Abstract: As we re-examine the known holographic $\mathcal{N} = 1$ supersymmetric renormalization group flow in four dimensions, we describe the mass-deformed Bagger-Lambert theory or equivalently the mass-deformed $\mathrm{U}(2) \times \mathrm{U}(2)$ Chern-Simons gauge theory with level $k = 1$ or 2, that has $G_2$ symmetry, by adding a mass term for one of the eight adjoint superfields. We obtain a detailed correspondence between the fields of $\mathrm{AdS}_4$ supergravity and composite operators of the infrared field theory in three dimensions. The geometric superpotential from an eleven dimensional viewpoint is obtained for M2-brane probe analysis.

Keywords: AdS-CFT Correspondence, M-Theory
1. Introduction

When one reduces 11-dimensional supergravity theory to four-dimensional $\mathcal{N} = 8$ gauged supergravity, the four-dimensional spacetime is warped by warp factor that depends on both four-dimensional coordinates and 7-dimensional internal coordinates. This warp factor provides an understanding of the different relative scales of the 11-dimensional solutions corresponding to the critical points in $\mathcal{N} = 8$ gauged supergravity. An important aspect of the holographic duals [1] is the notion that the radial coordinate of $AdS_4$ can be viewed as a measure of energy. A supergravity kink description interpolating between $r \to \infty$ and $r \to -\infty$ can be interpreted as an explicit construction of the renormalization group (RG) flow between the ultraviolet (UV) fixed point and the infrared (IR) fixed point of the three dimensional boundary field theory.

It is known [2] that there exist five nontrivial critical points for the scalar potential of gauged $\mathcal{N} = 8$ supergravity: $SO(7)^+, SO(7)^-, G_2, SU(4)^-$ and $SU(3) \times U(1)$. Among them $G_2$-invariant 7-ellipsoid and $SU(3) \times U(1)$-invariant stretched 7-ellipsoid are stable and supersymmetric. The holographic RG flow equations from $\mathcal{N} = 8$ SO(8)-invariant UV fixed point to $\mathcal{N} = 2$ $SU(3) \times U(1)$-invariant IR fixed point were constructed in [3]. Moreover, the holographic RG flow equations from $\mathcal{N} = 8$ SO(8)-invariant UV fixed point to $\mathcal{N} = 1$ $G_2$-invariant IR fixed point were obtained in [4, 5]. See also [6]. An exact solution to the 11-dimensional bosonic equations corresponding to the $M$-theory lift of the $\mathcal{N} = 2$ $SU(3) \times U(1)$-invariant RG flow was found in [7] and its Kahler structure was extensively...
studied in [8]. Furthermore, the $M$-theory lift of the $\mathcal{N} = 1$ $G_2$-invariant RG flow was done in [9].

Bagger and Lambert (BL) proposed a Lagrangian to describe the low energy dynamics of multiple M2-branes in [9]. See also related papers [10]. This BL theory is three dimensional $\mathcal{N} = 8$ supersymmetric theory with $SO(8)$ global symmetry based on new 3-algebra and this 3-algebra with Lorentzian signature was proposed by [11]. The generators of the 3-algebra consist of the generators of an arbitrary semisimple Lie algebra and two additional null generators.

Very recently, in [12], in order to have arbitrary number of M2-branes, three dimensional Chern-Simons matter theories with gauge group $U(N) \times U(N)$ and level $k$ which have $\mathcal{N} = 6$ superconformal symmetry are constructed. They describe this theory as the low energy limit of $N$ M2-branes at $\mathbb{C}^4/\mathbb{Z}_k$ singularity. In particular, when $N = 2$, this leads to the BL theory. Furthermore, the full $SU(4)_R$ symmetry of [12] is proved explicitly in [13]. By examining the holographic $\mathcal{N} = 2$ supersymmetric renormalization group flow solution among five nontrivial critical points above, in four dimensions, the mass-deformed BL theory that has $SU(3)_I \times U(1)_R$ symmetry is studied in [14] by the addition of mass term for one of the four adjoint chiral superfields. We list some relevant works on the M2-brane theory in [15]–[62].

Then it is natural to ask what happens for the holographic description with stable and $\mathcal{N} = 1$ supersymmetric $G_2$-invariant 7-ellipsoid compactification by deforming three dimensional Chern-Simons matter theories with gauge group $U(N) \times U(N)$ and level $k$? As a first step, we consider the $U(2) \times U(2)$ Chern-Simons gauge theory of [12] with level $k = 1$ or $k = 2$ which preserves $G_2$ global symmetry.

In this paper, starting from the first order differential equations, that are the supersymmetric flow solutions in four dimensional $\mathcal{N} = 8$ gauged supergravity interpolating between an exterior $AdS_4$ region with maximal $\mathcal{N} = 8$ supersymmetry and an interior $AdS_4$ with one eighth (i.e., $\mathcal{N} = 1$) of the maximal supersymmetry, we would like to interpret this as the RG flow in BL theory $^1$ which has $OSp(8|4)$ symmetry broken to the deformed BL theory which has $OSp(1|4)$ symmetry by the addition of a mass term for one of the eight adjoint superfields.

An exact correspondence is obtained between fields of bulk supergravity in the $AdS_4$ region in four dimensions and composite operators of the IR field theory in three dimensions. It is easy to check how the supersymmetry breaks for specific deformation and one can extract the correct full superpotential including the superpotential before the deformation also. The three dimensional analog of Leigh-Strassler RG flow in mass-deformed BL theory in three dimensions is expected by looking at its holographic dual theory in four dimensions along the line of [14].

In section 2, we review the supergravity solution in four dimensions in the context of RG flow, describe two supergravity critical points and present the supergravity multiplet in terms of $G_2$ invariant ones. The decomposition of $SO(8)$ into $G_2$ is presented.

$^1$When we describe BL theory in this paper, the two M2-branes theory ($N = 2$) is equivalent to $U(2) \times U(2)$ Chern-Simons gauge theory of [12] with level $k = 1$ or $k = 2$. 
In section 3, we deform BL theory by adding one of the mass term among eight superfields, along the lines of [63], write down the SO(7)$^+$-invariant superpotential in $\mathcal{N} = 1$ superfields which will be invariant under the $G_2$ after integrating out the massive superfield and describe the scale dimensions for the superfields at UV.

In section 4, the $OSp(1|4)$ representations (energy and spin) and $G_2$ representations in the supergravity mass spectrum for each multiplet at the $\mathcal{N} = 1$ critical point and the corresponding $\mathcal{N} = 1$ superfield in the boundary gauge theory are given. For this computation, the 11-dimensional “geometric” superpotential which reduces to the usual superpotential for the particular internal coordinate is needed to analyze the M2-brane analysis.

In section 5, we end up with the future directions.

