Robust and Approximately Stable Marriages under Partial Information

Vijay Menon*        Kate Larson*

Abstract

We study the stable marriage problem in the partial information setting where the agents, although they have an underlying true strict linear order, are allowed to specify partial orders either because their true orders are unknown to them or they are unwilling to completely disclose the same. Specifically, we focus on the case where the agents are allowed to submit strict weak orders and we try to address the following questions from the perspective of a market-designer: i) How can a designer generate matchings that are robust—in the sense that they are “good” with respect to the underlying unknown true orders? ii) What is the trade-off between the amount of missing information and the “quality” of solution one can get? With the goal of resolving these questions through a simple and prior-free approach, we suggest looking at matchings that minimize the maximum number of blocking pairs with respect to all the possible underlying true orders as a measure of “goodness” or “quality”, and subsequently provide results on finding such matchings.

In particular, we first restrict our attention to matchings that have to be stable with respect to at least one of the completions (i.e., weakly-stable matchings) and show that in this case arbitrarily filling-in the missing information and computing the resulting stable matching can give a non-trivial approximation factor (i.e., $o(n^2)$) for our problem in certain cases. We complement this result by showing that, even under severe restrictions on the preferences of the agents, the factor obtained is asymptotically tight in many cases. We then investigate a special case, where only agents on one side provide strict weak orders and all the missing information is at the bottom of their preference orders, and show that in this special case the negative result mentioned above can be circumvented in order to get a much better approximation factor; this result, too, is tight in many cases. Finally, we move away from the restriction on weakly-stable matchings and show a general hardness of approximation result and also discuss one possible approach that can lead us to a near-tight approximation bound.

1 Introduction

Two-sided matching markets have numerous applications, e.g., in matching students to dormitories (i.e., Stable Roommates problem (SR) [Irv85]), residents to hospitals (i.e., Hospital-Resident problem (HR) [Man16]) etc., and hence are ubiquitous in practice. Perhaps unsurprisingly, then, this line of research has received much attention, with plenty of work done on investigating numerous problems like SR and HR, and their many variations (we refer the reader to the excellent books by Gusfield and Irving [GI89] and Manlove [Man13] for a survey on two-sided matching problems). The focus of this paper, too, is on one such problem—one that is perhaps the most widely-studied, but yet the simplest—called the Stable Marriage problem (SM), first introduced by Gale and Shapley [GS62]. In SM we are given two disjoint sets (colloquially referred to as the set of men and women) and each agent in one set specifies a strict linear order over the
agents in the other set, and the aim is to find a stable matching, i.e., a matching where there is no man-woman pair such that each of them prefers the other over their partner in the matching. (Such a pair, if it exists, is called a blocking pair.)

While the assumption that the agents will be able to specify strict linear orders is not unreasonable in small markets, in general, as the markets get larger, it may not be feasible for an agent to determine a complete ordering over all the alternatives. Furthermore, there may arise situations where agents are simply unwilling to provide strict total orders due to, say, privacy concerns. Thus, it is natural for a designer to allow agents the flexibility to specify partial orders, and so in this paper we assume that the agents submit strict weak orders\(^1\) (i.e., strict partial orders where incomparability is transitive) that are consistent with their underlying true strict linear orders. Although the issue of partially specified preferences has received attention previously, we argue that certain aspects have not been addressed sufficiently. In particular, the common approach to the question of what constitutes a “good” matching in such a setting has been to either work with stable matchings that arise as a result of an arbitrary linear extension of the submitted partial orders (these are known as weakly-stable matchings) or to look at something known as super-stable matchings, which are matchings that are stable with respect to all the possible linear extensions of the submitted partial orders [IrV94; Ras+14]. In the case of the former, one key issue is that we often do not really know how “good” a particular weakly-stable matching is with respect to the underlying true orders of the agents, and in the case of the latter they often do not exist. Furthermore, we believe that it is in the interest of the market-designer to understand how robust or “good” a matching is with respect to the underlying true orders of the agents, for, if otherwise, issues relating to instability and market unravelling can arise since the matching that is output by a mechanism can be arbitrarily bad with respect to these true orders. Hence, in this paper we propose to move away from the extremes of working with either arbitrary weakly-stable matchings or super-stable matchings, and to find a middle-ground when it comes to working with partial preference information.

To this end, we aim to answer two questions from the perspective of a market-designer: i) How should one handle partial information so as to be able to provide some guarantees with respect to the underlying true preference orders? ii) What is the trade-off between the amount of missing information and the quality of a matching that one can achieve? We discuss our proposal in more detail in the following sections.

1.1 How does one work with partial information?

When agents do not submit full preference orderings, there are several possible ways to cope with the missing information. For instance, one approach that immediately comes to mind is to assume that there exists some underlying distribution from which the agents’ true preferences are drawn, and then use this information to find a “good” matching—which is, say, the one with the least number of blocking pairs in expectation. However, the success of such an approach crucially depends on having access to information about the underlying preference distributions which may not always be available. Therefore, in this paper we make no assumptions on the underlying preference distributions and instead adopt a prior-free and absolute-worst-case approach where we assume that any of the linear extensions of the given strict partial orders can be the underlying true order, and we aim to provide solutions that perform well with respect to all of them. We note that similar worst-case approaches have been looked at previously, for instance, by Chiesa et al. [CMA12] in the context of auctions.

The objective we concern ourselves with here is that of minimizing the number of blocking pairs, which is well-defined and has been considered previously in the context of matching problems (for instance, see [ABM05; BMM10]). In particular, for a given instance $I$ our aim is

---

\(^1\)All our negative results naturally hold for the case when the agents are allowed to specify strict partial orders. As for our positive results, most of them can be extended for general partial orders, although the resulting bounds will be worse.
to return a matching \( M_{opt} \) that has the best worst case—i.e., a matching that has the minimum maximum ‘regret’ after one realises the true underlying preference orders. (We refer to \( M_{opt} \) as the minimax optimal solution.) More precisely, let \( I = (p_U, p_W) \) denote an instance, where \( p_U = \{ p_{u_1}, \ldots, p_{u_n} \}, p_W = \{ p_{w_1}, \ldots, p_{w_n} \}, U = \{ u_i \}_{i \in \{1,2,\ldots,n\}} \) and \( W = \{ w_i \}_{i \in \{1,2,\ldots,n\}} \) are the set of men and women respectively, and \( p_i \) is the strict partial order submitted by agent \( i \). Additionally, let \( C(p_i) \) denote the set of linear extensions of \( p_i \), \( C \) be the Cartesian product of the \( C(p_i)s \), i.e., \( C = \times_{i \in U \cup W} C(p_i) \), \( bp(M,c) \) denote the set of blocking pairs that are associated with the matching \( M \) according to some linear extension \( c \in C \), and \( S \) denote the set of all possible matchings. Then the matching \( M_{opt} \) that we are interested in is defined as \( M_{opt} = \arg \min_{M \in S} \max_{c \in C} |bp(M,c)| \).

While we are aware of just one work by Drummond and Boutilier [DB13] who consider the minimax regret approach in the context of stable matchings (they consider it mainly in the context of preference elicitation; see Section 1.4 for more details), the approach, in general, is perhaps reminiscent, for instance, of the works of Hyafil and Boutilier [HB04] and Lu and Boutilier [LB11] who looked at the minimax regret solution criterion in the context of mechanism design for games with type uncertainty and preference elicitation in voting protocols, respectively.

**Remark:** In the usual definition of a minimax regret solution, there is a second term which measures the ‘regret’ as a result of choosing a particular solution. That is, in the definition above, it would usually be \( M_{opt} = \arg \min_{M \in S} \max_{c \in C} |bp(M,c)| - |bp(M_c,c)| \), where \( M_c \) is the optimal matching (with respect to the objective function \( |bp()| \)) for the linear extension \( c \). We do not include this in the definition above because \( |bp(M_c,c)| = 0 \) as every instance of the marriage problem with linear orders has a stable solution (which by definition has zero blocking pairs). Additionally, the literature on stable matchings uses the term “regret” to denote the maximum cost associated with a stable matching, where the cost of a matching for an agent is the rank of its partner in the matching and the maximum is taken over all the agents (for instance, see [Man+02]). However, here the term regret is used in the context of the minimax regret solution criterion.

### 1.2 How does one measure the amount of missing information?

For the purposes of understanding the trade-off between the amount of missing information and the “quality” of solution one can achieve, we need a way to measure the amount of missing information in a given instance. There are many possible ways to do this, however in this paper we adopt the following. For a given instance \( I \), the amount of missing information, \( \delta \), is the fraction of pairwise comparisons one cannot infer from the given strict partial orders. That is, we know that if every agent submits a strict linear order over \( n \) alternatives, then we can infer \( \binom{n}{2} \) comparisons from it. Now, instead, if an agent \( i \) submits a strict partial order \( p_i \), then we denote by \( \delta_i \) the fraction of these \( \binom{n}{2} \) comparisons one cannot infer from \( p_i \) (this is the “missing information” in \( p_i \)). Our \( \delta \) here is equal to \( \frac{1}{2n} \sum_{i \in U \cup W} \delta_i \). Although, given a strict partial order \( p_i \), it is straightforward to calculate \( \delta_i \), we will nevertheless assume throughout that \( \delta \) is part of the input. Hence, our definition of an instance will be modified the following way to include the parameter for missing information: \( I = (\delta, p_U, p_W) \).

**Remark:** \( \delta = 0 \) denotes the case when all the preferences are strict linear orders. Also, for an instance with \( n \) agents on each side, the least value of \( \delta \) when the amount of missing information is non-zero is \( \frac{1}{2n} \binom{n}{2} \) (this happens in the case where there is only one agent with just one pairwise comparison missing). However, despite this, in the interest of readability, we sometimes just write statements of the form “for all \( \delta > 0 \)”. Such statements need to be understood as being true for only realizable or valid values of \( \delta \) that are greater than zero.
1.3 Our Contributions

The focus of our work is on computing the minimax optimal matching, i.e., a matching that, when given an instance $I$, minimizes the maximum number of blocking pairs with respect to all the possible linear extensions (see Section 2.1 for a formal definition of the problem). Towards this end, we make the following contributions:

- We formally define the problem and show that, interestingly, the problem under consideration is equivalent to the problem of finding a matching that has the minimum number of super-blocking pairs (i.e., man-woman pairs where each of them weakly-prefers the other over their current partners).

- While an optimal answer to our question might involve matchings that have man-woman pairs such that each of them strictly prefers the other over their partners, we start by focusing our investigation on matchings that do not have such pairs. Given the fact that any matching with no such pairs are weakly-stable, through this setting we address the question “given an instance, can we find a weakly-stable matching that performs well, in terms of minimizing the number of blocking pairs, with respect to all the linear extensions of the given strict partial orders?” We show that by arbitrarily filling-in the missing information and computing the resulting stable matching, one can obtain a non-trivial approximation factor (i.e., one that is $o(n^2)$) for our problem for many values of $\delta$. We complement this result by showing that, even under severe restrictions on the preferences of the agents, the factor obtained is asymptotically tight in many cases.

