Abstract

In the framework of the first Born approximation, we present a semirelativistic theoretical study of the inelastic excitation ($1s_{1/2} \rightarrow 2s_{1/2}$) of hydrogen atom by electronic impact. The incident and scattered electrons are described by a free Dirac spinor and the hydrogen atom target is described by the Darwin wave function. Relativistic and spin effects are examined in the relativistic regime. A detailed study has been devoted to the nonrelativistic regime as well as the moderate relativistic regime. Some aspects of this dependence as well as the dynamic behavior of the DCS in the relativistic regime have been addressed.

1 Introduction

The theoretical study of relativistic electron-atom collisions is fundamental to our understanding of many aspects in plasma physics and astrophysics. The development of electron-atom collision studies has also been strongly motivated by the need of data for testing and developing suitable theories of the scattering and collision process, and providing a tool for obtaining detailed information on the structure of the target atoms and molecules. Many authors have studied this process using numerical tools. Thus, Kisielius et al. [1] employed, the R-matrix method with nonrelativistic and relativistic approximations for the hydrogen like $He^+$, $Fe^{25+}$ and $U^{91+}$ ions, where the case of transitions $1s \rightarrow 2s$ and $1s \rightarrow 2p$ as well as those between fine structure $n = 2$ levels was considered. Andersen et al. [2] have applied the semirelativistic Breit Pauli R-matrix to calculate the electron-impact excitation of the $^2S_{1/2} \rightarrow ^2P_{1/2,3/2}^o$ resonance transitions in heavy alkali atoms. Payne et al. [3] have studied the electron-impact excitation of the $5s \rightarrow 5p$ resonance transition in rubidium by using a semi-relativistic Breit
Pauli R-matrix with pseudo-states (close-coupling) approach. Attaourti et al. [4] have investigated the exact analytical relativistic excitation $1S_{1/2} \rightarrow 1S_{1/2}$ of atomic hydrogen, by electron impact in the presence of a laser field. They have found that a simple formal analogy links the analytical expressions of the unpolarized differential cross section without laser and the unpolarized differential cross section in the presence of a laser field.

The aim of this contribution is to add some new physical insights and to show that the non-relativistic formalism becomes enable to describe particles with high kinetic energies. Before we present the results of our investigation, we first begin by sketching the main steps of our treatment. For pedagogical purposes, we begin by the most basic results of our work using atomic units (a.u) in which one has $(\hbar = m_e = e = 1)$, where $m_e$ is the electron mass at rest, and which will be used throughout this work. We will also work with the metric tensor $g^{\mu\nu} = \text{diag}(1, -1, -1, -1)$ and the Lorentz scalar product which is defined by $(a.b) = a^\mu b_\mu$.

The layout of this paper is as follows. We present the necessary formalism of this work in section [2,3 and 4], the result and discussion in section 5 and we end by a brief conclusion in section 6.

2 Theory of the inelastic collision $1S_{1/2} \rightarrow 2S_{1/2}$

In this section, we calculate the exact analytical expression of the semirelativistic unpolarized DCS for the relativistic excitation of atomic hydrogen by electron impact. The transition matrix element for the direct channel (exchange effects are neglected) is given by

$$S_{fi} = -i \int dt \langle \psi_{pf}(x_1)\phi_f(x_2) | V_d | \psi_{pi}(x_1)\phi_i(x_2) \rangle$$

$$= -i \int_{-\infty}^{+\infty} dt \int d\mathbf{r}_1 \overline{\psi}_{pf}(t, \mathbf{r}_1)\gamma^0\psi_{pi}(t, \mathbf{r}_1)\langle \phi_f(x_2) | V_d | \phi_i(x_2) \rangle$$

