Abstract

The focus of present study was to characterize antimicrobial peptide produced by probiotic cultures, *Enterococcus durans* DB-1aa (MCC4243), *Lactobacillus plantarum* Cu2-PM7 (MCC4246) and *Lactobacillus fermentum* Cu3-PM8 (MCC4233) against *Staphylococcus aureus* and *E. coli*. The growth kinetic assay revealed 24 h of incubation to be optimum for bacteriocin production. The partially purified compound after ion-exchange chromatography was found to be thermoresistant and stable under wide range of pH. The compound was sensitive to proteinase-K, but resistant to trypsin, a-amylase and lipase. The apparent molecular weight of bacteriocin from MCC4243 and MCC4246 was found to be 3.5 KDa. Translated partial amino acid sequence of *plnA* gene in MCC4246 displayed 48 amino acid sequences showing 100% similarity with plantaricin A of *Lactobacillus plantarum* (WP_00364199). The sequence revealed 7 β sheets, 6 α sheets, 6 predicted coils and 9 predicted turns. The functions on cytoplasm show 10.82 isoelectric point and 48.6% hydrophobicity. The molecular approach of using Geneious Prime software and protein prediction data base for characterization of bacteriocin is novel and predicts “KSSAYSLQMGATAIKQVKKLFKKWG” as peptide responsible for antimicrobial activity. The study provides information about broad spectrum bacteriocin in native probiotic culture and paves a way towards its application in functional foods as biopreservative agents.

Introduction

In recent years, people are being attracted towards consumption of food, positively associated with health and nutrition. The attitude towards unacceptance of food products containing some of the artificial preservatives has increased due to growing awareness of its ill-effect on human and animal health. Hence, it is a major challenge in food sector to satisfy consumers demand for products free of chemical preservatives and also to ensure natural means of food safety. Further, the chemically synthesized antibiotics and their injudicious usage have resulted in emerging multidrug resistant pathogens and their devastating damage thereafter. Consequently, the need for new strategies and methodologies to control infectious pathogens is increasing. The health benefits executed by some of the traditional foods have attracted researchers to dig the mechanism and apply the knowledge for betterment of life. In this regard, antimicrobial peptides or the bacteriocins from food grade lactic acid bacteria (LAB) have engrossed because of their safety and broad range of antibacterial spectrum.

Bacteriocins are ribosomally synthesized proteinaceous compounds produced by bacteria to protect themselves as well as to competitively colonize in the gut through elimination of undesirable organisms. Bacterial ability to inhibit spoilage organisms has been exploited for its application as natural preservatives in various food formulations. LAB are the natural microflora of human intestine and has added advantage for its application in food due to their GRAS (Generally recognized as Safe) status. Bacteriocins from LAB are low molecular peptides which vary in their size, post-translation modifications, stability and mode of action (Amortegui et al. 2014). According to Nes and Holo (2000) as well as Drider et al. (2006), the bacteriocins have been classified into 3 groups based on presence or absence of post-translational modification: Class I-Lantibiotics containing lanthionine or β-methyl-lanthionine; Class II-heat stable unmodified bacteriocins; Class III-large heat liable bacteriocin. Class II bacteriocins are further subdivided into Class IIa (one peptide), Class IIb (two peptide), Class IIc (circular), Class IIId (unmodified, linear, non-pediocin like) and Class IIe (Microcin-like). Class IIa bacteriocins are < 10 kDa in size with 37–48 amino acids that inhibit growth of food spoilage organisms such as *Listeria monocytogenes*, *Bacillus cereus*, *Clostridium perfringens*, *Staphylococcus aureus* and *E. coli* (Rodrigues et al. 2005).

Bacteriocin produced by *Lactococcus lactis* subsp. lactis ie., Nisin is the only bacteriocin approved by US-FDA for commercial application in food products. However the application of nisin is limited in neutral and alkaline pH. Long-time preservation of foods by biopreservative process and inhibition of pathogenic microbes through natural means is therefore universal need in the present scenario. Considering this, the present work was carried out to optimize the
method for efficient extraction of antimicrobial peptide from LAB isolated from fermented foods. These LAB cultures including *Enterococcus durans* DB-1aa (MCC4231), *Enterococcus faecium* DB-b2-15b (MCC4263), *Lactiplantibacillus plantarum* (Basanym: *Lactobacillus plantarum* Cu2-PM7 (MCC4246), *Limosilactobacillus fermentum* (Basanym: *Lactobacillus fermentum* Cu3-PM8 (MCC4233) and *Lactobacillus fermentum* IB-PM15 have been previously characterized for their potential probiotic properties (Bindu and Lakshmidevi 2020). In the present study, we report the effect of physical and chemical parameter on the activity of partially purified antimicrobial peptide and PCR approach has been applied for characterization of antimicrobial peptide.

