -r^2 \sin^2 \theta\}. \]

(3.2)

(Hereafter, the Greek indices \( \lambda, \mu, \nu = 0, 1, 2, 3 \), the Latin indices \( i, j, k = 1, 2, 3 \); \( l, m \) are reserved for harmonic indices associated with \( Y_{lm} \)). The energy density, the time-component of the stress-energy-momentum tensor

\[ \sqrt{-\bar{g}} T^{\mu\nu} = \frac{\delta \mathcal{L}}{\delta \bar{g}_{\mu\nu}}, \]

(3.3)

reads

\[ \varepsilon_S = \frac{1}{2} \left[ \bar{\psi}^2 + \bar{\psi} \bar{\psi}_{/} \right], \]

(3.4)

\[ \bar{\nabla}_{/} \] are covariant derivatives associated with \( \bar{\nabla}_{/} \) for scalar \( \bar{\psi}, \) \( \bar{\nabla}_{/} \psi = \partial_{/} \psi, \) so in spherical coordinates

\[ \varepsilon_S = \frac{1}{2} \left[ \bar{\psi}^2 + \bar{\psi} \bar{\psi}_{/} + \frac{1}{r^2} \left( \partial_{/} \bar{\psi} \right)^2 + \frac{1}{r^2 \sin^2 \theta} (\partial_{/} \bar{\psi})^2 \right]. \]

(3.5)

The energy density satisfies the conservation law which can be written as

\[ \frac{d}{dt} \int_V \varepsilon_S dV = \frac{d}{dt} \int_S \bar{\psi} \bar{\nabla}_{/} \psi dS. \]

(3.6)

The angular momentum flux is given by the components \( \varepsilon_{ijk} x^j T^i_k \) through the surface \( S \). The angular momentum density along the \( z \)-axis is

\[ j_S = -\bar{\psi} \hat{\theta} \bar{\psi} \].

(3.9)

Let us calculate the energy density and the angular momentum density for rotating scalar waves. Consider a single \( (l, m) \) component, like in (2.2), written now in the form

\[ \psi_{lm} = \frac{1}{2} N_l m \left[ Q_{lm}(t, r)e^{im\varphi} + \bar{Q}_{lm}(t, r)e^{-im\varphi} \right] P_l m (\mu), \]

(3.10)
with $\mu = \cos \theta$, $P^m_n(\mu)$ are real Legendre functions. The energy density (3.5) of the scalar field becomes
\[
\varepsilon_S = \frac{1}{4} (N^m_l)^2 \left\{ \left( \dot{Q}_{lm} \dot{Q}_{lm}^{\ast} + Q_{lm}^{\ast} \dot{Q}_{lm}^{\ast} \right) (P^m_l)^2 \right\} + \frac{Q_{lm} \dot{Q}_{lm}^{\ast}}{r^2} \left[ \frac{m^2}{1 - \mu^2} (P^m_l)^2 + (1 - \mu^2) (P^m_l)^{\prime 2} \right] + \frac{1}{2} \left( \dot{Q}_{lm}^{\ast} + Q_{lm}^{\ast} \right) e^{2i \varphi} + \left( \dot{Q}_{lm} + Q_{lm} \right) e^{-2i \varphi} \right\} (P^m_l)^2 + \frac{1}{2r^2} \left( Q_{lm} e^{2i \varphi} + \overline{Q}_{lm} e^{-2i \varphi} \right) \times \left[ - \frac{m^2}{1 - \mu^2} (P^m_l)^2 + (1 - \mu^2) (P^m_l)^{\prime 2} \right],
\]
where we write $P^m_l$ for $(d/d\mu)P^m_l$. If we average over $\varphi$ terms, we obtain
\[
\langle \varepsilon_S \rangle = \frac{1}{2\pi} \int_0^{2\pi} \varepsilon_S d\varphi = \frac{1}{4} (N^m_l)^2 \left\{ \left( \dot{Q}_{lm} \dot{Q}_{lm}^{\ast} + Q_{lm}^{\ast} \dot{Q}_{lm}^{\ast} \right) (P^m_l)^2 \right\} + \frac{Q_{lm} \dot{Q}_{lm}^{\ast}}{r^2} \left[ \frac{m^2}{1 - \mu^2} (P^m_l)^2 + (1 - \mu^2) (P^m_l)^{\prime 2} \right].
\]

If we average over the latitude $\theta$ by taking $\frac{1}{2\pi} \int_0^{\pi} \langle \varepsilon_S \rangle d\mu$, and use the integrals of $P^m_l$'s evaluated in Appendix A, we arrive at the energy density, averaged in every direction, as a function of $r$, in the form
\[
\langle \varepsilon_S \rangle = \frac{1}{16\pi} \left[ Q_{lm} \overline{Q}_{lm}^{\ast} + Q_{lm}^{\ast} \overline{Q}_{lm} + l(l+1) \frac{Q_{lm} \dot{Q}_{lm}^{\ast}}{r^2} \right].
\]

The $z$-component of the angular momentum density is still simpler:
\[
J_S = \frac{im}{4} (N^m_l)^2 \left( \dot{Q}_{lm} \overline{Q}_{lm}^{\ast} - \dot{Q}_{lm}^{\ast} \overline{Q}_{lm} - c.c. \right) (P^m_l)^2,
\]
"c.c." denotes "complex conjugation".

So, after averaging over $\varphi$ and over $\theta$ (see Appendix A) we get
\[
\langle J_S \rangle = \frac{im}{16\pi} \left( \dot{Q}_{lm} \overline{Q}_{lm}^{\ast} - \dot{Q}_{lm}^{\ast} \overline{Q}_{lm} \right).
\]

IV. ROTATING LINEARIZED GRAVITATIONAL WAVES

We consider first the linearized theory of gravity in a flat background in spherical coordinates $(t, r, \theta, \varphi)$. It is natural to decompose the metric perturbations into tensor harmonics. These are given in terms of standard spherical harmonics $Y_{lm}$ and their derivatives, see, e.g., [13, 19, 20]. For any symmetric second-rank covariant tensor $S_{\mu\nu}$ we define the expansion
\[
S_{\mu\nu} = \sum_{l,m} (A_{\mu lm}(t, r) a_{\mu lm}^{\ast} + A_{lm}(t, r) a_{\mu lm}^{\ast}) (4.1)
\]
\[
\] + $A_{lm}(t, r) a_{\mu lm}^{\ast} + B_{\mu lm}(t, r) b_{lm}^{\ast} + B_{lm}(t, r) b_{\mu lm}$
\[
+ Q_{\alpha lm}(t, r) r_{\alpha lm}^{\ast} + Q_{\alpha lm}(t, r) r_{\alpha lm} + D_{lm}(t, r) d_{lm}^{\ast} + D_{lm}(t, r) d_{\mu lm}
\]
\[
\] + $G_{lm}(t, r) g_{lm}^{\ast} + F_{lm}(t, r) f_{lm}^{\ast}$,

where $a_{\mu lm}(\theta, \varphi), ..., f_{\mu lm}(\theta, \varphi)$ are tensor harmonics; we follow the notation and normalizations used by [20]. The harmonics can be classified into even- and odd-parities - those with even-parity transform by the parity $(-1)^l$ under the inversion, i.e., the transformation $(\theta, \varphi) \rightarrow (\pi - \theta, \pi + \varphi)$, in the same way as $Y_{lm}(\theta, \varphi)$ - while odd-parity harmonics are defined by the parity $(-1)^l + 1$. The harmonics are mutually orthogonal and normalized over the sphere of radius $r$ in the following sense:
\[
\int_0^{2\pi} \int_0^{\pi} X_{lm}^{\prime m'} \delta_{m'm} \delta^{\nu\sigma} X_{lm} \sin \theta d\theta d\varphi = \delta^{\nu\sigma} \delta_{lm},
\]
where $\delta^{\nu\sigma} = \text{diag}(1, 1, 1/r^2, 1/(r \sin \theta)^2)$.