where

$$V_d = \frac{1}{r_{12}} - \frac{Z}{r_1}$$

is the direct interaction potential, $\mathbf{r}_1$ are the coordinates of the incident and scattered electron, $\mathbf{r}_2$ the atomic electron coordinates, $r_{12} = | \mathbf{r}_1 - \mathbf{r}_2 |$ and $r_1 = | \mathbf{r}_1 |$. The function $\psi_{pi}(x_1) = \psi_p(t, \mathbf{r}_1) = u(p, s) \exp(-ip.x)/\sqrt{2EV}$ is the electron wave function, described by a free Dirac spinor normalized to the volume $V$, and $\phi_{i,f}(x_2) = \phi_{i,f}(t, \mathbf{r}_2)$ are the semirelativistic wave functions of the hydrogen atom where the index $i$ and $f$ stand for the initial and final states respectively. The semirelativistic wave function of the atomic hydrogen is the Darwin wave
function for bound states [5], which is given by:

\[ \phi_i(t, r_2) = \exp(-iE_b(1s_{1/2})t)\varphi_{1s}^{(\pm)}(r_2) \]  

(3)

where \( E_b(1s_{1/2}) \) is the binding energy of the ground state of atomic hydrogen and \( \varphi_{1s}^{(\pm)}(r_2) \) is given by:

\[ \varphi_{1s}^{(\pm)}(r_2) = (1 - \frac{i}{2c}\alpha \nabla_2)u^{(\pm)}\varphi_0(r_2) \]  

(4)

it represents a quasi relativistic bound state wave function, accurate to first order in \( Z/c \) in the relativistic corrections (and normalized to the same order), with \( \varphi_0 \) being the non-relativistic bound state hydrogenic function. The spinors \( u^{(\pm)} \) are such that \( u^{(+)} = (1, 0, 0, 0)^T \) and \( u^{(-)} = (0, 1, 0, 0)^T \) and represent the basic four-component spinors for a particle at rest with spin-up and spin-down, respectively. The matrix differential operator \( \alpha . \Delta \) is given by:

\[ \alpha . \Delta = \begin{pmatrix} 0 & 0 & \partial_z & \partial_x - i\partial_y \\ 0 & 0 & \partial_x + i\partial_y & -\partial_z \\ \partial_z & \partial_x - i\partial_y & 0 & 0 \\ \partial_x + i\partial_y & -\partial_z & 0 & 0 \end{pmatrix} \]  

(5)

For the spin up, we have:

\[ \varphi_{1s}^{(+)}(r_2) = N_{D_1} \begin{pmatrix} 1 \\ 0 \\ \frac{i}{2\sqrt{\pi}}(x + iy) \\ \frac{i}{2\sqrt{\pi}}z \end{pmatrix} \frac{1}{\sqrt{\pi}}e^{-r_2} \]  

(6)

and for the spin down, we have:

\[ \varphi_{1s}^{(-)}(r_2) = N_{D_1} \begin{pmatrix} 0 \\ 1 \\ \frac{i}{2\sqrt{\pi}}(x - iy) \\ -\frac{i}{2\sqrt{\pi}}z \end{pmatrix} \frac{1}{\sqrt{\pi}}e^{-r_2} \]  

(7)

where

\[ N_{D_1} = 2c/\sqrt{4c^2 + 1} \]  

(8)

is a normalization constant lower but very close to 1. Let us mention that the function \( \phi_f(t, r_2) \) in Eq. (1) is the Darwin wave function for bound states [6], which is also accurate to the order \( Z/c \) in the relativistic corrections. This is expressed as \( \phi_f(t, r_2) = \exp(-iE_b(2s_{1/2})t)\varphi_{2s}^{(\pm)}(r_2) \) with \( E_b(2s_{1/2}) \) as the binding energy of the 2s_{1/2} state of atomic hydrogen.

\[ \varphi_{2s}^{(\pm)}(r_2) = N_{D_2} \begin{pmatrix} \frac{2 - r_2}{4r_2c} \\ i(4 - r_2)^{-1}z \frac{2 - r_2}{4r_2c} \frac{4 - r_2}{4r_2c}(-y + ix) \end{pmatrix} \frac{1}{4\sqrt{2\pi}}e^{-r_2} \]  