**Material And Methods**

**Bacterial cultures and growth conditions**

The selected probiotic cultures *Enterococcus durans* DB-1aa (MCC4231), *Enterococcus faecium* DB-b2-15b (MCC4263), *Lactiplantibacillus plantarum* Cu2-PM7 (MCC4246), *Lactobacillus fermentum* Cu3-PM8 (MCC4233) and *Lactobacillus fermentum* IB-PM15 were isolated from fermented food products, identified and deposited at Microbial Culture Collection Center, Pune (Bindu and Lakshimidevi, 2020). Recently, *Lactobacillus plantarum* has been classified as *Lactiplantibacillus plantarum* and *Lactobacillus fermentum* as *Limosilactobacillus fermentum* (Zheng et al. 2020). They were grown in deMann Rogosa Sharpe (MRS) medium at 37°C for 16-18 h. To study the properties of bacteriocin two indicator organisms ie., *Staphylococcus aureus* MTCC 96 and *Escherichia coli* MTCC 118 were used. The indicator bacteria were grown in Brain Heart Infusion (BHI) media at 37°C under constant shaking condition. The selected cultures were stored under 40% glycerol at -20°C until use.

**Antimicrobial activity of selected probiotic cultures**

Antimicrobial activity was tested by the agar well diffusion assay using neutralized and filter sterilized cell free supernatant of selected probiotic culture as described by Xie et al. (2009). Each experiment was carried out in triplicates and the mean diameter of the inhibition zone was measured in mm and recorded. Antibiotic chloramphenicol (1 mg/mL) was used as positive control. The inhibitory activity was further quantified by the two-fold dilution method. Briefly, cell suspension of pathogenic culture grown in BHI broth was adjusted to turbidity of 0.5 McFarland which is equivalent to 1-2 x 10⁵ CFU/mL. Antibacterial activity was quantified by testing the two fold serially diluted sample of bacteriocin by agar well diffusion assay and the results were expressed as AU/mL. Arbitrary unit (AU) is defined as the reciprocal value of the highest dilution at which the zone of inhibition is observed.

**Minimum Inhibitory Concentration (MIC)**

MIC was estimated by using different concentration of the sample (10-100 µg) in a 96 well ELISA plate. Freshly, grown pathogenic cultures at a final concentration of 10⁵ CFU/mL was inoculated into each well and the plate was incubated at 37°C for 24 h. Chloramphenicol (5-50 µg) was used as a positive control and sample with un-inoculated broth as negative control. After incubation absorbance was measured at 600nm. MIC was defined as the lowest protein concentration (in mg/mL) which inhibited the growth of pathogenic culture completely. All assays were performed in triplicate.

**Determination of proteinacious nature of antimicrobial peptide**

The proteinacious nature of antimicrobial peptide was checked by agar well diffusion assay. The neutralized and filter sterilized CFS was treated with proteinase K at a final concentration of 2 mg/mL for 30 min. The untreated CFS and the enzyme alone in buffer (pH 7.0) served as controls.
Probiotic growth and bacteriocin production

Growth kinetics and bacteriocin production was studied for a period of 5 days. The selected cultures were inoculated (1% v/v) in 250 ml MRS broth and incubated at 37°C without agitation. An aliquot of sample was drawn after every 12 h during growth and checked for bacterial growth and antimicrobial activity. Bacterial growth was determined by measuring cell density at 600nm. The antimicrobial activity was evaluated after filter sterilizing the neutralized CFS by well diffusion assay.

Extraction of the bacteriocin

Optimization of the extraction procedure

The CFS of the selected probiotic cultures was subjected to various extraction procedures to determine a suitable protocol for maximum recovery of bacteriocin. **Protocol 1:** CFS was mixed with ice-cold ethanol (1:1 v/v) and allowed for precipitation overnight at 4°C. The precipitate was air-dried, resuspended in phosphate buffer (pH 7.0) and checked for inhibitory activity. **Protocol 2:** CFS was blended with equal volumes of chloroform on a magnetic stirrer for 1 h. The mixture was left at room temperature undisturbed for phase separation. Bacteriocin in the interphase was collected carefully and the residual chloroform was evaporated under nitrogen and monitored for the inhibitory activity. **Protocol 3:** Fine powder of ammonium sulfate was added slowly to the CFS until a saturation level of 80% under constant stirring. The procedure was followed at 4°C under aseptic condition. The precipitate obtained was dialyzed against phosphate buffer (pH 7.0) with three changes of buffer and then analyzed for inhibitory activity. **Protocol 4:** Butanol (1:0.5 v/v) was added to CFS and vigorously mixed in a separating funnel. The mixture was left at room temperature for phase separation. The butanol layer was carefully collected and evaporated to dryness using rotary evaporator and checked for the activity.

Ion exchange chromatography

The dialyzed sample (60 mg protein) of each culture was loaded separately onto a DEAE cellulose column (18 X 3 cm) pre-equilibrated with sodium phosphate buffer (0.2 mM; pH 7.0). A linear gradient of 0.0-1.0 M NaCl in the same buffer was used to elute the protein fractions at a flow rate of 1 ml/min. Fractions (2 ml) was collected and checked for absorbance at 280 nm. The fractions showing the highest protein content were pooled, lyophilized and examined for antimicrobial activity.

Stability of partially purified bacteriocin

Effect of Temperature and pH

The effect of temperature was evaluated by incubating the partially purified bacteriocin for 30 min at different temperatures (30, 40, 50, 60, 70, 80, 90°C). The residual activity was checked by agar well diffusion assay after cooling to room temperature. The effect of pH was studied by incubating bacteriocin in different buffer with pH ranging from 3-9. The sample was incubated at 37°C for 30 min. The inhibitory activity was later checked after neutralization.