$X$ stands for any of the harmonics $a, ..., f$. The orthogonality properties enable us to find the "coefficients" $A_{\mu lm}$, etc., in the decomposition (4.1) of the general covariant tensor $S_{\mu\nu}$. For example, in the following section we shall need the coefficient $Q_{\alpha lm}(t, r)$ multiplying $c_{\alpha lm}$. Using the orthogonality property of the tensor harmonics and multiplying $S_{\mu\nu}$ by $\tau_{\alpha lm}$, we find
\[
Q_{\alpha lm}(t, r) = \int_0^{2\pi} \int_0^{\pi} \delta^{\nu\rho} \delta^{\nu\sigma} S_{\mu\nu} \tau_{\alpha lm, \rho} \sin \theta d\theta d\varphi.
\]

It is well known that the resulting field equations for the radial factors may be discussed separately for odd- and even-parity perturbations of the Schwarzschild black hole, see, for instance, [13, 12, 21, 20], which of course remains true for flat space. For our purpose it is sufficient to consider odd-parity waves. In the expansions (4.1) the odd-parity harmonics are $c_{\alpha lm}, d_{\mu lm}$ and $d_{lm}$, with explicit forms of the non-zero components being
\[
c_{\alpha lm} \theta = \frac{r}{\sqrt{2(l + 1)}} \frac{1}{\sin \theta} \partial_{\varphi} Y_{lm},
\]
\[
c_{\alpha lm} \theta = \frac{-r}{\sqrt{2(l + 1)}} \sin \theta \partial_{\varphi} Y_{lm},
\]
\[
c_{\mu lm} \varphi = \frac{-i}{\sqrt{2(l + 1)}} \frac{1}{\sin \theta} \partial_{\varphi} Y_{lm},
\]
\[
c_{\mu lm} \varphi = \frac{-i}{\sqrt{2(l + 1)}} \sin \theta \partial_{\varphi} Y_{lm},
\]
\[
d_{lm} \theta = \frac{-br^2}{\sqrt{2(l + 1)(l - 1)(l + 2)}} \frac{1}{\sin \theta} X_{lm}.
\]
\[ d_{lm} \varphi = \frac{-i r^2}{\sqrt{2(l+1)(l-1)(l+2)}} \sin \theta X_{lm}, \quad (4.10) \]
\[ d_{lm} \theta = \frac{-i r^2}{\sqrt{2(l+1)(l-1)(l+2)}} \sin \theta W_{lm}, \quad (4.11) \]

where
\[ X_{lm} = 2 \partial_\varphi (\partial_\theta - \cot \theta) Y_{lm}, \quad (4.12) \]
\[ W_{lm} = \left( \partial_\theta^2 - \cot \theta \partial_\theta - \frac{1}{\sin^2 \theta} \partial_\varphi^2 \right) Y_{lm}. \]

For the explicit forms of the other tensor harmonics, see [13], [19], [21] and [20]. As mentioned above, our convention for harmonics is that used in [20] which differs slightly from [13] or [19]. However, following [20] we assume the expansion of the odd-parity metric perturbations \( h^{(i)}_{\mu \nu} \) \((i) = (1), (2)\) denotes the first- and second-order perturbations) to have the form
\[ h^{(i)}_{\mu \nu} = \sum_{lm} \left[ -\frac{\sqrt{2(l+1)}}{r} h^{(i)}_{0lm}(t,r)c_{0lm} \right. \]
\[ + i \frac{\sqrt{2(l+1)}}{r} h^{(i)}_{1lm}(t,r)c_{1lm} \]
\[ + i \frac{\sqrt{2(l+1)(l-1)(l+2)}}{2r^2} h^{(i)}_{2lm}(t,r) d_{lm}, \quad (4.13) \]

so that the factors multiplying the harmonics in (4.5) (4.11) cancel the multiplicative factors at \( h^{(i)}_{0lm}, h^{(i)}_{1lm}, h^{(i)}_{2lm} \) in [13]. Hence the radial functions, the \( h^i \)'s, are identical in [13], [14], [21] and [20].

In the literature time-dependent perturbations are usually Fourier analyzed and perturbations with even parity discussed. In [21] a complete account of the Hamiltonian, Regge-Wheeler-Zerilli and Newman-Penrose formalism for perturbations (with both parities) of a Reissner-Nordström black hole is given and the dipole \( l = 1 \) perturbations are also considered. Putting \( M = \epsilon = 0 \) there and choosing the Regge-Wheeler gauge condition for odd-parity perturbations, \( h^{(i)}_{2lm} = 0 \), we obtain the radial functions \( h^{(i)}_{0lm}(t,r) \) and \( h^{(i)}_{1lm}(t,r) \) in terms of a function \( R \) satisfying the wave equation as follows (disarding labels):
\[ h_0 = -\frac{1}{(l-1)(l+2)}(rR)', \quad (4.14) \]
\[ h_1 = -\frac{r}{(l-1)(l+2)} \hat{R}, \quad (4.15) \]
\[ -\hat{R} + R'' - \frac{l(l+1)}{r^2} R = 0. \quad (4.16) \]

We see that last equation can be put in the form of Eq. (2.5) for the scalar field amplitude \( Q_i(t,r) \) through the substitution
\[ R = rq. \quad (4.17) \]

So in terms of \( q(t,r) \) the odd-parity metric perturbations are given by
\[ h_0 = -\frac{1}{(l-1)(l+2)}(r^2q)', \quad (4.18) \]
\[ h_1 = -\frac{1}{(l-1)(l+2)}r^2q. \quad (4.19) \]

These formulas are valid for \( l \geq 2 \); in the linear theory in vacuum the dipole odd-parity perturbations \( (l = 1) \) can be transformed away by a simple gauge transformation [19, 21]. Later, in Section VI, we shall substitute for \( q(t,r) \) the solution given in (2.5) and consider (4.18-4.19) to be the first-order perturbations \( h^{(1)} \) generating the second-order perturbations.

V. ENERGY IN GRAVITATIONAL WAVES

In [22] we defined gravitational energy on \( x^0 = \text{const} \) slices in stationary asymptotically flat spacetimes by taking the difference between the total mass-energy and the total “mechanical” energy arising from the matter stress tensor. Many formulas given in [22] are true in general, non-stationary spacetimes.