(9)
for the spin up and
\[
\varphi_{2s}^{(-)}(r_2) = N_{D_2} \left( \frac{0}{4\pi r_2^2 (y + ix)} \right) \frac{1}{4\sqrt{\pi}} e^{-r_2^2}
\]
(10)
for the spin down. The transition matrix element in Eq. (1) becomes:
\[
S_{fi} = -i \int_{-\infty}^{+\infty} dt \int d\mathbf{r}_1 d\mathbf{r}_2 \psi_{p_f}(t, \mathbf{r}_1) \gamma^0 \psi_{p_i}(t, \mathbf{r}_1) \phi_f^\dagger(t, r_2) \phi_i(t, r_2) V_d
\]
(11)
and it is straightforward to get, for the transition amplitude,
\[
S_{fi} = -i \frac{\overline{\mathbf{p}}(p_f, s_f) \gamma^0 u(p_i, s_i)}{2\sqrt{E_f E_i}} 2\pi H_{inel}(\Delta) \delta(E_f + \mathcal{E}(2s_{1/2}) - E_i - \mathcal{E}(1s_{1/2}))
\]
(12)
where \(\Delta = |p_i - p_f|\) and \(\gamma^0\) is the Dirac matrix. Using the standard technique of the QED, we find for the unpolarized DCS
\[
\frac{d\sigma}{d\Omega_f} = \frac{|\mathbf{p}_f|}{|\mathbf{p}_i|} \frac{1}{(4\pi e^2)^2} \left( \frac{1}{2} \sum_{s_i s_f} |\overline{\mathbf{p}}(p_f, s_f) \gamma^0 u(p_i, s_i)|^2 \right) |H_{inel}(\Delta)|^2
\]
(13)

### 3 Calculation of the integral part

The function \(H_{inel}(\Delta)\) is found if one performs the various integrals:
\[
H_{inel}(\Delta) = \int_{0}^{+\infty} d\mathbf{r}_1 e^{i\Delta \mathbf{r}_1} I(\mathbf{r}_1)
\]
(14)

#### 3.1 Integral over \(r_2\)

The quantity \(I(\mathbf{r}_1)\) is easily evaluated in the following way. We first write the explicit form of \(I(\mathbf{r}_1)\):
\[
I(\mathbf{r}_1) = \int_{0}^{+\infty} d\mathbf{r}_2 \phi_{2s}^\dagger(\mathbf{r}_2) \left[ \frac{1}{r_{12}} - \frac{Z}{r_1} \right] \phi_{1s}(\mathbf{r}_2)
\]
(15)
Next, we develop the quantity \(r_{12}^{-1}\) in spherical harmonics as
\[
\frac{1}{r_{12}} = 4\pi \sum_{lm} Y_{lm}(\hat{r}_1) Y_{lm}^*(\hat{r}_2) \frac{(r_<)^l}{2l + 1} \frac{(r_>)^{l+1}}{(r_<)^{l+1}}
\]
(16)
where $r_>$ is the greater of $r_1$ and $r_2$, and $r_<$ the lesser of them. The angular coordinates of the vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ are such that: $\hat{r}_1 = (\theta_1, \varphi_1)$ and $\hat{r}_2 = (\theta_2, \varphi_2)$. We use the well known integral \[7\]

\[
\int_x^{+\infty} du \ u^m e^{-\alpha u} = \frac{m!}{\alpha^{m+1}} e^{-\alpha x} \sum_{\mu=0}^{m} \frac{\alpha^\mu x^\mu}{\mu!} \quad \text{Re}(\alpha) > 0
\]  

then, after some analytic calculations, we get for $I(\mathbf{r}_1)$:

\[
I(\mathbf{r}_1) = \frac{6}{27} \left( \frac{1}{c^2} - 4 \right) + \frac{4}{27c^2} \mathbf{r}_1 - \frac{4}{9} \left( 1 + \frac{1}{8c^2} \right) \mathbf{r}_1
\]  

\[18\]