- By assuming a special structure on the agents’ preferences—one where strict weak orders are specified by just agents on one side and all the missing information is at the bottom of their preference orders—we show that one can obtain a $O(n)$-approximation algorithm for our problem. The proof of the same is via finding a 2-approximation for another problem (see Problem 3) that might be of independent interest.

- In Section 4 we remove the restriction to weakly-stable matchings and show a general hardness of approximation result for our problem. Following this, we discuss one possible approach that can lead to a near-tight approximation guarantee for the same.

1.4 Related Work

There has recently been a number of papers that have looked at problems relating to missing preference information or uncertainty in preferences in the context of matching.

Drummond and Boutilier [DB13] used the minimax regret solution criterion in order to drive preference elicitation strategies for matching problems. While they discussed computing robust matchings subject to a minimax regret solution criteria, their focus was on providing an NP-completeness result and heuristic preference elicitation strategies for refining the missing information. In contrast, in addition to focusing on understanding the exact trade-offs between the amount of missing information and the solution “quality”, we concern ourselves with arriving at approximation algorithms for computing such robust matchings.

Rastegari et al. [Ras+14] studied a partial information setting in labour markets. However, again, the focus of this paper was different than ours. They looked at pervasive-employer-optimal matchings, which are matchings that are employer-optimal (see [Ras+14] for the definitions) with respect to all the underlying linear extensions. In addition, they also discussed how to identify, in polynomial time, if a matching is employer-optimal with respect to some linear extension.

Recent work by Aziz et al. [Azi+16] looked at the stable matching problem in settings where there is uncertainty about the preferences of the agents. They considered three different models
of uncertainty and primarily studied the complexity of computing the stability probability of a
given matching and the question of finding a matching that will have the highest probability of
being stable. In contrast to their work, in this paper we do not make any underlying distribu-
tional assumptions about the preferences of the agents and instead take an absolute worst-case
approach, which in turn implies that our results hold irrespective of the underlying distribution
on the completions.

Finally, we also briefly mention another line of research which deals with partial information
settings and goes by the name of interview minimization (see, for instance, [RCIL13; DB14]).
One of the main goals in this line of work is to come with a matching that is stable (and
possibly satisfying some other desirable property) by conducting as few ‘interviews’ (which
in turn helps the agents in refining their preferences) as possible. We view this work as an
interesting, orthogonal, direction from the one we pursue in this paper.

2 Preliminaries

Let $U$ and $W$ be two disjoint sets. The sets $U$ and $W$ are colloquially referred to as the set of
men and women, respectively, and $|U| = |W| = n$. We assume that each agent in $U$ and $W$ has
a true strict linear order (i.e., a ranking without ties) over the agents in the other set, but this
strict linear order may be unknown to the agents or they may be unwilling to completely disclose
the same. Hence, each agent in $U$ and $W$ specifies a strict partial order over the agents in the
other set (which we refer to as their preference order) that is consistent with their underlying
true orders, and $p_U$ and $p_W$, respectively, denote the collective preference orders of all the men
and women. For a strict partial order $p_i$ associated with agent $i$, we denote the set of linear
extensions associated with $p_i$ by $C(p_i)$ and denote by $C$ the Cartesian product of the $C(p_i)$s,
i.e., $C = \times_{i\in U\cup W} C(p_i)$. We refer to the set $C$ as “the set of all completions” where the term
completion refers to an element in $C$. Also, throughout, we denote strict preferences by $\succ$ and
use $\succeq$ to denote the relation ‘weakly-prefers’. So, for instance, we say that an agent $c$ strictly
prefers $a$ to $b$ and denote this by $a \succ_c b$ and use $a \succeq_c b$ to denote that either $c$ strictly prefers
$a$ to $b$ or finds them incomparable. As mentioned in the introduction, we restrict our attention
to the case when the strict partial orders submitted by the agents are strict weak orders over the
set of agents in the other set.

Remark: Strict weak orders are defined to be strict partial orders where incomparability
is transitive. Hence, although the term tie is used to mean indifference, it is convenient to
think of strict weak orders as rankings with ties. Therefore, throughout this paper, whenever
we say that agent $c$ finds $a$ and $b$ to be tied, we mean that $c$ finds $a$ and $b$ to be incomparable.
Additionally, we will use the terms ties and incomparabilities interchangeably.

An instance $I$ of the stable marriage problem (SM) is defined as $I = (\delta, p_U, p_W)$, where
$\delta$ denotes the amount of missing information in that instance and this in turn, as defined in
Section 1.2, is the average number of pairwise comparisons that are missing from the instance,
and $p_U$ and $p_W$ are as defined above. Given an instance $I$, the aim is usually to come up with
a matching $M$—which in turn is a set of disjoint pairs $(m, w)$, where $m \in U$ and $w \in W$—that
is stable. There are different notions of stability that have been proposed and below we define
two of them that are relevant to our paper: i) weak-stability and ii) super-stability. However,
before we look at their definitions we introduce the following terminology that will be used
throughout this paper. (Note that in the definitions below we implicitly assume that in any
matching $M$ all the agents are matched. This is so because of the standard assumption that is
made in the literature on SM (i.e., the stable marriage problem where every agent has a strict
linear order over all the agents in the other set) that an agent always prefers to be matched to
some agent than to remain unmatched.)

**Definition 1** (blocking pair/obvious blocking pair). Given an instance $I$ and a matching $M$
associated with $I$, $(m, w)$ is said to be a blocking pair associated with $M$ if $w \succ_m M(m)$ and
Given the definitions above we can now define weak-stability and super-stability.

**Definition 3 (weakly-stable matching).** Given an instance \( I \) and matching \( M \) associated with \( I \), \( M \) is so said to be weakly-stable with respect to \( I \) if it does not have any obvious blocking pairs. When the preferences of the agents are strict linear orders, such a matching is just referred to as a stable matching.

**Definition 4 (super-stable matching).** Given an instance \( I \) and matching \( M \) associated with \( I \), \( M \) is so said to be super-stable with respect to \( I \) if it does not have any super-blocking pairs.

### 2.1 What problems do we consider?

As mentioned in the introduction, we are interested in finding the minimax optimal matching where the objective is to minimize the number of blocking pairs, i.e., to find, from the set \( S \) of all possible matchings, a matching that has the minimum maximum number of blocking pairs with respect to all the completions. This is formally defined below.

**Problem 1** (\( \delta \)-minimax-matching). Given a \( \delta \in [0, 1] \) and an instance \( I = (\delta', p_U, p_W) \), compute \( M_{\text{opt}} \) where \( M_{\text{opt}} = \arg \min_{M \in S} \max_{c \in C} |\text{bp}(M, c)| \).

Although the problem defined above is our main focus, for the rest of this paper we will be talking in terms of the following problem which concerns itself with finding an approximately super-stable matching (i.e., a super-stable matching with the minimum number of super-blocking pairs). As we will see below, the reason we do the same is because both the problems are equivalent.

**Problem 2** (\( \delta \)-min-bp-super-stable-matching). Given a \( \delta \in [0, 1] \) and an instance \( I = (\delta', p_U, p_W) \), where \( \delta' \leq \delta \) is the amount of missing information and \( p_U, p_W \) are the preferences submitted by men and women respectively, compute \( M^{SS}_{\text{opt}} \) where \( M^{SS}_{\text{opt}} = \arg \min_{M \in S} |\text{super-bp}(M)| \) and \( \text{super-bp}(M) \) is the set of super-blocking pairs associated with \( M \) for the instance \( I \).

Below we show that both the problems described above are equivalent. However, before that we prove the following lemma.

**Lemma 1.** Let \( M \) be a matching associated with some instance \( I = (\delta, p_U, p_W) \), \( \alpha \) denote the maximum number of blocking pairs associated with \( M \) for any completion of \( I \), and \( \beta \) denote the number of super-blocking pairs associated with \( M \) for the instance \( I \). Then, \( \alpha = \beta \).

**Proof.** First, it is easy to see that if there are \( \alpha \) blocking pairs associated with \( M \) for a completion, then there are at least as many super-blocking pairs associated with \( M \). Therefore, \( \alpha \leq \beta \).

Next, we will show that if \( \beta \) is the number of super-blocking pairs associated with \( M \), then \( I \) has at least one completion such that it has \( \beta \) number of blocking pairs associated with \( M \). To see this, for each \( m_i \in U \) and for each \( w_j \in W \) such that \( (m_i, w_j) \) is a super-blocking pair, do the following:
• if \( m_i \) finds \( w_j \) incomparable to \( M(m_i) \), then construct a new partial order \( p'_{m_i} \) for \( m_i \) such that it is the same as \( p_{m_i} \) except for the fact that in \( p'_{m_i} \) we have that \( m_i \) strictly prefers \( w_j \) over \( M(m_i) \).

• if \( w_j \) finds \( m_i \) incomparable to \( M(w_j) \), then construct a new partial order \( p'_{w_j} \) for \( w_j \) such that it is the same as \( p_{w_j} \) except for the fact that in \( p'_{w_j} \) we have that \( w_j \) strictly prefers \( m_i \) over \( M(w_j) \).

Once the above steps are done, if there still exists any agent whose preference order is partial, then complete it arbitrarily. Now, consider this instance \( I' \) that is obtained. Then, again, it is easy to see that every \((m_i, w_j)\) which was a super-blocking pair associated with \( M \) in \( I \) forms a blocking pair in \( M \) with respect to \( I' \). Therefore, this completion has \( \beta \) blocking pairs, and since the maximum number of blocking pairs in any completion is \( \alpha \), we have that \( \beta \leq \alpha \). Combining this with the case above, we have that \( \alpha = \beta \).

Given the lemma above, we can now prove our theorem.

**Theorem 2.** For any \( \delta \in [0, 1] \), the \( \delta \)-minimax-matching and \( \delta \)-min-bp-super-stable-matching problems are equivalent.

**Proof.** To see this, let \( I = (\delta', p_U, p_W) \) be some instance, where \( \delta' \leq \delta \), and \( M \) be some matching associated with \( I \). We show that \( M \) is an optimal solution for the \( \delta \)-minimax-matching problem if and only if it is an optimal solution for the \( \delta \)-min-bp-super-stable-matching problem.