2. The holographic $\mathcal{N} = 1$ supersymmetric RG flow in four dimensions

In $\mathcal{N} = 8$ supergravity [64], there exists an $\mathcal{N} = 1$ supersymmetric $G_2$-invariant vacuum [65]. To arrive at this critical point, one should turn on expectation values of both scalar and pseudo-scalar fields where the completely antisymmetric self-dual and anti-self-dual tensors are invariant under $G_2$ since the $G_2$ is the common subgroup of SO(7)$^+$ acting on the scalar and SO(7)$^-$ acting on the pseudo-scalar respectively. Then the 56-bein can be written as $56 \times 56$ matrix whose elements are some functions of these scalar and pseudo-scalars. Then the $G_2$-invariant scalar potential of $\mathcal{N} = 8$ supergravity in terms of the original variables of [66] is given by, through the superpotential found in [4, 5],

$$V(\lambda, \alpha) = g^2 \left[ \frac{16}{7} \left( \frac{\partial W}{\partial \lambda} \right)^2 + \frac{2}{7p^2q^2} \left( \frac{\partial W}{\partial \alpha} \right)^2 - 6W^2 \right], \quad (2.1)$$

where $g$ is a coupling of the theory, we introduce the hyperbolic functions of $\lambda$ as

$$p = \cosh \left( \frac{\lambda}{2\sqrt{2}} \right), \quad q = \sinh \left( \frac{\lambda}{2\sqrt{2}} \right) \quad (2.2)$$

and the superpotential, which can be read off from the element of $A_1$ tensor of the theory, is a magnitude of complex function on the variables $\lambda$ and $\alpha$

$$W(\lambda, \alpha) = |p^7 + e^{7i\alpha}q^7 + 7(p^3q^4e^{4i\alpha} + p^4q^3e^{3i\alpha})|. \quad (2.3)$$

There exist two critical points and let us summarize these in table 1.

**SO(8) critical point.** This is well-known, trivial critical point at which the $\lambda$ field vanishes with arbitrary $\alpha$ and whose cosmological constant $\Lambda = -6g^2$ from (2.1) and which preserves $\mathcal{N} = 8$ supersymmetry.

**$G_2$ critical point.** There is a critical point at $\lambda = \sqrt{2} \sinh^{-1} \sqrt{\frac{2}{5}(\sqrt{3} - 1)}$ and $\alpha = \cos^{-1} \frac{1}{2} \sqrt{3} - \sqrt{3}$ and the cosmological constant $\Lambda = -\frac{216\sqrt{2}}{25\sqrt{3}} \frac{3^{1/4}}{q^2}$. This critical point has an unbroken $\mathcal{N} = 1$ supersymmetry.
Table 1: Summary of two critical points with symmetry group, supergravity fields ($\lambda$ and $\alpha$), scalar potential ($V$) and superpotential ($W$).

| Symmetry | $\lambda$ | $\alpha$ | $V$ | $W$ |
|----------|-----------|-----------|-----|-----|
| $SO(8)$  | $\sqrt{2} \sinh^{-1} \sqrt{2/(\sqrt{3} - 1)}$ | $\cos^{-1} \left( \frac{1}{2} \sqrt{3 - \sqrt{3}} \right)$ | $-6g^2$ | $\frac{-216\sqrt{2931/4}g^2}{25\sqrt{2}}$ |
| $G_2$    | $\sqrt{2} \sinh^{-1} \sqrt{2/(\sqrt{3} - 1)}$ | $\cos^{-1} \left( \frac{1}{2} \sqrt{3 - \sqrt{3}} \right)$ | $-6g^2$ | $\frac{-216\sqrt{2931/4}g^2}{25\sqrt{2}}$ |

For the supergravity description of the nonconformal RG flow from one scale to another connecting these two critical points, the three dimensional Poincare invariant metric has the form $ds^2 = e^{2A(r)} \eta_{\mu'\nu'} dx^{\mu'} dx^{\nu'} + dr^2$ where $\eta_{\mu'\nu'} = (-, +, +)$ and $r$ is the coordinate transverse to the domain wall. Then the supersymmetric flow equations [4, 5] with (2.3) and (2.2) are described as

$$\frac{d\lambda}{dr} = \frac{8\sqrt{2}}{7} g \partial_\lambda W, \quad \frac{d\alpha}{dr} = \frac{\sqrt{2}}{7p^2 g^2} g \partial_\alpha W, \quad \frac{dA}{dr} = -\sqrt{2} g W. \quad (2.4)$$

We’ll come back these flow equations when we discuss about the scalar function at IR in section 4.

The fields of the $\mathcal{N} = 8$ theory transforming in $SO(8)$ representations should be decomposed into $G_2$ representations. According to the decomposition $SO(8) \rightarrow G_2$ given in (A.3) which can be obtained from the branching rules of $SO(8) \rightarrow SO(7)$ by (A.1) and $SO(7) \rightarrow G_2$ by (A.2) we present in the appendix A, the spin $\frac{3}{2}$ field breaks into a singlet and a fundamental of $G_2$

$$Spin \frac{3}{2} : \quad 8 \rightarrow [1] \oplus 7 \quad (2.5)$$

under $SO(8) \rightarrow G_2$ and the singlet in square bracket corresponds to the massless graviton of the $\mathcal{N} = 1$ theory. From the further branching rule of $G_2 \rightarrow SU(3)$ by (A.4) one sees that the above septet(7) which will be located at $\mathcal{N} = 1$ massive gravitino multiplet breaks into triplet(3) and anti-triplet($\bar{3}$) that enter into the component of $\mathcal{N} = 2$ short massive gravitino multiplet as well as a singlet(1) which enters into the component of $\mathcal{N} = 2$ massless graviton multiplet under the $G_2 \rightarrow SU(3)$ breaking. Although the global symmetry $G_2$ is reduced to $SU(3)$, the $\mathcal{N} = 1$ supersymmetry is enhanced to $\mathcal{N} = 2$ supersymmetry.

According to the decomposition $SO(8) \rightarrow G_2$ given in (A.3), one obtains the following decomposition by a singlet, two fundamentals, adjoint and a symmetric representation

$$Spin \frac{1}{2} : \quad 56 \rightarrow 1 \oplus [7] \oplus 7 \oplus [14] \oplus 27, \quad (2.6)$$

and the seven Goldstino modes that are absorbed into massive spin $\frac{3}{2}$ fields (2.5) are identified with septet in square bracket and the adjoint representation fourteen(14) in square bracket corresponds to the massless vector multiplet of the $\mathcal{N} = 1$ theory. From the further branching rule of $G_2 \rightarrow SU(3)$ by (A.4) one sees that the above twenty-seven representation(27) which will be located at Wess-Zumino multiplet breaks into a...
singlet(1)(entering into the component of $\mathcal{N} = 2$ long massive vector multiplet), triplet(3) and anti-triplet(3) (entering into the component of $\mathcal{N} = 2$ short massive gravitino multiplet), sextet(6) and anti-sixtet(6) (entering into the component of $\mathcal{N} = 2$ short massive hypermultiplet) and octet(8) (entering into the component of $\mathcal{N} = 2$ massless vector multiplet) under the $G_2 \rightarrow SU(3)$ breaking. Moreover, a singlet in (2.6) which will be located at Wess-Zumino multiplet goes to the component of $\mathcal{N} = 2$ long massive vector multiplet while the septet in (2.6) which will be located at massive gravitino multiplet goes to the component of $\mathcal{N} = 2$ long massive vector multiplet and the component of $\mathcal{N} = 2$ short massive gravitino multiplet.

For spin 1 field, one has the following breaking under $SO(8) \rightarrow G_2$ leading to two fundamentals and adjoint

$$\text{Spin 1 : } 28 \rightarrow 7 \oplus 7 \oplus 14$$

which implies that the representation fourteen(14) in square bracket corresponds to the massless vector multiplet of the $\mathcal{N} = 1$ theory. The two septets which will be located at massive gravitino multiplet break into two triplets and anti-triplets, that enter into the component of $\mathcal{N} = 2$ short massive gravitino multiplet, a singlet which enters into the component of $\mathcal{N} = 2$ massless graviton multiplet and a singlet that enters into the component of $\mathcal{N} = 2$ long massive vector multiplet under the further $G_2 \rightarrow SU(3)$ breaking.