Consider the slice \( x^0 = \text{const} \) and the metric in the 1+3 decomposition associated with the Hamiltonian formulation (see, e.g., [23])
\[ ds^2 = g_{00} dt^2 + 2 g_{0k} dt dx^k + g_{ik} dx^i dx^k, \quad (5.1) \]
\[ = (w^2 - W^2) dt^2 + 2 W_k dt dx^k - \gamma_{ik} dx^i dx^k, \]
\[ i, k = 1, 2, 3, \ w = \sqrt{g_{00} + W^2} \text{ and } W^2 = \gamma_{ik} W^k W^k \ (\text{cf. (2.36) in [22]}). \]

The energy of matter can be calculated using the Einstein constraint equation for
\[ 2wG^{00} = \mathcal{R} + K^2 - K^{ik} K_{ik}, \quad (5.2) \]
where \( \mathcal{R} \) is the scalar curvature of the 3-metric \( \gamma_{ik} \) and the external curvature of \( x^0 = \text{const} \) slices is
\[ K_{ik} = w^{-1} (\nabla_i W_k - \frac{2}{3} \delta_i^k \gamma_{ik} ), \quad K = \gamma^{ik} K_{ik}, \quad (5.3) \]
\( \nabla_k \) is a \( \gamma \)-covariant derivative. The total (gravitational and matter) mass-energy as measured at infinity is \( M \). The gravitational field energy on the \( x^0 = \text{const} \) slice can be defined as
\[ E_G = M - \frac{1}{2K} \int (\mathcal{R} + K^2 - K^{ik} K_{ik}) \sqrt{\gamma} d^3x, \quad (5.4) \]
\( \kappa \) is Einstein’s gravitational constant, \( \gamma = \text{det} \gamma_{ik} \), all volume integrals here and below are taken over \( x^0 = \text{const} \).
It is often advantageous to use more general spatial coordinates than Cartesian coordinates at infinity, so assume that the metric of the background Minkowski space-time which at infinity is "the limiting space-time" to the physical space-time, has the general form:

$$dS^2 = dt^2 - \gamma_{ik}dx^i dx^k.$$

Denoting $\nabla$-covariant derivatives by $\nabla_k$ and introducing tensorial quantities

$$\Delta_{m}^{ik} = \Gamma_{m}^{ik} - \Gamma_{im}^{k}$$

$$= \frac{1}{2\gamma} \varepsilon^{m}{}_{nk} \nabla_k \gamma_{ni} - \nabla_n \gamma_{ik},$$

one can write the scalar 3-curvature density entering (5.4) as follows:

$$\frac{1}{2\kappa} \sqrt{\gamma} R = \frac{1}{2\kappa} \sqrt{\gamma} \mathcal{L} - \frac{1}{2\kappa} \partial_i (\sqrt{\gamma} k^i).$$

Here $\mathcal{L}$ is the Einstein Lagrangian

$$\mathcal{L} = -\gamma^{ik} (\Delta_{mk}^{m} - \Delta_{mn}^{m} - \Delta_{in}^{m} - \Delta_{mk}^{n}),$$

and $k^i$ are given by (cf. (3.16) in [22]):

$$k^i = \gamma^{-1} \nabla_k (\gamma \gamma^{ik}).$$

In an asymptotically flat space-time the integral of the second term on the right-hand side of (5.7) gives again the mass,

$$- \frac{1}{2\kappa} \int \partial_i (\sqrt{\gamma} k^i) d^3x = - \frac{1}{2\kappa} \int \sqrt{\gamma} k^i dS_i = M.\quad (5.10)$$

This is the total mass of space-time as measured at spatial infinity. In our case of pure gravitational waves the surface integral gives the total mass-energy of the waves. In a general case of radiation going through spatial infinity for all times, time-dependent radiative terms $\sim 1/r$ would also contribute to the surface integral (5.10), however for pulse-type radiation considered in this work only the static mass-energy results. Returning to $E_G$ in (5.4), substituting from (5.7) and (5.10) we find the gravitational energy as a volume integral over the slice $x^0=\text{const}$:

$$E_G = \frac{1}{2\kappa} \int \left( K^{ik} K_{ik} - K^2 - \mathcal{L} \right) \sqrt{\gamma} \, d^3x \quad (5.11)$$

with $\mathcal{L}$ and $K_{ik}$ given in (5.8) and (5.3). The energy density $\varepsilon_G$ is a scalar density on $x^0=\text{const}$ due to the use of the background metric$^3$.

Assume now the physical metric $\gamma_{ik}$ to be close to the background metric $\overline{\gamma}_{ik}$ and $\gamma_{00} = 1 + \text{h}_{00}$ so that

$$\gamma_{ik} = \overline{\gamma}_{ik} + \text{h}_{ik}, \quad W_k = \text{h}_{0k}, \quad w = 1 + \frac{1}{2} \text{h}_{00}.\quad (5.12)$$

The terms proportional to $O(h^2)$ will be neglected. The extrinsic curvature (5.3) then becomes

$$K_{ik} = \nabla_i (h_{k0}) - \frac{1}{2} \text{h}_{ik},$$

the Lagrangian (5.9) is

$$-\mathcal{L} = \frac{1}{2} \nabla_m h \nabla_k h^{km} - \frac{1}{2} \nabla_m h \nabla^m h - \frac{1}{2} \nabla_k h^{km} \nabla_m \text{h}_{ik} + \frac{1}{2} \nabla_k h^{km} \nabla_i \text{h}_{km}.$$

Since we are considering waves by using tensor spherical harmonics it is natural to choose the background metric $\overline{\gamma}_{ik}$ in spherical coordinates:

$$\overline{\gamma}_{11} = 1, \quad \overline{\gamma}_{22} = r^2, \quad \overline{\gamma}_{33} = r^2 \sin^2 \theta.\quad (5.15)$$

We start from the metric for odd-parity perturbations in the general form (4.13) with harmonics given by (4.5-12). However, since in the odd-parity case only four (non-diagonal) components are non-vanishing, the following simple notation will turn out to be useful:

$$h_{02} = h_{02}, \quad h_{03} = h_{03}, \quad h_{12} = h_{12}, \quad h_{13} = h_{13}, \quad h_{33} = h_{33},$$

$$f_2 = - \frac{1}{\sin \theta} \partial_\varphi Y_{lm}, \quad f_3 = \sin \theta \partial_\theta Y_{lm}.\quad (5.16)$$

Starting from these expressions, calculating $K_{ik}$ and $\mathcal{L}$ from (5.13), (5.14) using $\nabla_k$ in flat-space spherical coordinates, we arrive, after straightforward - though not short - calculations at the following expression for the gravitational energy density of odd-parity waves

$$\varepsilon_G = \frac{1}{2\kappa} \left( K^{ik} K_{ik} - K^2 - \mathcal{L} \right),\quad (5.17)$$

where

$$K^{ik} K_{ik} - K^2 = \frac{h_0^2}{2r^4 \sin^2 \theta} \left[ (\partial_\varphi f_2 + \partial_\theta f_3 - 2 \cot \theta f_3) \right]^2$$

$$+ \frac{1}{2r^4} \left( r h_1 - r h'_1 + 2h_0 \right)^2 \left( f_2^2 + \frac{1}{\sin^2 \theta} f_3^2 \right)$$

$$- 4\partial_\theta f_2 (\sin \theta \cos \theta f_2 + \partial_\varphi f_3),$$

and

$$-\mathcal{L} = \frac{1}{2r^4} \left[ 4h_1 (r h_1' - h_1) \left( f_2^2 + \frac{1}{\sin^2 \theta} f_3^2 \right) \right]$$

$$+ \frac{h_0^4}{\sin^2 \theta} (\partial_\varphi f_2 - \partial_\theta f_3)^2.\quad (5.19)$$

We now express the radial parts of perturbations from (4.18-4.19) in terms of the gauge invariant quantity $q$ satisfying the wave equation (2.5) ($Q$ there is denoted by $q$.)
vi. second-order odd parity dipole perturbations

In general the second-order metric perturbations $h^{(2)}$ can be obtained by solving the equations

$$ G^{(1)}_{\mu\nu}[h^{(2)}] = -G^{(2)}_{\mu\nu}[h^{(1)}, h^{(1)}], \quad (6.1) $$

where $h^{(i)}$ represent quantities given in (4.13) with all indices seen explicitly. The right-hand side of (6.1) is the source term in the form of an effective energy-momentum tensor quadratic in the first-order perturbations $h^{(1)}$ and their derivatives known from the solutions of $G^{(1)}_{\mu\nu}[h^{(1)}] = 0$. In principle writing down the right-hand side of Eq. (6.1) and solving it is a clear task, in practise a formidable one.