### 3.2 Integral over $\mathbf{r}_1$

The integration over $\mathbf{r}_1$ gives rise to the following formula:

\[
H_{inel}(\Delta) = \int_0^{+\infty} d\mathbf{r}_1 e^{i\Delta \mathbf{r}_1} I(\mathbf{r}_1) = -\frac{4\pi}{\sqrt{2}} (I_1 + I_2 + I_3)
\]  

\[19\]

the angular integrals are performed by expanding the plane wave $e^{i\Delta \mathbf{r}_1}$ in spherical harmonics as:

\[
e^{i\Delta \mathbf{r}_1} = \sum_{lm} 4\pi i^l j_l(\Delta \mathbf{r}_1) Y_{lm}(\hat{\Delta}) Y^{*}_{lm}(\hat{\mathbf{r}}_1)
\]  

\[20\]

with $\Delta = \mathbf{p}_i - \mathbf{p}_f$ is the relativistic momentum transfer and $\hat{\Delta}$ is the angular coordinates of the vector $\Delta$. Then, after some analytic computations, we get for $I_1$, $I_2$ and $I_3$ the following result:

\[
I_1 = \frac{4}{27c^2} \int_0^{+\infty} d\mathbf{r}_1 r_1 e^{-\frac{3}{2} r_1} j_0(\Delta r_1) = \frac{1}{27c^2} \frac{1}{((3/2)^2 + \Delta^2)}
\]

\[
I_2 = \frac{6}{27} \left( \frac{1}{c^2} - 4 \right) \int_0^{+\infty} d\mathbf{r}_1 r_1^2 e^{-\frac{3}{2} r_1} j_0(\Delta r_1) = \frac{2}{27} \left( \frac{1}{c^2} - 4 \right) \frac{3}{((3/2)^2 + \Delta^2)^2}
\]  

\[
I_3 = \frac{-4}{9} \left( 1 + \frac{1}{8c^2} \right) \int_0^{+\infty} d\mathbf{r}_1 r_1^3 e^{-\frac{3}{2} r_1} j_0(\Delta r_1) = \frac{8}{9} \left( 1 + \frac{1}{8c^2} \right) \frac{\Delta^2 - 27/4}{((3/2)^2 + \Delta^2)^3}
\]  

\[21\]

It is clear that the situation is different than in elastic collision \[4\], since we have no singularity in the case $(\Delta \to 0)$

### 4 Calculation of the spinorial part

The calculation is now reduced to the computation of traces of $\gamma$ matrices. This is routinely done using Reduce \*[8]. We consider the unpolarized DCS. Therefore, the various polarization
states have the same probability and the actual calculated spinorial part is given by summing over the final polarization $s_f$ and averaging over the initial polarization $s_i$. Therefore, the spinorial part is given by:

$$\frac{1}{2} \sum_{s_i,s_f} |\Pi(p_f, s_f)\gamma^0 u(p_i, s_i)|^2 = Tr \left\{ \gamma^0 (i \gamma^\mu c + c^2) \gamma^0 (i \gamma_\mu c + c^2) \right\}$$

$$= 2c^2\left[ \frac{2E_fE_i}{c^2} - (p_i p_f) + c^2 \right]$$

(22)

We must, of course, recover the result in the nonrelativistic limit ($\gamma \to 1$), situation of which the differential cross section can simply given by:

$$\frac{d\sigma}{d\Omega} = \frac{|K_f|}{|K_i|} \frac{128}{(|\Delta_{nr}|^2 + \frac{9}{4})^6}$$

(23)

with $|\Delta_{nr}| = |K_i - K_f|$ is the nonrelativistic momentum transfer and the momentum vectors $(K_i, K_f)$ are related by the following formula:

$$K_f = (|K_i|^2 - 3/4)^{1/2}$$

(24)

Figure 1: Behavior of the probability density for radial Darwin wave function compared with that of the Dirac wave function for small distances and for increasing values of the atomic charge number.
5 Results and discussions

In presenting our results it is convenient to consider separately those corresponding to non-relativistic regime (the relativistic parameter $\gamma \simeq 1$) and those related to relativistic one (the relativistic parameter $\gamma \simeq 2$). Before beginning the discussion of the obtained results, it is worthwhile to recall the meaning of some abbreviation that will appear throughout this section. The NRDCS stands for the nonrelativistic differential cross section, where nonrelativistic plane wave are used to describe the incident and scattered electrons. The SRDCS stands for the semirelativistic differential cross section.

