A novel total synthesis of aculeatin A via a stepwise approach†

Zhibin Zhang,a Xiao Leng,b Shenkun Yang,a Cheng Liang,a Shuangping Huang*a and Xiaoji Wang*c

Aculeatin A, isolated from the plant Amomum aculeatum, is a dispirocyclic compound having antimalarial activity. In this paper, we describe a novel synthetic approach to aculeatin A from 1-tetradecanal in nine steps via a stepwise strategy. The key features of this approach include the 1,3-diketone preparation from Claisen condensation of ketone and acyl chloride, cyclodehydration, and intramolecular oxa-Michael addition to 2,3-dihydro-4H-pyran-4-one.

Introduction

Traditional medicines, which usually contain rich bioactive natural products with fascinating architectures, play a significant role in the cure of diseases such as malaria, and are therefore important sources of lead compounds. Malaria is the most important parasitic disease, causing serious effects to infected humans and killing more than 500 000 every year.1 Artemisinin and chloroquine are commonly used clinically to reduce morbidity and mortality. With the widespread use of these agents, however, resistance to them has emerged in many regions.2 Therefore, identifying new and effective antimalarial agents, especially with novel mechanisms of action and neoteric chemical structures, is an important problem to be addressed by scientists. In Papua New Guinea, the plant Amomum aculeatum has long been used in folk medicine for the treatment of fever and malaria. In 2000 and 2001, Heilmann and coworkers reported four novel dispirocyclic natural products from petroleum extracts of its rhizomes, namely, aculeatins A–D (Fig. 1).3

Aculeatins A–D have attracted tremendous interest from scientists since their isolation. This new novel class of natural products exhibit interesting antimalarial activities at sub-micromolar level, as shown by in vitro experiments. For example, they have an IC_{50} of 0.18–3.0 μM against Plasmodium falciparum, Trypanosoma brucei rhodesiense and Trypanosoma cruzi. Aculeatins, however, contain a novel 1,7-dioxdispiro[5.1.5.2]pentadecane skeleton, which poses a significant challenge in synthesis. Their potency as antimalarial agents and their complex structure have thus made them popular synthetic targets in recent years.4

Over the past 15 years, more than 20 total syntheses of aculeatins have been developed using various strategies such as asymmetric allylation,4c–f, q–r kinetic resolution,4l and chiral pool approaches.4g–j, p In 2015, we described a versatile approach to the syntheses of aculeatins A/B/D/6-epi-D via an asymmetric Mukaiyama aldol reaction,4t ending with the protocol developed by Prof. Wong which characterized a [bis(trifluoroacetoxy)iodo] benzene (PIFA)-mediated oxidative spirocyclization (Scheme 1). However, what we obtained are the mixture of aculeatins A and B or D and 6-epi-D because of the absence of significant diaselectivity of the spirocyclization. Recently, Tong’s group...
developed a novel double intramolecular oxa-Michael addition (DIOMA) of secondary/tertiary alcohols and subsequent selective reduction to synthesize aculeatin A, as illustrated in Scheme 1. However, details of the sequence of DIOMA are not given in their paper, although he hypothesized in his newest review paper that 6-endo-dig double oxa-Michael addition might occur and precede a second 5-exo-trig cyclization. This synthesis implies that we can obtain the single spiroisomer of aculeatin if we construct the spiro structure stepwise. Herein, we report a novel and straightforward approach to the total synthesis of aculeatin A via a stepwise strategy.

Our retrosynthetic analysis is depicted in Scheme 2. Inspired by Tong’s work, we envisioned that aculeatin A could be prepared by chemo- and diaselective reduction of the precursor 1. For intermediate 1, we assumed that we could carry out PIFA oxidation of the phenol and acid catalyzed intramolecular oxa-Michael addition to provide it. Therefore, we disconnected 1 from 2. We envisioned that the hydroxyl in 2 would attack from the less hindered direction of the 2,3-dihydro-4H-pyran-4-one ring, resulting in the desired spiro structure during cyclization. Compound 2 could be prepared from 3 under standard conditions for PIFA oxidation. The desired 2,3-dihydro-4H-pyran-4-one 3 was hypothesized to be derived from the diketone 4.