However, to determine the influence of gravitational waves on the rotation of local inertial frames at the axis of symmetry we do not need to solve (6.1) in general. First, following our method in the translational symmetric case [2], [3], we shall average over $\varphi$ so that the source term on the right-hand side will become axisymmetric. Before averaging it will contain terms of the form $\partial_t h^{(1)} \partial_\varphi h^{(1)}$ each of which involves two terms independent of $\varphi$ and two terms varying like $\sin 2m\varphi$ or $\cos 2m\varphi$. Those terms cannot cause any rotation of the inertial frames on the axis. Hence, we shall concentrate on the terms that are independent of $\varphi$ and denote them again, as in previous sections, by the average symbol $\langle \rangle$. In addition, as in the translational symmetric case the dragging will be fully determined by solutions of just one equation in (6.1) – that with $\mu = t, \nu = \varphi$.

Therefore, we consider the equation

$$ G^{(1)}_{t\varphi}[h^{(2)}] = -\langle G^{(2)}_{t\varphi}[h^{(1)}, h^{(1)}] \rangle, \quad (6.2) $$

or equivalently,

$$ R^{(1)}_{t\varphi}[h^{(2)}] = -\langle R^{(2)}_{t\varphi}[h^{(1)}, h^{(1)}] \rangle, \quad (6.3) $$

which follows from (6.1) because in the background $\mathbf{P}_{\mu\nu}$ is the flat metric in spherical coordinates and $R^{(1)}_{t\varphi}[h^{(1)}] = 0$. To solve these equations we shall expand both sides in tensor spherical harmonics. Any symmetric second-rank covariant tensor can be expanded as in (4.1). We are interested in the axisymmetric $(t, \varphi)$ component, so the only harmonic entering the left-hand side of (6.3) linear in $h^{(2)}$ is the odd-parity harmonic $c_{0m}$ given in (4.13). In order to extract the contribution proportional to the same harmonic on the right-hand side of (6.3) we imagine it to be expanded as the general covariant tensor $S_{\mu\nu}$ in (4.11). The coefficient $Q_{0m}(t, r)$ multiplying $c_{0m}$ can be derived using formula (4.4). In our case of the averaged – and thus axially symmetric – component $(R^{(2)}_{t\varphi}[h^{(1)}, h^{(1)}])$ we put $m = 0$ and $\langle \mu \nu \rangle = (t, \varphi)$ to obtain

$$ Q_{0m}(t, r) = \int_0^{2\pi} \frac{\pi}{0} -2\langle R^{(2)}_{t\varphi} \rangle \mathbf{P}_{00} \frac{\sin \theta \theta}{r^2} \sin \theta \sin \varphi \ d\varphi = \frac{4\pi}{2l(l+1)r} \int_0^{2\pi} \langle R^{(2)}_{t\varphi} \rangle \partial_\theta Y_{l0} \ d\theta, \quad (6.4) $$
where we substituted for $\frac{\partial}{\partial_{l=0}} \xi_c$ from (4.6). Hence, the right-hand side of equation (6.3) reads

$$2\pi \left\{ \int_0^{\pi} (R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}]) \partial_\theta Y_{10} d\theta \right\} \left( -\sin \theta \partial_\theta Y_{10} \frac{l(l+1)}{l(l+1)} \right).$$ (6.5)

The left-hand side of (6.1) in flat background (in spherical coordinates) is formed from the second derivatives of the second-order perturbations:

$$G^{(1)}_{\mu \nu}[h^{(2)}] = \frac{1}{2} \left[ h^{(2)}_{\mu \alpha} + h^{(2)}_{\nu \alpha} + h^{(2)}_{\mu \beta} \alpha - h^{(2)}_{\alpha \beta} \right],$$

$$-\pi \left[ h^{(2)}_{\beta \alpha} \alpha - h^{(2)}_{\beta \alpha} \beta \right].$$ (6.6)

We expand $G^{(1)}_{\mu \nu}$ in tensor spherical harmonics and realize that we need only the axisymmetric component $G^{(1)}_{t \xi}$; the result will thus be proportional to $c_{l=0}$. It is now important that by using the gauge transformation $x' \to x + 6\pi$ to the second order we can choose the Regge-Wheeler gauge also for the second-order perturbations (12), (20), so for odd-parity perturbations we can again set $h^{(2)}_0 = 0$ and keep just $h^{(2)}_{1}$ and $h^{(2)}_2$. Calculations of $G^{(1)}_{t \xi}[h^{(2)}]$ from (6.5) lead us to the following expression:

$$\frac{1}{2} \left[ -h^{(2)}_{0} + \frac{l(l+1)}{r^2} h^{(2)}_0 + \frac{l(l+1)}{r^2} h^{(2)}_1 \right] \sin \theta \partial_\theta Y_{10}. \quad (6.7)$$

Combining this with the right-hand side (6.5) we arrive at the differential equation implied by the field equation (6.2) for radial parts in the form

$$\frac{1}{2} \left[ h^{(2)}_{0} - \frac{l(l+1)}{r^2} h^{(2)}_0 + \frac{l(l+1)}{r^2} h^{(2)}_1 \right] = \frac{2\pi}{l(l+1)} \int_0^{\pi} (R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}]) \partial_\theta Y_{10} d\theta.$$ (6.8)

This equation suggests that we need to consider more field equations to determine both second-order perturbations $h^{(2)}_0$ and $h^{(2)}_1$ from the first-order ones. Indeed, if we wish to calculate both $h^{(2)}_0$ and $h^{(2)}_1$ for all $l$’s we have to take into account equations (6.1) also for $(\mu \nu) = (\theta, \varphi), (r, \varphi)$ and by combining them we can achieve just one wave-type equation for $h^{(2)}_1$:

$$r \left( \partial_t^2 - \partial_r^2 + \frac{l(l+1)}{r^2} \right) \frac{h^{(2)}_1}{r} = S_{\theta \varphi} + S_{\theta \varphi}^* - \frac{2}{r} S_{\theta \varphi}, \quad (6.9)$$

where components $S_{\mu \nu}$ stand for the averaged components $(R_{\mu \nu}^{(2)}[h^{(1)}, h^{(1)})]$. This is a hyperbolic equation indicating that for general $l$ the effects of the first-order terms are perturbations of the second-order terms that are non-instantaneous. However, in all our previous work on dragging of inertial frames due to angular momentum of the sources (see, for example, [9] and references therein), the effects were instantaneous, at least at this lowest order. In fact, the same situation arises here. Inertial frames at the origin will be influenced primarily by the dipole perturbations since all waves behave as $r^l$ there. Now it is well known that for $l = 1$ one can achieve $h_1 = 0$ by an appropriate gauge transformation [13, 21]. For the dipole second-order perturbations the equation (6.5) becomes

$$h^{(2)}_{0} - \frac{2}{r^2} h^{(2)}_0 = g(t, r), \quad (6.10)$$

where

$$g(t, r) = -\sqrt{3} \int_0^{\pi} \int_0^{2\pi} \langle R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}] \sin \theta \partial_\theta \partial_\varphi. \quad (6.11)$$