( \( \Rightarrow \) ) Let us suppose that \( M \) is not an optimal solution for the \( \delta \)-min-bp-super-stable-matching problem. This implies that there exists some other \( M' \) such that \( |\text{super-bp}(M')| < |\text{super-bp}(M)| \). However, from Lemma 1 we know that the maximum number of blocking pairs associated with \( M' \) for any completion with respect to \( I \) is equal to \( |\text{super-bp}(M')| \), which in turn contradicts the fact that \( M \) was optimal for the \( \delta \)-minimax-matching problem.

( \( \Leftarrow \) ) We can prove this analogously.

For the rest of this paper, we assume that we are always dealing with instances which do not have a super-stable matching as this can be checked in polynomial-time [Irv94, Theorem 3.4]. So, now, in the context of the \( \delta \)-min-bp-super-stable-matching problem, it is easy to show that if the number of super-blocking pairs \( k \) in the optimal solution is a constant, then we can solve it in polynomial-time. We state this in the theorem below. Later, in Section 4, we will see that the problem is NP-hard, even to approximate.

**Theorem 3.** An exact solution to the \( \delta \)-min-bp-super-stable-matching problem can be computed in \( O(n^{2(k+1)}) \) time, where \( k \) is the number of super-blocking pairs in the optimal solution.

**Proof.** We will describe the algorithm below whose main idea is based on the following observation.

For an instance \( I \), consider its optimal solution \( M_{opt} \) and let the \( k \) super-blocking pairs associated with \( M_{opt} \) be \( B = \{(m_1, w_1), \ldots, (m_k, w_k)\} \). Next, for each such pair \((m_i, w_i)\), put \( m_i \) (\( w_i \)) at the end of \( w_i \)'s (\( m_i \)'s) preference list (i.e., make every other man (woman), except those involved in another blocking pair with \( w_i \) (\( m_i \)), rank better than \( m_i \) (\( w_i \))). If either of them are involved in multiple blocking pairs in \( B \), then make those partners as incomparable at the end of the preference list. Let us call the new instance \( I' \). Notice that \( M_{opt} \) is super-stable with respect to \( I' \) as the pairs in \( B \) are no longer blocking and no new blocking pairs are created because of our manipulations to the preference list.

Given the above observation, we can now describe the exponential algorithm.

• Initially \( j = 1 \). Given a \( j \), try out every possible set of pairs of size \( j \) to see if they are the right blocking pairs.
• For each set generated in the previous step, modify the original instance \( I \) to \( I' \) as described above and see if \( I' \) has a super-stable matching (this can be done in polynomial time). If yes, then return the super-stable matching as that is the solution. Otherwise, if none of the sets of size \( j \) result in a “yes”, then go back to step 1 and try again with the next value of \( j \).

Now, it is easy to see that we end up with the optimal solution this way since we try all possible sets of blocking pairs. As for the time, we know that for each \( j \) we have at most \( (n^2)^j \) choices of sets and for each set we need at most \( 2n^2 \) time to do the necessary manipulations to the instance and to check for super-stability. Hence, the total time required is \( \sum_{j=1}^{k} 2n^{2j+2} = O(n^{2(k+1)}) \).

3 Investigating weakly-stable matchings

In this section we focus on situations where obvious blocking pairs are not permitted in the final matching. In particular, we explore the space of weakly-stable matchings and ask whether it is possible to find weakly-stable matchings that also provide good approximations to the \( \delta \)-min-bp-super-stable-matching problem (and thus the \( \delta \)-minimax-matching problem).

3.1 Approximating \( \delta \)-min-bp-super-stable-matching with weakly-stable matchings

It has previously been established that a matching is weakly-stable if and only if it is stable with respect to at least one completion [Man+02, Section 1.2]. Therefore, given this result, one immediate question that arises in the context of approximating the \( \delta \)-min-bp-super-stable-matching problem is “what if we just fill in the missing information arbitrarily and then compute a stable matching associated with such a completion?” This is the question we consider here, and we show that weakly-stable matchings do give a non-trivial (i.e., one that is \( o(n^2) \), as any matching has only \( O(n^2) \) super-blocking pairs) approximation bound for our problem for certain values of \( \delta \). The proof of the following theorem is through a simple application of the Cauchy-Schwarz inequality.

**Theorem 4.** For any \( \delta > 0 \) and an instance \( I = (\delta', p_U, p_W) \) where \( \delta' \leq \delta \), any weakly-stable matching with respect to \( I \) gives an \( O \left( \min \left\{ n^3 \delta, n^2 \sqrt{\delta} \right\} \right) \)-approximation for the \( \delta \)-min-bp-super-stable-matching problem.

**Proof.** Let \( \mathcal{M} \) be a weakly-stable matching associated with \( I \). By the definition of weakly-stable matchings we know that \( \mathcal{M} \) does not have any obvious blocking pairs. This implies that for every super-blocking pair \((m, w)\) associated with \( \mathcal{M} \), either \( m \) finds \( w \) incomparable to his partner \( \mathcal{M}(m) \) or \( w \) finds \( m \) incomparable to her partner \( \mathcal{M}(w) \). If it is the former then we refer to the super-blocking pair \((m, w)\) as one that is associated with \( m \) and if not we say that it is associated with \( w \). Next, let us suppose that there are \( d \) agents who have a blocking pair associated with them and let \( b_i \) denote the number of super-blocking pairs associated with agent \( i \). So, now, the number of super-blocking pairs, \( |\text{super-bp}(\mathcal{M})| \), associated with \( \mathcal{M} \) can be written as

\[
|\text{super-bp}(\mathcal{M})| = \sum_{i=1}^{d} b_i \leq \sum_{i=1}^{d} (\ell_i - 1) = \sum_{i=1}^{d} \ell_i - d,
\]

where \( \ell_i \) refers to the length of largest tie associated with agent \( i \) and the inequality follows from the definition of an association of a super-blocking pair with an agent.
Additionally, for each \( i \in \{1, \cdots, d\} \), we know that at least \( \binom{\ell_i}{2} \) pairwise comparisons are missing with respect to \( i \) (since \( i \) has a tie of length \( \ell_i \)). Therefore, using the Cauchy-Schwarz inequality, we have that

\[
\sum_{i=1}^{d} \left( \frac{\ell_i}{2} \right) = \frac{1}{2} \sum_{i=1}^{d} \ell_i^2 - \ell_i \geq \frac{1}{2} \left[ \frac{1}{d} \left( \sum_{i=1}^{d} \ell_i \right)^2 - \sum_{i=1}^{d} \ell_i \right].
\]

(2)

Also, since the total amount of missing information \( \delta' \) in the instance \( I \) is less than or equal to \( \delta \) and since each \( \ell_i \geq 2 \) (as it is a weak order and a tie, if it exists, is of length at least 2) we have that

\[
d \leq \sum_{i=1}^{d} (\ell_i - 1) \leq \sum_{i=1}^{d} \left( \frac{\ell_i}{2} \right) \leq \delta (2n) \left( \frac{n}{2} \right) \leq \delta n^3.
\]

(3)

Now, using Equation 3 and the fact that \( d \) is also upper-bounded by \( 2n \) (as there are only \( 2n \) agents in the instance), we have that \( d \leq \min\{2n, \delta n^3\} \). Therefore, using Equation 2 and again using the fact that \( \delta \) is the maximum amount of missing information, we have,

\[
\frac{1}{2} \left[ \frac{1}{d} \left( \sum_{i=1}^{d} \ell_i \right)^2 - \sum_{i=1}^{d} \ell_i \right] \leq \sum_{i=1}^{d} \left( \frac{\ell_i}{2} \right) \leq \delta (2n) \left( \frac{n}{2} \right).
\]

(4)

This in turn implies that if we solve for \( \sum_{i=1}^{d} \ell_i \), we have,

\[
\sum_{i=1}^{d} \ell_i \leq \frac{1}{2} \left( d + \sqrt{d^2 + 8dn^2(n-1)\delta} \right) < d + \sqrt{d^2 + 8dn^2(n-1)\delta}.
\]

So, now, we can use the fact that \( d \leq \min\{2n, \delta n^3\} \) to see that

\[
\sum_{i=1}^{d} \ell_i - d \leq \min\{4n^3\delta, 5n^2\sqrt{\delta}\}.
\]

Finally, this along with Equation 1 gives our result since the number of super-blocking pairs in the optimal solution is at least 1 (since, as mentioned in Section 2.1, we are only considering instances that do not have a super-stable matching).

\[\square\]

### 3.2 Can we do better when restricted to weakly-stable matchings?

While Theorem 4 established an approximation factor for the \( \delta \)-min-bp-super-stable-matching problem when considering only weakly-stable matchings, it was simply based on arbitrarily filling-in the missing information. Therefore, there remains the question as to whether one can be clever about handling the missing information and as a result obtain improved approximation bounds. In this section we consider this question and show that for many values of \( \delta \) the approximation factor obtained in Theorem 4 is asymptotically the best one can achieve when restricted to weakly-stable matchings.

**Theorem 5.** For any \( \delta \in \left[ \frac{16}{n^2}, \frac{1}{2} \right] \), if there exists an \( \alpha \)-approximation algorithm for \( \delta \)-min-bp-super-stable-matching that always returns a matching that is weakly-stable, then \( \alpha \in \Omega \left( n^2 \sqrt{\delta} \right) \).

Moreover, this result is true even if we allow only one side to specify ties and also insist that all the ties need to be at the top of the preference order.
Claim 1. First, note that in any weakly-stable matching \( I \) is at most \( 1 \).

At a very high-level, the key idea in this proof is to create an instance do this, first note that the optimal solution \( I \) effect”, thus in turn causing a very sharp blow-up in the number of super-blocking pairs. With otherwise it will result in an obvious blocking pair. Next, let us suppose that there exists an \( m \) \( \{ \cdots \} \) : place all the remaining alternatives in some strict order.

Next, we will show that all the weakly-stable matchings associated with \( I \) have \( O\left(n^2 \sqrt{\delta}\right) \) super-blocking pairs, whereas the optimal solution has exactly one super-blocking pair. To do this, first note that the optimal solution \( \mathcal{M}_{\text{opt}} \) associated with the instance is \( \mathcal{M}_{\text{opt}} = \{ (m_1, w_1), (m_2, w_2), \cdots (m_n, w_n) \} \), where \((m_2, w_1)\) is the only super-blocking pair (and it is an obvious blocking pair). Also, it can be verified that the total amount of missing information in \( I \) is at most \( \delta \). So, next, we prove the following claim.

**Claim 1.** If \( \mathcal{M} \) is a weakly-stable matching associated with the instance \( I \), then \( \forall i \in \{ \frac{n}{2} + 1, \cdots, n \} \), \( \mathcal{M}(m_i) \neq w_i \).

