INTRODUCTION

*Physalis angulata* L., popularly known as Kuzhi in Chinese, has been prescribed for centuries for treatments of a variety of diseases, such as fever, malaria, liver disorders, and diabetes (Abe et al., 2006; Damu et al., 2007; Reyes-Reyes et al., 2013). Currently, crude extracts of *P. angulata* are reported to show antinociceptive (Choi and Hwang, 2003), anti-breast cancer (Hsieh et al., 2006), and anti-inflammatory activities (Bastos et al., 2008). The medicinal effects of *P. angulata* are mainly due to the presence of polyoxygenated steroids with an ergosterol backbone possessing a C-22, 26-lactone (Damu et al., 2007). Concerning modifications of their side chains, especially the cleavage of C13-C14 bond and the formation of a 16,24-carbocyclic bond, these steroid lactones can be classified as physalin and withanolide (Figure 1A; Huang et al., 2020; Xia et al., 2021). Of the *P. angulata* physalin, physalin B has received the most interest due to its diversely pharmacological activities.
For example, it has been reported that physalin B showed significant activities in inhibition of several cancers, including breast (Wang et al., 2018) and prostate (Han et al., 2011) tumors.

Despite the pharmacological importance of physalin, the pathways leading to their biosyntheses are largely unknown. Physalin or withanolide are derived from a 24-alkyl sterol, and accordingly 24-methylenecholesterol is believed to be an intermediate in their biosynthetic steps (Pal et al., 2019). The 24-methylenecholesterol represents a branching point leading to biosynthesis of brassinolide via campesterol (i.e., 24-methyl cholesterol), catalyzed by sterol side chain reductase 1 (SSR1), or withanolide via 24-methylcholesterol that is catalyzed by a sterol Δ24-isomerase (24ISO; Figure 1B; Knoch et al., 2018). The C24-C25 double bond in the intermediate 24-methylcholesterol (Figure 1B) is retained in accumulated withanolide (see the structure of a representative withanolide, withanolide C, in Figure 1A). On the contrary, the C24-C25 double bond is not present in physalin-type compounds (see the structure of a representative physalin, physalin B, in Figure 1A). Probably because of this, Wang et al. have proposed an intermediacy role of campesterol (see its structure in Figure 1B) in physalin biosynthesis (Zhan et al., 2018). However, when taking analogous structures of physalin and withanolide (Figure 1A) into consideration, this study contemplated that physalin may be derived from withanolide, and this C24-C25 double bond may be rearranged later in the conversion stage from withanolide to physalin. If this hypothesis is followed, the enzyme 24ISO (Figure 1B) must involve in physalin biosynthesis.

To investigate whether 24ISO is involved in physalin biosynthesis in vivo, here, we reported the cDNA cloning and functional analysis of a 24ISO gene, designated as Pa24ISO, from P. angulata. The biochemical activity of Pa24ISO was confirmed by heterologous expression in yeast. To further study its function in vivo, we are the first to develop a virus-induced gene silencing (VIGS) system for P. angulata. A direct role of Pa24ISO in physalin biosynthesis was discovered by silencing it in P. angulata through the VIGS approach. The Pa24ISO expression pattern also matched well with the accumulation of physalin B across different tissues.

**MATERIALS AND METHODS**

**Plant Materials**

Seeds of P. angulata were harvested from the Langxi county, Anhui province of China in August 2018. The identity of the plant material was confirmed by Dr. Xiaodong Li at the Wuhan Botanical Garden, Chinese Academy of Science. P. angulata plants were grown in a growth chamber at 22°C under long-day (16 h of light/8 h of darkness) conditions. Transgenic plants were grown at an open field, located at the campus of Shanghai University, China.

**Identification of Pa24ISO and Phylogenetic Analysis**

Using Ws24ISO (GenBank accession: AXG64144.1) as a query, a BLASTP analysis of our recently constructed P. angulata calyx-derived transcriptome (unpublished data) revealed the candidate Pa24ISO. Deduced amino acid sequences of Pa24ISO were aligned with the previously reported sequences of SSR1 and SSR2 (see their accession numbers in Supplementary Table 2) using ClustalW software embedded in MEGA7. A maximum likelihood tree was inferred in MEGA7 using bootstrap method with 1000 replications. Arabidopsis DWF1 was used to root the tree.
Establishment of a VIGS System for Physalis angulata and Generation of the Pa24ISO-Silenced Plants