Effect of enzymes

The effect of enzymes such as trypsin, amylase and lipase on inhibitory activity was evaluated by treating the partially purified bacteriocin with each enzyme at a final concentration of 1mg/mL. Samples were incubated at 37°C for 30 min. After incubation, samples were heat treated at 90°C for 5 min to inactivate the enzymes and then the residual activity was determined as described earlier.
Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and overlay assay to detect antimicrobial peptide

Crude sample, dialyzed sample as well as column purified fractions of bacteriocin were subjected to SDS-PAGE (Laemmli 1970) along with low range protein marker ranging from 3.5-43 KDa. The antimicrobial activity in the partially purified sample was determined by overlay assay (Barboza-Corona et al. 2007). The sample containing 80 µg of protein was mixed with equal volume of non-reducing loading buffer and directly loaded in the SDS-PAGE gel without boiling. Following electrophoresis, the gel was cut vertically and immersed in fixing solution (25% isopropanol, 10% acetic acid) for 1 h and washed with double-distilled water with three changes after every 30 min. Later, the gel was sterilized by exposing to UV for 30 min and then aseptically placed in a sterile petriplate and overlaid with BHI agar pre-inoculated with 1% (equivalent to $10^8$ CFU/mL) overnight grown test organism (*Staphylococcus aureus* or *E. coli*). The petriplate was later incubated at 37°C for 24 h and observed for the presence of inhibition zone.

Detecting bacteriocin genes by polymerase chain reaction (PCR)

The presence of bacteriocin gene was identified in *L. plantarum* Cu2-PM7 using plantaricin A (F: GTA CAG TAC TAA TGG GAG; R: CTT ACG CCA ATC TAT ACG) and P1/P2 primers (F: AAAATATCTAATACTTTG; R: TAAAAAGATATTTGACCAAAA). The gene was amplified in 25 µl reaction mixture containing 2 µl of 1X PCR buffer, 1.5 µl of MgCl$_2$, 5 µl of dNTPs, 0.5 µl of each (Forward and reverse) primer, 2.5 U of *Taq* polymerase and 100 ng of genomic DNA. PCR conditions include denaturation at 95°C for 5 min followed by 35 cycles of denaturation at 95°C for 30 sec, annealing at 50°C for *pln* primer and 52°C for P1/P2 primer, for 45 sec and extension at 72°C for 1 min and final extension of 72°C for 10 min. The amplified PCR product was sequenced at GENESPY Research Services, Mysore. Sequence was matched with similar sequence from NCBI data base.

Bacteriocin peptide analysis

Bacteriocin peptide structure for the putative amino acid was predicted by using Geneious Prime® 2019.2.1 Software (Kearse et al. 2012). Using the software, secondary structure, antigenic regions, signal cleavage sites, transmembrane regions and protein domains prediction plugins was determined. Further the amino acid sequence data was analyzed. The peptide showing activity was later analyzed by using protein predict server (https://open.predictprotein.org/) followed by PDB database (Armstrong et al. 2020).

Statistical analysis

The experiments were conducted in triplicates and the data analysis was done using STATISTICA version 6 software (Statsoft Inc., Tulsa, USA). The significant different between the samples were analyzed by using ANOVA (analysis of variance), and the mean separation was accomplished by Duncan’s multiple range test.

Results

Minimum inhibitory concentration of bacteriocin

According to the results obtained, MIC was in the range of 2200 to 2400 µg against *S. aureus* and *E. coli*. Higher activity against *S. aureus* (228.6 AU/mg) and *E. coli* (114.3 AU/mg) was noticed in bacteriocin of *L. plantarum* Cu2-PM7, followed by *L. fermentum* Cu3-PM8 (139.1 and 69.6 AU/mg against *S. aureus* and *E. coli* respectively). *Enterococcus faecium* DB-b2-15b displayed lowest activity (38.1 and 38.1 AU/mg against *S. aureus* and *E. coli* respectively). Based on the data, three cultures viz., *Enterococcus durans* DB-1aa, *L. plantarum* Cu2-PM7 and *L. fermentum* CU3-PM8, showing higher activities were selected for further study.
Proteinaceous nature of antimicrobial peptide from probiotic culture

Proteinaceous nature of the neutralized CFS was confirmed by treating with proteinase K. According to the results obtained, the activity was not lost after neutralization but was significantly reduced on treating with proteinase K. This confirms that the inhibitory activity was not due to acidity but was due to proteinaceous compound.

