Abstract

Let $(\Gamma, d)$ be the $3D$-calculus or the $4D_\pm$-calculus on the quantum group $SU_q(2)$. We describe all pairs $(\pi, F)$ of a $\ast$-representation $\pi$ of $\mathcal{O}(SU_q(2))$ and of a symmetric operator $F$ on the representation space satisfying a technical condition concerning its domain such that there exist a homomorphism of first order differential calculi which maps $dx$ into the commutator $[iF, \pi(x)]$ for $x \in \mathcal{O}(SU_q(2))$. As an application commutator representations of the 2-dimensional left-covariant calculus on Podles quantum 2-sphere $S^2_{qc}$ with $c = 0$ are given.

Subj. Class.: Quantum groups, Non-commutative geometry

1991 MSC: 17B37, 46L87, 81R50

Keywords: Non-commutative differential calculus

1. Introduction

There are various ways to develop a noncommutative differential calculus on a given $\ast$-algebra $\mathcal{A}$. Some approaches are based on derivations $[3,7]$ of the algebra $\mathcal{A}$, while others consider differential forms as the basic objects. In Alain Connes’ programm [2] of noncommutative geometry, the fundamental concept for the quantized calculus is the $K$-cycle. Other names for closely related notions are Fredholm modules and spectral triples. If we omit technical subtleties, then the underlying idea of all these concepts is easy to explain: One has a $\ast$-representation $\pi$ of the algebra $\mathcal{A}$ and a self-adjoint operator $F$ on the representation space, and the differentiation of an algebra element $a$ is defined by the commutator of the operators $iF$ and $\pi(a)$, where $i$ is the imaginary unit.

On the other hand, for quantum groups there is a well-developed theory of covariant differential calculi which was initiated by S.L. Woronowicz [15], see also the monograph [6]. The relations between this theory and Connes’ approach via $K$-cycles or spectral triples are still open. Let us be more specific and consider the simplest non-trivial compact quantum group $SU_q(2)$. Then we have three distinguished left-covariant differential calculi on the Hopf $\ast$-algebra $\mathcal{O}(SU_q(2))$: the $3D$-calculus and the $4D_\pm$-calculi. All three calculi are due to S.L. Woronowicz [14],[15]. The $4D_\pm$-calculi are even bicoordinated, but we shall not use this here. These calculi have a number of nice properties, and there is a common belief that they are favoured candidates for the study of noncommutative geometry on the quantum group $SU_q(2)$. Thus it seems to be natural to ask whether or not one of these calculi can be described by means of a $K$-cycle or more generally by the commutators $[iF, \pi(\cdot)]$ for some $\ast$-representation $\pi$ of $\mathcal{O}(SU_q(2))$ and some symmetric operator $F$. 
Under an additional technical condition called admissibility we describe all such pairs \((\pi, F)\) which represent the 3D-calculus or the \(4D_{\pm}\)-calculus on \(SU_q(2)\). The main results about this matter are stated as Theorems 1–3 in Section 4, while the proofs of these results are postponed to Section 7. It turns out that the 3D-calculus can be faithfully represented as a commutator. Some properties of such commutator representation of the 3D-calculus and some examples are treated in Section 5. An application to the Podles quantum sphere \(S_q^2\) with \(c = 0\) is sketched in Section 6. The \(4D_{\pm}\)-calculus does not admit a faithful admissible commutator representation, because any such representation passes to a 3-dimensional left-covariant quotient calculus. Further, we prove that neither for the 3D-calculus nor for the \(4D_{\pm}\)-calculus there exists a non-trivial commutator representation \((\pi, F)\) such that all operators \([iF, \pi(x)], x \in \mathcal{A}\) are bounded. This shows in particular that none of these calculi can be given by means of a K-cycle in the sense of A. Connes.

In Section 2 we collect some basic definitions on differential calculi and some simple facts needed later. In Section 3 we repeat the structure of a general \(*\)-representation of the \(*\)-algebra \(O(SU_q(2))\) and some facts about the 3D- and the \(4D_{\pm}\)-calculus on \(SU_q(2)\). Further, we develop the 2-dimensional calculus on the Podles sphere \(S_q^2\) for \(c = 0\) as the induced FODC of the 3D-calculus on \(SU_q(2)\).

Let us fix some general notation. We use the Sweedler notation \(\Delta(x) = (x_1 \otimes x_2)\) for the comultiplication of a Hopf algebra element \(x\). Let \(x(n)y\) denote the equation which is obtained by multiplying equation \((n)\) by \(x\) from the left and by \(y\) from the right. Throughout we set \(\lambda := q - q^{-1}\) and \(\lambda_+ := q + q^{-1}\).