The PDS (phytoene desaturase) gene, associated with the photobleaching phenotype, was used as a reporter gene to test the TRV-based VIGS system for P. angulata. The cDNA sequence of PaPDS, as shown in Supplementary Figure 1, was obtained from the P. angulata calyx transcriptome, and a 382bp-fragment of PaPDS was amplified from the P. angulata calyx cDNA. For silencing the Pa24ISO gene expression, a 297bp-region, which is specific to Pa24ISO, but is not conserved in the putative PaSSR1 and PaSSR2, was selected (see their sequences in Supplementary Figures 2–4). All the primers used in this study are shown in Supplementary Table 1 in the Supporting Information. The TRV system constitutes the pTRV1 and pTRV2 vectors, which represent two RNA strands of the TRV virus system. The amplified DNA fragments of targeted genes were cloned into the pTRV2 vector via restriction cloning sites, yielding the pTRV2-PaPDS and pTRV2-Pa24ISO plasmids.

For down-regulating the expression of PaPDS gene, the pTRV2 (empty vector), pTRV1, and pTRV2-PaPDS were separately transformed into the Agrobacterium GV3101. The transgenic Agrobacterium strains were inoculated into LB medium supplemented with kanamycin at 50μg/ml and rifampicin at 50μg/ml at 28°C, and used for infection when OD_{600} value of the Agrobacterium culture reaching 1.5. For infiltration of the P. angulata leaf, the TRV1-contained Agrobacterium culture was mixed at a 1:1 ratio with the cultures containing pTRV2-PaPDS, as well as the empty vector pTRV2 as a control. To improve the infection efficiency, 0.01% Silwet L-77 was added into the Agrobacterium mixer. Four to six-leaf-stage plants were selected for the infection. The infected plants were kept in darkness for 48h, and then grown at an open field at the campus of the Shanghai University, China. The phenotype was then evaluated after 6–8 weeks. The same procedure was applied to generate the Pa24ISO-silenced plants.

Quantitative Real-Time PCR Analysis

The Real-time PCR (qRT-PCR) was performed on Bio-Rad CFX96™ Real-Time PCR instrument (Bio-Rad, Inc., United States) using TransStart Green qPCR SuperMix (Transgen). Primers used in this article are listed in Supplementary Table 1. The PCR program consisted of an initial step of 94°C for 30s; 40cycles of 94°C for 5s and 60°C for 30s; and then a dissociation stage of 95°C for 10s, 65°C for 5s and 95°C for 5s. Each gene was assessed at least three biological replicates. The relative expression levels of the genes were calculated by the 2^{ΔΔCt} method.

Extraction of Physalin and UPLC–MS Analysis

Every 1 g of powdered P. angulata samples was extracted with 1.7 ml of 90% methanol by sonication for 30 min, and this procedure was repeated three times. To normalize variations between the different extractions, isofraxidin at a final concentration of 1.5μg/ml was added as an internal standard. The solvent extracts were collected by centrifugation at 12,000 g for 20 min, and passed through a membrane filter (0.22 mm) prior to the Ultra Performance Liquid Chromatography–Tandem Mass Spectrometry (UPLC–MS) analysis.

One microliter of the extracts was injected for the UPLC-MS analysis. LC-MS analysis was performed using a Q-Exactive Focus mass spectrometer, coupled with a VanquishTM UPLC system (Thermo Fisher Scientific, Bremen, Germany) and a HESI source (Thermo Fisher Scientific). The column (100 mm×2.1 mm, 1.8μm) was used to separate the sample, the column temperature was 40°C, and the flow rate was 0.35 ml/min. The mobile phases contain 0.1% formic acid (solvent A) and acetonitrile (solvent B), and the solvent gradient is set as follows: 15% solution B (0.0–1.0 min), 20–25% solution B (2.0–13.0 min), 25–40% solution B (13.0–25.0 min), 40–90% solution B (25–26 min), 90% solution B (26.0–29.0 min), and 15% solution B (29.0–33.0 min). The MS detection was performed with a full MS mode. The parameters of the mass spectrometers were as follows: spray voltage, 3.2 kV; source capillary temperature, 320°C; sheath gas flow rate (nitrogen), 25-ml/min; Aux gas flow rate (nitrogen), 8 ml/min; Aux gas heater temperature, 30°C, Scan range 150.0–700.0 m/z.

