Background: Cardiovascular complications with myocarditis in multisystem inflammatory syndrome in children (MIS-C) associated with severe acute respiratory syndrome coronavirus 2 infection have been reported, but the optimal therapeutic strategy remains unknown.

Methods: A retrospective cohort study included 19 patients with acute left ventricular systolic dysfunction associated with MIS-C, average years of age 13.2 ± 3.8, treated from April 2020 to April 2021. Patients were initially treated with IVIG according to the protocols for KD; IVIG-nonresponsive patients were treated with IVIG. Patients with acute LV systolic dysfunction or cardiogenic shock were initially treated with IVMP (CS—three intravenous methylprednisolone pulses (IVMPs). How-ever, we observed that most patients required CS without IVIG. Patients with acute LV systolic dysfunction or cardiogenic shock associated with MIS-C were initially treated with IVMP without IVIG (see Figure, Supplemental Digital Content 1; http://www.pidj.com). The overlapping features between these syndromes suggest that they may share similar pathophysiology, probably explaining why they respond to similar therapies. Early reports support the use of intravenous immunoglobulins (IVIGs)—which is the standard treatment for KD—to treat MIS-C patients. However, due to the refractory nature of the disease, many children required second-line treatment—corticosteroids (CSs) and immune modulators. This retrospective cohort study aimed to compare the outcomes in patients with myocardial damage related to MIS-C depending on the initial treatment—IVIG or CSs.

METHODS

The retrospective cohort study included all children under 18 with acute left ventricular (LV) systolic dysfunction or cardiogenic shock associated with MIS-C admitted to our Clinic from April 2020 to April 2021. A serologic examination for SARS-CoV-2 was performed using the enzyme-linked immunosorbent assay and the immunochromatography technique. The diagnosis of MIS-C temporar-ily associated with COVID-19 was based on the criteria of the US Centers for Disease Control and Prevention. MIS-C shock was defined as the persistence of systolic arterial hypotension, a decrease of at least 20% from a basal systolic blood pressure, or the appearance of signs of peripheral hypoperfusion,10,11 the refractory nature of the disease, many children required second-line treatment—corticosteroids (CSs) and immune modulators. This retrospective cohort study aimed to compare the outcomes in patients with myocardial damage related to MIS-C depending on the initial treatment—IVIG or CSs.
links.lww.com/INF/E469); only 3 patients received dexamethasone initially.

We divided the patients into 2 groups depending on their initial treatment for MIS-C: IVIG and CS. The groups were compared according to clinical presentation, vital and laboratory parameters, electrocardiogram, clinical course and disease outcome.

The therapy’s impact was analyzed by reviewing the vital parameters and laboratory analyses for the first 5 in-hospital days. Treatment failure (TF) was defined as fever persistence (≥38 °C or > 100.4 °F) for 48 hours after therapy initiation or the occurrence of acute LV systolic dysfunction (ejection fraction [EF] < 55%) and a need for vasoactive drugs.

The study was approved by the local ethics committee, which waived the need for informed parental consent (authorization number: 9/13).

**Statistical Analysis**

The data were processed using the statistical software SPSS 25.0 for Windows 10. All statistical methods were considered significant if the P value was ≤0.05. The descriptive statistics included the mean values, median, standard deviations and the interquartile range (IQR) of the parameters monitored. The difference in the distribution of specific parameters among the groups tested was determined using the χ² or Fisher test. The normality of the numerical variables’ distribution was tested using the Shapiro Wilk and Kolmogorov-Smirnov tests. The comparison between 2 related samples was made using the Student’s t-test and the Mann-Whitney test. Paired T tests and Wilcoxon tests were used to compare 2 related samples. The correlation between vital parameters in different groups was tested using the Pearson test or Spearman test. Binominal logistic regression analysis was used to explain the relationship between the dependent binary variable and the independent variables.