**Proof.** First, note that in any weakly-stable matching \( m_2 \) will always be matched to \( w_1 \) as otherwise it will result in an obvious blocking pair. Next, let us suppose that there exists an \( i \in \{ \frac{n}{2} + 1, \cdots, n \} \) such that \( \mathcal{M}(m_i) = w_i \). Now, we will consider the following two cases and show that in both the cases this is impossible.
Case 1. \( m_1 \) is matched to a woman \( w \in W_{F \setminus \{i\}} \) in \( M \): In this case one can see that \((m_1, w_i)\) forms an obvious blocking pair.

Case 2. \( m_1 \) is matched to a woman \( w \in W_S \) in \( M \): Note that if this is the case, then there is at least one \( j \in S \) such that \( m_j \) is matched with a woman \( w \in W_F \). Now, notice that \((m_j, w_i)\) forms an obvious blocking pair.

Given the claim above, consider a man \( m \) whose index is in some block \( B_j \) and let his index value be \( k \). From the way the preferences are defined, it is easy to see that in any weakly-stable matching, \( m \) will be matched to a woman \( w \) whose index lies in the same block \( B_j \) (because otherwise it will result in an obvious blocking pair). At the same time, from the claim above we know that this \( w \)'s index is not \( k \). Now, let us consider the woman \( w_{b_j - 1} \) who is the woman with the highest index value in \( B_j \) and let \( m' \) denote the man who is matched to \( w_{b_j - 1} \) in a weakly-stable matching. From the observation above we know that \( m' \) has an index value in \( B_j \). Additionally, given the way the preferences are defined for \( m' \) and using the fact that any woman \( w_p \) such that \( p \in B_j \) finds all the men in \( B_j \setminus \{p\} \) to be incomparable, one can see that \( m' \) forms \(|B_j| - 2\) super-blocking pairs (with all the women in \( B_j \) except \( w_{b_j - 1} \) and the one with the same index value as \( m' \)). Also, by using the same argument again, but with respect to \( w_{b_j - 2} \), we can show that partner of \( w_{b_j - 2} \) in the matching forms at least \(|B_j| - 3\) super-blocking pairs (with all women except \( w_{b_j - 2}, w_{b_j - 1} \), and the one with the same index). Continuing this way we see that each block \( B_j \) contributes \( O(|B_j|^2) \) super-blocking pairs. And so, since there are \( z \) blocks and \(|B_j| = y \) for all \( j \), we have that there are \( O(n^2 \sqrt{\delta}) \) super-blocking pairs in any weakly-stable matching.

3.3 The case of one-sided top-truncated preferences: An \( O(n) \) approximation algorithm for \( \delta \)-min-bp-super-stable-matching

Although Theorem 5 is an inherently negative result, in this section we consider an interesting restriction on the preferences of the agents and show how this negative result can be circumvented. In particular, we consider the case where only agents on one side are allowed to specify ties and all the ties need to be at the bottom. Such a restriction has been looked at previously in the context of matching problems and as noted by Irving and Manlove [IM08] is one that appears in practise in the Scottish Foundation Allocation Scheme (SFAS). Additionally, restricting ties to only at the bottom models a very well-studied class of preferences known as top-truncated preferences, which has received considerable attention in the context of voting (see, for instance, [BFLR12]).

Top-truncated preferences model scenarios where an agent is certain about their most preferred choices, but is indifferent among the remaining ones or is unsure about them. More precisely, in our setting, the preference order submitted by, say, a woman \( w \) is said to be a top-truncated order if it is a linear order over a subset of \( V \) and the remaining men are all considered to be incomparable to \( w \). In this section we consider one-sided top-truncated preferences, i.e., where only men or women are allowed to specify top-truncated orders, and show an \( O(n) \)-approximation algorithm for \( \delta \)-min-bp-super-stable-matching under this setting. (Without loss of generality we assume throughout that only the women submit strict weak orders.) Although arbitrarily filling-in the missing information and computing the resulting weakly-stable matching can lead to an \( O(n^2 \sqrt{\delta}) \)-approximate matching even for this restricted case (see Appendix A for an example), we will see that not all weakly-stable matchings are “bad” and that in fact the \( O(n) \)-approximate matching we obtain is weakly-stable.

However, in order to arrive at this result, we first introduce the following problem which might be of independent interest. (To the best of our knowledge, this has not been previously considered in the literature.) Informally, in this problem we are given an instance \( I \) and are asked if we can delete some of the agents to ensure that the instance, when restricted to the remaining agents, will have a perfect super-stable matching.
Problem 3 (min-delete-super-stable-matching). Given an instance $I = (\delta, p_U, p_W)$, where $\delta$ is the amount of missing information and $p_U, p_W$ are the preferences submitted by men and women respectively, compute the set $D$ of minimum cardinality such that the instance $I_{D} = (\delta_{-D}, p_U \setminus D, p_W \setminus D)$, where $\delta_{-D} = \dfrac{1}{|U \cup W| \setminus D} \sum_{i \in (U \cup W) \setminus D} \delta_i$, has a perfect super-stable matching (i.e., every agent in $(U \cup W) \setminus D$ is matched in a super-stable matching).

Below we first show a 2-approximation for the min-delete-super-stable-matching problem when restricted to the case of one-sided top-truncated preferences. Subsequently, we use this result in order to get an $O(n)$-approximation for our problem. However, before that, we introduce the following terminology which will be used throughout in this section.

- An instance $I$ of the min-delete-super-stable-matching problem can also be thought of as the set of agents along with their preference lists. Initially for every agent this list has all the agents in the other set listed in some order. Now, during the course of our algorithm sometimes we use the operation “delete($a, b$)” which removes agent $a$ from $b$’s list and $b$ from $a$’s. After such a deletion (or after a series of such deletions) our instance now refers to the set of agents along with their updated lists.

- We say that a matching $M$ is internally super-stable with respect to an instance $I$ if $M$ is super-stable with respect to the instance that is obtained by only considering the matched agents in $M$ (i.e., consider $I$ and remove all the agents who are not matched in $M$ from $I$).

- We say that an instance $I$ with no ties has an exposed rotation $\rho = (m_1, w_1), \cdots , (m_r, w_r)$ if, in $I$, $w_i$ is the first agent in $m_i$’s list and $w_{i+1}$ is the second agent in $m_i$’s list (here $(i + 1)$ is done modulo $r$).

Proposition 6. Algorithm 1 is a polynomial-time 2-approximation algorithm for the min-delete-super-stable-matching problem when restricted to the case of one-sided top-truncated preferences.

Proof. The main idea for Algorithm 1 is inspired by the work of Tan [Tan90] who looked at the problem of finding the maximum internally stable matching for the stable roommates problem (which is equivalent to the problem of finding the minimum number of agents to delete so that the rest of the agents will have a stable matching when the instance is just restricted to themselves). Informally, at a very high level, the key idea in Tan’s algorithm was to show that some of the entries in each agent’s list can be deleted by running the proposal-rejection sequence like in Gale-Shapley algorithm and through rotation eliminations, while at the same time maintaining at least one solution of the maximum size. As we will see below, this is essentially what we do here as well, adapting this idea as necessary for our case when there are ties on one side but only at the bottom.

Before we go on to the main lemmas, let us suppose that $I = (\delta, p_U, p_W)$ is an arbitrary instance of the min-delete-super-stable-matching problem when restricted to the case of one-sided top-truncated preferences, where $\delta$ is the amount of missing information, $p_U, p_W$ are the preference orders submitted by the men and women, respectively, and $|U| = |W| = n$. Also, let $D_{opt}$ be the optimal solution for this instance. This in turn implies that we can form a perfect and internally super-stable matching of size $k = n - \frac{D_{opt}}{2}$, and that in fact $k$ is the maximum size of any such matching (as otherwise $D_{opt}$ cannot be optimal). Next, for now, let us assume the correctness of the following lemmas (note that all the instances we talk about in this section are restricted to the case of one-sided top-truncated preferences). We will prove them later, in Sections 3.3.1, 3.3.2, and 3.3.3.

Lemma 7. Let $I_1$ denote some instance and $I_2$ denote the instance returned by the procedure proposeWith($A, I_1$), where the set $A$ represents the proposing side. If there exists a matching of size $t$ in $I_1$ that is internally super-stable with respect to $I$, then there exists a matching of size $t$ in $I_2$ that is internally super-stable with respect to $I$. 
Algorithm 1: For the case of one-sided top-truncated preferences, the set $D$ returned by the algorithm is a 2-approximation for the min-delete-super-stable-matching problem and the matching $\mathcal{M}$ returned is an $O(n)$-approximation for $\delta$-min-bp-super-stable-matching.

Lemma 8. Let $\mathcal{I}_1$ denote some instance that does not contain any ties, $(m_1, w_1), (m_2, w_2), \ldots, (m_r, w_r)$ be a rotation that is exposed in $\mathcal{I}_1$, and $\mathcal{I}_2$ be the instance that is obtained by deleting the entries $(m_i, w_i)$ for all $i \in \{1, \ldots, r\}$ from $\mathcal{I}_1$. If there exists a matching of size $t$ in $\mathcal{I}_1$ that is internally super-stable with respect to $\mathcal{I}$, then there exists a matching of size $t$ in $\mathcal{I}_2$ that is internally super-stable with respect to $\mathcal{I}$.

Lemma 9. If $\mathcal{I}_1$ is an instance that does not contain any exposed rotation, then the list of every man in $\mathcal{I}_1$ has only one woman and vice versa.

Given the above lemmas and given the fact that the instance $\mathcal{I}$ has an internally super-stable matching of size $k = n - \frac{2n}{2\delta + 1}$, we can start with the instance $\mathcal{I}$ and repeatedly apply Lemma 7 and see that the instance $\hat{\mathcal{I}}$ that we obtain after line 24 of Algorithm 1 has a matching of size $k$ that is internally super-stable matching with respect to $\mathcal{I}$. Next, starting with the instance $\hat{\mathcal{I}}$, we can again repeatedly apply Lemma 8 and see that the instance $\mathcal{I}'$ that remains after
line 29 of Algorithm 1 also has a matching of size $k$ that is internally super-stable matching with respect to $I$. Additionally, from Lemma 9 we know that in this instance each man has only one woman in his list and vice versa. So, now, consider the matching $M$ that can be obtained by matching each man with the only woman in his list. Next, consider the bipartite graph $G = (V, E)$ where $V = U \cup W$ and $(m, w) \in E$ if $(m, w)$ is a super-blocking pair with respect to the original instance $I$, and consider a minimum vertex cover $C$ of $G$. We show below that $k \leq n - \frac{|C|}{2}$.

Suppose this is false and that $I$ has an internally super-stable matching of size greater than $n - \frac{|C|}{2}$. Now, from the discussion above, we know that this implies $I'$ also has a matching of size greater than $n - \frac{|C|}{2}$ such that it is internally super-stable with respect to $I$. This in turn implies that we can remove less than $|C|$ agents and have a matching that is internally super-stable with respect to $I$. That is, we can remove less than $|C|$ agents and also at the same time ensure that for every $(m, w) \in E$, this matching has only one of $m$ or $w$ matched in it, for if otherwise it will not be internally super-stable with respect to $I$. However, this implies that $|C|$ is not the size of the minimum vertex cover of $G$, and hence we have a contradiction.