Heterologous Expression of Pa24ISO in Yeast

To optimize the expression of Pa24ISO in yeast, the full-length sequences of Pa24ISO were manually synthesized following the S. cerevisiae codon usage preference (see the optimized Pa24ISO cDNA sequence in Supplementary Figure 5), and inserted into a yeast expression vector pESC-HIS3 at BamHI/Sall sites, yielding the construct pESC-HIS3-Pa24ISO. The plasmid pESC-HIS3-Pa24ISO was transferred into a 24-methylenecholesterol-producing yeast strain YS11, which was recently developed by our group (Yang et al., 2021). As a negative control, the empty vector pESC-HIS3 was also transformed. The transgenic yeast colonies were selected on selection medium omitting histidine. Expression of the transformed gene was induced by 2% galactose.

To extract sterols from the transformed yeast cultures, yeast cells were pelleted from 2 ml of the yeast culture, broken with acid-washed glass beads, and extracted with 500μl of 20% potassium hydrate in methanol (w/v) at 90°C for 2 h. When the saponified sample was cooled down, it was extracted with 2 ml of hexane for 30 min, and then was repeatedly extracted two times with another 1 ml hexane. The pooled hexane extracts were then dried in a vacuum freeze drier, and derivatized in 50 μl of N,O-bis(trimethylsilyl)-trifluoroacetamide (BSTFA) at 60°C for at least 1 h for sterol analysis by GC–MS.

Phytosterol Extraction and Analysis by GC–MS

Phytosterol was extracted as described previously (Knoch et al., 2018) with small modifications. One gram of powered sample was extracted with 3 ml chloroform/methanol (2:1, v/v) at 75°C for 1.5 h. After removing the solvent, the dried residue was saponified in 1 ml 10% (w/v) KOH in MeOH for 1 h at 80°C. When the samples were cooled to room temperature, 500 μl of H2O and 500 μl of hexane were added, and extracted with shaking for 30 min. After centrifugation, the upper clear hexane extract was collected. The lower aqueous phase was then extracted
twice with an additional 500μl of hexane. The pooled hexane extracts were evaporated to dryness, and treated with 50μl of the silylating reagent BSTFA [bis(trimethylsilyl) trifluoroacetamide]. The trimethylsilyl esters were dissolved in 80μl of hexane, and a 1-μl sample was used for GC–MS analysis. For quantifying the sterol content, 40μg of cholesterol (YuanYe, Shanghai, China) was added to each sample as an internal standard. GC–MS analysis was performed using a Shimadzu 2010 Plus GC machine coupled to a QP2020 Ultra mass spectrometer (Shimadzu Corporation, Canby, OR, United States). Samples were separated using a RTX-5 MS column (30 m × 0.25 mm × 0.25 mm) with helium being used as a carrier gas at a flow rate of 1.0 ml/min. The injection temperature was 280°C. The GC oven temperature program was as follows: 90°C for 1 min, then increased by 30°C/min to 300°C and hold at 300°C for 15 min. The mass of sterol compounds was detected in a select ion-scan mode with electronic ionization (70 eV), and monitored at multiple ions of m/z 343, 382, and 472 for campesterol, m/z 341, 365, and 470 for 24-methylenecholesterol, m/z 365, 386, and 470 for 24-methyldesmosterol, and m/z 329, 368, and 458 for the internal standard cholesterol.

RESULTS

Identification of the 24ISO Gene From Physalis angulata

Firstly we have shown that physalin B accumulates to higher levels in leaf, compared to other tissues of P. angulata (Figure 2A). This result is different from a previous report (Huang et al., 2014), in which calyx was identified to be the physalin-accumulating site with the highest amounts. This discrepancy is probably due to the difference of the P. angulata cultivars utilized between this and that studies. The identity of physalin B was determined by comparing its MS/MS fragmented pattern (Supplementary Figure 7) with that published in a previous literature (Huang, 2014). A Ws24ISO gene was previously cloned from Withania somnifera (Knoch et al., 2018). In this work, using Ws24ISO as a query, we performed a BLASTP analysis against the transcriptome derived from P. angulata calyx that was recently constructed by our group. One unigene (ID number: PB.4414.9), hereafter refer to as Pa24ISO, was found to show the highest amino acid identity (96.0%) with Ws24ISO. A phylogenetic analysis shows that Pa24ISO closely clustered with Ws24ISO in the tree (Supplementary Figure 7), indicating that it is a potential 24ISO candidate. The expression of Pa24ISO was profiled in different organs with real-time RT-PCR. Pa24ISO transcripts were detected in the highest levels in the leaf of P. angulata, but in much less levels in other tissues (Figure 2B). The expression pattern of Pa24ISO matched well with the accumulation profile of physalin B across these tissues (Figure 2A).