We begin our numerical work, by the study of the dependence of the probability density for radial Darwin and Dirac wave functions, on the atomic charge number $Z$. As long as the condition $Z\alpha \ll 1$ is verified, the use of Darwin wave function do not have any influence at all on the results at least in the first order of perturbation theory. So, the semi-relativistic treatment when $Z$ increases may generate large errors but not in the case of this work. In this paper, we can not have numerical instabilities since there are none. For the sake of illustration,

![Figure 2](image1.png)  
**Figure 2:** The long-dashed line represents the semi-relativistic DCS, the solid line represents the corresponding non-relativistic DCS for a relativistic parameter ($\gamma = 1.5$) as functions of the scattering angle $\theta$.

![Figure 3](image2.png)  
**Figure 3:** The solid line represents the semi-relativistic DCS, the long-dashed line represents the corresponding non-relativistic DCS for various values of the relativistic parameter ($\gamma = 1.5$, $\gamma = 2$ and $\gamma = 2.5$) as functions of the scattering angle $\theta$. 

we give below the behavior of the probability density for radial Darwin wave functions as well as that of the exact relativistic Dirac wave functions for different values of $Z$. As you may see, even if it is not noticeable on the figure 1, there are growing discrepancies for $Z = 10$ and these become more pronounced when $Z = 20$. The QED formulation shows that there are relativistic and spin effects at the relativistic domain and the non relativistic formulation is no longer valid.

In the relativistic regime, the semirelativistic differential cross section results obtained for the $1s \rightarrow 2s$ transition in atomic hydrogen by electron impact, are displayed in figures 2 and 3. In this regime, there are no theoretical models and experimental data for comparison as in nonrelativistic regime. In such a situation, it appears from figures 2 and 3 that in the limit of high electron kinetic energy, the effects of the additional spin terms and the relativity begin to be noticeable and that the non-relativistic formalism is no longer applicable. Also a pick in the vicinity of $\theta_f = 0^\circ$ is clearly observed.

The investigation in the nonrelativistic regime were conducted with $\gamma$ as a relativistic parameter and $\theta$ as a scattering angle. In atomic units, the kinetic energy is related to

![Figure 4](image1)

**Figure 4:** The solid line represents the semi-relativistic DCS, the long-dashed line represents the corresponding non-relativistic DCS for a relativistic parameter $\gamma = 1.00053$ as functions of the scattering angle $\theta$.

![Figure 5](image2)

**Figure 5:** The variation of the SRDCSs with respect to $\theta$, for various kinetic energies.
Figure 6: The variation of the differential $1s - 2s$ cross section of $e^- - H$ scattering at 200 eV. The dots are the observed values of J. F. Williams (1981); the solid line represents the semi-relativistic approximation and the long-dashed line corresponds to the non-relativistic DCS.

$\gamma$ by the following relation: $E_k = c^2(\gamma - 1)$. Figure 4 shows the dependence of DCS, obtained in two models (SRDCS, NRDCS), on scattering angle $\theta$. In this regime, it appears clearly that there is no difference between these models. Figure 5 shows the variation of the SRDCS with $\theta$ for various energies. It also shows approximatively in the interval [-5, 5], the SRDCS increases with $\gamma$, but decreases elsewhere. Figure 6 presents the observed and calculated angular dependence of $1s - 2s$ differential cross section of $e^- - H$ scattering at incident energy 200 eV. Results obtained in two approaches semirelativistic and non-relativistic approximations are indistinguishable and in good agreement with the experimental data provided by J. F. Williams [9].

6 Conclusion

In this paper we have presented the results of a semirelativistic excitation of atomic hydrogen by electronic impact. We have used the simple semirelativistic Darwin wave function that allows to obtain analytical results in an exact and closed form within the framework of the first Born approximation. This model gives good results if the condition $Z/c \ll 1$ is fulfilled. We have compared our results with previous nonrelativistic results and have found that the agree-
ment between the different theoretical approaches is good in the nonrelativistic regime. We have also showed that the non-relativistic treatment is no longer reliable for energies higher. We hope that we will be able to compare our theoretical results with forthcoming experimental data in the relativistic regime.