For spin zero field, the breaking goes to a sum of two singlets, two fundamentals and two symmetric representations

$$\text{Spin 0 : } 70 \rightarrow 1 \oplus 1 \oplus [7 \oplus 7] \oplus 27 \oplus 27$$

under $SO(8) \rightarrow G_2$ and the fourteen Goldstone bosons modes are identified with two septets in square bracket. Their quantum numbers are in agreement with those of massive vectors in (2.7). The two twenty-seven representations which will be located at Wess-Zumino multiplet break into two singlets(entering into the component of $\mathcal{N} = 2$ long massive vector multiplet), triplet and anti-triplet(entering into the component of $\mathcal{N} = 2$ short massive gravitino multiplet), two sextets and two anti-sixtets(entering into the component of $\mathcal{N} = 2$ short massive hypermultiplet) and two octets(entering into the component of $\mathcal{N} = 2$ massless vector multiplet) under the further $G_2 \rightarrow SU(3)$ breaking. The remaining triplet and anti-triplet can be identified with six Goldstone boson modes under the further $G_2 \rightarrow SU(3)$ breaking. Moreover, two singlets in (2.7) which will be located at Wess-Zumino multiplet enter into the component of $\mathcal{N} = 2$ long massive vector multiplet.

Finally, from the breaking

$$\text{Spin 2 : } 1 \rightarrow [1]$$

under $SO(8) \rightarrow G_2$, this field is located at $\mathcal{N} = 1$ massless graviton multiplet. Of course, under the $SU(3)$, this enters into the component of $\mathcal{N} = 2$ massless graviton multiplet.

We’ll reorganize (2.5), (2.6), (2.7), (2.8) and (2.9) in the context of supergravity multiplet with corresponding $OSp(1|4)$ quantum numbers in section 4. The singlets are placed
at Wess-Zumino multiplet and massless graviton multiplet, septets are located at massless gravitino multiplet, the adjoints are at massless vector multiplet and twenty seven representations sit in another Wess-Zumino multiplet.

3. An \( \mathcal{N} = 1 \) supersymmetric membrane flow in three dimensional deformed theory

Let us describe the deformed BL theory by adding eight mass parameters \( m_1, \cdots, m_8 \). The theory by \([12] \) is closely related to the BL theory. Moreover, it is conjectured in \([13] \) that the SU(3) \( \times \) U(1) \( Y \)-invariant U(2) \( \times \) U(2) Chern-Simons gauge theory with level \( k = 1 \) with the effective 6-th order superpotential is dual to the background by two units of four-form flux while the theory at level \( k = 2 \) is dual to a \( \mathbb{Z}_2 \) orbifold of the background in \([6, 66] \). Recall that the self-dual and anti self-dual tensors that are invariant under the \( G_2 \) symmetry in \( \mathcal{N} = 8 \) gauged supergravity are given by \([3, 4, 67, 5, 66, 68] \)

\[
Y_{ijkl}^+ = [(\delta_{ijkl}^{1234} + \delta_{ijkl}^{5678}) + (\delta_{ijkl}^{1256} + \delta_{ijkl}^{3478}) + (\delta_{ijkl}^{3456} + \delta_{ijkl}^{1278})] + [- (\delta_{ijkl}^{1357} + \delta_{ijkl}^{2468}) + (\delta_{ijkl}^{2457} + \delta_{ijkl}^{1368}) + (\delta_{ijkl}^{3467} + \delta_{ijkl}^{1458}) + (\delta_{ijkl}^{1467} + \delta_{ijkl}^{2358})],
\]

\[
Y_{ijkl}^- = i[(\delta_{ijkl}^{1234} - \delta_{ijkl}^{5678}) + (\delta_{ijkl}^{1256} - \delta_{ijkl}^{3478}) + (\delta_{ijkl}^{3456} - \delta_{ijkl}^{1278})] + i[- (\delta_{ijkl}^{1357} - \delta_{ijkl}^{2468}) + (\delta_{ijkl}^{2457} - \delta_{ijkl}^{1368}) + (\delta_{ijkl}^{3467} - \delta_{ijkl}^{1458}) + (\delta_{ijkl}^{1467} - \delta_{ijkl}^{2358})].
\]

Turning on the scalar fields proportional to \( Y_{ijkl}^+ \) yields an SO(7) \( + \) invariant vacuum while turning on the pseudo-scalar fields proportional to \( Y_{ijkl}^- \) yields an SO(7) \( - \) invariant vacuum. Simultaneous turning on both scalar and pseudo-scalar fields leads to \( G_2 \)-invariant vacuum with \( \mathcal{N} = 1 \) supersymmetry. The choice of the mass parameters we describe corresponds to the self-dual tensor or anti self-dual tensor for the indices 5678, 3478, 3456, 2468, 2457, 2367, 2358, if we shift all the indices by adding 2 to \((3.1)\), besides an identity. In \([58] \) there are three mass parameters while in \([4, 63] \) there exist four mass parameters. Then the fermionic mass terms from \([4] \) are given by

\[
\mathcal{L}_{f.m.} = -\frac{i}{2} h_{ab} \bar{\Psi}^a (m_1 \Gamma^{78910} + m_2 \Gamma^{56910} - m_3 \Gamma^{5678} + m_4 \Gamma^{46810} + m_5 \Gamma^{4679} + m_6 \Gamma^{4589} - m_7 \Gamma^{45710} - m_8 \Gamma) \Psi^b.
\]

The indices \( a, b, \cdots \) run over the adjoint of the Lie algebra. Then the corresponding fermionic supersymmetric transformation is given by

\[
\delta_m \Psi^a = (m_1 \Gamma^{78910} + m_2 \Gamma^{56910} - m_3 \Gamma^{5678} + m_4 \Gamma^{46810} + m_5 \Gamma^{4679} + m_6 \Gamma^{4589} - m_7 \Gamma^{45710} - m_8 \Gamma) \chi_f^a \Gamma_f \epsilon.
\]

We impose the constraints on the \( \epsilon \) parameter that satisfies the \( \frac{1}{8} \) BPS condition (the number of supersymmetries is two):

\[
\Gamma^{5678} \epsilon = \Gamma^{56910} \epsilon = \Gamma^{78910} \epsilon = \Gamma^{46810} \epsilon = \Gamma^{34910} \epsilon = \Gamma^{3478} \epsilon = \Gamma^{3456} \epsilon = - \Gamma^{4679} \epsilon = - \Gamma^{4589} \epsilon = - \Gamma^{45710} \epsilon = - \epsilon.
\]
The first three conditions in (3.4) provide $\frac{1}{4}$ BPS condition and the remaining seven conditions restrict to the $\epsilon$ parameter further and we are left with the right number of supersymmetry we are dealing with.