Pa24ISO Converts 24-Methylene Cholesterol to 24-Methyldesmosterol

To test the enzymatic function of Pa24ISO, the Pa24ISO gene was codon-optimized by manually chemical synthesis for preferential expression in Saccharomyces cerevisiae, and inserted into a yeast expression vector pESC-HIS3. As a positive control, the known gene Ws24ISO was also synthesized, and expressed in the same way as Pa24ISO. Pa24ISO or Ws24ISO was expressed in a 24-methylenecholesterol-producing yeast strain YS11, which was previously made by Yang et al. (2021). The yeast extracts were subsequently prepared, and analyzed by GC–MS for the presence of 24-methyldesmosterol. The negative control was prepared by transferring the empty vector pESC-HIS3 into the YS11 strain.

Cells expressing Pa24ISO showed a clear GC–MS product peak, which was missing from the empty vector control. This new GC–MS peak showed the same retention times (Figure 3A) and the same mass spectra with the 24-methyldesmosterol product synthesized by Ws24ISO (Figure 3B). Thus, it is
confirmed that the protein encoded by Pa24ISO is able to convert 24-methylenecholesterol to 24-methyldesmosterol (see the proposed reaction in Figure 3C).

Development of a VIGS System for Physalis angulata

To test functions of genes in vivo in P. angulata, it is necessary to establish a virus-induced gene silencing (VIGS) system for P. angulata, as there have been no reports of VIGS in this plant. For this purpose, the tobacco rattle virus (TRV; Burch-Smith et al., 2006) vector based VIGS system was employed, using phytoene desaturase (PDS; Cunningham and Gantt, 1998) as a reporter gene. The sequence of P. angulata PDS (PaPDS) was retrieved from the calyx transcriptome, which is available in our laboratory, and a 382bp-fragment of PaPDS was selected as a target sequence. Six-to-eight week-old seedlings were infected with the Agrobacterium slurry containing the pTRV2-PaPDS vector or the empty pTRV2 vector as a control. At around 4 weeks post infiltration, a greenish–whitish variegated phenotype was observed in the upper leaves. With the growing of the infected seedlings, some of the newly emerging leaves exhibited a completely white phenotype (Figure 4A). Interestingly, at around 10–12 weeks post infiltration, a complete white phenomenon was also observed in the newly developed flowers and calyx of some of the infected plants (Figure 4A). We harvested the seeds that were generated from the plants showing completely white flowers or calyx, and grew them in soils to see whether the photobleaching phenomenon can be inherited in their offspring. However, they grew as wild type plants, and no photobleaching phenomenon was observed in their newly grown leaves.

To check whether the white phenotype correlated with the decreased PaPDS transcripts by VIGS, the PaPDS expression was monitored by real-time PCR. As shown in Figure 4B, the transcript levels of PaPDS were largely decreased in the photobleached leaf, flower and calyx, respectively, by the PaPDS-VIGS, compared with their corresponding empty vector controls. This result suggests that the TRV-based VIGS system can be used to suppress expression of genes of interest in P. angulata.

The silencing of Pa24ISO Led to Reduced Levels of Physalin B in Physalis angulata

After successfully establishing the VIGS system for P. angulata, we embarked experiments to silence the expression of Pa24ISO in vivo. Seven-week old plants were separately infiltrated with each of the Agrobacterium strains, which carried pTRV2-Pa24ISO, pa24iso, and empty vector, respectively. At around 4 weeks post infiltration, a dark greenish–whitish variegated phenotype was observed in the upper leaves. With the growing of the infected seedlings, some of the newly emerging leaves exhibited a completely white phenotype (Figure 4A). Interestingly, at around 10–12 weeks post infiltration, a complete white phenomenon was also observed in the newly developed flowers and calyx of some of the infected plants (Figure 4A). We harvested the seeds that were generated from the plants showing completely white flowers or calyx, and grew them in soils to see whether the photobleaching phenomenon can be inherited in their offspring. However, they grew as wild type plants, and no photobleaching phenomenon was observed in their newly grown leaves.