2. Commutator representations of first order differential calculi

Let \(\mathcal{A}\) be a complex \(*\)-algebra with unit element. The involution of \(\mathcal{A}\) is denoted by \(*\).

A first order differential calculus (abbreviated, a FODC) over \(\mathcal{A}\) is a pair \((\Gamma, d)\) of an \(\mathcal{A}\)-bimodule \(\Gamma\) with a linear mapping \(d : \mathcal{A} \to \Gamma\) such that the following two conditions hold:

(i) \(d\) satisfies the Leibniz rule \(d(xy) = x \cdot dy + dx \cdot y\) for \(x, y \in \mathcal{A}\),

(ii) \(\Gamma = \text{Lin}\{x \cdot dy \cdot z; x, y, z \in \mathcal{A}\}\).

A first order differential \(*\)-calculus (briefly, a \(*\)-FODC) over \(\mathcal{A}\) is a FODC \((\Gamma, d)\) equipped with an involution \(* : \Gamma \to \Gamma\) of the complex vector space \(\Gamma\) such that

(iii) \((x \cdot dy \cdot z)^* = z^* \cdot d(y^*) \cdot x^*\) for \(x, y, z \in \mathcal{A}\).

By a homomorphism of a FODC \((\Gamma_1, d_1)\) into a FODC \((\Gamma_2, d_2)\) over \(\mathcal{A}\) we mean a linear mapping \(\rho : \Gamma_1 \to \Gamma_2\) such that \(\rho(x \cdot d_1 y \cdot z) = x \cdot d_2 y \cdot z\) for \(x, y, z \in \mathcal{A}\). A homomorphism of a \(*\)-FODC \((\Gamma_1, d_1, *_1)\) into a \(*\)-FODC \((\Gamma_2, d_2, *_2)\) is a FODC homomorphism \(\rho : \Gamma_1 \to \Gamma_2\) such that \(\rho(\omega^{*_1}) = \rho(\omega)^{*_2}\) for \(\omega \in \Gamma_1\). If no ambiguity can arise, we denote a FODC \((\Gamma, d)\) or a \(*\)-FODC \((\Gamma, d, *)\) by \(\Gamma\).

Now let \(\mathcal{A}\) be a Hopf \(*\)-algebra. A \(*\)-FODC \(\Gamma\) over \(\mathcal{A}\) is called left-covariant if there exists a linear mapping \(\varphi : \Gamma \to \mathcal{A} \otimes \Gamma\) such that \(\varphi(x \cdot dy) = \Delta(x)(\text{id} \otimes d)\Delta(y)\) for all \(x, y \in \mathcal{A}\). Suppose \(\Gamma\) is a left-covariant \(*\)-FODC. We define

\[
\omega_\Gamma(x) := S(x(1))dx(2), \quad x \in \mathcal{A}, \text{ and } R_\Gamma := \{x \in \ker \varepsilon : \omega_\Gamma(x) = 0\}.
\]

It is well-known [15,6] that \(R_\Gamma\) is a right ideal of \(\mathcal{A}\) which characterizes the left-covariant FODC \(\Gamma\) up to isomorphism.
Suppose that $\pi$ is a $*$-representation of the $*$-algebra $A$ by bounded operators on a Hilbert space $H$ and $F$ is a symmetric linear operator on $H$ with dense domain $D(F)$. Let us assume that there exists a linear subspace $D_F$ of $D(F)$ such that $D_F$ is dense in $H$ and $\pi(A)D_F \subseteq D(F)$. Let $\Gamma_{\pi,F}$ denote the linear span of operators

$$\pi(x)(F\pi(y) - \pi(y)F)\pi(z)\mid D_F, \quad x, y, z \in A,$$

where the symbol $\mid D_F$ denotes the restriction of the corresponding operator to $D_F$. It is clear that $\Gamma_{\pi,F}$ is an $A$-bimodule with left and right action of an element $x \in A$ given by multiplication by $\pi(x)$ from the left and the right, respectively. Define a linear mapping $d_{\pi,F} : A \to \Gamma_{\pi,F}$ and an antilinear mapping $* : \Gamma_{\pi,F} \to \Gamma_{\pi,F}$ by

$$d_{\pi,F}(x) := (iF\pi(x) - \pi(x)iF)\mid D_F, \quad x \in A,$$

where $i$ is the imaginary unit, and

$$T^* := \sum_j \pi(x_j)(\pi(y_j)F - F\pi(y_j))\pi(z_j)\mid D_F \subseteq \Gamma_{\pi,F}.$$