Now, to get our approximation bound, consider the set $D$ that is returned by the algorithm. We know that $D \leq 2|C| \leq 4(n - k) = 2D_{opt}$, where the first inequality arises because of lines 33-35 in Algorithm 1 and the second inequality uses the observation above that $k \leq n - \frac{|C|}{2}$. Finally, it is easy to see that all the steps can be done in polynomial-time (it is well-known through the König’s Theorem that one can find a minimum vertex cover of a bipartite graph in polynomial-time).

Given Proposition 6, we can now prove the following theorem.

**Theorem 10.** For any $\delta > 0$, Algorithm 1 is a polynomial-time $O(n)$-approximation algorithm for the $\delta$-min-bp-super-stable-matching problem when restricted to the case of one-sided top-truncated preferences. Moreover, the $O(n)$-approximate matching that is returned is also weakly-stable.

**Proof.** Consider an arbitrary instance $I$ of the $\delta$-min-bp-super-stable-matching problem when restricted to the case of one-sided top-truncated preferences. Let $M_{opt}$ be the optimal solution associated with $I$. Next, consider the same instance $I$ for the min-delete-super-stable-matching problem and let us consider the matching $M$ that is returned by Algorithm 1 for this instance. Also, let $D_{opt}$ be the optimal solution of the min-delete-super-stable-matching problem for the instance $I$ and $D$ be the set that is returned by Algorithm 1. (We can assume throughout that $D_{opt} \geq 1$, for if otherwise this implies that it has a super-stable matching, and as mentioned in Section 2.1 we do not consider such instances.) First, it is easy to see that this matching is weakly-stable (because in every instance that results after the first proposal-rejection sequence (which is in line 23), a matching that is formed by matching each man with the first woman on his list will be weakly-stable). Second, note that we can rewrite $M$ as $M = M_1 \cup M_2$, where $M_1 = M \setminus \{\cup_{a \in D}(a, M(a))\}$ and $M_2 = \cup_{a \in D}(a, M(a))$. Now, if $S_1$ ($S_2$) denotes the number of super-blocking pairs associated with men in $M_1$ ($M_2$), then

$$|\text{super-bp}(M)| = S_1 + S_2 \leq \left(n - \frac{|D|}{2}\right) \cdot \frac{|D|}{2} + \frac{|D|}{2} \cdot n \leq n \cdot |D| \leq 2n \cdot |D_{opt}|,$$

where the second step is using the fact that the men in $M_1$ can form at most $\frac{|D|}{2}$ super-blocking pairs with women outside of $M_1$ and the men in $M_2$ can in the worst case form a blocking pair.
with all the women, and the last step is using the fact that \( D_{\text{opt}} \geq 1 \) and that \( |D| \leq 2 \cdot |D_{\text{opt}}| \), which we know is true by Proposition 6.

Also, if \( \mathcal{M}_{\text{opt}} \) is the optimal solution for the \( \delta \)-min-bp-super-stable-matching problem, then we know that

\[
|\text{super-bp}(\mathcal{M}_{\text{opt}})| \geq \frac{|D_{\text{opt}}|}{2}, \tag{6}
\]
as otherwise one can delete all the men who are involved in super-blocking pairs in \( \mathcal{M}_{\text{opt}} \) and their corresponding partners and get a super-stable matching on the remaining agents.

Finally, using Equations 5 and 6 we have our theorem. \( \square \)

3.3.1 Proof of Lemma 7

Let us first prove the following claims. However, before that we introduce the following terminology. When the procedure proposeWith\((A, I_1)\) is executed, for every run of the while loop in line 2 with respect to an agent \( a \), we can track the instance that is currently being used. That is, initially we have the instance \( I_1 \) and this is referred to as the instance that is “currently being used” by the agent \( a_1 \) where \( a_1 \) is the first agent with respect whom the while loop is executed. Now, after the first run of the while loop (w.r.t. \( a_1 \)) we have an updated instance (because of some delete operations that happened in lines 3-14), say, \( I_{\text{curr}} \). Therefore, the next time the while loop is run with respect to some agent \( a_2 \), this is the instance that is “currently being used” with respect to \( a_2 \). We use this terminology in the following claim.

Claim 2. Let \( a \in A \) be an agent who is assigned to be ‘free’ in the procedure proposeWith\((A, I_1)\), \( I_{\text{curr}} \) denote the instance that is currently being used with respect to \( a \), and \( I'_1 \) be the instance obtained by running lines 3-14 with respect to agent \( a \). If there exists a matching of size \( t \) in \( I_{\text{curr}} \) that is internally super-stable with respect to \( I \), then there exists a matching of size \( t \) in \( I'_1 \) that is internally super-stable with respect to \( I \).

Proof. First, note that every time the procedure proposeWith() is called with the set \( A \), the agents in this set do not have any ties. This is because, when proposeWith() is called with the set of women \( W \) for the first time in line 24, all ties are already broken due to the first call of proposeWith() with the set of men in line 23. Therefore, in all the arguments below we do not need to concern ourselves with issues that can arise as a result of the agents in \( A \) having ties.

Now, to prove this claim we consider the following two cases separately.

1. when \( b \), the first agent in \( a \)’s list, is either engaged to \( p \), but prefers \( a \) to \( p \), or is not engaged currently

2. when \( b \) is engaged to \( p \in A \) and finds \( p \) and \( a \) incomparable

Case 1: In this case the only change that happens to the instance \( I_{\text{curr}} \) are due to deletions of the form \((c, b)\) where \( a \succ_b c \). Let the resulting instance be \( I'_1 \). So, in order to prove that \( I'_1 \) has a matching of size \( t \) that is internally super-stable with respect to \( I \), we just need to prove that there exists a matching of size \( t \) in \( I_{\text{curr}} \) that is internally super-stable matching with respect to \( I \) and does not have any matches of the form \((c, b)\). Now, let us suppose that’s not the case and that in every matching \( \mathcal{M} \) of size \( t \) in \( I_{\text{curr}} \) that is internally super-stable with respect to \( I \) there exists such a pair. This in turn implies that \( a \) is unmatched in \( \mathcal{M} \), for if otherwise \((a, b)\) will form an obvious-blocking pair. Hence, we can form the matching \( \mathcal{M}' = (\mathcal{M} \setminus (c, b)) \cup (a, b) \). Note that \( \mathcal{M}' \) is internally-stable with respect to \( I \) as this does not introduce any new super-blocking pair (since \( b \) is the first agent on \( a \)’s list and \( b \) does not block any other agent in \( \mathcal{M}' \) as he prefers the new partner over his old partner \( c \)) and has the same size as \( \mathcal{M} \). This in turn is a contradiction and hence we have that \( I'_1 \) has a matching of size \( t \) that is internally super-stable with respect to \( I \).
Case 2: In this case, the only change that happens to the instance $I_{\text{curr}}$ is the deletion of $(a, b)$. Let the resulting instance be $I'_1$. So, in order to prove that $I'_1$ has a matching of size $t$ that is internally super-stable with respect to $I$, we just need to prove that there exists a matching of size $t$ in $I_{\text{curr}}$ that is internally super-stable matching with respect to $I$ and does not have any matches of the form $(a, b)$. Suppose that’s not the case and that every matching $\mathcal{M}$ of size $t$ in $I_{\text{curr}}$ that is internally super-stable matching with respect to $I$ has $(a, b)$. This in turn implies that $p$ is unmatched in $\mathcal{M}$, for if otherwise $(p, b)$ will form a super-blocking pair (since $b$ is the first agent on $p$’s list and $b$ finds $p$ and $a$ incomparable). Hence, we can now form the matching $\mathcal{M}' = (\mathcal{M} \setminus (a, b)) \cup (p, b)$, which is internally super-stable with respect to $I$ as this does not introduce any new super-blocking pair (since $b$ is the first agent on $p$’s list and $b$ does not block any other agent in $\mathcal{M}'$ as it finds $a$ and $b$ incomparable and so if he blocks someone now he also blocked them when $(a, b)$ was present, thus contradicting the fact that $\mathcal{M}$ was internally super-stable) and has the same size as $\mathcal{M}$. This in turn is a contradiction and hence, again, we have that $I'_1$ has a matching of size $t$ that is internally super-stable with respect to $I$.

Next, we prove the following claim whose proof is omitted since it can be proved in a way that is similar to Case 2 in the proof of Claim 2.

Claim 3. Let $m$ be a man, $w$ be the first woman on $m$’s list, $I_3$ be some instance obtained after line 15, and $I_4$ be the instance obtained after deleting each $(m', w)$ in line 19. If there exists a matching of size $t$ in $I_3$ that is internally super-stable with respect to $I$, then there exists a matching of size $t$ in $I_4$ that is internally super-stable with respect to $I$.

Given the two lemmas above, we are now ready to prove Lemma 7. First, starting with $I_1$ and by repeatedly using Claim 2 with respect to each free agent $a \in A$, we can see that the instance $I'_1$ that we obtain at the end of the while loop (i.e., line 15) has a matching of size $t$ that is internally super-stable matching with respect to the initial instance $I$. Second, starting with $I'_1$ and by repeatedly using Claim 3 with respect to each man, we can see that the instance $I_2$ that is returned from the procedure proposeWith($A, I_1$) has a matching of size $t$ that is internally super-stable with respect to the instance $I$. This in turn proves our lemma.

3.3.2 Proof of Lemma 8

Let $\mathcal{M}$ be a matching of size $t$ in $I_3$ that is internally super-stable with respect to $I$. We will consider the following two cases separately and show that in each case there exists a matching of size $t$ in $I_2$ that is internally super-stable with respect to $I$.

1. for all $i \in \{1, \ldots, r\}$, $(m_i, w_i) \in \mathcal{M}$
2. there exists some $j \in \{1, \ldots, n\}$ such that $(m_j, w_j) \notin \mathcal{M}$

Case 1: Consider the matching $\mathcal{M}'$ that is obtained by removing $(m_i, w_i)$ and instead adding $(m_i, w_{i+1})$ for all $i \in \{1, \ldots, r\}$ (here $i + 1$ is done modulo $r$). Now, it is easy to see that this does not lead to any new internal super-blocking pairs with respect to $I$. Hence, $\mathcal{M}'$ is internally super-stable with respect to $I$, has the same size as $\mathcal{M}$ (as every agent matched in $\mathcal{M}$ is also matched in $\mathcal{M}'$), and all the matched pairs in $\mathcal{M}'$ are in $I_2$.