To check whether the white phenotype correlated with the decreased PaPDS transcripts by VIGS, the PaPDS expression was monitored by real-time PCR. As shown in Figure 4B, the transcript levels of PaPDS were largely decreased in the photobleached leaf, flower and calyx, respectively, by the PaPDS-VIGS, compared with their corresponding empty vector controls. This result suggests that the TRV-based VIGS system can be used to suppress expression of genes of interest in P. angulata.

March 2022 | Volume 13 | Article 850711

pTRV2-PaPDS, or pTRV2 empty vector, respectively. The pTRV2-PaPDS construct was utilized, as an indicator group, to monitor the silencing efficiency under different time lengths post the inoculation. Based on the visible phenomenon by pTRV2-PaPDS, the highest silencing efficiency was achieved at 8 weeks post the infection. Thus, after 8 weeks, the newly developed leaves from the infected plants transformed with the pTRV2-Pa24ISO, as well as the empty vector pTRV2, were harvested. To evaluate the silencing efficiency of Pa24ISO, quantification of the transcript level of Pa24ISO was performed with real-time PCR. In comparison with the control plants, which were infiltrated with the empty vector, the transcript level of Pa24ISO was down-regulated by 46% in the Pa24ISO-silenced plants (Figure 5A). It should be noted that the silencing of Pa24ISO also led to a decrease in the expression of a putative PaSSR1, however, it was not statistically significant (Supplementary Figure 8). Consistent with the reduced levels of Pa24ISO transcript, the Pa24ISO-silenced plants showed a sharp decline (54.3%) in the content of 24-methyldesmosterol, which was accompanied with increased accumulation of 24-methylenecholesterol and campesterol (Figure 5B and Supplementary Figure 8), when compared to the empty vector control samples. This result demonstrates that Pa24ISO is indeed the branch enzyme diverting the common substrate 24-methylenecholesterol toward biosynthesis of 24-methyldesmosterol-derived sterols, in competition with the campesterol-mediated carbon flux, as depicted in Figure 1B.

To investigate the effect of Pa24ISO silencing on biosynthesis of physalin, we quantified the content of physalin B in the newly developed leaves of the infected plants, through LC–MS/MS anlaysis. Physalin B appeared to be the major physalin compound in the P. angulata cultivar used in this study. The Pa24ISO-silenced plants displayed a 47% reduction in physalin B (Figure 5B), as compared with control leaves, indicating that Pa24ISO play a pivotal role in biosynthesis of physalin in P. angulata.

**DISCUSSION**

Physalin are the characteristic constituents identified in P. angulata, and they exhibit a broad spectrum of medicinal properties (Damu et al., 2007). The pathways leading to physalin are largely unknown. Since physalin is a class of 24-alkyl sterols, thus it is believed that they are undoubtedly synthesized from 24-methylenecholesterol. As depicted in Figure 1B, 24-methylenecholesterol is the branching point, which can be either directed into 24-methyldesterol-mediated
flux for withanolide via 24ISO (Knoch et al., 2018), or into campesterol-mediated flux for regular physterols via SSR1. Apparently, 24ISO competes with SSR1 at the level of 24-methylenecholesterol in the steps leading to withanolide production (Knoch et al., 2018). To date, there are no reports of physalin biosynthetic pathways in literatures. However, two possible pathways below were previously predicted by other groups: (1) physalins are biosynthesized from withanolides and (2) physalins are formed through the campesterol-pathway. The route 1 was recently proposed primarily based on a chemical viewpoint (Araki et al., 2021), in which withanolides can be transformed into compounds with a physalin-skeleton, through multiple oxidations. The route 2 was suggested, because that the withanolide content in Withania somnifera L was increased by feeding campesterol (Singh et al., 2014). For either route, there is no direct experimental evidence provided so far. For this reason, this project was designed with an aim to provide insight of which route that really occurs in nature for physalin production, through the silencing of Pa24ISO gene in P. angulata. This study is the first to isolate the Pa24ISO gene from P. angulata. Upon expression of Pa24ISO in a 24-methylenecholesterol-producing yeast strain YS11 (Yang et al., 2021), 24-methylenecholesterol was isomerized to 24-methyldesmosterol (Figure 3), implying that it is a functional 24ISO in P. angulata. The silencing of Pa24ISO was significant, with its transcript level being almost halved, as compared to the empty vector-transferred plants (Figure 5A). Physalin B was selected for the analysis, as it is present in high amounts in the P. angulata cultivar of this study, and could be reliably identified by comparing MS/MS fragmentation pattern with literature data (Huang, 2014). Compared to the empty vector controls, the Pa24ISO silencing led to significantly reduced level of physalin B (Figure 5). We also observed a 63% reduction for one unknown compound in the Pa24ISO-silenced plants (data not shown). Based on its mass spectra (Supplementary Figure 6), the molecular mass of this unknown compound matched that of withanolide C. If it was the withanolide C, the data that we have acquired is consistent with the previous finding, which clearly concluded that 24ISO is the first committed enzyme in the steps beyond 24-methylenecholesterol toward withanolide biosynthesis (Knoch et al., 2018). Therefore, it is highly likely that physalin is biogenetically synthesized from withanolide, and 24ISO is involved in physalin biosynthesis. An involvement of Pa24ISO in physalin biosynthesis could also be supported by a positive correlation of its transcripts with the accumulation profile of physalin B across different tissues of P. angulata (Figure 2). Taken together, these data corroborate that 24ISO plays a pivotal role in regulating physalin biosynthesis in vivo.