Let us introduce the bosonic mass term which preserves $\mathcal{N} = 1$ supersymmetry:

$$
\mathcal{L}_{b.m.} = -\frac{1}{2}h_{ab}X^a_I(m^2)^{I,J}X_J^b. \quad (3.5)
$$

Using the supersymmetry variation for $X^a_I$, $\delta X^a_I = i\epsilon \Gamma_I \Psi^a$, and the supersymmetry variation for $\Psi^a$ by the equation (3.3), the variation for the bosonic mass term (3.5) plus the fermionic mass term (3.2) leads to

$$
\delta \mathcal{L} = ih_{ab}X^a_I(m^2)^{I,J}\bar{\Psi}^b J \Gamma_J \epsilon
- ih_{ab}\Psi^a \left( m_1 \Gamma^{78910} + m_2 \Gamma^{56910} - m_3 \Gamma^{5678} + m_4 \Gamma^{46810} + m_5 \Gamma^{4679} + m_6 \Gamma^{4589} - m_7 \Gamma^{45710} - m_8 \right)^2 \bar{X}^b_I \Gamma_J \epsilon. \quad (3.6)
$$

In order to vanish this, the bosonic mass term $(m^2)^{I,J} \Gamma_J$ should take the form

$$
(m^2)^{I,J} \rightarrow (m_1 + m_2 - m_3 + m_4 - m_5 - m_6 - m_7 - m_8)^2 \Gamma_3
+(m_1 + m_2 - m_3 - m_4 + m_5 + m_6 - m_7 - m_8)^2 \Gamma_4
+(m_1 - m_2 + m_3 + m_4 - m_5 + m_6 - m_7 - m_8)^2 \Gamma_5
+(m_1 - m_2 + m_3 - m_4 + m_5 - m_6 + m_7 - m_8)^2 \Gamma_6
+(m_1 - m_2 - m_3 - m_4 + m_5 + m_6 + m_7 + m_8)^2 \Gamma_7
+(m_1 - m_2 - m_3 + m_4 + m_5 - m_6 - m_7 + m_8)^2 \Gamma_8
+(m_1 + m_2 + m_3 - m_4 - m_5 - m_6 - m_7 + m_8)^2 \Gamma_9
+(m_1 + m_2 + m_3 + m_4 + m_5 + m_6 + m_7 + m_8)^2 \Gamma_{10} \quad (3.7)
$$

by computing the mass terms for second and third lines of (3.6) explicitly.\(^2\) When all the mass parameters are equal

$$
m_1 = m_2 = m_3 = m_4 = m_5 = m_6 = m_7 = m_8 = m,
$$

then the diagonal bosonic mass term in (3.7) has nonzero component only for 1010 and other components(33, 44, 55, 66, 77, 88 and 99) are vanishing. This resembles the structure of $A_4^{I,J}$ tensor of AdS$_4$ supergravity where the $A_4^{I,J}$ tensor has two distinct eigenvalues with degeneracies 7 and 1 respectively \cite{Bianchi:2009ui}. The degeneracy 1 is related to the $\mathcal{N} = 1$ supersymmetry. Then one obtains the bosonic mass term which appears in (3.3)

$$
(m^2)^{I,J} = \text{diag}(0, 0, 0, 0, 0, 0, 0, 0, 0, 64m^2). \quad (3.8)
$$

\(^2\)The relevant terms become $m_1^2 + m_2^2 + m_3^2 + m_4^2 + m_5^2 + m_6^2 + m_7^2 + m_8^2 + 2(-m_1m_2 - m_1m_7 - m_1m_8 + m_2m_3 + m_2m_7 + m_2m_8)\Gamma^{5678} + 2(m_1m_3 + m_1m_8 + m_2m_7 - m_3m_7 - m_3m_8)\Gamma^{56910} + 2(m_1m_4 + m_1m_5 - m_3m_6 - m_3m_8)\Gamma^{4679} + 2(m_1m_5 + m_2m_6 + m_3m_7 - m_4m_8)\Gamma^{46810} + 2(-m_3m_6 - m_2m_5 - m_3m_4 + m_7m_8)\Gamma^{45710} + 2(m_1m_7 + m_2m_4 + m_3m_5 - m_6m_8)\Gamma^{4589} + 2(m_2m_3 + m_4m_5 + m_6m_7 - m_1m_8)\Gamma^{75910}$ explicitly. We also used the conditions (3.4).
Let us introduce the eight $\mathcal{N} = 1$ superfields as follows:

\[
\begin{align*}
\Phi_1 &= X_3 + \cdots, & \Phi_2 &= X_4 + \cdots, & \Phi_3 &= X_5 + \cdots, \\
\Phi_4 &= X_6 + \cdots, & \Phi_5 &= X_7 + \cdots, & \Phi_6 &= X_8 + \cdots, \\
\Phi_7 &= X_9 + \cdots, & \Phi_8 &= X_{10} + \cdots,
\end{align*}
\tag{3.9}
\]

where we do not include the $\mathcal{N} = 1$ fermionic fields. The $\Phi_1, \ldots, \Phi_7$ constitute a fundamental $7$ representation of $G_2$ while $\Phi_8$ is a singlet $1$ of $G_2$. The potential in the BL theory [9] is given by

\[
\frac{1}{3\kappa^2} h_{abc} f_{cde} X_i^a X_j^d X_k^e f_{fgh} X_i^f X_j^g X_k^h
\]

where $\kappa$ is a Chern-Simons coefficient. In terms of $\mathcal{N} = 1$ superfields, this contains the following expressions

\[
\frac{1}{\kappa^2} h_{abc} f_{cde} f_{fgh} \left( \Phi_i^a \Phi_j^d \Phi_k^b + \text{other terms} \right)
\]

by using the relation (3.9) between the component fields and superfields. This provides the superpotential and it is given by [39] with (3.1)

\[
\frac{1}{\kappa} f_{abcd} Y^{ijkl} \text{Tr} \Phi_i^a \Phi_j^b \Phi_k^c \Phi_l^d.
\tag{3.10}
\]

This form has manifest $\text{SO}(7)^+$ global symmetry and by fixing the coefficients of $\mathcal{N} = 1$ superspace action [39] this global symmetry is enhanced to $\text{SO}(8)$ symmetry with maximal supersymmetry. In $\mathcal{N} = 1$ language, the superpotential consisting of the mass term (3.8) and quartic term (3.10) where we absorbed the $\kappa$ into the structure constant is given by

\[
W = \frac{1}{2} M \text{Tr} \Phi_8^2 + (\text{Tr} \Phi_1 \Phi_2 \Phi_7 \Phi_8 + \text{other 6-terms with } \Phi_8)
\]

\[
+ (\text{Tr} \Phi_3 \Phi_4 \Phi_5 \Phi_6 + \text{other 6-terms without } \Phi_8).
\]

The fourteen terms except the first term are the superpotential required by $\mathcal{N} = 8$ supersymmetry and the first term breaks $\mathcal{N} = 8$ down to $\mathcal{N} = 1$. The theory has matter multiplet in seven flavors $\Phi_1, \Phi_2, \cdots, \Phi_7$ transforming in the adjoint with flavor symmetry under which the matter multiplet forms a septet($7$) of the $\mathcal{N} = 1$ theory. Therefore, we turn on the mass perturbation in the UV and flow to the IR. This maps to turning on certain fields in the $\text{AdS}_4$ supergravity where they approach to zero in the UV($r \to \infty$) and develop a nontrivial profile as a function of $r$ as one goes to the IR($r \to -\infty$). We can integrate out the massive scalar $\Phi_8$ with adjoint index at a low enough scale and this results in the 6-th order superpotential $\text{Tr}(Y^{ijkl} \Phi_i \Phi_j \Phi_k \Phi_l)^2 + \text{Tr} \epsilon_{ijklmn} Y^{ijkl} (\Phi_i \Phi_j \Phi_k \Phi_l)$. The scale dimensions of eight superfields $\Phi_i (i = 1, 2, \cdots, 8)$ are $\Delta_i = \frac{3}{4}$ at the UV. This is because the sum of $\Delta_i$ is equal to the canonical dimension of the superpotential which is $3 - 1 = 2$ [70]. By symmetry, one arrives at $\Delta_i = \frac{1}{4}$.