Here we indicated the $\varphi$-averaging explicitly (which cancelled the factor $2\pi$) and we substituted for $\partial_\theta Y_{10}$. With $g(t, r)$ known, the solution of (6.11) can easily be found by variation of constants from the simple solutions proportional to $1/r$ and $r^2$ of the homogeneous equation. Putting the arbitrary constants entering the homogeneous solution equal to zero, the complete solution for $h^{(2)}_0(t, r)$ reads

$$h^{(2)}_0 = \frac{1}{3r} \int_0^{r} g(t, r') r^2 dr' - \frac{r^2}{3} \int_r^{\infty} g(t, r') dr'. \quad (6.12)$$

VII. HOW ROTATING WAVES DRAG INERTIAL FRAMES

Since we are interested in the dragging of inertial frames near the origin we wish to express

$$h^{(2)}_0(t, r) \approx \frac{1}{3r} \int_0^{r} g(t, r') \frac{1}{r'} dr', \quad (7.1)$$

with $g(t, r)$ given by (6.11) and $\langle R_{\xi_c}^{(2)} \rangle$ in Appendix B.

The general form of the odd-parity metric perturbations (4.13), with the tensor spherical harmonics (4.12), for the special case of $l = 1, m = 0$ perturbations with only $h^{(2)}_{010} \neq 0$ yields the metric component $g_{\theta \varphi}$ near the origin in the form

$$g^{(2)}_{\theta \varphi} = -\sqrt{\frac{3}{4\pi}} \int_0^{\pi} \int_0^{2\pi} \langle R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}] \partial_\theta \partial_\varphi. \quad (7.2)$$

where the rotation of an inertial frame (of a gyroscope) located near the origin has the angular velocity

$$\omega_0 = \frac{1}{4\pi} \int_0^{\pi} \int_0^{2\pi} \langle R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}] \partial_\theta \partial_\varphi. \quad (7.3)$$

where $d\Omega = \sin \theta d\theta d\varphi$. To evaluate $\langle R_{\xi_c}^{(2)}[h^{(1)}, h^{(1)}]$, which has more complicated structure than any expression calculated so far, we found it more convenient to start from the real form of the solution of the original scalar wave equation (2.1) and
use it to express the gravitational wave perturbations – see Eqs. (7.4), (7.5) below. As a consequence, also the metric coefficients will be real from the start, rather than of the form (5.10). With real expressions one does not have to be careful when grouping together properly the corresponding terms in the quadratic expressions like we had to do in calculating the energy densities (cf. footnote 4) and it is much easier to find the results using the standard (commutative) computer algebra codes such as tensor package in Maple. In fact, we first proceeded by using the same methods as in the case of energies and, after going to the real variables, we checked that both results agree.

So now we start from the metric perturbations written as follows

\[
\begin{align*}
    h_{\theta\theta} &= \frac{1}{\sin \theta} \frac{\partial \chi}{\partial \theta} \frac{\partial \chi}{\partial \theta}, \\
    h_{\varphi\varphi} &= -\sin \theta \frac{\partial \chi}{\partial \theta} \frac{\partial \chi}{\partial \theta}, \\
    h_{r\theta} &= \frac{1}{\sin \theta} \frac{\partial \chi}{\partial \theta} \frac{\partial \chi}{\partial \varphi}, \\
    h_{r\varphi} &= -\sin \theta \frac{\partial \chi}{\partial \theta} \frac{\partial \chi}{\partial \varphi},
\end{align*}
\]

where function \( \chi(t, r, \theta, \varphi) = r^2 \psi_{tm} \) ( roulette satisfies the scalar wave equation (2.1) in flat space); introducing \( \tilde{R} \) as the product of the corresponding terms in the quadratic expressions like we turn out to simplify the second-order Ricci tensor.

Inserting the function \( \tilde{R} \) from (7.4) into (7.5) and em- noting note 4) and it is much easier to find the results using the formulas for the integrals of the products of the Legendre functions given in Appendix A to find the average over the spherical angles we first find

\[
\int \tilde{R}_{\tilde{t}\tilde{r}}^2 d\Omega = -\tilde{B}_{\tilde{t}} \frac{2}{2\pi} \frac{m(l + 1)(l + 2)}{a(l + 3)l} \times
\]

\[
\left[ \left( U_i - V_i t^2 \right) \left( 1 + \tilde{t}^2 \right) I_{l+3}^1(i) + \left( U_i + V_i t^2 \right) \right] I_{l+3}^1(i),
\]

Substituting for \( \kappa \) and \( \lambda \) the expressions (7.8) and (2.15) and integrating over the radial coordinate we obtain the angular velocity \( \omega_0 \) in the form

\[
\omega_0(t) = -\tilde{b}_{\tilde{t}} \frac{2}{2\pi} \frac{m(l + 1)(l + 2)}{a(l + 3)l} \times
\]

\[
\left[ \left( U_i - V_i t^2 \right) \left( 1 + \tilde{t}^2 \right) I_{l+3}^1(i) + \left( U_i + V_i t^2 \right) \right] I_{l+3}^1(i),
\]

where

\[
U_i = \left( 2t^5 + 7t^4 + 4t^3 - 7t^2 + 24t + 36 \right),
\]

\[
V_i = 3 \left( t^4 + 2t^3 + 3t^2 + 8t + 12 \right) .
\]

Here the radial integrals \( I_{l+3}^1 \) are defined and analyzed in Appendix C. Although the last result has indeed an analytic, explicit character, it is not very practical for calculations because the integrals \( I_{l+3}^1 \) are determined by high-order derivatives for large \( l \). Hence, we describe their properties in detail in Appendix C.

Turning to the numerical evaluation of the angular velocity of dragging we obtain nice “bell-shaped” figures for \( \omega_0 \) for various values of \( m \) at a given \( l \). In Figure 2 \( \omega_0 \) is plotted for \( l = 10 \) and \( m = 1, 2, 3, ... 10 \).

Also, the integrals can be explicitly calculated at the moment of time-symmetry when the dragging near the
The dependence of normalized angular velocity of the central inertial frame \( \omega_0(l, 1; t) / \omega_0(l, 1; t = 0) \) on the parameter \( l = 2, 3, 10, 20, 30 \) (from inside to out). Also the function \( (1 + \ell^2)^{-3/2} \) is shown as a dashed line to indicate the limit for large \( \ell \) (cf. Eq. (7.11)).