Growth kinetics and bacteriocin production

The selected cultures entered the late exponential phase in 24 h and remained constant in stationary phase upto 5 days. The OD (optical density) at 600nm is presented in Table 1. Inhibition zone in the range of 12-16 mm dia was observed upto 3 days against \textit{S. aureus}. On day 4\textsuperscript{th} and 5\textsuperscript{th}, no activity was observed. MIC against \textit{S. aureus} was 2400 µg for all the tested bacteriocins after 24 h of growth (Table 1). However on the 5\textsuperscript{th} day MIC was 5200, 5000 and 3800 µg for bacteriocin from DB-1aa, Cu2-PM7 and Cu3-PM8 respectively. Activity was highest at 24\textsuperscript{th} h, later the activity gradually decreased. According to the data obtained, maximum activity (266.02 AU/mg) was noticed in \textit{L. plantarum} Cu2-PM7. The bacteriocin of Cu2-PM7 and Cu3-PM8 showed inhibitory activity against \textit{E. coli} upto 5 days, but DB-1aa displayed zone of inhibition upto 3 days (Table 1). With increase in incubation days, a gradual reduction in the size of inhibition zone was observed. The MIC was 2400 µg on the 1\textsuperscript{st} day but displayed 5600, 5200 and 3800 µg on the 5\textsuperscript{th} day. The activity was maximum (133.01 AU/mg) with \textit{L. plantarum} Cu2-PM7 after 24 h of incubation.

\textbf{Table 1.} Antimicrobial activity of selected cultures during growth
| Culture | Incubation period (hours) | Optical density at 600 nm | Inhibition zone (mm in dia) | MIC (µg) | Activity (AU/mg protein) |
|---------|--------------------------|---------------------------|-----------------------------|----------|--------------------------|
|         |                          |                           | \( S. aureus \) | \( E. coli \) | \( S. aureus \) | \( E. coli \) | \( S. aureus \) | \( E. coli \) |

Values are average of two experiments performed individually (Mean ± SD). '-' indicate no activity.

**Extraction of bacteriocin from selected cultures**

Bacteriocin from selected cultures was extraction by four different techniques to determine the best method for extraction. Ethanol precipitation did not show any inhibitory activity against \( S. aureus \), however against \( E. coli \) lesser zone of inhibition (10 mm dia) was observed (Fig. S1). Comparatively, sample after ammonium sulphate precipitation-dialysis displayed maximum zone of inhibition than chloroform extract and butanol extract (Table 2). MIC against \( S. aureus \) was in the range of 1900 – 2200 µg and 2000 – 2300 µg against \( E. coli \). According to the data obtained, ammonium sulphate precipitation-dialysis was found to be the best method for extraction which showed an activity of...
155.27, 212.72 and 179.80 AU/mg with *E. durans* DB-1aa, *L. plantarum* Cu2-PM7 and *L. fermentum* Cu3-PM8 respectively. Hence, further step of purification was carried out after ammonium sulphate precipitation and dialysis.

Table 2. MIC and activity of bacteriocin extracted with various methods

| Culture            | Extraction method | Inhibition zone (mm in dia) | MIC (µg) | Activity (AU/ mg protein) |
|--------------------|-------------------|----------------------------|----------|---------------------------|
|                    |                   |                            | *S. aureus* | *E. coli* | *S. aureus* | *E. coli* |          |
| *E. durans* DB-1aa | 1                 | -                          | 10 ± 0.01 | 6200 ± 0.12 | 2800 ± 0.11 | -         | 60.39 ± 0.11 |
|                    |                   | 2                          | 12 ± 0.01 | 2400 ± 0.11 | 2300 ± 0.23 | 34.50 ± 0.00 | 69.00 ± 0.02 |
|                    |                   | 3                          | -         | 6800 ± 0.21 | 2200 ± 0.12 | -         | 15.79 ± 0.00 |
|                    |                   | 4                          | 15 ± 0.01 | 2200 ± 0.11 | 2300 ± 0.11 | 155.27 ± 0.02 | 155.27 ± 0.15 |

Purification of bacteriocin by ion exchange chromatography

An increase in the inhibition zone size was observed in the dialyzed sample (Fig. S2). Further, ion-exchange chromatography was carried out using DEAE cellulose column as a next step of bacteriocin purification. As shown in Fig. 1, the sample from each culture was separated into three fractions. Protein fraction of DB-1aa was eluted between 0.06 – 0.2 M (fraction 1), 0.24 – 0.4 M (fraction 2) and 0.4 – 1.0 M (fraction 3). In case of Cu2-PM7 elute from 0.06-0.36 M, 0.45 – 0.6 M and 0.63 – 1.0 M was considered as fraction 1, 2 and 3 respectively. Similarly, in Cu3-PM8 fractions from 0.06 – 0.33 M, 0.48 – 0.6 M and 0.63 – 1.0 M was selected. The elute of each peak was collected and concentrated by lyophilization. The antimicrobial activity assay confirmed the zone of inhibition in fraction 1 and 2 of all the three culture against *S. aureus* and *E. coli* (Fig. 1). The data obtained revealed highest inhibition zone of 20 and
18 mm against \textit{S. aureus} and \textit{E. coli} by fraction-1 of \textit{L. plantarum} Cu2-PM7 with MIC of 1200 and 1300 µg respectively. The details of purification data are summarized in Table 3. The final yield of bacteriocin obtained after ion-exchange chromatography was 0.4, 0.5 and 0.4% for DB-1aa, Cu2-PM7 and Cu3-PM8 respectively against \textit{S. aureus}. Correspondingly, a final yield of 0.35, 0.76 and 0.68% was found against \textit{E. coli}.