Thus we have found $\mathcal{N} = 1$ superconformal Chern-Simons theories with global $G_2$ symmetry and $k = 1$ Chern-Simons gauge theories with $G_2$-invariant superpotential deformation are dual to the holographic RG flows in [4]. We expect that $G_2$-invariant $\text{U}(N) \times \text{U}(N)$
### Table 2: The $OSp(1|4)$ representations (energy, spin) and $G_2$ representations singlets in the supergravity mass spectrum for Wess-Zumino multiplet at the $\mathcal{N} = 1$ critical point and the corresponding $\mathcal{N} = 1$ superfield $S$ in the boundary gauge theory.

| Boundary Operator | Energy     | Spin 0 | Spin $\frac{1}{2}$ |
|-------------------|------------|--------|---------------------|
| $S = \left( \sum_{i=1}^{7} \Phi_i^2 \right)^{\frac{1}{2}}$ | $E_0$      | 1      |                     |
|                   | $E_0 + \frac{1}{2}$ | 1      |                     |
|                   | $E_0 + 1$    |        | 1                   |

Chern-Simons gauge theory for $N > 2$ with $k = 1, 2$ where there exists an enhancement of $\mathcal{N} = 8$ supersymmetry $\mathbb{R}$ is dual to the background of $\mathbb{R}$ with $N$ unit of flux. In next section, the gauge invariant composites in the superconformal field theory at the IR in three dimensions are mapped to the corresponding supergravity bulk fields in four dimensions.

### 4. The $OSp(1|4)$ spectrum and operator map between bulk and boundary theories

A further detailed correspondence between fields of $AdS_4$ supergravity in four dimensions and composite operators of the IR field theory in three dimensions is described in this section.

The even subalgebra of the superalgebra $OSp(1|4)$ is $Sp(4,R) \simeq SO(3,2)$ that is the isometry algebra of $AdS_4$ $\mathbb{R}$, $\mathbb{R}$. The maximally compact subalgebra is then $SO(2)_E \times SO(3)_S$ where the generator of $SO(2)_E$ is the hamiltonian of the system and its eigenvalues $E$ are the energy levels of states for the system, the group $SO(3)_S$ is the rotation group and its representation $s$ describes the spin states of the system. A supermultiplet, a unitary irreducible representations (UIR) of the superalgebra $OSp(1|4)$, consists of a finite number of UIR of the even subalgebra and a particle state is characterized by a spin $s$ and energy $E$.

Let us classify the supergravity multiplet, which is invariant under $G_2$, we explained in section 2 and describe them in the three dimensional boundary theory.

**Wess-Zumino multiplet.** The conformal dimension $\Delta$, which is irrational and unprotected, is given by $\Delta = E_0 > \frac{1}{2}$. Let us denote $S(x, \theta)$, that is a scalar superfield, by the corresponding boundary operator in boundary gauge theory. This scalar field has a dimension $\frac{5}{6}(6 + \sqrt{3})$ in the IR. We'll come back this issue at the end of this section. The corresponding $OSp(1|4)$ representations and corresponding $\mathcal{N} = 1$ superfield in three dimensions are listed in table 2.

**Wess-Zumino multiplet.** The conformal dimension $\Delta$ for the lowest component of this multiplet is given by $\Delta = E_0 > \frac{1}{2}$. The $AdS_4$ supergravity multiplet corresponds to the scalar superfield $\Phi(x, \theta)$. That is, in the $\theta$ expansion, there are three component fields in the bulk. Then the bilinear of the seven $\Phi_i$ superfields by symmetrizing the two $G_2$
Table 3: The $OSp(1|4)$ representations (energy, spin) and $G_2$ symmetric representations in the supergravity mass spectrum for Wess-Zumino multiplet at the $\mathcal{N} = 1$ critical point and the corresponding $\mathcal{N} = 1$ superfield in the boundary gauge theory.

| Boundary Operator | Energy | Spin 0 | Spin $\frac{1}{2}$ |
|-------------------|--------|--------|-------------------|
| $\text{Tr} \Phi_{(i} \Phi_{j)}$ | $E_0$ | 27     | 27                |
|                   | $E_0 + \frac{1}{2}$ | 27     |                   |
|                   | $E_0 + 1$     | 27     |                   |

Table 4: The $OSp(1|4)$ representations (energy, spin) and $G_2$ fundamental representations in the supergravity mass spectrum for massive gravitino multiplet at the $\mathcal{N} = 1$ critical point and the corresponding $\mathcal{N} = 1$ superfield in the boundary gauge theory.

| Boundary Operator | Energy | Spin $\frac{1}{2}$ | Spin 1 | Spin $\frac{3}{2}$ |
|-------------------|--------|-------------------|--------|-------------------|
| $\text{Tr} D_\alpha W_\beta \Phi_j$ | $E_0$ | 7                 | 7      | 7                 |
|                   | $E_0 + \frac{1}{2}$ | 7                 |        |                    |
|                   | $E_0 + 1$     | 7                 |        |                    |

indices present in them provides a symmetric representation of $G_2$, $27$, corresponding to $\text{Tr} \Phi_{(i} \Phi_{j)}$. Note that from the tensor product between two 7's of $SO(7)$, one writes down $7 \times 7 = 1_s \oplus 21_a \oplus 27_s$. Using the branching rule of $A_2 \otimes A_2$, this leads to $1 \oplus 7 \oplus 14 \oplus 27_s$ under the breaking $SO(7)$ into $G_2$. Therefore, one obtains the symmetric representation $27$ of $G_2$. Group theoretically, the structure of this Wess-Zumino multiplet and $\mathcal{N} = 2$ short massive hypermultiplet in $[14]$ looks similar. The symmetric representations $6$ and $\bar{6}$ of $SU(3)$ originate from only this symmetric representation $27$ of $G_2$ when we look at the branching rule by $(A.4)$. As we observed in section 2, through the supersymmetry enhancement from $\mathcal{N} = 1$ to $\mathcal{N} = 2$, some other components among the representation $27$ of $G_2$ distribute into other $\mathcal{N} = 2$ multiplets while the symmetric representations $6$ and $\bar{6}$ of $SU(3)$ remain and constitute $\mathcal{N} = 2$ short massive hypermultiplet. The corresponding $OSp(1|4)$ representations and corresponding superfield are listed in table 3.

**Massive gravitino multiplet.** The conformal dimension $\Delta$ is given by $\Delta = E_0 > 2$. This corresponds to spinorial superfield $\Phi_{\alpha}(x, \theta)$. In the $\theta$ expansion, the component fields in the bulk are located with appropriate quantum numbers. Then one can identify $\text{Tr} D_\alpha W_\beta \Phi_j$ with 7 of $G_2$. Although the group structure between this massive gravitino multiplet and $\mathcal{N} = 2$ short massive gravitino multiplet is different from each other, they have both fundamental representations and one obtains this multiplet when one takes $\mathcal{N} = 1$ superderivative $D_\alpha$ on $\mathcal{N} = 2$ short massive gravitino multiplet in $[3]$. Some of the fundamental and anti-fundamental representations $3$ and $\bar{3}$ of $SU(3)$ in $\mathcal{N} = 2$ theory originate from this fundamental representation 7 of $G_2$ when we look at the branching rule by $(A.4)$ and some of them come from others $14$ and $27$ of $G_2$. As we observed in section 2, from $\mathcal{N} = 1$ to $\mathcal{N} = 2$, the singlets among the representation 7 of $G_2$ enter into $\mathcal{N} = 2$ massless graviton multiplet or long massive vector multiplet. The corresponding $OSp(1|4)$ representations and corresponding superfield are listed in table 4.
\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
Boundary Operator & Energy & Spin $\frac{1}{2}$ & Spin 1 & Spin $\frac{3}{2}$ & Spin 2 \\
\hline
Tr $D_\alpha \Phi T^A \Phi$ & $E_0 = \frac{3}{2}$ & [14] & [14] & [14] & [14] \\
\hline
$D^\alpha T^{3\gamma}$ & $E_0 = \frac{5}{2}$ & [1] & [1] & [1] & [1] \\
\hline
\end{tabular}
\caption{The $OSp(1|4)$ representations (energy, spin) and $G_2$ representations (adjoints and singlets) in the supergravity mass spectrum for massless vector and graviton multiplets at the $\mathcal{N} = 1$ critical point and the corresponding $\mathcal{N} = 1$ superfields in the boundary gauge theory.}
\end{table}