Finally, at late times the analytic behavior of \( I^M_\ell \) implies

\[
\frac{\omega_0(t)}{\omega_0(t = 0)} \sim \frac{a}{t} + O \left( \frac{1}{t^5} \right),
\]

and in Figure 3 we illustrate that \( \omega(t) \) for large \( l \) and given \( m \) can be approximated by function

\[
\omega_{l \rightarrow \infty} = \frac{\omega_0(l = 0)}{[1 + \ell^2]^{3/2}}.
\]

VIII. OBSERVING STARS THROUGH GRAVITATIONAL WAVES

Since our waves are sufficiently weak near infinity, we can consider static stars there and ask how they would move across the sky as seen by an observer fixed in the flat region at the origin. We shall evaluate the first-order effects of the waves on the propagation of photons, the effects due to dragging of observer’s frame are of second order and will be discussed subsequently. The influence of gravitational waves on the passing photons can be computed as a perturbation of the ingoing radial null geodesic

\[
x^{(0)\mu} = [T + \lambda, -\lambda, \theta, \varphi], \quad \lambda \in (-\infty, 0),
\]

which describes a ray from the star with celestial coordinates \( \theta, \varphi \) which reaches the center at time \( T \). The geodesic equation can be written in the form

\[
\frac{d}{d\lambda} x^{(0)\mu} = p^{(0)\mu} + p^{(1)\mu} + \ldots,
\]

\[
\frac{d}{d\lambda} p^{(1)\mu} = -\Gamma^{(1)\mu}_{\rho\sigma} \left( x^{(0)\nu}(\lambda) \right) p^{(0)\rho} p^{(0)\sigma} - 2r \Gamma^{(0)\mu}_{\rho\sigma} \left( x^{(0)\nu}(\lambda) \right) p^{(1)\rho} p^{(0)\sigma}.
\]

To solve these differential equations we use covariant components of the perturbed photon momenta for which the effects of curvilinear coordinates cancel out; we omit superscript \( (0) \) for simplicity. Then we can write

\[
\frac{d}{d\lambda} x^{(1)}_\theta = -r^2 \frac{d}{d\lambda} p^{(1)}_\theta - 2rp^{(1)}_\theta p^r,
\]

\[
= -(p^r)^2 h_{\theta r, t} - (p^r)^2 h_{\theta r, r} - t^2 p^r \left[ h_{\theta r, t} + h_{t \theta, r} \right],
\]

\[
\frac{d}{d\lambda} x^{(1)}_\varphi = -r^2 \sin^2 \theta \frac{d}{d\lambda} p^{(1)}_\varphi - 2rp^{(1)}_\varphi \sin^2 \theta p^r,
\]

\[
= -(p^r)^2 h_{\varphi t, t} - (p^r)^2 h_{\varphi r, r} - t^2 p^r \left[ h_{\varphi \varphi, t} + h_{t \varphi, r} \right].
\]

We see that along the radial rays (for which \( \sin \theta = \text{const} \)) the covariant components of photons momenta \( p_\theta^{(1)} \) and \( p_\varphi^{(1)} \) can be written as integrals along the unperturbed ray and we do not need to solve the geodesic equation as set of differential equations. Similarly, the differential equations for \( \theta^{(1)} \) and \( \varphi^{(1)} \) can be written as follows

\[
\frac{d}{d\lambda} \theta^{(1)} = -\frac{1}{r^2} p^{(1)}_\theta
\]

\[
= \frac{1}{p^r} \frac{d}{d\lambda} \left( \frac{1}{r^2} p^{(1)}_\theta \right),
\]

\[
\frac{d}{d\lambda} \varphi^{(1)} = -\frac{1}{r^2} \sin^2 \theta p^{(1)}_\varphi
\]

\[
= \frac{1}{p^r} \frac{d}{d\lambda} \left( \frac{1}{r \sin^2 \theta} p^{(1)}_\varphi \right) - \frac{1}{r^2} \frac{1}{r^2} \frac{d}{d\lambda} p^{(1)}_\varphi.
\]

For photons which reach the origin the boundary terms arising after integration by parts vanish, so we can write

\[
\delta \theta(T) = \left[ \theta^{(1)} \right]_{T = 0}^{T = \infty} = -\int_{-\infty}^{0} \frac{1}{r} \frac{d}{d\lambda} p^{(1)}_\theta d\lambda,
\]

\[
= -\int_{ \infty}^{0} \frac{1}{(p^r)^2} \frac{1}{r} d\lambda p^{(1)}_\theta dr,
\]

\[
= \int_{0}^{\infty} \left[ h_{\theta r, t} + h_{t \theta, r} - h_{t \theta, t} - h_{\theta r, r} \right]_{T = \infty} \frac{dr}{r},
\]

\[
\delta \varphi(T) = \left[ \varphi^{(1)} \right]_{T = 0}^{T = \infty} = -\int_{-\infty}^{0} \frac{1}{r \sin^2 \theta} \frac{1}{r^2} \frac{d}{d\lambda} p^{(1)}_\varphi d\lambda
\]

\[
= -\int_{\infty}^{0} \frac{1}{(p^r)^2} \frac{1}{r^2} \frac{d}{d\lambda} p^{(1)}_\varphi dr,
\]

\[
= \int_{0}^{\infty} \left[ h_{\varphi \varphi, t} + h_{t \varphi, r} - h_{t \varphi, t} - h_{\varphi \varphi, r} \right]_{T = \infty} \frac{dr}{r \sin^2 \theta}.
\]
Since now we work in the linear approximation to find the light deflection we can go back to the simpler, complex-valued formulas (8.11) and (8.14). When we introduce amplitudes

$$\Delta \theta = B_l N_l^m 2(l-1)! m P^m_m \frac{(\cos \theta)}{\sin \theta}, \quad (8.10)$$
$$\Delta \varphi = -B_l N_l^m 2(l-1)! P^m_m \frac{(\cos \theta)}{\sin \theta}, \quad (8.11)$$

the integrals (8.8) and (8.9) simplify to

$$\delta \theta(T) = \text{Re} \left[ \Delta \theta \rho(a + iT) \right], \quad (8.12)$$
$$\delta \varphi(T) = \text{Re} \left[ \Delta \varphi i \rho(a + iT) \right], \quad (8.13)$$

where the complex function $\rho(a + iT)$ reads

$$\rho = -i e^{im\varphi} \frac{l(l+1)(l+2)}{(a+iT)^{l+1}} \int_0^\infty \frac{a^{l+2} (2r)^{l-1}}{(a+iT - 2ir)^{l+3}} dr$$
$$= -e^{im\varphi} \frac{1}{(1 + \frac{T^2}{a^2})^{l+2}}. \quad (8.14)$$

If we assume a telescope pointed towards the star’s initial position at $T \to -\infty$, the quantities $\delta \theta$ and $\sin \theta \delta \varphi$ are proportional to star’s coordinates on telescope’s photographic plate; star’s trajectory can be described by a simple formula

$$\frac{\delta \varphi}{\Delta \varphi} + \frac{i}{\Delta \theta} \frac{\delta \theta}{\delta \varphi} = \frac{i^l e^{im\varphi}}{(1 + \frac{T^2}{a^2})^{l+2}}. \quad (8.15)$$

We see that the same image is replicated for all stars (Figure 4). Depending on the star’s position the image is rotated by $e^{im\varphi}$ and then scaled by factors $\Delta \theta$ in the latitudinal and by $\Delta \varphi$ in the longitudinal direction. Surprisingly, the images are time-symmetric with the maximal deflection occurring at $T = 0$ despite the fact that the deflection is calculated using retarded integrals (8.8) and (8.9).