**Table 3.** Summary of bacteriocin purification from selected cultures

| Isolate        | Purification step | Volume (ml) | Activity (AU/ml) | Total activity (AU) | Yield (%) | Protein (mg/ml) | Total protein (mg) | Specific activity (AU/mg) | Purification factor |

**Effect of temperature and pH on bacteriocin activity**

According to the results obtained, the bacteriocins from all the tested cultures were active in all the temperature tested (Table 4). However, bacteriocin from Cu3-PM8 showed slight reduction in the activity at higher temperature. Further, the pH stability of bacteriocin purified from selected probiotic culture was analyzed at various pH ranging from pH 3-10 (Table 5). The data revealed that the inhibitory activity was more active at acidic pH (inhibition zone ranging from 14-20 mm dia). As the pH approached neutral, the activity reduced and was completely inhibited at alkaline pH.
Table 4. Stability of bacteriocin at different temperature

| Temperature (°C) | Inhibitory activity against *Staphylococcus aureus* | Inhibition zone (mm dia) | Activity (AU/mg protein) |

Values are average of two experiments performed individually (Mean ± SD). ‘-’ indicate no activity.

### Effect of enzymes on bacteriocin activity

According to the data obtained, the inhibitory activity was retained in all the three bacteriocin after treating with α-amylase and lipase. However, in presence of trypsin 55, 34 and 43% activity was retained.

### SDS-PAGE analysis of antimicrobial compound

Molecular weight of the antimicrobial compound from selected probiotic culture (Cu2-PM7 and Cu3-PM8) was determined by SDS-PAGE (Fig. 2). Accordingly, apparent molecular weight of both antimicrobial peptide was found to be 3.5 kDa. Inhibition zone corresponding to their respective protein bands was developed on performing activity assay by overlaying indicator strain (Fig. 2).

### Detecting plantaricin gene by PCR

PCR analysis of plantaricin gene was carried out in Cu2-PM7 using plnA and P1/P4 primer. A good amplification of 450 bp was observed with plnA F/R primer. On the other hand, no amplification was detected with P1/P4 primer. The control
culture, *E. durans* DB-1aa did not show any amplification in presence of any of the tested primer. Further, the PCR product was sequenced and the obtained sequence was subjected to BLASTn search in NCBI database and aligned with hit sequences. The results indicated 100% homology with plantaricin *plnA* sequence of *Lactobacillus plantarum* strain EG.LP 18.7 (MN172266.1) (Fig. 3).

The nucleotide sequence was translated to amino acid sequence and checked for homology with BLAST search. Translated partial amino acid sequence of *plnA* gene of Cu2-PM7 displayed 48 amino acid sequence which had 100% similarity with plantaricin A of *L. plantarum* (WP_0036419). Fig. 4 represents the similarity of plnA-PM7 amino acid sequence with related sequence from NCBI data base.

**Bacteriocin peptide analysis**

The translation of *plnA* gene sequence gave 138 amino acids which were studied for its structural and functional properties. It was observed that the partial sequence of Cu2-PM7 possessed isoelectric point of 10.82 and 48.6% hydrophobicity. The sequence possessed 7 β sheets, 6 α sheets, 6 predicted coils and 9 predicted turns and functions on cytoplasm. One topological domain, which encodes the bacteriocin-like sequence (MKQLSNKEMQKIVGG) was noticed with a GG cleavage motif at their N-terminal region. Further, four antigenic regions were detected in the acquired sequence which were located at sites 6-26, 28-46, 65-77 and 122-135 with sequence read LSILRCAVNILSSKYVQSNQ, LFKIVTLTIFIKYILAEFLH, THYPKSEVIIMKI and WLIYITVQIFRIGDGV, respectively. A 3D structure for the bacteriocin-like peptide was inferred from Phyre2 and indicated alpha and beta sheet structure fragments (Fig. 5). The protein-predict database showed maximum homology towards bacteriocin plantaricin A of *Lactobacillus plantarum* WCFS1, with the ID P80214. Hence, it can be perceived that the amino acid sequence stretch of our native isolate Cu2-PM7 possessed “KSSAYSLQMGATAIKQVKKLFKKGWG” peptide showing a molecular weight of 3 kDa.

**Discussion**

The increasing awareness among consumers about the side effect caused by some of the chemically synthesized artificial preservatives motivated the study to characterize bacteriocins from probiotic culture that can positively enhance the characteristic taste, wellness and safety of the product. The present probiotic cultures were isolated from fermented food and were shown to exhibit potential probiotic properties (Bindu and Lakshmidevi 2020). The selected cultures showed acid and bile tolerance, gastrointestinal survival, good adhesion property and also possible functional properties including antioxidant activity and industrially important enzyme production. The selected probiotic cultures displayed large spectrum of inhibitory activity against pathogenic and spoilage bacteria including *Micrococcus luteus*, *Staphylococcus aureus*, *Listeria monocytogenes*, *Bacillus subtilis*, *Klebsiella* sp., *E. coli*, *Pseudomonas aeruginosa*, *Yersinia enterocolitica*, *Salmonella* sp, and *Enterobacter aeroginosa*. In the view of their probiotic candidacy, the antimicrobial peptides from these cultures were characterized in the present investigation.