**RESULTS**

From April 2020 to April 2021, 51 patients with MIS-C were treated in our institute, 21 women and 30 men (9.3 ± 5.0 years). There were positive serologic tests for SARS-CoV-2 for 49 patients who were treated in our institute, 21 women and 30 men (9.3 ± 5.0 years). There were positive serologic tests for SARS-CoV-2 for 49 patients (in the IVIG group 7/10; in the CS group 2/9). There was a higher prevalence of TF in the IVIG group than in the CS group (P = 0.03). Specifically, treatment with IVIG as compared with CS was an independent risk factor for TF (OR 11.7, 95% CI: 1.5–89.3, P = 0.02). In 7 of 10 patients initially treated with IVIG, CS was subsequently added on day 3 on average (IQR 2–4); IVMP in 5 of 7 patients and dexamethasone in 2 of 7 patients. The clinical presentation did not influence TF (see Figure, Supplemental Digital Content 2B; http://links.lww.com/INF/E471). The difference between groups is presented in Table 2. Patients with phosphate levels lower than 1 mmol/L and fibrinogen higher than 5.5 g/L had 24 times and 10 times higher probability of TF, respectively (OR 24, 95% CI: 1.7–330.8, P = 0.02; OR 9.6, 95% CI: 0.9–105.2, P = 0.049), than children with a phosphate level higher than 1 mmol/L and fibrinogen level lower than 5.5 g/L.

IVIG as compared with CS was an independent risk factor for TF (OR 11.7, 95% CI: 1.5–89.3, P = 0.02). In 7 of 10 patients initially treated with IVIG, CS was subsequently added on day 3 on average (IQR 2–4); IVMP in 5 of 7 patients and dexamethasone in 2 of 7 patients. The clinical presentation did not influence TF (see Figure, Supplemental Digital Content 2B; http://links.lww.com/INF/E471). The difference between groups is presented in Table 2. Patients with phosphate levels lower than 1 mmol/L and fibrinogen higher than 5.5 g/L had 24 times and 10 times higher probability of TF, respectively (OR 24, 95% CI: 1.7–330.8, P = 0.02; OR 9.6, 95% CI: 0.9–105.2, P = 0.049), than children with a phosphate level higher than 1 mmol/L and fibrinogen level lower than 5.5 g/L.

**Myocardial injury** was observed in 22 patients, and those patients were included in our retrospective study. Patients with MIS-C older than 10 had 12 times higher probability of myocardial affection (odds ratio [OR] 10.9, 95% confidence interval [CI]: 2.8–39.6; p < 0.001). Only those patients had shock syndrome on admission (P = 0.001).

Among the 22 children, 10 received IVIG as the initial treatment, while CS was used as the initial treatment in 12 patients (IVMP—9 patients and dexamethasone—3 patients). The difference between groups in terms of age distribution and fever duration before first-line therapy was not significant (P = 0.4, P = 0.42, respectively) (Table 1). The clinical presentation of the groups is presented in Figure, Supplemental Digital Content 2A; http://links.lww.com/INF/E471. On admission, 8 of 22 patients met MIS-C shock syndrome criteria (IVIG treated 5, CS alone—3; P = 0.65). However, during IVIG infusion 1 patient experienced clinical deterioration and 3 patients developed shock syndrome (P = 0.03).

TF was observed in 9 patients (in the IVIG group 7/10; in the CS group 2/9). There was a higher prevalence of TF in the IVIG group than in the CS group (P = 0.03). Specifically, treatment with IVIG as compared with CS was an independent risk factor for TF (OR 11.7, 95% CI: 1.5–89.3, P = 0.02). In 7 of 10 patients initially treated with IVIG, CS was subsequently added on day 3 on average (IQR 2–4); IVMP in 5 of 7 patients and dexamethasone in 2 of 7 patients. The clinical presentation did not influence TF (see Figure, Supplemental Digital Content 2B; http://links.lww.com/INF/E471). The difference between groups is presented in Table 2. Patients with phosphate levels lower than 1 mmol/L and fibrinogen higher than 5.5 g/L had 24 times and 10 times higher probability of TF, respectively (OR 24, 95% CI: 1.7–330.8, P = 0.02; OR 9.6, 95% CI: 0.9–105.2, P = 0.049), than children with a phosphate level higher than 1 mmol/L and fibrinogen level lower than 5.5 g/L.

Patients initially treated with CS became afebrile during in-hospital day 1 (1.5, IQR 1–2), while patients initially treated with IVIG became afebrile on average on in-hospital day 4 (IQR 2–4.25; P = 0.007) (Fig. 1A). A significant difference between the body temperature and heart rate of those groups was registered after 9 and 15 hours of in-hospital stay, respectively (P = 0.004, P = 0.04) (Fig. 1B).