Using the facts that $D_F$ is dense in $H$, the operator $F$ is symmetric and $\pi$ is a $*$-representation it is easy to check that the mapping $T \mapsto T^*$ is well-defined (that is, $T^* = 0$ when $T = 0$). Further, it is not difficult to verify that the triple $(\Gamma_{\pi,F}, d_{\pi,F}, *)$ is a $*$-FODC over $A$. We call it the $*$-FODC associated with the pair $(\pi, F)$ and denote it simply by $\Gamma_{\pi,F}$. (With a few modifications concerning the domains the preceding construction carries over to unbounded $*$-representations $\pi$ as well. We shall not need this in this paper, because we consider the coordinate $*$-algebra $O(SU_q(2))$ which has only bounded $*$-representations.) The above notion is closely related to Alain Connes’ concept of a $K$-cycle\(^1\). If in addition $F$ is a self-adjoint operator with compact resolvent and the commutator $[\pi(x), F]$ is bounded for any $x \in A$ the pair $(\pi, F)$ is called a $K$-cycle over the $*$-algebra $A$.

Now let $\Gamma$ be an arbitrary $*$-FODC over $A$ and let $\pi$ and $F$ be as above. We shall say that the pair $(\pi, F)$ is a commutator representation of the $*$-FODC $\Gamma$ if there exists a homomorphism $\rho$ of the $*$-FODC $\Gamma$ to the $*$-FODC $\Gamma_{\pi,F}$ associated with $(\pi, F)$. If $\rho$ is injective, then $(\pi, F)$ is called a faithful commutator representation of $\Gamma$. A slight reformulation of this definition is given by

**Lemma 1.** A pair $(\pi, F)$ as above is a commutator representation of the $*$-FODC $\Gamma$ if and only if

$$\sum_j x_j dy_j = 0 \quad \text{in} \quad \Gamma \quad \text{with} \quad x_j, y_j \in A \quad \text{always implies that} \quad \sum_j \pi(x_j)(iF\pi(y_j) - \pi(y_j)iF)\mid D_F = 0.$$

**Proof.** The only if part is trivial. If this condition is fulfilled, then there exists a well-defined linear map $\rho : \Gamma \to \Gamma_{\pi,F}$ such that $\rho(\sum_j x_j dy_j) = \sum_j \pi(x_j)(iF\pi(y_j) - \pi(y_j)iF)\mid D_F$. One easily checks that $\rho$ is a homomorphism of $\Gamma$ to $\Gamma_{\pi,F}$.

Let $(\pi, F)$ be a pair of a $*$-representation $\pi$ of $A$ and a symmetric linear operator as above. For $x \in A$ we define the linear operator

$$\Omega_{\pi,F}(x) := (\pi(S(x_{(1)}))F\pi(x_{(2)}) - \varepsilon(x)F)\mid D_F. \quad (1)$$

The following very simple observations are needed in the proofs of the main theorems below.
Lemma 2. Suppose that $(\pi, F)$ is a commutator representation of the left-covariant FODC $\Gamma$ and let $\rho$ denote a FODC homomorphism of $\Gamma$ to $\Gamma_{\pi,F}$. Then we have $\rho(\omega_\Gamma(x)) = \Omega_{\pi,F}(x)$ for all $x \in A$. In particular, if $x$ belongs to the right ideal $R_\Gamma$ associated with $\Gamma$, then $\Omega_{\pi,F}(x) = 0$.

Proof. Using the definitions of $\omega_\Gamma(x)$ and $\Omega_{\pi,F}(x)$ and the fact that $\rho$ is a FODC homomorphism we compute

$$
\rho(\omega_\Gamma(x)) = \rho(S(x(1)))\rho(d(x(2))) = \rho(S(x(1)))d_{\pi,F}(x(2))
= \pi(S(x(1)))(iF\pi(x(2)) - \pi(x(2))iF)|D_F = i\Omega_{\pi,F}(x).
$$

Lemma 3. Let $\rho : \Gamma_1 \to \Gamma_2$ be a homomorphism of the left-covariant FODC $\Gamma_1$ into another FODC $\Gamma_2$. Suppose that $B$ is a subset of ker $\varepsilon$ such that $\rho(\omega_{\Gamma_1}(b)) = 0$ for all $b \in B$. Let $\Gamma_0$ denote the quotient FODC of $\Gamma_1$ whose associated right ideal $R_{\Gamma_0}$ is generated by $R_{\Gamma_1}$ and $B$. Then $\rho$ passes to a homomorphism of the quotient FODC $\Gamma_0$ to the FODC $\Gamma_2$.