Since the calculation of the second-order metric everywhere would be very complicated we cannot, of course, describe all second-order effects. However we can describe the second-order effect of the total rotation of the central observer’s telescope due to the dragging of his inertial frames given above, cf. (7.10), (7.11). Since the pulse starts and ends at infinity at $t = \pm \infty$, the total rotation of the telescope is clearly gauge invariant. As a consequence, the curves in Figure 4 will no longer be closed. The stellar initial position at $T \to -\infty$ will differ from the final position at $T \to +\infty$ by an amount proportional to the area under the graph of $\omega_0(t)$.

**IX. CONCLUDING REMARKS**

The results obtained here extend significantly our past studies of gravitational waves with the translational symmetry that rotate about the axis of cylindrical symmetry and cause a rotation of local inertial frames at the axis. In the present work we investigated the effects of the rotating gravitational waves in a general, asymptotically flat situation. The main conclusions following from these studies demonstrate explicitly that any statement of Mach’s principle that attributes all dragging of inertial frames solely to the distribution of energy and momentum of matter, characterized by $T_{\mu\nu}$, as the origin of inertia is false – gravitomagnetic effects are also caused by gravitational waves satisfying Einstein’s field equations in vacuum for which a local energy and momentum cannot in general be defined.

We found that the dragging of inertial frames at the origin occurs *instantaneously*, with no time-delay depending on the position of the pulse. The dipole perturbations determining the dragging follow from the constraint equation which is elliptic (see equation (6.10)). Gravity is a tensor field, so gravitational waves cannot have a dipolar part. This is the case with our first-order rotating pulse. It is the non-linearity of Einstein’s field equations causing a self-interaction of the waves which produces an effective source for the second-order perturbations. For a general multipole moment $l \geq 2$, the...
resulting equations are again wave-type equations indicating that the effects of the first-order terms cause the second-order terms in a non-instantaneous way. However, inertial frames at the origin will only be influenced by the dipole perturbations since waves decay as $r^l$ at the origin. And for the dipole ($l = 1$) second-order perturbations, the equation becomes elliptical, with the source term given by a component of the second-order Ricci tensor $R^{(2)}_{t\varphi}$ quadratic in the first-order metric and its derivatives.

The instantaneous character of the dragging of inertial frames by angular momentum of sources implied by the Einstein constraint equation can, in fact, be seen in diverse situations, including those in cosmological perturbation theory. We encountered the effect in the study of local inertial frames affected by the rotations beyond the cosmological horizon [9], [10], or in the general analysis of “rotations and accelerations” of local inertial frames in the linearly perturbed Friedmann-Robertson-Walker spacetimes [2]. In the cosmological context we introduced desirable gauges - we call them the “Machian gauges” - as those in which local inertial frames can be determined instantaneously from the distributions of energy and momentum in the universe by means of the perturbed Einstein constraint field equations. The “uniform-Hubble-expansion-gauge” or the “minimal-shear hypersurface” gauge combined with “the minimal distortion” gauge on the spatial metric are examples of the Machian gauges: the synchronous gauge or the generalized Lorentz-de Donder (harmonic) gauge are not. (See [2] for detailed analysis and preferences of the Machian gauges.)

Likewise, in the context of gravitational waves we should bear in mind that such physical effects like the dragging of inertial frames are of a global nature and require the introduction of suitable coordinates in which the waves are described.

In the present work we also investigated for the first time, as far as we are aware, the effects of the rotating gravitational waves on the propagation of light from distant fixed stars at (asymptotically flat) infinity.

There are various open problems in these themes which deserve further study. In order to have more natural understanding of the effect of rotating gravitational waves one should consider the waves within a cosmological (not asymptotically flat) context. Although in [2] we emphasized the role of the instantaneous Machian gauges, it would be also interesting to study these effects, in particular those connected with gravitational waves, in other type of gauges like the Lorentz-de Donder gauge (cf. Appendix D in [2]).

Of course, any simple model problem illustrating the Machian effects exactly within general relativity, like that employing the conformal stationary metrics in our recent note on the linear gravitational dragging [27], deepens considerably our understanding of such effects.

Appendix A: Integrals over products of Legendre functions

The following integrals over $\theta$ or $\mu = \cos \theta$ are needed to evaluate functions $h_0(t, r)$ in (6.12) in terms of radial integrals over $g(t, r)$ given by (6.11) and (B3). Most of them can be found in [19], two follow from simple integration by part. These are $(0 < m \leq l)$:

$$\int_{-1}^{1} (P^m_l)^2 d\mu = \frac{2}{2l + 1} \frac{(l + m)!}{(l - m)!}$$ (A1)

$$\int_{-1}^{1} (P^m_l)^2 d\mu = \frac{1}{m(2l - m)!}$$ (A2)

$$\int_{-1}^{1} \mu P^m_l P^m_l' d\mu = -\frac{1}{2l + 1} \frac{(l + m)!}{(l - m)!}$$ (A3)

$$\int_{-1}^{1} (1 - \mu^2)(P^m_l)^2 d\mu = \frac{(l + m)!}{(l - m)!} \left[ \frac{2l(l + 1)}{2l + 1} - m \right]$$ (A4)

Appendix B: Calculating and averaging the second-order Ricci tensor component

To compute $R_{t\varphi}^{(2)} \left[ h^{(1)}, h^{(1)} \right]$ we use metric perturbations (7.2), (7.8) which in coordinates $x^\mu = \{t, r, \theta, \varphi\}$ yield a linearized metric with odd-parity perturbations on a flat background. We start from the general form

$$g_{\mu\nu} = \begin{bmatrix} 1 & 0 & h_{t\theta} & h_{t\varphi} \\ 0 & -1 & h_{r\theta} & h_{r\varphi} \\ h_{t\theta} & h_{r\theta} & -r^2 & 0 \\ h_{t\varphi} & h_{r\varphi} & 0 & -r^2 \sin^2 \theta \end{bmatrix}$$ (B1)

With the metric functions given by (7.4), (7.5) the components of the Ricci tensor in the first-order approximation yield zero either identically or due to the fact that $\psi_{lm}$ solves the wave equation (2.1). The only second-order component we need is

$$-R_{t\varphi}^{(2)} = \frac{1}{2r^2} \left[ h_{t\theta,t} r_{\varphi,\theta} - h_{t\varphi,\theta} h_{r\theta,r} - h_{t\varphi,r} h_{r\theta,\theta} + h_{t\theta}(h_{t\varphi,\theta} + h_{t\theta,\varphi}) + h_{r\varphi,t} h_{r\theta,\theta} - h_{r\theta,\varphi} h_{r\theta,t} + h_{r\theta}(h_{t\varphi,\theta} - 2h_{t\varphi,r} - 2h_{t\theta,\varphi}) + h_{t\theta,\varphi} h_{r\theta,r} \right]$$
where dimensionless variables \( r, \kappa, \omega \) are introduced. When integration over the spherical angles \( \varphi \) and \( \theta \) is performed, we get \( \eqref{7.9} \). At this moment we use functions \( \kappa \) and \( \lambda \) given in \( \eqref{7.8} \) and \( \eqref{7.10} \) and obtain