**TABLE 1. Patients Characteristics at the Admission**

|                     | IVIG 10 Patients (45.4%) | CS 12 Patients (54.5%) | P   |
|---------------------|--------------------------|------------------------|-----|
| Male gender         | 8                        | 7                      | 0.38|
| Age                 | 13.4 ± 3.7               | 11.8 ± 4.4             | 0.38|
| KD-like             | 7                        | 9                      | 1.0 |
| Shock               | 5                        | 3                      | 0.37|
| Fever (days)        | 6 (IQR 5 to 7)           | 5 (IQR 4.25 to 6.75)   | 0.37|
| Heart rate (l/min)  | 116.5 ± 16.8             | 111.5± 17.4            | 0.49|
| CRP (mg/mL)         | 175 (IQR 121.9 to 258.7) | 248.5 (IQR 180.3 to 293) |
| NT-pro BNP (pg/mL)  | 4839 (IQR 2730 to >5000) | 4296 (IQR 2175 to >5000) |
| Elevated Ctn         | 7                        | 8                      | 1.0 |
| Elevated SGOT       | 5                        | 4                      | 0.7 |
| Elevated SGPT       | 6                        | 6                      | 0.7 |
| Thrombocytopenia    | 6                        | 7                      | 1.0 |
| Na (mmol/L)         | 133.1 ± 3.75             | 132.7 ± 2.5            | 0.75|
| Albumin (g/L)       | 35.2 ± 4.6               | 31.7 ± 4.3             | 0.08|
| Phosphate (mmol/L)  | 0.93 ± 0.3               | 1.03 ± 0.2             | 0.37|
| D-dimer (mg/mL)     | 753 (IQR 494 to 1758)    | 1312 (IQR 685 to 2488) |
| Fibrinogen (g/L)    | 5.6 ± 2.5                | 5.3 ± 1.7              | 0.7 |
| Ejection fraction (%)| 47.9 ± 7.7               | 51.7 ± 5.7             | 0.27|
| Fraction of shortening (%) | 24.5 ± 4.17 | 27.1 ± 5.7 | 0.31|
| Left ventricle EDD (Z score) | 0.54 (IQR -0.5 to 1.06) | 0.4 (IQR 0.06 to 1.17) | 0.46|
| Left ventricle ESD (Z score) | 2.05 (IQR 0.7 to 3.13) | 1.97 (IQR 1.55 to 2.22) | 0.72|
| Posterior wall (Z score) | 0.9 (IQR 0.46 to 1.6) | 1.44 (IQR 1.1 to 2.34) | 0.13|

EDD indicates end-diastolic diameter; ESD, end-systolic diameter.

FIGURE 1. The vital parameters dynamics during in-hospital stay. Red star—the moment of corticosteroid administration in IVIG-nonresponders. IVIG indicates intravenous immunoglobulin.

A significant higher systolic blood pressure was registered in the CS group after 15 hours of in-hospital stay ($P = 0.04$) compared with IVIG-treated patients (Fig. 1C). Hypertension was observed in 5/22 patients (22.7%) during the in-hospital stay. The therapy applied did not influence hypertension ($P = 0.63$) or renal injury ($P = 0.4$), but these patients were older (16.8 ± 0.6 years) than the others (11.9 ± 3.5 years; $P = 0.008$).

On admission, 10 patients had electrocardiogram abnormalities. The most common abnormality was a negative T wave in the inferior leads. A prolonged corrected QT interval was observed in 13 patients, on day 7 on average (IQR 5.25–9.75).

Echocardiography examination on admission identified depressed systolic function (EF 49.9 ± 7.8%), and walls edema. A moderate negative correlation was proved between the cardiac troponin I (cTnI) value and EF ($r = -0.53$, $P = 0.03$). Uniform coronary artery (CA) dilatation was observed in 4 patients (LCA—3 patients; LCA and RCA—1 patient; LCA Z score 2.95 ± 0.3; RCA Z score 2.6), only in patients with KD-like clinical presentation; CA were of appropriate diameter on discharge. No difference was observed between the groups in terms of the echocardiography parameters on admission (Table 1), but CS-treated patients had normal and a significantly higher EF (EF 61.1 ± 5.1%) on in-hospital day 3 than patients treated with IVIG (EF 54.1 ± 6.5%) ($P = 0.015$). A significant improvement of systolic function during the first 3 days was observed in the CS group ($P = 0.005$) (Fig. 2).

On admission, all patients had elevated inflammatory parameters in serum. The CRP significantly declined in patients initially treated with CS on days 2, 3 and 4 ($P = 0.008$, $P = 0.003$, $P = 0.008$ respectively), while in the IVIG group, CRP decreased significantly on day 4, immediately after CS was added ($P = 0.04$). A significant difference in CRP value between groups was observed on day 4 ($P = 0.001$) (Fig. 3A). No significant difference in D-dimers and fibrinogen levels was observed between groups (Fig. 3B and C).