Upon the Pa24ISO silencing, physalin B and the intermediate 24-methyldesmosterol displayed a concurrently decreased accumulation pattern, whereas the change trend of campesterol was the reverse (Figure 5). This data further favors the proposal that physalin is biosynthesized through the 24ISO-catalyzed 24-methyldesmosterol pathway, while not through the SSR1-catalyzed campesterol (Figure 1B). The data of this study seem to be contradictory with a previous report (Singh et al., 2014), in which increased withanolide contents were found in W. somnifera plants fed with campesterol. However, campesterol is generally a precursor of
C28-brassinosteroids (BRs; Bajguz et al., 2020), and feeding of campesterol would modulate levels of BRs, which, as signaling compounds (Kim and Russinova, 2020), may in turn regulate expression of withanolide biosynthesis genes. One might argue that the intermediate 24-methyldesmosterol is also the intermediate in the SSR1-catalyzed two-step conversions of 24-methylene cholesterol to campesterol (Figure 1B; Klahre et al., 1998; Takahashi et al., 2006), and physalin biosynthesis enzymes may also have access to the 24-methyldesmosterol produced by SSR1. However, although both 24ISO and SSR1 may co-localize to the same subcellular site (i.e., endoplasmic reticulum; Silvestro et al., 2013; Knoch et al., 2018), the 24-methyldesmosterol formed by SSR1 seems to be quickly subjected to the next reduction step instead of being released by SSR1. For example, expression of Physalis alkekengi SSR1 in a 24-methylenecholesterol-producing yeast strain led to the production of only campesterol with no trace of 24-methyldesmosterol (Knoch et al., 2018).

In short, this study provides experimental evidence to support that 24ISO is involved in physalin biosynthesis. Elucidation of the physalin biosynthetic pathway needs further isolation of the genes in the later steps beyond 24ISO, such as the genes encoding cytochrome P450s, which probably catalyze multiple oxidations of the 24ISO product 24-methyldesmosterol to form the physalin.

CONCLUSION

This study reports the isolation and functional analysis of a 24ISO-encoding gene (Pa24ISO) from P. angulata. Heterologous expression of Pa24ISO in yeast suggested that Pa24ISO is able to convert 24-methylenecholesterol to 24-methyldesmosterol. Silencing of Pa24ISO in P. angulata by the VIGS approach revealed a direct role of Pa24ISO in biosynthesis of physalin, such as physalin B at this case.

AUTHOR CONTRIBUTIONS

YZ received the funding to support this project. YZ and JY contributed to the writing. JY performed the experiments. CL provided the calyx transcriptome database and conducted the LC-MS/MS analysis. JT, YY, and YZ provided assistance in gene cloning, construct preparation, and chemical analysis. All authors contributed to the article and approved the submitted version.

FUNDING

The work was jointly supported by a grant from the National Key R&D Program of China (2018YFC1706200) and the start-up funding grant to YZ from Shanghai University (N.13–G210–20–327).

ACKNOWLEDGMENTS

We thank Xiaodong Li, who is from the Wuhan Botanical Garden, Chinese Academy of Sciences, for the plant identification.