We first prepared the intermediate 4 (Scheme 3). Its route commences with the commercially available 1-tetradecanal. We introduced the chiral center via a Crimmins modification of the Evans aldol reaction; in the presence of TiCl4, DIPEA, and NMP, the aldol reaction between 6 and 5 thus affords the aldol adduct 7 at 65% overall yield with a diastereoselectivity of 93:7. In a preliminary study, we attempted an addition between an enolate anion with a Weinreb amide to obtain 4.
Similarly, removal of the auxiliary in compound 13 by hydrolysis with LiOH and H2O2 afforded acid 14. To avoid deprotection of the TBS group, mild condition was used to prepare the acyl chloride of acid 14. Treatment using the catalyst DMF at 0 °C in the presence of oxalyl chloride resulted in smooth conversion of 14 to its acyl chloride,11 which was immediately subjected to Claisen condensation with the enolate anion derived from 10.12 This step generated the desired diketone intermediate 4 at 71% yield.

With diketone 4 in hand, we proceeded to construct the 2,3-dihydro-4H-pyrano-4-one unit (Table 1) under typical conditions13 including acid and TBAF. In the presence of TFA in DCM, the desired product was not obtained even after an extended period. One equivalent of TsOH·H2O in the solvent DCM could promote the cyclization, leading to a yield of 53%. Increasing the amount of TsOH·H2O to 5 equiv. resulted in a higher yield (80%) and shorter reaction time (10 h). Because of the poor solubility of excess TsOH·H2O in DCM, we replaced the solution with acetone. A similar yield of 3 was thus obtained in much shorter time (5 h). Using TBAF as the deprotection reagent, we obtained 3 at relatively low yield (62%). We also conducted the reaction using the Lewis acid of BF3·OEt2,14 however, it gave a very low yield (30%) after 20 h.

Preparation of the precursor 3 enabled us to study the construction of the spiro unit of aculeatin A. Here, PIFA is an effective oxidizing agent; it is a common reagent for the oxidation of phenol to a cyclohexadienone ring with a tertiary hydroxyl. This hydroxyl can undergo intramolecular oxo-Michael addition to the 2,3-dihydro-4H-pyrano-4-one unit, as described by Tong. We thus attempted the oxidation of 3 using PIFA, following the protocol of Tong.16 We first treated 3 with PIFA in a solvent mixture (acetone/H2O at 9 : 1 ratio) and then removed the solvent without further purification. The product was immediately subjected to CSA because of the possible instability of intermediate 2. Fortunately, we successfully obtained a single isomer of the desired polyspirocyclic compound 1 in 58% yield from compound 3. The latter was easily and...
diaselectively reduced to aculeatin A as a single isomer through a lithium tri-sec-butylborohydride (L-selectride)/MnO₂ strategy at 42% overall yield (Scheme 6).

In our approach, preparation of aculeatin A depended critically on the highly diastereoselective intramolecular oxa-Michael addition of 2. We assumed that the spirocyclization proceeded via the transition state T-2 (Fig. 2), in which the hydrogen occupied an axial position. Under the condition of acid, hydroxyl at C-8 attacked the enone from the less-hindered side, that is, the side of hydrogen at C-2. This step produced diastereoselectively the desired stereocenter of aculeatin A without aculeatin B. The physical properties, as well as ¹H and ¹³C NMR spectra of the product are consistent with those reported in the literature.⁴

Conclusions

In summary, we have developed a novel and straightforward approach to the total synthesis of aculeatin A via a stepwise strategy, using commercially available 1-tetradecanal. This approach is the second example of a process that leads to aculeatin A as a single spiroisomer and is also the second example that does not end in PIFA-mediated cascade reaction involving oxidative cyclization (oxidation/spiroketalization). The total synthesis features 1,3-diketone preparation from Claisen condensation of ketone and acyl chloride, deprotection–cyclo-dehydration in a one-pot reaction, and intramolecular oxa-Michael addition of 2,3-dihydro-4H-pyran-4-one. The highly diastereoselective spirocyclization can occur during the intramolecular 5-exo-dig oxa-Michael addition in which the hydroxyl attacks from the less-hindered side. This stepwise strategy was demonstrated to be an effective protocol for constructing the spiro structure of aculeatin A, which can be useful in the syntheses of analogues of aculeatins and other natural products having a similar structure.