Each indigenous strain exhibited a variable titer and pattern of inhibition against selected pathogens. On the context of inhibitory activity of all the selected probiotic culture, studies were continued with *Staphylococcus aureus* and *E. coli* as indicator organisms because of their know pathogenicity (Croxen et al. 2013; Kadariya et al. 2014). According to the results obtained, inhibitory activity against *S. aureus* and *E. coli* was in the following increasing order: DB-b2-15b < DB-1aa < IB-PM15 < Cu3-PM8 < Cu2-PM7. Further studies were therefore continued with DB-1aa, Cu2-PM7 and Cu3-PM8.

Generally, bacteriocins are proteinaceous compound produced by certain bacteria to hinder the growth of similar or closely related strains. Hence, to confirm the proteinaceous nature of the antimicrobial peptide, the CFS of the probiotic culture was treated with proteinase K. The enzyme “proteinase K” is a serine protease responsible for degradation of protein. Accordingly, the CFS treated with the enzyme was unable to inhibit the pathogen indicating the denaturation of
proteinaceous compound present in CFS which is responsible for antimicrobial activity. As these probiotic cultures are lactic acid bacteria, the action of lactic acid was initially nullified by adjusting the pH of CFS to 7.0 using 1N NaOH.

Growth kinetic studies reveal that the selected probiotic cultures enter late exponential phase within 24 h and in stationary phase for the next 5 consecutive days tested. With respect to *S. aureus*, inhibitory activity was observed up to 5 days. Maximum activity was determined in Cu2-PM7 after 24 h against *S. aureus* (266.02 AU/mg) and *E. coli* (133.01 AU/mg). Bello et al. (2018) have shown bacteriocins from *L. plantarum* Z1116 with 500 AU/mL at the 9th hour. The inhibitory activity gradually increased and reached 12,000 AU/mL after 18th hour of growth in MRS broth at 30°C where high cell density (6.8 OD600 nm) was recorded. In the same study, *Enterococcus faecium* AU02 and *Leuconostoc lactis* PKT0003 showed highest level of bacteriocins activity (3200 AU/mL and 1600 AU/mL) at 21st and 24th h of growth where highest (2.8 and 2.75 OD600 nm) cell density was recorded. Milioni et al. (2015) compared bacteriocin production of *Lactobacillus plantarum* LpU4 grown in MRS broth and MRS broth buffered with citrate at 25°C. In normal MRS broth, the antimicrobial activity was initiated at the beginning of the exponential phase reaching a maximum (1,600 AU ml⁻¹) at late exponential phase (24 h) and remained constant during the stationary phase up to 48 h. In buffered MRS broth, the activity increased from 100 to 3,200 AU/mL during the exponential growth phase and was stable until 48 h. According to Barbosa et al. (2013), the optimum condition for bacteriocins production (1600 AU/mL) was 25°C and 20 h of incubation time.

As a first step of purification, various extraction techniques were evaluated for optimum yield. Accordingly, ammonium sulphate precipitation-dialysis technique was found to be more favorable compared to chloroform extraction, ethanol precipitation or butanol extraction. Likewise, Song et al. (2014) used ammonium sulphate precipitation as first step of bacteriocin purification from *Lactobacillus plantarum* ZJ5 and reported an activity of 317.14 AU/mg. Earlier studies have reported most of the bacteriocin to contain positively charged amino acid residues with hydrophobic features (Barbosa et al. 2013). Hence, ion exchange chromatography is the commonly applied strategy which has been successfully used for purification of bacteriocin. In the present investigation, therefore ion exchange chromatography has been applied for purification of bacteriocin. According to the data obtained, increase in the purification fold of 2.75, 1.87 and 1.92 was noticed with respect to DB-1aa, Cu2-PM7 and Cu3-PM8 against *S. aureus*. With regard to *E. coli*, purification fold of 2.4, 2.84 and 3.26 was perceived. Song et al. (2014) obtained 1.7% yield after RP-HPLC purification of plantaricin from *Lactobacillus plantarum* ZJ5. In another study, RP-HPLC purified bacteriocin from *Lactobacillus sakei* showed 74949.6 AU/mg activity with 32% yield and 40.05 fold increase in the activity as tested against *Enterococcus faecalis* J2-2 (Barbosa et al. 2013).