On admission hyponatremia was observed in 16 of 22 patients. The sodium level was higher on in-hospital day 3 in the CS group than in the IVIG group ($P = 0.008$) (Fig. 3D). In the IVIG group, serum phosphate increased significantly after CS was added on day 4 ($P = 0.02$) (Fig. 3F).

FIGURE 2. Recovery of the left ventricular systolic function during in-hospital stay in the different groups. (A) A significant improvement of EF during the first 3 days was observed in the CS group ($P = 0.005$); in the IVIG group, in the discharge ($P = 0.001$); (B) The left ventricle ESD Z score decreased significantly during the first 3 days in the CS group ($P = 0.04$); in the IVIG group on discharge ($P = 0.005$); (C) The left ventricle EDD Z-score reduced significantly on discharge in both groups, IVIG and CS ($P = 0.003$, $P = 0.02$). CS, corticosteroid; ESD, end-systolic diameter; EDD, end-diastolic diameter; IVIG indicates intravenous immunoglobulin.

TABLE 2. The Differences Between Patients With and Without Treatment Failure

| Treatment Failure | No | Yes | $P$ value |
|-------------------|----|-----|----------|
| CRP (mg/L) fourth day | 65.0, IQR 38.0–80.0 | 100.0, IQR 97.5–195.0 | 0.001 |
| Na (mmol/L) second day | 136.8 ± 4.2 | 131.5 ± 2.7 | 0.005 |
| LV EF (%) third day | 60.3 ± 4.6% | 54.33 ± 7.66 | 0.004 |

CRP indicates C-reactive protein; Na, sodium; LV EF, left ventricle ejection fraction.
ICU stays were shorter in the CS group (4, IQR 2–5.2) than in the IVIG group (IVIG group 7, IQR 6–8.5) ($P < 0.001$).

During the follow-up period (1.25 months, IQR 1–2.65), 1 patient had a 1-day fever of 38.5°C with elevated acute phase reactants (CRP 83.9 mg/L, ESR 35 mm/h) and microscopic hematuria followed by spontaneous resolution. Two patients had systolic hypertension on the control Holter monitoring of blood pressure, despite antihypertensive therapy; one of them also had calcinuria, phosphaturia, uricosuria and proteinuria. Neither the gender, age, initially prescribed therapy, nor TF influenced the short-term sequelae of MIS-C ($P = 0.17$, $P = 1.0$, $P = 0.7$ and $P = 0.66$).

**DISCUSSION**

Although many similarities between MIS-C and KD were identified, it has become evident that cardiovascular involvement, shock, gastrointestinal symptoms, and coagulopathy, which are rarely seen in classic KD, are prominent features of this unique syndrome. The etiology of cardiovascular involvement in MIS-C is likely multifactorial. Cardiac injury was caused through multiple hypothesized mechanisms, including cardiomyocyte injury due to an acute and dysregulated inflammatory response related to a cytokine storm, microvascular dysfunction, and a viral invasion of cardiomyocytes resulting in cellular damage and ischemic injury. Almost half of all our patients with MIS-C had a myocardial injury (22/51), and those patients were significantly older than patients without myocardial damage. All patients had elevated N-terminal-pro hormone b-type natriuretic peptide, while cTnl was increased in 15 of 22 patients. The cTnl release results from increased permeability of the cardiomyocyte cell membrane and does not exclusively reflect cell necrosis. These findings support myocardial stunning or edema rather than myocarditis in MIS-C. We proved the moderate negative correlation between CRP and EF, which suggests that LV systolic function is conditioned by the degree of inflammation. In KD, myocardial edema is the main finding without or with limited cardiomyocytes necrosis as evidenced by the mild to moderate elevation of cTnl. In the autopic hearts, the cardiac tissue’s inflammatory process seemed to permeate the vascular wall, consequently leading to arterial obliteration and ischemic tissue damage, without signs of typical lymphocytic or viral myocarditis.

Although KD is presumed to be triggered by a viral infection, investigations remained inconclusive, given the lack of reproducibility of a putative viral pathogen resulting in KD. We assume MIS-C and KD represent a spectrum of postviral, immune-mediated myocarditis with shared similar immunopathogenesis. It is recommended that patients with immune-mediated myocarditis should be treated with immunosuppressive drugs, such as CS. In the last decade, CS was commonly used in KD, especially with a high Kobayashi index and myocarditis, and CS would probably help prevent IVIG resistance in KD. Some authors have reported IVMP as a rescue therapy in children with refractory KD who had myocarditis and symptomatic congestive heart failure during the acute stage of the disease.