Experimental

General

All reactions were carried out under N₂ atmosphere with dry solvents unless otherwise noted and monitored by thin-layer chromatography (TLC) carried out on 0.25 mm silica gel plates (60F-254). Silica gel (200–300 mesh) supplied by Qingdao Marine chemical factory in China was used for flash column chromatography. Anhydrous THF was distilled from sodium-benzophenone. DCM (CH₂Cl₂) and DMF were distilled from CaH₂. Other solvents or reagents weren’t purified. Yield refers to chromatographically and spectroscopically (¹H, ¹³C NMR), unless otherwise stated. NMR spectra were recorded on either a 400 MHz spectrometer (¹H: 400 MHz, ¹³C: 100 MHz) or 500 MHz (¹H: 500 MHz, ¹³C: 125 MHz). High-resolution mass spectra were obtained from a MALDI-TOF Mass Spectrometer. IR spectra were recorded on a Shimadzu FT-IR spectrophotometer. Optical rotations were measured on a digital polarimeter in CHCl₃ at 25 °C.

(R)-1-((S)-4-Benzyl-2-thioxothiazolidin-3-yl)-3-((tert-butyl-dimethylsilyl)oxy)hexadecan-1-one (13). 2,6-Lutidine (1.34 mL, 11.43 mmol, 2.0 equiv.) was added to the cooled (0 °C) solution of compound 7 (2.65 g, 5.70 mmol, 1.0 equiv.) dissolved in dry DCM (57 mL) under the protection of N₂. After 10 min, TBSCOTf (1.60 mL, 6.86 mmol, 1.2 equiv.) was added to the above solution dropwise and then kept the reaction stirred at 0 °C. When the TLC monitor indicated compound 7 was consumed, the reaction was quenched with sat. NaHCO₃. Then the resultant mixture was extracted with DCM (100 mL × 3). The combined organic layer was washed with sat. NaCl solution, dried over sodium sulfate, filtered through a funnel and concentrated under reduced pressure. The residue was purified with flash chromatography (hexane/EtOAc = 20 : 1) to give compound 13 (3.13 g, 95%). [α]D²⁵ = 174.6 (c 2.3, CHCl₃). ¹H NMR (500 MHz, CDCl₃): δ 7.38–7.35 (m, 2H), 7.31–7.27 (m, 3H), 5.30–5.26 (m, 1H), 4.38–4.33 (m, 1H), 3.58 (dd, J = 16.7, 8.2 Hz, 1H), 3.35 (dd, J = 11.5, 7.3 Hz, 1H), 3.27 (dd, J = 13.2, 3.8 Hz, 1H), 3.17 (dd, J = 16.7, 3.8 Hz, 1H), 3.06 (dd, J = 13.1, 10.7 Hz, 1H), 2.89 (d, J = 11.6 Hz, 1H), 1.56–1.52 (m, 2H), 1.30–1.21 (m, 22H), 0.90 (t, J = 6.9 Hz, 3H), 0.88 (s, 9H), 0.11 (s, 3H), 0.07 (s, 3H); ¹³C NMR (125 MHz, CDCl₃): 201.0, 172.5, 136.6, 129.4, 128.9, 127.2, 69.3, 68.7, 45.8, 37.8, 36.5, 32.1, 31.9, 29.7–29.6 (br, 6C), 29.3, 25.8, 24.9, 22.7, 18.0, 14.1, −4.4, −4.7; IR (film): 2925, 2853, 1699, 1464, 1362, 1341, 1257, 1165, 1042, 836, 775, 701 cm⁻¹; HRMS [ESI]: m/z calcd for C₁₂H₁₆NO₅S₂Si⁺ [M + H]+: 578.3516, found 578.3519.
(R)-3-((tert-Butyldimethylsilyloxy)hexadecanoic acid (14). LiOH·H₂O (0.96 g, 22.76 mmol, 2.2 equiv.) and 30% H₂O₂ (6.40 mL, 62.08 mmol, 6.0 equiv.) was added to the solution of compound 13 (5.98 g, 10.35 mmol, 1.0 equiv.) in THF/H₂O (35 mL, 4 : 1) at 0°C. The mixture was then stirred at 0°C for 1 h. When the TLC monitor indicated compound 13 was consumed, the reaction was quenched with NH₄Cl and the pH was adjusted to 0 using 1 N HCl. The organic layer was separated and the aqueous layer was extracted with EtOAc (100 mL × 3). The combined organic layer was then washed with sat. NaCl solution, dried over sodium sulfate, filtered, and concentrated in reduced pressure. The residue was purified by flash chromatography (hexane/EtOAc = 15 : 1) to afford the desired acid 14 as a white solid (3.84 g, 96%).