$\mathcal{N} = 1$ massless graviton multiplet. The bulk field $\Phi_{\alpha\beta\gamma}(x, \theta)$ can be identified with $D^\alpha T^{3\gamma}(x, \theta)$ where $T^{3\gamma}(x, \theta)$ is the stress energy tensor superfield. In components, the $\theta$ expansion of this superfield has the $\mathcal{N} = 1$ supercurrent and the stress energy tensor. Also in this case, one obtains this multiplet when one takes $\mathcal{N} = 1$ superderivative $D^\alpha$ on $\mathcal{N} = 2$ massless graviton multiplet in [14]. The conformal dimension $\Delta = \frac{3}{2}$. The structure of this massless graviton multiplet and $\mathcal{N} = 2$ massless graviton multiplet looks similar to each other. Some of the singlet representation 1 of SU(3) in $\mathcal{N} = 2$ theory originate from this singlet representation 1 of $G_2$ when we look at the branching rule by (A.4) and some of them come from 7 and 27 of $G_2$. The corresponding $OSp(1|4)$ representations and corresponding superfield are listed in table 5.

$\mathcal{N} = 1$ massless vector multiplet. This conserved vector current is given by a scalar superfield $D_\alpha J^A(x, \theta)$. This transforms in the adjoint representation of $G_2$ flavor group. The boundary object is given by Tr $D_\alpha \Phi T^A \Phi$ where the generator $T^A$ is $N \times N$ matrix with $A = 1, 2, \cdots, N^2 - 1$ for general $N$. One obtains also this multiplet when one takes $\mathcal{N} = 1$ superderivative $D_\alpha$ on $\mathcal{N} = 2$ massless vector multiplet in [14] although the group structure is different from each other but they have both adjoint representations. The conformal dimension $\Delta = \frac{3}{2}$. By taking a tensor product between two 7’s, one gets this adjoint 14 of $G_2$ representation as in Wess-Zumino multiplet above. The structure of this massless vector multiplet and $\mathcal{N} = 2$ massless vector multiplet resembles each other. Some of the adjoint representation 8 of SU(3) in $\mathcal{N} = 2$ theory originate from this adjoint representation 14 of $G_2$ when we look at the branching rule by (A.4) and some of them come from 27 of $G_2$. As we observed in section 2, from $\mathcal{N} = 1$ to $\mathcal{N} = 2$, triplets and anti-triplets among the representation 14 of $G_2$ enter into $\mathcal{N} = 2$ short massive gravitino multiplet. The corresponding $OSp(1|4)$ representations and corresponding superfield are listed in table 5 also.

The 11-dimensional metric with warped product ansatz is given by [43, 72, 5, 66]:

$$ds^2_{11} = ds^2_4 + ds^2_7 = \Delta(x, y)^{-1} g_{\mu\nu}(x) dx^\mu dx^\nu + G_{mn}(x, y) dy^m dy^n,$$

where $\mu, \nu = 1, 2, \cdots, 4$ and $m, n = 1, 2, \cdots, 7$. The 4-dimensional metric which has a 3-dimensional Poincare invariance takes the form $g_{\mu\nu}(x) dx^\mu dx^\nu = e^{2A(r)} \eta_{\mu'\nu'} dx^{\mu'} dx^{\nu'} + dr^2$, where $\eta_{\mu'\nu'} = (-, +, +)$ and $r = x^4$ is the coordinate transverse to the domain wall as in section 2 and the scale factor $A(r)$ behaves linearly in $r$ at UV and IR regions. The
metric formula by \[65\] generates the 7-dimensional metric from the two input data of AdS\(_4\) vacuum expectation values for scalar and pseudo-scalar fields \((\lambda, \alpha)\). Let us introduce the redefined fields \[\text{a} \equiv \cosh \left( \frac{\lambda}{\sqrt{2}} \right) + \cos \alpha \sinh \left( \frac{\lambda}{\sqrt{2}} \right) , \quad \text{b} \equiv \cosh \left( \frac{\lambda}{\sqrt{2}} \right) - \cos \alpha \sinh \left( \frac{\lambda}{\sqrt{2}} \right) .\]

We recall that the two input data of \((a, b)\) are

\[a = 1, \quad b = 1 \quad (4.1)\]

for the SO(8)-invariant UV critical point whereas

\[a = \sqrt{\frac{6\sqrt{3}}{5}}, \quad b = \sqrt{\frac{2\sqrt{3}}{5}} \quad (4.2)\]

for the \(G_2\)-invariant IR critical point.\(^3\)

From the standard metric of a 7-dimensional ellipsoid, the diagonal 8 \(\times\) 8 matrix \(Q_{AB}\) is given by \[5, 66\] and the 7-dimensional ellipsoidal metric \(ds^2_{EL(7)} = dX^A Q^{-1}_{AB} dX^B\) where \(X^A\) is a coordinate for \(R^8\) and \(A, B = 1, 2, \cdots , 8\) arises via

\[ds^2 = G_{mn}(x, y) dy^m dy^n = \sqrt{\Delta} a^2 L^2 \left( a^{-2} \xi^2 d\theta^2 + \sin^2 \theta d\Omega^2_6 \right) \quad (4.3)\]

where the quadratic form \(\xi^2\) is given by \[65, 5, 66\]

\[\xi^2 = a^2 \cos^2 \theta + b^2 \sin^2 \theta \quad (4.4)\]

and the warped factor \(\Delta\) is given by

\[\Delta = a^{-1} \xi^{-\frac{4}{3}} . \quad (4.5)\]

The metric \(d\Omega^2_6\) on \(S^6 \cong G_2 / SU(3)\) in \[43\] preserves the Fubini-Study metric on \(CP^2\) \[73, 66\]. Note that the corresponding base 6-sphere for \(SU(3) \times SU(3) \times U(1)\)-invariant sector \[74, 14\] is given by \(CP^3\) which is the homogeneous space \(SU(4)/[SU(3) \times SU(3) \times SU(2)]\) characterized by the Kahler form \(J\) \[75, 66\].