Case 2: First, note that if $(m_i, w_i) \notin \mathcal{M}$ for all $i \in \{1, \ldots, r\}$, then we are done as the only deleted entries in $I_2$ are $(m_i, w_i)$ for all $i \in \{1, \ldots, r\}$. So this implies that we can, without loss of generality, consider the smallest $k \in \{1, \ldots, r\}$ such that $(m_j, w_j) \notin \mathcal{M}$ for all $j \in \{1, \ldots, k\}$, but $(m_{k+1}, w_{k+1}) \in \mathcal{M}$ (since there is at least one $j$ such that $(m_j, w_j) \notin \mathcal{M}$, this can always be done because we can re-index the rotation so that the first element $(m_1, w_1)$ of the rotation is not in $\mathcal{M}$). Let $I_2'$ be the instance that is formed by deleting the entries $(m_i, w_i)$ for all $i \in \{1, \ldots, k + 1\}$. Below, we will show that $I_2'$ satisfies the conditions of the lemma, i.e., we
show that $I'_2$ has a matching of size $t$ that is internally super-stable with respect to $I$. And so once we have that, we can just repeat this argument until we get to the instance $I_2$.

To see why $I'_2$ satisfies the conditions of the lemma, notice that $m_k$ needs to be unmatched in $\mathcal{M}$, for if otherwise then $(m_k, w_{k+1})$ will be an obvious blocking-pair. This in turn implies that we can construct another matching $\mathcal{M}'$ such that $\mathcal{M}' = (\mathcal{M} \setminus (m_{k+1}, w_{k+1})) \cup (m_k, w_{k+1})$, both of them have the same size, and all the matched pairs in $\mathcal{M}'$ are in $I'_2$. Also, one can see that this does not lead to any new super-blocking pairs since i) $w_{k+1}$ improved and so will not be part of any new super-blocking pair and ii) $m_k$ does not form a super-blocking pair as it is matched to the agent who is second in his list and $w_k$ who is first in his list, if matched in $\mathcal{M}$, has to be matched to someone better (as $m_k$ is the last agent in $w_k$’s list).

3.3.3 Proof of Lemma 9

First, note that throughout an agent $a$ is in $b$’s list if and only if $b$ is in $a$’s list. Second, we prove the following claim.

Claim 4. Let $I_2$ be some initial instance, $I_3$ be the instance that is obtained after running the procedure proposeWith() with the men’s side proposing, and $I_4$ be the instance that is obtained after running the procedure proposeWith() with the women’s side proposing. For any two agents $a$ and $b$ in $I_4$, if $a$ is the only agent in $b$’s list, then $b$ is the only agent in $a$’s list.

Proof. To prove our claim let us consider the following two cases in the instance $I_3$.

1. there exists a woman $w_1$ such that $m_1$ is the only man on $w_1$’s list, but $m_1$ has at least one other woman other than $w_1$ in his list

2. there exists a man $m_1$ such that $w_1$ is the only woman on $m_1$’s list, but $w_1$ has at least one other man other than $m_1$ in her list

Case 1: Since we are looking at $I_3$, note that $w_1$ must be the first woman on $m_1$’s list, for if otherwise there is some other man, say, $m_k$ who is not engaged (because $w_1$ has only $m_1$ in her list). However, we know that this is not possible and so $w_1$ is the first woman on $m_1$’s list. Therefore, now, when we run the procedure proposeWith() with the women’s side proposing, $w_1$ will propose to $m_1$ and as a result $m_1$ will delete all other women from his list. And so, in $I_4$, $w_1$ is the only agent in $m_1$’s list and vice versa.

Case 2: For this case, let us suppose that even after running the procedure proposeWith() with the women’s side proposing, $w_1$ still has at least one other man other than $m_1$ in her list (if not, then we are already done). Let this man be $m_2$. This in turn implies that in the engagement relation that results, at least one of the women, say, $w_k$, is not engaged (because $m_1$ has only $w_1$ in his list). However, we know that this is not possible as this would imply that the engagement relation has an obvious blocking pair $(m_k, w_k)$, where $m_k$ is the last agent on $w_k$’s list (and we know this cannot happen since we are just running the same proposal-rejection sequence as in the Gale-Shapley algorithm).

Given the observations above, let us assume for the sake of contradiction that there exists an instance $I_3$ such that it does not have any exposed rotation but has at least one agent who has a list of size greater than one. Using Claim 4 and the fact that an agent $a$ is in $b$’s list if and only if $b$ is in $a$’s list, we can assume without loss of generality that there exists a man $m_1$ such that he has at least two women in his list. Let $w_1$ and $w_2$ be the first and second woman, respectively, in $m_1$’s list. Since $I_1$ is obtained after running the procedure proposeWith() twice, once each with the men’s and women’s side proposing, from Claim 4 we know that $m_2$, who is the last man on $w_2$’s list, too has at least two women in his list as otherwise $w_2$ would also have just one man $m_2$ in her list. Let $w_3$ be the second woman in $m_2$’s list. Now, we can see that we can just inductively keep on applying the above argument and form the following pairs
is asymptotically the best one can do under this restriction.

of these can men can be matched to \( w \) \( M \) that pair. Therefore, in any weakly-stable matching \( M \) we also know that for all \( j \)

\[ m_1 : w_2 \succ w_1 \succ \cdots \]

\[ m_n : w_n \succ w_{n-2} \succ \cdots \]

Figure 2: The instance \( \mathcal{I} \) that is used in the proof of Theorem 11

\[ \rho = (m_1, w_1), (m_2, w_2), (m_3, w_3), \ldots, (m_r, w_r) \text{ for some } r \in \{2, \ldots, n\}, \text{ where } m_i \text{ is the last man on } w_i \text{'s list and } w_{i+1} \text{ is the second woman on } m_i \text{'s list.} \]

However, note that \( \rho \) is an exposed rotation, and hence we have a contradiction.

Before we end this section, we address one final question as to whether, for the class of one-sided top-truncated preferences, one can obtain a better approximation result if one continues to consider only weakly-stable-matchings. In the theorem below we show that for \( \delta \in \Omega\left(\frac{1}{n^2}\right) \) Algorithm 1 is asymptotically the best one can do under this restriction.

**Theorem 11.** For \( \delta \leq \frac{1}{2} \), if there exists an \( \alpha \)-approximation algorithm for \( \delta \)-min-bp-super-stable-matching that always returns a matching that is weakly-stable for the case of one-sided top-truncated preferences, then \( \alpha \in \Omega\left(\min\left\{n^\frac{7}{2}, n\right\}\right) \).

**Proof.** To prove this, consider the instance \( \mathcal{I} \) defined as in Figure 2, where \( y = \min\left\{\lfloor 2n^\frac{3}{2}\sqrt{\delta}, n\rfloor\right\} \). Below we will show that the statement of the theorem is true when \( \delta \leq \frac{1}{2n} \), i.e., show that in this case \( \alpha \in \Omega\left(n^\frac{\delta}{\sqrt{\delta}}\right) \). For \( \delta > \frac{1}{2n} \) it is then trivial to extend our instance by just having some of the other women (other than \( w_1 \)) specify partial preferences.

First, it is easy to verify that this instance has at most \( \delta \) amount of information missing. Second, one can see that the optimal solution, i.e., the matching with the minimum number of super-blocking pairs, for this instance is

\[ \mathcal{M}_{opt} = \{(m_1, w_1), (m_2, w_3), \ldots, (m_{n-y+1}, w_{n-y+2}), (m_{n-y+2}, w_2), (m_{n-y+3}, w_{n-y+3}), \ldots, (m_n, w_n)\}, \]

where \((m_1, w_2)\) is the only super-blocking pair.

Given the above observation, let us now consider an arbitrary matching \( \mathcal{M} \) that is weakly-stable. Since \( m_i \) prefers \( w_{i+1} \) the most and vice versa for all \( i \in \{1, \ldots, n-y+1\} \), we know that \( \mathcal{M}(m_i) = w_{i+1} \). Hence, \( \mathcal{M}(w_1) = m_k \), for some \( k \in \{n-y+2, \ldots, n\} \). Additionally, we also know that for all \( j \in \{n-y+2, \ldots, n\} \) such that \( j \neq k, w_1 \succ_m j, \mathcal{M}(m_j) \), as none of these can men can be matched to \( w_{n-y+2} \). This in turn implies that since \( w_1 \) finds \( m_k \) and \( m_j \) incomparable for \( j \in \{n-y+2, \ldots, n\} \) such that \( j \neq k, (m_j, w_1) \) is a super-blocking pair. Therefore, in any weakly-stable matching \( \mathcal{M} \) we have \((y-2)\in \mathcal{O}(n^\frac{3}{2}\sqrt{\delta})\) super-blocking pairs.

\[ \square \]
4 Beyond Weak-Stability

In the previous section we investigated weakly-stable matchings and we showed several results concerning this situation. Here we move away from this restriction and explore what happens when we do not place any restriction on the matchings. In particular, we begin this section by showing a general hardness of approximation result, and then follow it with a discussion on one possible approach that can lead to a near-tight approximation result.

4.1 Inapproximability result for $\delta$-min-bp-super-stable-matching

We show a hardness of approximation result for the $\delta$-min-bp-super-stable-matching problem through a gap-producing reduction from the Vertex Cover (VC) problem, which is a well-known NP-complete problem [Kar72]. In the VC problem, we are given a graph $G = (V, E)$, where $V = \{v_1, \cdots, v_k\}$, and a $k_0 \leq k$ and are asked if there exists a subset of the vertices with size less than or equal to $k_0$ such that it contains at least one endpoint of every edge. When given an instance $I$ of VC, the key idea in the proof is to create an instance $I'$ of $\delta$-min-bp-super-stable-matching such that if $I$ is a "yes" instance of VC, then $I'$ will have a very small number of super-blocking pairs, and if otherwise, then $I'$ will have a large number of super-blocking pairs.

**Theorem 12.** For any constant $\epsilon \in (0, 1]$ and $\delta \in (0, 1)$, one cannot obtain a polynomial-time $(n\sqrt{\delta})^{1-\epsilon}$ approximation algorithm for the $\delta$-min-bp-super-stable-matching problem unless $P = NP$.

**Proof.** The proof here is similar to the one by Hamada et al. [HIM16, Theorem 1]. The main difference is in the construction of the instance, which in our case is more involved; once we have that we can essentially use the same proof as the one by Hamada et al.