2.2.1.11. NMR (500 MHz, CDCl₃): δ 4.14–4.11 (m, 1H), 2.48 (d, J = 5.5 Hz, 2H), 1.59–1.50 (m, 2H), 1.30–1.21 (m, 2H), 0.90 (t, J = 6.3 Hz, 3H), 0.88 (s, 9H), 0.08 (s, 3H), 0.07 (s, 3H); 13C NMR (125 MHz, CDCl₃): 177.4, 69.4, 42.3, 37.5, 31.9, 29.7, 25.8, 25.0, 22.7, 18.0, 14.1, 1.0, –4.5, –4.8; IR (film): 3292, 2958, 2856, 1612, 1511, 1472, 1258, 1023, 917, 837, 773 cm⁻¹; HRMS (ESI): m/z calcd for C₃₆H₇₉NO₃Si⁺ [M + H]⁺: 547.4885, found 547.4894.

(R)-6-(4-Hydroxyphenethyl)-2-tridecyl-2H-pyran-4(3H)-one (3). p-TsOH (53 mg, 0.31 mmol, 5.0 equiv.) was added to the stirred solution of compound 4 (40 mg, 0.062 mmol, 1.0 equiv.) in acetone (0.5 mL) in one portion. The reaction was kept stirred at room temperature for 5 h. Subsequently, sat. NaHCO₃ was added to quench the reaction. The resultant mixture was extracted with DCM (10 mL × 3) and the combined organic layer was washed with sat. NaCl, dried over anhydrous sodium sulfate, filtered through a funnel, and concentrated under reduced pressure. Purification of the residue by flash chromatography (hexane/EtOAc = 4 : 1) afforded the desired compound 3 in yield of 80% (20 mg). [α]D²⁵ = 64.0 (c 0.53, CHCl₃). 1H NMR (500 MHz, CDCl₃): δ 7.01 (d, J = 8.0 Hz, 2H), 6.77 (d, J = 8.0 Hz, 2H), 5.31 (s, 1H), 4.32–4.30 (m, 1H), 2.80 (t, J = 7.5 Hz, 2H), 2.57–2.48 (m, 2H), 2.46–2.35 (m, 2H), 1.81–1.76 (m, 1H), 1.67–1.61 (m, 1H), 1.49–1.42 (m, 1H), 1.40–1.23 (m, 21H), 0.88 (t, J = 6.7 Hz, 3H); 13C NMR (125 MHz, CDCl₃): 193.9, 177.4, 154.6, 153.7, 129.3, 115.4, 104.3, 79.3, 40.8, 36.8, 34.4, 31.9, 31.7, 29.6–29.3 (br, 8C), 24.9, 22.6, 14.1; IR (film): 3270, 2925, 2854, 1654, 1595, 1517, 1466, 1400, 1340, 1221, 1023, 826, 773 cm⁻¹; HRMS (ESI): m/z calcd for C₂₆H₄₃O₃Si⁺ [M + H]⁺: 401.3050, found 401.3052.

**Ketone (1).** PIFA (0.45 g, 1.05 mmol, 1.0 equiv.) was added to the stirred solution of compound 3 (0.42 g, 1.05 mmol, 1.0 equiv.) dissolved in acetonitrile/water (36 mL, 9 : 1) at 0°C. The reaction was then kept stirred in the dark for 2 h. When the TLC monitor indicated compound 3 was consumed, anhydrous Na₂SO₄ and anhydrous NaHCO₃ were added to the reaction. The mixture was then filtered and concentrated under reduced pressure. Without further purification, the residue was dissolved in DCM (20 mL) and CSA (0.24 g, 1.05 mmol, 1.0 equiv.) was added to this solvent. The resultant mixture was then kept stirred overnight and quenched with sat. NaHCO₃. The organic layer was separated and the aqueous layer was extracted with DCM (20 mL × 3). Subsequently, the combined organic layer was washed with sat. NaCl, dried over sodium sulfate, filtered and concentrated in vacuum. The residue was purified by flash chromatography (hexane/EA = 3 : 1) to provide ketone 1 (0.25 g, 58% from compound 3).