As in \[7\], let us go to the SL(8, \(R\)) basis and introduce the rotated vielbeins

\[U^i_{\ ij} = u^i_{\ ij}(\Gamma_{IJ})^{ab}, \quad V^i_{\ ij} = v^i_{\ ij}(\Gamma_{IJ})^{ab}, \quad U_{\ ij} = u_{\ ij}(\Gamma_{IJ})^{ab}, \quad V_{\ ij} = v_{\ ij}(\Gamma_{IJ})^{ab}\]

where 28-beins and gamma matrices are the same as those in \[4\]. Now let us define

\[A_{ij\ell j} = \frac{1}{\sqrt{2}} \left( U^i_{\ ij} + V_{\ ij} \right) , \quad B_{ij\ell j} = \frac{1}{\sqrt{2}} \left( U^i_{\ ij} - V_{\ ij} \right) , \quad C_{ij\ell j} = \frac{1}{\sqrt{2}} \left( U^i_{\ ij} + V_{\ ij} \right) , \quad D_{ij\ell j} = \frac{1}{\sqrt{2}} \left( -U^i_{\ ij} + V_{\ ij} \right).\]

\(^3\)The scalar potential \[24\] can be rewritten as \(V(a, b) = \frac{1}{8} a^2 (a^5 - 28a^2b + 14a^3b^2 - 84b^3 + 49ab^4)\).
Then “geometric” $T$-tensor can be written as

$$\tilde{T}^{kij}_{lm} = \frac{1}{16\sqrt{2}} G_{LM}^{ij} \left( A_{lmJK} D^{kmKI} \delta_f^j x_M x_J - B_{lm}^{JK} C_{KI}^M \delta_f^j x_M x_I \right)$$  \hspace{1cm} (4.6)$$

and furthermore the “geometric” $A_1$-tensor is given by

$$\tilde{A}_{ij}^{1} = \tilde{T}^{imj}.$$  \hspace{1cm} (4.7)

The idea of \cite{76} is to replace $\delta^I_J$ in the original $T$-tensor with $x^I x^J$ but $\delta^I_J$ remains unchanged, as in (4.6).

The 88 component of $\tilde{A}_{ij}^{1}$, $\tilde{A}_{88}^{1}$, provides the “geometric” superpotential in terms of $a$, $b$ and $\theta$ and from the complete expressions in appendix B (B.1), one gets

$$W_{gs} \equiv |\tilde{A}_{88}^{1}|^2 = a^3 \sqrt{(a^2 \cos^2 \theta + b^2 \sin^2 \theta)^2 - 16(ab - 1) \sin^2 \theta \cos^2 \theta}. \hspace{1cm} (4.8)$$

This superpotential is different from $W_{AI}$ in \cite{5}, in general. More explicitly, one obtains

$$W_{gs}^2 = 4W_{AI}^2 + \frac{1}{4W^2} a^6 (-2 + ab)^2 (-1 + ab) (3 + 4 \cos 2\theta)^2.$$  \hspace{1cm} (4.9)

In particular, when $\theta = \cos^{-1} \frac{1}{\sqrt{8}}$, one obtains $W_{gs} = W = W_{AI}$. Although there are two different solutions for the superpotential, $W_{gs}$ and $W_{AI}$, in 11-dimensions, there exists the same superpotential $W$ in 4-dimensions. For SO(8) maximal $\mathcal{N} = 8$ supersymmetric critical point with (4.1), it is easy to check $W_{gs} = 2W_{AI} = W = 1$.

Performing the M2-brane probe analysis \cite{77, 76, 8}, one can compute the effective Lagrangian for the probe moving at a small velocity transverse to its world-volume. If the potential vanishes, then the kinetic term gives us to a metric on the corresponding moduli space. By combining some part of determinant for the induced metric for M2-brane world-volume with 3-form potential, one reads off the corresponding potential. Then the potential has the factor

$$\Delta^{-\frac{1}{2}} W_{gs} = a^\frac{3}{2} \left( a^2 \cos^2 \theta + b^2 \sin^2 \theta \right) \left[ 1 - \frac{1}{\sqrt{1 - \frac{16(ab - 1) \sin^2 \theta \cos^2 \theta}{(a^2 \cos^2 \theta + b^2 \sin^2 \theta)^2}}} \right]$$

where we substituted (4.5), (4.4) and (4.8). This potential vanishes for $\theta = \frac{\pi}{2}$. Of course, there exists trivial solution for $\theta = 0$ where the metric becomes zero. On this subspace, the metric on the 7-dimensional moduli space transverse to the M2-branes is given by

$$ds^2_{\text{moduli}} = \sqrt{a} L^2 e^A d\Omega_6^2 + e^A a^\frac{3}{2} b^2 dr^2.$$  \hspace{1cm} (4.9)

where we used the fact that for $\theta = 0$ we have simple relations from (4.4) and (4.3): $\xi^2 = b^2$ and $\Delta = a^{-1}b^{-\frac{5}{2}}$.  

\footnote{The superpotential $W$ is the same as \cite{23}: $W = \frac{1}{8} \sqrt{a^4 \left[ (a^2 + 7b^2)^2 - 112(ab - 1) \right]}$ and the superpotential by \cite{3} is $W_{AI} = \frac{1}{\text{tan}^2} \left( 48(1 - ab) + (a^2 - b^2)(a^2 + 7b^2) \right) \cos^2 \theta + 8 (1 - ab) + b^2 \left( a^2 + 7b^2 \right)$.}
As we approach the IR critical point, we can introduce a new radial coordinate
\( u \simeq e^{\frac{1}{2} A(r)} \) with \( \frac{du}{dr} = \frac{1}{L} \sqrt{\frac{6}{5} a b} u \) to obtain the asymptotic form for the metric by inserting (4.2), (2.4) and the IR critical value of \( W \) in table 1 into (4.9)

\[
d s^2|_{\text{moduli}} = \frac{5^{\frac{3}{2}} 3^{\frac{1}{2}}}{6^{\frac{5}{2}}} L^2 \left( du^2 + \frac{6}{5} u^2 d\Omega_6^2 \right). \tag{4.10}
\]

Also at the IR critical point, one can see that

\[
\frac{d}{dr} \left( e^{A(r)} \sqrt{a} \right) \bigg|_{\text{IR}} = \frac{2}{L} \sqrt{\frac{6}{5}} a b e^{A(r)} \bigg|_{\text{IR}}
\]

by using the supersymmetric flow equations (2.4) we introduced in section 2. The mass spectrum for the \( \frac{\sqrt{7}}{2} \lambda \) around \( G_2 \) fixed point was computed in [6] and it is \( \frac{5}{6} (6 + \sqrt{3}) \).

At the IR end of the flow, \( A(r) \sim 2 \sqrt{\frac{36 \sqrt{2} \lambda^{1/4}}{25 \sqrt{3}}} r \) with \( g \equiv \frac{\sqrt{2}}{L} \) from the solution (2.4) for \( A(r) \) and \( W = \sqrt{\frac{36 \sqrt{2} \lambda^{1/4}}{25 \sqrt{3}}} \) from table 1. Moreover, \( u \sim e^{\frac{1}{2} A(r)} \) from the factor in the metric (4.10) of the moduli. Obviously, from the tensor product between 7 and 7 of \( G_2 \) representation, one gets a singlet 1 as before. For the superfield \( S(x, \theta) \), the action looks like \( \int d^3 x d^2 \theta S(x, \theta) \). The component content of this action can be worked out straightforwardly using the projection technique. This implies that the highest component field in \( \theta \)-expansion, the last element in table 2, has a conformal dimension \( 6 + \frac{5}{6} \sqrt{3} \) in the IR as before.

We have presented the gauge invariant combinations of the massless superfields of the gauge theory whose \( G_2 \) quantum numbers exactly match the four multiplets in tables 3, 4, 5 observed in the supergravity. There exists one additional Wess-Zumino multiplet in table 2 which completes the picture.