Some studies have shown that 51%–80% of patients with MIS-C did not respond to IVIG treatment, while 70% of our patients with MIS-C appear to be unresponsive to IVIG. CS was added to this group’s therapy on day 3 on average. Immediately after CS introduction to those patients, on day 4 of in-hospital stay, serum levels of sodium and phosphate increased significantly, CRP decreased significantly and patients became afebrile.

Patients treated with CS had a faster normalization of body temperature, heart rate and systolic pressure than patients treated with IVIG and a rapid decline in pro-inflammatory parameters in the blood. Compared with the IVIG group, CS-treated patients had a lower CRP on day 4, but higher sodium, albumin, and phosphate levels. Echocardiography evaluation on day 3 showed that CS-treated patients had a normal and significantly higher EF compared with IVIG-treated patients. Belhadjer et al concluded that adding CS to IVIG was associated with a shorter cardiac function recovery time in patients with MIS-C. We showed that patients treated with CS had shorter ICU stays than another group, which is similar to the results from Ouldali et al.

IVIG-treated patients had an almost 19-times higher probability of TF than patients treated with CS. SARS-CoV-2 epithelial injury at an initial stage may provoke secondary local endotheliitis with delayed auto-inflammatory vasculitic phenotype with upregulation of IL-1β or IL-6. The constellation of elevated cytokines mediated an increase in vascular permeability, causing fluid leakage into the extravascular compartment. More than half of our patients had hypoalbuminemia, hyponatremia, hypophosphatemia and thrombocytopenia on admission. Severe hyponatremia and hypoalbuminemia are common features in previous “classic” KD myocarditis reports, and they were associated with more severe and more prolonged acute disease. This finding supports the fact that MIS-C inflammation is much more intense than in classic KD. More intense inflammation could explain the ineffectiveness of
IVIG to block fluid leakage, leading to hypoalbuminemia, hypoa-
tremia and hypovolemia, contributing to the newly formed MIS-C
distributive shock in 4 of 10 IVIG-treated patients. Hyponatremia
could be explained by third-space loss of fluid and sodium or theenal loss of sodium and increased BNP concentration or intensive
inflammation, elevated plasma IL-6 and the tumor necrosis fac-
tor α (TNF-α) influenced the release of antidiuretic hormone.23,24
We showed that having a phosphate level lower than 1 mmol/L
and fibrinogen higher than 5.5 g/L increased the probability of TE,
resulting from more intense inflammation. The phosphate level
negatively correlated with TNF-α and IL-6 in early sepsis,27,28
while cytokines regulated fibrinogen production in the liver, and
the production is greatly enhanced in the acute phase of infection
response and other inflammatory processes.29 The significant eleva-
tion of the phosphate level after CS introduction in IVIG-nonre-
sponsive patients was a consequence of CS dose-dependent inhibi-
tion of cytokine (TNF-α and IL-6) release.27,28 CS acutely reduces
the hyperinflammatory response, inhibits vasodilatation and the
increased vascular permeability that occurs following inflamma-
tory insult; these anti-inflammatory effects are apparent within
minutes due to the expression of IL-1α and IL-1β being inhibited.30
This study has several limitations. First, it was not a rand-
omized trial, which might provide the best level of evidence. Sec-
ond, the number of patients included in the study was small. Third,
the follow-up period was insufficient to draw conclusions.

CONCLUSION

Among children with a myocardial injury during MIS-C,
treatment with CS only was associated with a faster normalization
of fever, improved laboratory results, and a shorter ICU stay
than IVIG-treated patients. Additionally, in CS-treated
patients, normalization of LV EF was observed on in-hospital day
3. CS should also be used for refractory MIS-C because after CS
was added, patients became afebrile, the CRP value dropped and the
sodium and phosphate levels increased significantly. The short-term
sequela of MIS-C and CS side-effect were reversible in our study.

ACKNOWLEDGMENTS

We thank and acknowledge the following for their assistance
in the treatment of patients with MIS-C: Predrag Minic, MD, PhD,
Natasa Statjic, MD, and Srdjan Pasic, MD, PhD (Head of Immunol-
omy Department), Mother and Child Health Institute of Serbia. Addi-
tionally, we truly appreciate the following for performing the bio-
chemical analysis: Ljubica Zatezalo, MD, Dragana Bojanin Mr Ph.