\[
\int_0^\infty \int_0^\infty R_{t,\varphi} d\Omega \frac{dr}{r} = \int_0^\infty 2B^2 I_0(l+1) + 12 + 12l + 12l \times \left\{ r_t^2 \left[ (r_t^2 + 4a^2 t^2) \left( t^4 + 2l^3 + 3l^2 + 12l \right) + 4 \left( t^2 + a^2 \right) \left[ 3r_t^4 - 4r^2 (2a^2 + 2r^2 + t^2) \right] + 8r_t^2 \left( a^4 + r^4 + 2a^2 t^2 - t^4 - 2(l + 4) a^2 r_t^2 + 1 \right) \right] \right\},
\]

where \( r_t^2 = r^2 + a^2 \pm t^2 \). After the numerator is expanded in powers of \( r \), using \( \tau = t/a \), this integral can be converted into a linear combination of integrals \( I^M_L \) defined in Appendix C:

\[
\int_0^\infty \int_0^\infty R_{t,\varphi} d\Omega \frac{dr}{r} = \frac{2B^2 I_0(l+1)}{a} \times \left[ Z_l I_{l+3}^0 + (Z_l + 8l + 12)(\tau^2 + 1)^3 I_{l+3}^0 \right. \\
+ (\tau^2 + 1) \left[ 3Z_l - 16(l+1)^2 + 8 - (Z_l - 8) \tau^2 \right] I_{l+3}^0 \\
\left. + 3Z_l - (4 + 5)^2 + 5 - (Z_l + 8l + 20) \tau^2 \right] I_{l+3}^0 \right],
\]

where \( Z_l = l(l^2 + 2l^2 + 3l + 4) \). Using identities \( \eqref{C15} \) in Appendix C the number of integrals \( I^M_L \) can be reduced down to two, as is shown in the final form of the formula for \( \omega_0 \) in \( \eqref{7.10} \).

**Appendix C: Radial Integrals** \( I^M_L, J^M_L \)

To evaluate the metric function \( h_0 \) at a general radius \( r \) we need indefinite integrals in \( \eqref{6.12} \) to determine the rotation of the inertial frame at the origin we have to evaluate the definite integral in \( \eqref{183} \). If we introduce dimensionless variables \( \zeta = r/a^2 \) and \( \tau = t/a \), the definite integrals we need to evaluate simplify into

\[
I^M_L(\tau) = \int_0^\infty \frac{\zeta^{L-M-1}}{\left[ (1 + \tau^2) + 2(1 - \tau^2) \zeta + \zeta^2 \right]^L} d\zeta, \quad \text{(C1)}
\]

where \( L \) will be \( l - 3 \), \( M \) is a small integer. We first put

\[
x = \frac{\zeta}{1 + \tau^2}, \quad \beta = \frac{1 - \tau^2}{1 + \tau^2}, \quad \text{(C2)}
\]

so that

\[
I^M_L = \frac{(1 + \tau^2)^{L-M}}{(1 + \tau^2)^2L} \int_0^\infty \frac{x^{L-M-1}}{(1 + 2\beta x + x^2)^L} dx. \quad \text{(C3)}
\]

To evaluate this integral we start from the following simple integral (with \( \alpha = \text{const parameter} \))

\[
H_0 = \int_0^\infty \frac{dx}{\alpha + 2\beta x + x^2} = \frac{1}{\sqrt{\alpha - \beta^2}} \left( \frac{\pi}{2} - \arctan \frac{\beta}{\sqrt{\alpha - \beta^2}} \right). \quad \text{(C4)}
\]

Setting then

\[
H_M \equiv \int_0^\infty \frac{dx}{\left( \alpha + 2\beta x + x^2 \right)^{M+1}} = \left( -\frac{\partial}{\partial \alpha} \right)^M H_0 \left| \frac{d^M H_0}{d\alpha^M} \right|_{\alpha=1}. \quad \text{(C5)}
\]

we can find the integral which appears in \( \eqref{C3} \) by evaluating \( (L - M - 1) \)-th partial derivative of \( H_M(\alpha, \beta) \) with respect to \( \beta \), so the original integral turns out to be

\[
I^M_L = \frac{2(1 + \tau^2)^{L-M} - \tau^{L-M}}{(-1)^M} \frac{\partial^{L-M-1} H_0}{\partial \alpha^{L-M-1}} \left| \alpha=1 \right. \quad \text{(C6)}
\]

Since it is inconvenient to use this general form we will write the two integrals which appear in \( \eqref{7.10} \) explicitly:

\[
I^M_{l+3} = \frac{(1 + \tau^2)^{-l-4}}{2^{l+6}(l+2)!} \left( \frac{\tau^2 + 1}{\tau} \frac{d}{d\tau} \right)^{l+1} \quad \Pi_1, \quad \text{(C7)}
\]

\[
\Pi_1 = \frac{(\tau^2 + 1)^3}{\tau^3} \text{arctan} \frac{\tau + 1}{\tau^2}, \quad \Pi_2 = \frac{(\tau^2 + 1)^5}{\tau^5} \text{arctan} \frac{\tau^4 - 1}{\tau^4}, \quad \text{(C8)}
\]

The expressions for these integrals become much simpler at \( \tau = 0 \) (and at \( \tau = \pm 1 \) which, however, we will not discuss further). At the moment of time symmetry the denominator of the integral \( \eqref{C1} \) simplifies to \( (1 + \zeta)^2 \), and we get integrals of the form

\[
J^M_L = \int_0^\infty \frac{x^M}{(1 + x)^L} dx. \quad \text{(C9)}
\]

Assuming \( L - M \geq 2 \) (which is satisfied in the cases we need), we can easily integrate by parts and get

\[
J^M_L = \left[ -\frac{1}{L - 1} \frac{x^M}{(1 + x)^{L-1}} \right]_0^\infty + \frac{M}{L - 1} J^{M-1}_L, \quad \text{(C10)}
\]

where the first term vanishes if \( L - M \geq 2 \). Continuing with integration by parts we arrive at the simple result:

\[
J^M_L = \frac{M(L - M - 2)!}{(L - 1)!}. \quad \text{(C11)}
\]
This yields
\[ I_M^L(\tau = 0) = \frac{(L - M - 1)!(L + M - 1)!}{(2L - 1)!}. \] (C12)

For large \(|\tau|\), (C7) and (C8) provide
\[ I_{l+3}^1(\tau) \approx \frac{(2l + 3)!}{2^{2l+9}(l+2)!} \frac{\pi}{|\tau|^3} + O\left(\frac{1}{|\tau|^5}\right), \] (C13)
\[ I_{l+3}^2(\tau) \approx \frac{(2l + 3)!}{2^{2l+9}(l+2)!} \frac{\pi}{|\tau|^3} + O\left(\frac{1}{|\tau|^5}\right). \] (C14)

Even though (B4) contains integrals \(I_{l+3}^M\) with \(M = 0, 1, 2, 3\), only two of them are “independent” because of the fact that \(\int_0^\infty f'(x)dx = 0\) for functions satisfying \(f(0) = f(\infty)\) implies
\[ (L - M - 1)(1 + \tau^2)^2 I_{l+1}^M - 2M(1 - \tau^2) I_{l+1}^M = 0. \] (C15)