Given an instance $I = (G = (V, E), k_0)$ of the VC problem, where $|V| = k$, we construct the following instance $I'$ of the $\delta$-min-bp-super-stable-matching problem, where

- $d = \lceil \frac{8}{\epsilon} \rceil$, $y = k^d + 1$, $z = \lceil \frac{1}{\sqrt{\delta}} \rceil$
- $M_A_1 = \{m_1, \cdots, m_{k_0}\}$, $M_A_2 = \{m_{k_0+1}, \cdots, m_k\}$, $W_A = \{w_1, \cdots, w_k\}$
- for every $i < j$ such that $(v_i, v_j) \in E$ and $c \in \{1, \cdots, z\}$, $S^{i,j}_c = \{s^{i,j}_1, \cdots, s^{i,j}_c \}$, $T^{i,j}_c = \{t^{i,j}_1, \cdots, t^{i,j}_c \}$, $P^{i,j}_c = \{p^{i,j}_1, \cdots, p^{i,j}_c \}$, and $V^{i,j}_c = \{v^{i,j}_1, \cdots, v^{i,j}_c \}$
- $S^{i,j} = \{S^{i,j}_1, \cdots, S^{i,j}_z\}$, $T^{i,j} = \{T^{i,j}_1, \cdots, T^{i,j}_z\}$, $P^{i,j} = \{P^{i,j}_1, \cdots, P^{i,j}_z\}$, and $V^{i,j} = \{V^{i,j}_1, \cdots, V^{i,j}_z\}$
- $M_A = M_A_1 \cup M_A_2$, $S = \bigcup S^{i,j}$, $T = \bigcup T^{i,j}$, $P = \bigcup P^{i,j}$, and $V = \bigcup V^{i,j}$
- $U = M_A \cup S \cup P$ and $W = W_A \cup T \cup V$
- for each $i, j$ the preference orders of the agents are as given in Figure 3. For an agent $a$, if $R_S$ appears in its preference list for some $R$ and $S$, then this implies that $a$ finds all the agents in $R_S$ as incomparable. Also, $\lceil \cdots \rceil$ denotes that the rest of the agents can be placed in any order.

Note that $n = |U| = |W| = k + 2yz|E|$. Also, the amount of missing information per agent is at most

$$\binom{k}{2} + \binom{y}{2} \leq \binom{k+y}{2} \leq \frac{(2y)^2}{(2)} \leq \frac{4y^2}{n} \leq \frac{4y^2}{4yz} \leq \delta.$$ 

Next, in order to show the correctness, we prove the following claims. Again, as noted above, the proofs of these use similar ideas as in Hamada et. al's proof of
Claim 5. If a matching $M$ contains a bad pair, then it has at least $y - 1$ super-blocking pairs.

Proof. Consider the case when $m_i$ is matched to a woman $w'$ who is not in $W_A$. This implies that it at least forms a super-blocking pair with all $w \in V_{1,j}^i$ such that $w \neq w'$. And since every woman in $V_{1,j}^i$ finds all the men in $M_A$ as incomparable, therefore we at least have $|V_{1,j}^i| - 1 = y - 1$ super-blocking pairs.

Next, consider the case when there is a man $s_{a,b}^{i,j}$ who is matched to a woman $w'$ who is outside of the top three women in his list. This implies that it at least forms a super-blocking pair with all $w \in V_{a,j}^j$ such that $w \neq w'$. And since we can assume that no women in $V_{a,j}^j$ is matched to a man in $M_A$ (as this would anyway result in $y - 1$ super-blocking pairs as proved above) and since all of them find the men in $S_{a,j}^j$ as incomparable, this implies that we have at least $|V_{a,j}^j| - 1 = y - 1$ super-blocking pairs.
Before we go on to the next claim, for every \(i < j\) such that \((v_i, v_j) \in E\), consider the sets \(S^{i,j}\) and \(T^{i,j}\) and let us define the following two perfect matchings, \(M_1^{i,j}\) and \(M_2^{i,j}\), between \(S^{i,j}\) and \(T^{i,j}\). The matching \(M_1^{i,j}\) (\(M_2^{i,j}\)) can be inferred from Figure 3 by matching every man in \(S^{i,j}\) with the woman coloured red (blue) in his list.

\[
M_1^{i,j} = \left\{ \left( s^{i,j}_{1,1}, t^{i,j}_{1,1} \right), \cdots, \left( s^{i,j}_{j,y}, s^{i,j}_{j+1,y} \right), \cdots, \left( s^{i,j}_{y,2}, t^{i,j}_{y,2} \right), \cdots, \left( s^{i,j}_{i,j}, t^{i,j}_{i,j} \right) \right\}
\]

\[
M_2^{i,j} = \left\{ \left( s^{i,j}_{1,1}, t^{i,j}_{1,1} \right), \cdots, \left( s^{i,j}_{j,y}, t^{i,j}_{j,y} \right), \cdots, \left( s^{i,j}_{i,j}, t^{i,j}_{i,j} \right) \right\}
\]

**Claim 6.** For every \(i < j\) such that \((v_i, v_j) \in E\), \(M_1^{i,j}\) and \(M_2^{i,j}\) are the only perfect matchings between \(S^{i,j}\) and \(T^{i,j}\) that do not include a bad pair. Moreover, both \(M_1^{i,j}\) and \(M_2^{i,j}\) have only one super-blocking pair \((m, w)\) such that \(m \in S^{i,j}\) and \(w \in T^{i,j}\).

**Proof (sketch).** It is easy to observe the first part. As for the second part, note that none of \(s^{i,j}_{1,1}, \cdots, s^{i,j}_{j,y}\) form any super-blocking pair in \(M_1\) as they are matched to their topmost choices. Also, none of \(s^{i,j}_{1,1}, \cdots, s^{i,j}_{j,y}\) form any super-blocking pairs since the only woman they can form super-blocking pairs with, which are \(t^{i,j}_{1,1}, \cdots, t^{i,j}_{j,y}\) respectively, strictly prefers their currently matched partner, which are \(s^{i,j}_{1,1}, \cdots, s^{i,j}_{j,y}\) respectively. Hence, the only super-blocking pair is \((s^{i,j}_{1,1}, t^{i,j}_{1,2})\). We can make similar arguments with respect to \(M_2\) to show that \((s^{i,j}_{1,1}, t^{i,j}_{1,1})\) is the only super-blocking pair.

Given the two claims above, we can now prove the correctness reduction through the following lemmas.

**Lemma 13.** If \(I = (G, k_0)\) is a “yes” instance of VC, then \(I'\) has a solution with at most \(2k^2\) super-blocking pairs.

**Proof.** Let the vertex cover of \(G\) be \(C\) and since it is a “yes” instance, we know that \(|C| \leq k_0\). If the size of \(C\) is strictly less than \(k_0\), then add arbitrary vertices to it in order to make its size \(k_0\). So from now on we can assume that \(|C| = k_0\). Next, construct the following matching \(M\) for the instance \(I'\).

- For every woman \(w_i \in W_A\), if \(v_i \in C\), then match \(w_i\) with some man in \(M_{A_1}\). Otherwise, match \(w_i\) with some man in \(M_{A_2}\).
- For every \(i < j\) such that \((v_i, v_j) \in E\), if \(v_i \in C\), then match every man in \(S^{i,j}\) with a woman in \(T^{i,j}\) using \(M_2^{i,j}\) as defined above. Otherwise, match every man in \(S^{i,j}\) with a woman in \(T^{i,j}\) using \(M_1^{i,j}\) as defined above.
- For every \(i < j\) such that \((v_i, v_j) \in E\), match \(p_{i,j}^{a,b}\) with \(v_{i,j}^a\).

Now, we know that the each man in \(M_A\) can form at most \(k\) super-blocking pairs (one with each woman in \(W_A\)). Additionally, we know from Claim 6 that both \(M_1^{i,j}\) and \(M_2^{i,j}\) have at most one super-blocking pair, and that none of the men in \(P\) form any super-blocking pair as they all get their topmost choice. Hence, the total number of blocking pairs is at most \(k^2 + |E| \leq 2k^2\).

**Lemma 14.** If \(I = (G, k_0)\) is a “no” instance of VC, then every matching for \(I'\) has at least \(y - 1\) super-blocking pairs.

**Proof.** Here we will show that if there exists a matching \(M\) with less than \(y - 1\) super-blocking pairs for \(I'\), then \(I\) has a vertex cover of size at most \(k_0\). To see this, consider \(M\). Since it has less than \(y - 1\) blocking pairs, we know from Claim 5 that it does not have any bad pair. This
in turn implies that all the men in $M_A$ are matched with a woman in $W_A$ (since all men in $M_A$ have to be attached to a woman in $W_A$ and size of both the sets are equal).

Next, for every $i < j$ such that $(v_i, v_j) \in E$, let us consider the men and women in $S^i,j$ and $T^i,j$. Since, again, we cannot have any bad pairs, we know that there has to be a perfect matching between these two sets. Additionally, from Claim 6 we know that $\mathcal{M}_1^{i,j}$ and $\mathcal{M}_2^{i,j}$ are the only two perfect matchings that have no bad pairs. Now, for an $(i, j)$, if we were using $\mathcal{M}_1^{i,j}$, then it is easy to see that $w_j$ should be matched with a man in $M_{A_1}$ as otherwise she would form a super-blocking pair with all the men in $\{s^{i,j}_1, \ldots, s^{i,j}_s\}$, thus resulting in at least $zy > y - 1$ super-blocking pairs for $\mathcal{M}$. Similarly, if we were using $\mathcal{M}_2^{i,j}$, then $w_i$ should be matched with a man in $M_{A_1}$ as otherwise we would have at least $zy > y - 1$ blocking pairs. Therefore, we have that for each edge $(v_i, v_j) \in E$ at least one of the women $w_i$ or $w_j$ should be matched to a man in $M_{A_1}$. So, now, if we define $C = \{v_i \mid M(w_i) \in M_{A_1}\}$, then we have a vertex cover of size at most $k_0$ (as size of $M_{A_1}$ is $k_0$).

Finally, from Lemmas 13 and 14, we have an inapproximability gap of $\alpha$, where

$$\alpha \geq \frac{y - 1}{2k^2} \geq \frac{d}{2k^2} > \frac{n\sqrt{\delta}}{16k^4} \quad \text{(using the fact that } n = 2yzk^2 + k \leq 8k^{d+2}\sqrt{\frac{1}{\delta}}) \quad \text{(using the fact that } n = 2yzk^2 + k > 2yz > 2k^d\sqrt{\frac{1}{\delta}})$$

$$\alpha = \frac{y - 1}{2k^2} \geq \frac{d}{2k^2} > \frac{n\sqrt{\delta}}{16k^4} \quad \text{(using the fact that } n = 2yzk^2 + k \leq 8k^{d+2}\sqrt{\frac{1}{\delta}}) \quad \text{(using the fact that } n = 2yzk^2 + k > 2yz > 2k^d\sqrt{\frac{1}{\delta}})$$

4.2 A possible general approach for obtaining a near-tight approximation factor for $\delta$-min-bp-super-stable-matching

While obtaining a general near-tight approximation result for the $\delta$-min-bp-super-stable-matching problem is still open, in this section we propose a potentially promising direction for this problem. In particular, we demonstrate how solving even a very relaxed version of the min-delete-stable-matching problem will be enough to get an $O(n)$-approximation for $\delta$-min-bp-super-stable-matching in general. Below, we first define the relaxation in question, which we refer to as an $(\alpha, \beta)$-approximation to the min-delete-super-stable-matching problem.