Stability study of partially purified bacteriocin at different temperature revealed that the compound is resistant upto 90°C. Earlier literature also support the data that the bacteriocin from *Lactobacillus plantarum* are heat stable (Todorov 2009). Earlier studies have shown bacteriocins stable upto 60°C (Nowroozi et al. 2004; Sowani and Thorat 2012; Martinez et al. 2013), however at higher temperature above 80°C, a significant reduction in the antimicrobial activity has been reported. In the present study, the tested bacteriocin was stable even at 90°C. Similar results of temperature stability have also been reported for bacteriocins LPBM10, bacST202Ch, bacST216Ch, enterocin AS-48, and plantaricin OL15 (Mourad et al. 2005; Zapata et al. 2009; Todorov et al. 2010). Barbosa et al. (2013) have reported a anti-listerial bacteriocin from *Lactobacillus sakei* MBSa1 which is stable even at 121°C for 15 min. Lactocin NK24 from *Lactococcus lactis* display 87% reduction in the inhibitory activity at 100°C and gets completely inactivated after steam sterilization (Lee and Paik 2001). Ferchichi et al. (2001) reports almost 25 and 8.3% reduction in the antimicrobial activity of lactocin MMFII, from *Lactococcus lactis* at 80 and 110°C respectively. Bacteriocin tolerance to higher temperature would be an essential property for their application in thermally processed food. In this regards, the three bacteriocins purified from the selected probiotic culture indicate their possible application as biopreservative agents.
The data on pH stability showed that the bacteriocins from the selected probiotic cultures are active at acidic pH. The activity, however significantly reduced at neutral pH and alkaline pH. Similarly, previous studies have reported that bacteriocins are highly stable at acidic pH but get inactivated at alkaline pH (Todorov et al. 2010; Hernandez et al. 2005). The bacteriocin with anti-listerial activity from *Lactobacillus sakei* MBSa1 was found stable at pH 2 to 6, but lost part of the activity at pH 8 and 10 (Barbosa et al. 2013). Todorov and Dicks (2005) reports almost 50% reduction in antimicrobial activity of bacteriocins ST28MS and ST26MS from *L. plantarum* at pH values lower than 4.0. Zapata et al. (2009) observed a marked reduction in the inhibitory activity of bacteriocin from *L. plantarum* LPBM10 with increase in pH value higher than 5. However, several studies have shown bacteriocins (ST23LD, ST341LD, bacST202Ch, bacST216Ch, and ST71KS) from *Lactobacillus plantarum*, which are stable between pH 2.0 and 12.0 (Todorov and Dicks 2005; Todorov et al. 2010; Martinez et al. 2013).

The effect of digestive enzyme such as trypsin, lipase and α-amylase on the bacteriocin activity was analyzed and the residual activity was determined. According to the data obtained, bacteriocin of all the three selected cultures were stable in presence of lipase and α-amylase indicating the lack of carbohydrate or lipid moiety. However in presence of trypsin partial inactivation was observed.

SDS-PAGE analysis and over-lay assay revealed a molecular weight of bacteriocin to be 3.5 kDa in both Cu2-PM7 and Cu3-PM8. Earlier reports confirms that the bacteriocin produced by *Lactobacillus* spp have molecular weight lower than 10 kDa (Cintas et al. 2001; Cotter et al. 2013) as well as morethan 14 kDa (Todorov et al. 2004; Todorov and Dicks 2006). In the similar line, bacteriocin-producing lactic acid bacteria (LAB) were isolated from fermented *Parkia biglobosa* seeds and were identified as *Lactobacillus plantarum* Z1116, *Enterococcus faecium* AU02 and *Leuconostoc lactis* PKT0003. They produced bacteriocins of size 3.2 kDa, 10 kDa and 10 kDa, respectively (Bello et al. 2018). Tome et al. (2009) partially purified bacteriocins from nine LAB isolated from vacuum-packaged cold-smoked salmon (CSS) which was active against *Listeria monocytogenes, E. faecalis, E. faecium*, and *Staphylococcus aureus*. The molecular size of bacteriocins ranged from 2.8 to 4.5 kDa. Messi et al. (2001) isolated LAB from italian sausages that produced plantaricin with a molecular weight of 4.5 kDa which showed broad spectrum activity against food pathogens including *S. aureus, L. monocytogenes* and *A. hydrophila*. *Lactobacillus plantarum* SA6 isolated from fermented sausage produced a plantaricin peptide with molecular mass of 3.4 kDa. Amortegui et al. (2014) isolated *Lactobacillus plantarum* from ensiled corn and purified the bacteriocin by ammonium sulphate precipitation (70%) and dialysis. They reported 5 and 10 kDa protein with antagonistic activity against *Listeria innocua, Listeria monocytogenes*, and *Enterococcus faecalis*. Milioni et al. (2015) characterized 4.8 kDa plantaricin from *Lactobacillus plantarum* which was isolated from sheep-milk cheese. Plantaricin IIA-1A5 active against *Staphylococcus aureus* was purified which showed single band on SDS-PAGE with apparent molecular weight of 6.4 kDa (Arief et al. 2015).

In an attempt to determine the plantaricin gene in the selected probiotic strain *L. plantarum* Cu2-PM7, PCR was carried out using specific primers. As expected, an amplified product of 450 bp was found with plnA F/R primer in *L. plantarum* Cu2-PM7. However no amplification was observed with P1/P4 primer. *E. durans* DB-1aa genomic DNA was used as control where no amplification was observed. The results indicate that the present strain *L. plantarum* Cu2-PM7 harbors the plantaricin A gene. BLASTn analysis of the sequence showed highest similarity with *Lactobacillus plantarum* strain EG.LP 18.7 (MN172266.1). Similarly, Remiger et al. (1996) reported the binding position of primer plnA5p and S7, outside the structural gene of plantaricin A, which allowed the amplification of 450 bp DNA fragment in *L. plantarum* strains. Earlier studies on comparative genome analysis have reported significant variation in the plantaricin operon in the gene cluster of *Lactobacillus plantarum* strains (Maldonado et al. 2004; Rojo-Bezares et al. 2008). Ben Omar et al. (2008) isolated *Lactobacillus* strains from poto-poto, a congolese fermented maize product and observed significant variation in the number of genes between the strains. The operon of *Pln* locus of plantaricin encoding genes is either
simple or complex (Diep et al. 2009). Devi and Halami (2019) reported different plantaricin types based on the presence or absence of pln genes.