5. Conclusions and outlook

By analyzing the mass-deformed Bagger-Lambert theory (or the mass-deformed U(2) × U(2) Chern-Simons gauge theory with level \( k = 1 \) or 2), preserving \( G_2 \) symmetry, with the addition of mass term for one of the eight adjoint superfields, one identifies an \( \mathcal{N} = 1 \) supersymmetric membrane flow in three dimensional deformed theory with the holographic \( \mathcal{N} = 1 \) supersymmetric RG flow in four dimensions. Therefore, the \( \mathcal{N} = 8 \) gauged supergravity critical point is indeed the holographic dual of the mass-deformed \( \mathcal{N} = 8 \) BL theory (or the mass-deformed U(2) × U(2) Chern-Simons gauge theory with level \( k = 1 \) or 2). So far, we have focused on the particular mass deformation (3.2) preserving \( G_2 \) symmetry. As we mentioned in introduction, there are three more nonsupersymmetric critical points, \( SO(7)^+, SO(7)^- \) and \( SU(4)^- \). It would be interesting to find out all the possible cases for the mass deformations and see how they appear in the \( AdS_4 \times X^7 \) background in the context of \( U(N) \times U(N) \) Chern-Simons gauge theory.
Acknowledgments

I would like to thank K. Hosomichi for discussion on BL theory and T. Itoh, K. Woo and J. Hwang for earlier related works on gauged supergravity. This work was supported by grant No. R01-2006-000-10965-0 from the Basic Research Program of the Korea Science & Engineering Foundation. I would like to thank the participants and the organizers of the mini workshop on “Chern-Simons theories for M2-branes at CQUeST” during 6/26-6/27, 2008 for discussions.

A. Branching rules

In this appendix we list some useful branching rules with the help of [78]. In order to obtain the branching rule $SO(8) \rightarrow G_2$, we need to consider the following two branching rules, $SO(8) \rightarrow SO(7)$ and $SO(7) \rightarrow G_2$. The former is given by

$SO(8) \rightarrow SO(7)$ branching rule:

\[
\begin{align*}
1 & \rightarrow 1, \\
8_v & \rightarrow 8, \\
8_s & \rightarrow 1 \oplus 7, \\
8_c & \rightarrow 8, \\
28 & \rightarrow 7 \oplus 21, \\
35_v & \rightarrow 35, \\
35_s & \rightarrow 1 \oplus 7 \oplus 27, \\
35_c & \rightarrow 35, \\
56_v & \rightarrow 8 \oplus 48, \\
56_s & \rightarrow 21 \oplus 35, \\
56_c & \rightarrow 8 \oplus 48
\end{align*}
\] (A.1)

and the latter is given by

$SO(7) \rightarrow G_2$ branching rule:

\[
\begin{align*}
1 & \rightarrow 1, \\
7 & \rightarrow 7, \\
8 & \rightarrow 1 \oplus 7, \\
21 & \rightarrow 7 \oplus 14, \\
27 & \rightarrow 27 \\
35 & \rightarrow 1 \oplus 7 \oplus 27, \\
48 & \rightarrow 7 \oplus 14 \oplus 27.
\end{align*}
\] (A.2)

Combining the two results (A.1) and (A.2), one obtains the following branching rule which is necessary to analyze the section 2.
SO(8) → G_2 branching rule:

\[
\begin{align*}
1 & \rightarrow 1, \\
8 & \rightarrow 1 \oplus 7, \\
28 & \rightarrow 7 \oplus 7 \oplus 14, \\
56 & \rightarrow 1 \oplus 7 \oplus 7 \oplus 14 \oplus 27, \\
70 & \rightarrow 1 \oplus 1 \oplus 7 \oplus 7 \oplus 27 \oplus 27. \\
\end{align*}
\]

(A.3)

It is better to present the following branching rule for the correspondence between \( \mathcal{N} = 1 \) and \( \mathcal{N} = 2 \) critical points.

G_2 → SU(3) branching rule:

\[
\begin{align*}
1 & \rightarrow 1, \\
7 & \rightarrow 1 \oplus 3 \oplus \bar{3}, \\
14 & \rightarrow 3 \oplus \bar{3} \oplus 8, \\
27 & \rightarrow 1 \oplus 3 \oplus \bar{3} \oplus 6 \oplus \bar{6} \oplus 8. \\
\end{align*}
\]

(A.4)

B. Explicit form for \( \tilde{A}_1 \)-tensor

The \( R^8 \) coordinates \( x_I \) in (4.6) are related to the ones \( X_I \) in (4.3) as follows:

\[
\begin{align*}
X_1 & \equiv \frac{1}{\sqrt{2}}(x_2 - x_6), \\
X_2 & \equiv -\frac{1}{\sqrt{2}}(x_3 - x_7), \\
X_3 & \equiv \frac{1}{\sqrt{2}}(x_4 - x_8), \\
X_4 & \equiv -\frac{1}{\sqrt{2}}(x_1 - x_5), \\
X_5 & \equiv \frac{1}{\sqrt{2}}(x_2 + x_6), \\
X_6 & \equiv \frac{1}{\sqrt{2}}(x_3 + x_7), \\
X_7 & \equiv \frac{1}{\sqrt{2}}(x_4 + x_8), \\
X_8 & \equiv \frac{1}{\sqrt{2}}(x_1 + x_5) = \cos \theta
\end{align*}
\]

and we list here for the expressions for \( \tilde{A}_1 \)-tensor in (4.7).

\[
\begin{align*}
\tilde{A}_{18} & = \frac{(1 + a + i\sqrt{-1} + ab)^3}{(2 + a + b)^2} \left[ 8 + 16b - 8ab + 12b^2 - 12ab^2 + 4a^2b^2 + 4b^3 - 6ab^3 + a^3b + (a - b)(2 + a + b)(8 + a^2 + a(2 - 6b) + b(2 + b)) \cos^2 \theta + \sqrt{-1} + ab \right. \\
& \left. \times (-4i(1 + b)(2 + b)(2 + a + b)) + 4i(2 + a + b)(2 + a + a^2 + b - 2ab + b^2) \cos^2 \theta \right], \\
\tilde{A}_{1mn} & = \frac{1}{\sqrt{2} + a + b} \left[ a(1 + a)(b^2 + (a - b)(a + b) \cos^2 \theta) - 4(2 + b)(-1 + ab)X_m^2 \\
& - i\sqrt{-1} + ab(a^2 + (a - b)(a + b) \cos^2 \theta) + 4(-2 + (-1 + a)ab)X_m^2 \right], \\
\tilde{A}_{1mn} & = \frac{4}{\sqrt{2} + a + b} \left[ -i(-2 + (-1 + a)ab)\sqrt{-1} + ab - (2 + b)(-1 + ab) \right] X_m X_n, \quad m \neq n \\
\tilde{A}_{18} & = \frac{4(1 + a + i\sqrt{-1} + ab)^3}{(2 + a + b)^2(a - b + 2i\sqrt{-1} + ab)} \left[ 2a + i(ab) \sqrt{-1} + ab \right] X_m \cos \theta.
\end{align*}
\]

(B.1)
where \(m, n = 1, 2, \cdots, 7\). Also one can obtain the full expressions for the \(\tilde{A}_2\)-tensor of the theory which we do not present here. We have checked from these \(\tilde{A}_1\) and \(\tilde{A}_2\)-tensors that the scalar potential has a simple form and it is given by \(V = 2a^3 \left[ a^2 + b^2 + (a^2 - b^2) \cos 2\theta \right]^2\).