**Definition 5** ($(\alpha, \beta)$-min-delete-super-stable-matching). Given an instance $I = (\delta, p_U, p_W)$, compute a set $D'$ such that $|D'| \leq \alpha \cdot |D_{opt}|$, where $|D_{opt}|$ is the size of the optimal solution to the min-delete-super-stable-matching for the same instance, and the instance $I_{-D'} = (\delta_{-D'}, p_U\setminus D', p_W\setminus D')$, where $\delta_{-D'} = \frac{1}{|U \cup W| |D'|} \sum_{i \in (U \cup W) \setminus D'} \delta_i$, has a matching with at most $\beta$ super-blocking pairs.

Next, we show that an $(\alpha, \beta)$-approximation to the min-delete-super-stable-matching problem gives us an $(\alpha \gamma + \beta)$-approximation for $\delta$-min-bp-super-stable-matching. So, in particular, if we have an $(\alpha, \beta)$-approximation where $\alpha$ is a constant and $\beta \in O(n)$, then this in turn gives us an $O(n)$-approximation for $\delta$-min-bp-super-stable-matching in general.

**Proposition 15.** If there exists an $(\alpha, \beta)$-approximation algorithm for the min-delete-super-stable-matching problem, then there exists an $(\alpha \gamma + \beta)$-approximation algorithm for the $\delta$-min-bp-super-stable-matching problem.

**Proof (sketch).** We can proceed to prove this almost exactly as in the proof of Theorem 10. Here, if $D$ denotes the $(\alpha, \beta)$-approximate solution returned by the algorithm, then the only
difference is that we define $M_1$ to be the matching with the set of agents in $(U \cup W) \setminus D$ such that it has at most $\beta$ super-blocking pairs (from the definition of the problem we know that such a matching exists) and $M_2$ to be an arbitrary matching on the set of agents in $D$. Once we have this, then we can arrive at the bound by proceeding exactly as in the proof of Theorem 10, with the only difference being that here we would use $S_1$, which is the number of super-blocking pairs associated with $M_1$, to be equal to $(n - \frac{|D|}{2}) \cdot \frac{|D|}{2} + \beta$. □

5 Conclusion

In this paper we initiated a study on matching with partial information in order to investigate what makes a matching “good” in this context, and to better understand the trade-off between the amount of missing information and the quality of different matchings. Towards this end, we introduced a measure for accounting for missing preference information in an instance, and argued that a natural definition of a “good” matching in this context is one that minimizes the maximum number of blocking pairs with respect to all the possible completions. Subsequently, using an equivalent problem ($\delta$-min-bp-super-stable-matching) we first explored the space of matchings that contained no obvious blocking pairs (i.e., weakly-stable matchings) in order to better understand how missing preference information effected/affected the quality, in terms of approximation with respect to the objective of minimizing the number of super-blocking pairs. Later on, by expanding the space of matchings we considered (i.e., removing the restriction that matches must be weakly-stable), we asked whether it was possible to improve on the approximation factors that were achieved under the restriction to weakly-stable matchings.

There are a number of interesting directions for future work. First, while in Section 4.2 we proposed one possible approach that can lead to near-tight approximations, there may be other approaches that can prove fruitful. Second, we believe that the min-delete-super-stable-matching problem, and its relaxation we introduced, are both of independent interest, and so an open question is to see if one can obtain general results on them. In Proposition 6 we saw that a 2-approximation was achievable for the case of one-sided top-truncated preferences and hence it would also be interesting to determine if there are other interesting classes of preferences for which constant-factor approximations are possible. Finally, there are possible extensions, like, for instance, allowing incompleteness—meaning the agents can specify that they are willing to be matched to only a subset of the agents on the other set—that one could consider and ask similar questions like the ones we considered.

Furthermore, we define the following:

$$m_1 : w_1 \succ W_{F(1)} \succ W_{B_1} \succ \cdots \succ W_{B_s}$$
$$m_2 : w_1 \succ w_2 \succ \cdots$$
$$m_3 : w_2 \succ w_3 \succ W_{F(2,3)} \succ W_S$$
$$m_4 : w_2 \succ w_4 \succ W_{F(2,4)} \succ W_S$$

$$m_\varphi : w_2 \succ w_\varphi \succ W_{F(2, \varphi)} \succ W_S$$
$$m_{b_0} : w_1 \succ W_{B_1 \setminus \{b_0\}} \succ w_{b_0} \succ W_{S_1 \setminus B_1} \succ W_{F(1)}$$

$$m_{b_1-1} : w_1 \succ W_{B_1 \setminus \{b_1-1\}} \succ w_{b_1-1} \succ W_{S_1 \setminus B_1} \succ W_{F(1)}$$
$$m_{b_1} : w_1 \succ W_{B_1 \setminus \{b_1\}} \succ w_{b_1} \succ W_{S_1 \setminus B_1} \succ W_{F(1)}$$

$$m_{b_2-1} : w_1 \succ W_{B_2 \setminus \{b_2-1\}} \succ w_{b_2-1} \succ W_{S_2 \setminus B_2} \succ W_{F(1)}$$
$$m_{b_2} : w_1 \succ W_{B_2 \setminus \{b_2\}} \succ w_{b_2} \succ W_{S_2 \setminus B_2} \succ W_{F(1)}$$

$$m_{b_3-1} : w_1 \succ W_{B_3 \setminus \{b_3-1\}} \succ w_{b_3-1} \succ W_{S_3 \setminus B_3} \succ W_{F(1)}$$
$$m_{b_3} : w_1 \succ W_{B_3 \setminus \{b_3\}} \succ w_{b_3} \succ W_{S_3 \setminus B_3} \succ W_{F(1)}$$

$$m_{b_{n-1}} : w_1 \succ W_{B_{n-1} \setminus \{b_{n-1}\}} \succ w_{b_{n-1}} \succ W_{S_{n-1} \setminus B_{n-1}} \succ W_{F(1)}$$

$$w_{b_0} : M_{F(1)} \succ m_1 \succ m_{b_0} \succ M_{F(1)} \succ M_{B_1 \setminus \{b_0\}}$$

$$w_{b_1-1} : M_{S_1 \setminus B_1} \succ m_1 \succ m_{b_1-1} \succ M_{F(1)} \succ M_{B_1 \setminus \{b_1-1\}}$$
$$w_{b_1} : M_{S_1 \setminus B_1} \succ m_1 \succ m_{b_1} \succ M_{F(1)} \succ M_{B_1 \setminus \{b_1\}}$$

$$w_{b_2-1} : M_{S_2 \setminus B_2} \succ m_1 \succ m_{b_2-1} \succ M_{F(1)} \succ M_{B_2 \setminus \{b_2-1\}}$$
$$w_{b_2} : M_{S_2 \setminus B_2} \succ m_1 \succ m_{b_2} \succ M_{F(1)} \succ M_{B_2 \setminus \{b_2\}}$$

$$w_{b_3-1} : M_{S_3 \setminus B_3} \succ m_1 \succ m_{b_3-1} \succ M_{F(1)} \succ M_{B_3 \setminus \{b_3-1\}}$$
$$w_{b_3} : M_{S_3 \setminus B_3} \succ m_1 \succ m_{b_3} \succ M_{F(1)} \succ M_{B_3 \setminus \{b_3\}}$$

Figure 4: The instance $\mathcal{I}$ that is used to illustrate that there can be weakly-stable matchings with $O(n^2 \sqrt{n})$ super-blocking pairs even in the case of one-sided top-truncated preferences

### A Example to illustrate “bad” weakly-stable matchings in the case of one-sided top-truncated preferences

Consider the instance $\mathcal{I}$ as shown in Figure 4, where ties appear only on the women’s side. Furthermore, we define the following:

- $\delta \in \left[\frac{16}{\sqrt{2}}, \frac{1}{4}\right], y = \frac{nz^2}{2}, z = \frac{2}{ny}$ (for simplicity we assume that $y$ and $z$ are integers; we can appropriately modify the proof if that is not the case)
- $b_j = \frac{y}{z} + jy + 1, \forall j \in [0, \cdots z]$
- $B_i = \{b_{i-1}, \cdots, b_i - 1\}, \forall i \in [1, \cdots z], F = \{1, \cdots, \frac{y}{2}\}, S = \{\frac{y}{2} + 1, \cdots, n\}$
- $W_X(M_X)$: for some set $X$, place all the women (men) with index in $X$ in the increasing order of their indices
- $W^T_X(M^T_X)$: for some set $X$, place all the women (men) with index in $X$ as tied
- $[\cdots]$, place all the remaining alternatives in some strict order.

First thing is to see that the optimal solution $\mathcal{M}_{opt}$ associated with the instance is

$$\mathcal{M}_{opt} = \{(m_1, w_1), (m_2, w_2), \cdots, (m_n, w_n)\},$$

where $(m_2, w_1)$ is the only super-blocking pair (and it is an obvious blocking pair). Also, it can be verified that the total amount of missing information in $\mathcal{I}$ is at most $\delta$.

Now, consider the matching $\mathcal{M}$, where

$$\mathcal{M} = \{(m_1, w_2), (m_2, w_1), (m_3, w_3), (m_4, w_4) \cdots, (m_{\varphi}, w_{\varphi}), (m_{b_0}, w_{b_0 + 1}), (m_{b_0 + 1}, w_{b_0 + 2}), \cdots, (m_{b_1 - 2}, w_{b_1 - 1}), (m_{b_1 - 1}, w_{b_0})\}.$$
\( (m_{b_1}, w_{b_1+1}), (m_{b_1+1}, w_{b_1+2}), \ldots, (m_{b_2-2}, w_{b_2-1}), (m_{b_2-1}, w_{b_1}), \ldots, \\
\quad \ldots, (m_{b_{z-1}}, w_{b_{z-1}+1}), (m_{b_{z-1}+1}, w_{b_{z-1}+2}), \ldots, (m_{b_{z-2}, w_{b_{z-1}}}, (m_{b_{z-1}}, w_{b_{z-1}})) \).

It is easy to check that \( M \) is weakly-stable. Also, it can be verified that it has \( O\left(n^2 \sqrt{\delta}\right) \) super-blocking pairs (this is because with respect to each block \( B_j \) one can see that \( M \) has \( O\left(|B_j|^2\right) \) super-blocking pairs). □