The translated protein sequence of plnA gene of L. plantarum Cu2-PM7 showed 100% homology with plantaricin A of L. plantarum (WP 0036419). As described by Diep et al. (1996), plantaricin system in L. plantarum is organized into five operon. (1) plnABCD: The regulatory operon encoding bacteriocin –like peptide (plnA), a histidine protein kinase (plnB) and two cytoplasmic response regulators (pln C and pln D). (2) pln GHSTUV: operon associated with transport (3) plnJKLR (4) plnMNOP (5) plnEF1 : related to plantaricin production and immunity. Plantaricin A is a single peptide bacteriocin without post translational modification (Diep et al. 2009). They are included in subclass Iic. L. plantarum CTC305 originally isolated from fermented sausage and L. plantarum CII isolated from cucumber fermentation were shown to share the plantaricin A encoding gene plnA (Diep et al. 1994).

In the current analysis, bioinformatic tools were used to characterize the peptide nature. Geneious Prime software predicted the protein domain MKQLSNKEMQKIVGG which codes for bacteriocin like protein. On further analysis of this motif, it was observed that this motif is responsible for the entry of the bacteriocin peptide, with a GG cleavage motif at their N-terminal region. The sequence also confirmed the presence of four antigenic regions at sites 6–26, 28–46, 65–77 and 122–135.

It is well known that bacteriocin encoding genes are found along with immunity proteins and other accessory proteins which are arranged in an operon cluster (Noda et al. 2018). In continuation, the bacteriocin-like signal sequence was targeted to predict the peptide which shows activity. The bacteriocin sequence showed maximum homology towards plantaricin A of Lactobacillus plantarum WCFS1, with the ID P80214. Further, the peptide with bacteriocin plantaricin-A had a PDB ID of IYTR, this ID possessed a sequence of 26 amino acids with 2.99 kDa molecular weight (Fig. 5) (Kristiansen et al. 2005). Hence, it can be perceived that the amino acid sequence stretch of our native isolate Cu2-PM7 possessed “KSSAYSLQMGATAIKQVKKLFKKWGW” peptide which is responsible for antimicrobial activity.

Conclusions

The overall data support the potential inhibitory activity of bacteriocin against Staphylococcus aureus and E. coli. On the basis of two important observations, i.e. proteinaceous nature of antagonistic substances and their heat stability, they can be considered as bacteriocins. The peptide analysis reveals the plantaricin A type bacteriocin present in the native probiotic culture, L. plantarum Cu2-PM7 isolated from fermented foods. The data obtained enhances our knowledge on the biocontrol of undesirable bacteria that could be used as an alternative therapy for treating infectious disease.

Declarations

Acknowledgements: This work was support by University Grants Commission for the award of NFSC research fellowship.

Ethical Approval: This article does not contain any studies with human or animals

Consent for publication: This manuscript does not contain any individual person ‘s data.

Availability of data and material: Data sharing not applicable to this article as no datasets were generated or analyzed during the current study

Conflict of Interest: Dr. Lakshmidevi and Mrs. Amrutha Bindu declare that they have no conflict of interest
Funding: This work was support by University Grants Commission for the award of NFSC research fellowship.

Authors contribution: Lakshmidevi and Amrutha Bindu conceived and designed the experiment. Amrutha Bindu conducted experiment and wrote the manuscript. Both the authors read and approved the manuscript for submission.

Authors’ information: Dr. Lakshmidevi N is professor from Department of Microbiology, University of Mysore. She is expertise in bacterial metabolites, immunology and peptide analysis. Mrs. Amrutha Bindu is a research scholar doing her PhD in the same department.

Informed consent: Informed consent was obtained from both the participants included in the study.

**Figures**

Figure 1
Elution profile of protein by ion-exchange chromatography. (A) E. durans DB-1aa; (B) L. plantarum Cu2-PM7; (C) L. fermentum Cu3-PM8. Inhibitory activity of protein fractions (1, 2 and 3) eluted by ion-exchange chromatography against S. aureus and E. coli. A = Antibiotic chloramphenicol (1 mg/ml) was used as positive control

**Figure 2**

SDS-PAGE analysis of antimicrobial peptide (A) Cu2-PM7; (B) Cu3-PM8. (1) Crude; (2) Ammonium sulphate and dialyzed sample; (3) Column fraction; (M) Protein marker. Circle indicate inhibition zone in overlay plates
Figure 3

Plantaricin gene characterization (A) phylogenetic similarity between plnA-PM7 and related sequence from NCBI database (B) Sequences aligned (dark shade indicate maximum homology).
Figure 4

Plantaricin peptide analysis (A) Amino acid sequence similarity between plnA-PM7 and related sequence from NCBI database (B) Amino acid sequence aligned (dark shade represents maximum homology)

Figure 5
Structure and functional analysis of Cu2-PM7 bacteriocin like peptide (A) Sequence analysis (B) 3D structure (C) Properties of active fraction