[a]D²⁵ = –7.8 (c 1.0, CHCl₃). 1H NMR (400 MHz, CDCl₃): δ 6.77 (ddd, J = 20.8, 9.6, 2.8 Hz, 2H), 6.16–6.10 (m, 2H), 4.17–4.11 (m, 1H), 2.77 (d, J = 14.4 Hz, 1H), 2.56 (d, J = 14.4 Hz, 1H), 2.44–2.40 (m, 3H), 2.27–2.24 (m, 1H), 2.10–2.09 (m, 2H), 1.67–1.65 (m, 1H), 1.65–1.53 (m, 1H), 1.30–1.22 (m, 22H), 0.88 (t, J = 6.4 Hz, 3H); 13C NMR (125 MHz, CDCl₃): 204.3, 185.1, 150.2, 148.4, 127.6, 127.7, 109.6, 79.7, 69.7, 49.8, 46.7, 38.7, 36.1, 34.9, 31.9, 29.6–29.3 (br, 8C), 25.4, 22.6, 14.1; IR (film): 3400, 2924, 2854, 1727, 1674, 1467, 1021, 883, 857, 773 cm⁻¹; HRMS (ESI): m/z calcd for C₃₀H₅₀O₃⁺ [M + H]⁺: 417.3006, found 417.3000.

(−)-Aculeatin A. L-Selectride (0.3 mL, 0.3 mmol, 2.5 equiv.) was added dropwise to a solution of ketone 1 (50 mg, 0.12 mmol, 1.0 equiv.) in THF (2.5 mL) at −78°C. The reaction was kept stirred at the same temperature for 1 h and then quenched by addition of sat. NaHCO₃ (2.5 mL), EtOAc (5 mL), H₂O (1.25 mL). The organic was collected and the aqueous layer...
was extracted with EtOAc (5 mL × 3). Subsequently, the combined organic layer was washed with sat. NaCl, dried over sodium sulfate, filtered and concentrated in vacuum. Without further purification, the residue was immediately subject to the next step. Activated MnO₂ (0.21 g, 2.4 mmol, 20 equiv.) was added to the above crude reduction product in dry DCM (2.5 mL). Five hours later, the suspension was filtered through a short pad of Celite. The solvent was removed under reduced pressure and the residue was purified by flash chromatography (hexane/EtOAc = 4 : 1) to provide aculetin A (21 mg, 42% from compound 1). [α]₁₃₁⁰D = −13.5 (c 0.2, CHCl₃). ¹H NMR (300 MHz, CDCl₃): δ 6.85 (dd, J = 10.0, 2.8 Hz, 1H), 6.75 (dd, J = 10.0, 2.8 Hz, 1H), 6.16–6.09 (m, 2H), 4.13–4.07 (m, 2H), 2.39–2.36 (m, 1H), 2.26–2.20 (m, 1H), 2.05–2.00 (m, 3H), 1.92 (br d, J = 14.0 Hz, 1H), 1.79 (br d, J = 12.0, 1H), 1.52–1.40 (m, 5H), 1.38–1.20 (m, 20H), 0.88 (t, J = 6.8 Hz, 3H); ¹³C NMR (75 MHz, CDCl₃): 185.3, 150.9, 148.7, 127.3, 127.0, 109.0, 79.7, 79.1, 65.3, 64.8, 39.1, 39.0, 37.9, 35.8, 34.1, 31.9, 29.6–29.3 (br, 8C), 25.6, 22.6, 14.1; IR (film): 3552, 2925, 2854, 1674, 1632, 1465, 1392, 1220, 1099, 1046, 1000, 853, 772 cm⁻¹; HRMS (ESI): m/z calc. for C₂₀H₄₁O₄⁺ [M + H⁺]: 419.3156, found 419.3156.