Proof. If $\Gamma_f$ denotes the universal FODC over $A$, then any other left-covariant FODC $\Gamma$ over $A$ is isomorphic to the quotient FODC $\Gamma_f/A\omega_{\Gamma_f}(R_{\Gamma_f})$ (see, for instance, [6], Proposition 14.1). This implies that the FODC $\Gamma_0$ is isomorphic to the quotient FODC $\Gamma_1/A\omega_{\Gamma_1}(R_{\Gamma_1})$. Therefore, it is sufficient to prove that $\rho(x\omega_{\Gamma_1}(by)) = 0$ for all $b \in B$ and $x, y \in A$. Indeed, using the facts that $\rho$ is a bimodule homomorphism and $\omega_{\Gamma_1}(by) = S(y(1))\omega_{\Gamma_1}(b)y(2)$ (see formula (14.3) in [6]) we obtain

$$
\rho(x\omega_{\Gamma_1}(by)) = \rho(xS(y(1)))\rho(\omega_{\Gamma_1}(b))\rho(y(2)) = 0.
$$

3. Preliminaries on the quantum group $SU_q(2)$

From now let $A$ be the coordinate $*$-algebra $\mathcal{O}(SU_q(2))$ of the compact quantum group $SU_q(2)$ [14,13,8,6]. In what follows we shall assume that $0 < q < 1$. The generators of $A$ are the four entries $a, b, c, d$ of the fundamental matrix and the involution of $A$ is given by

$$
a^* = d, \quad b^* = -qc, \quad c^* = -q^{-1}b, \quad d^* = a.
$$

3.1. Star representations of $\mathcal{O}(SU_q(2))$

Suppose that $\pi$ is an arbitrary $*$-representation of the $*$-algebra $A = \mathcal{O}(SU_q(2))$. From Proposition 4.19 in [6] or from the description of the irreducible $*$-representations in [13] it follows that up the unitary equivalence the $*$-representation $\pi$ is given by the following operator-theoretic model:

Let $v$ and $w$ be unitary operators on Hilbert spaces $\mathcal{G}$ and $\mathcal{H}_0$, respectively. Put $\mathcal{H} = \bigoplus_{n=0}^{\infty} \mathcal{H}_n$, where $\mathcal{H}_n = \mathcal{H}_0$ for all $n \in \mathbb{N}_0$. For $\eta \in \mathcal{H}_0$, let $\eta_n$ denote the vector of $\mathcal{H}$ which has $\eta$ as its $n$-th component and zero otherwise. The $*$-representation $\pi$ acts on the direct sum Hilbert space $\mathcal{G} \oplus \mathcal{H}$ and it is determined by the formulas

$$
\pi(a) = v, \quad \pi(d) = v^*, \quad \pi(b) = \pi(c) = 0 \quad \text{on} \quad \mathcal{G},
$$

$$
\pi(a)\eta_n = \lambda_n\eta_{n-1}, \quad \pi(d)\eta_n = \lambda_{n+1}\eta_{n+1}, \quad \pi(c)\eta_n = q^*w^*\eta_n, \quad \pi(b)\eta_n = -q\pi(c)^*\eta_n = -q^{n+1}w^*\eta_n
$$

for $\eta \in \mathcal{H}_0$ and $n \in \mathbb{N}_0$, where we have set $\eta_{-1} := 0$ and

$$
\lambda_n := (1 - q^{2n})^{1/2}, \quad n \in \mathbb{N}_0.
$$
from Section 6 below, we use only the following facts concerning the $3D$ and $3D$ terms of the above model for the proofs of the main results in Section VI. This condition becomes rather natural if it is considered in the domain used in the definition of the commutator representation $(\pi, F)$ given in the preceding section. The admissibility of a representation $(\pi, F)$ is a technical condition which is essentially used in the proofs of the main results in Section VI. This condition becomes rather natural if it is considered in terms of the above model for the $*$-representation $\pi$. Clearly, we have $\mathcal{G} = \ker \pi(c), \mathcal{H}_0 = \ker \pi(a)$ and $\mathcal{H}_n = \pi(d^n)\mathcal{H}_0$. That $(\pi, F)$ is admissible means that there are linear subspaces $\mathcal{E}$ of $\mathcal{G}$ and $\mathcal{D}_0$ of $\mathcal{H}_0$ such that $v\mathcal{E} = \mathcal{E}, w\mathcal{D}_0 = \mathcal{D}_0$ and $\mathcal{D}_F := \mathcal{E} \oplus \mathcal{D}$ is a core for the operator $F$, where $\mathcal{D} := \ker \{D_n; n \in \mathbb{N}_0\}$ and $D_n := \{\eta_n; \eta \in \mathcal{D}_0\}$ is the $n$-th shift of the domain $\mathcal{D}_0$.

3.2 The 3D-calculus

The 3D-calculus was introduced by Woronowicz [14]. A short approach was given in [12]. Apart from Section 6 below, we use only the following facts concerning the 3D-calculus.

The right ideal of the 3D-calculus is generated by the following six elements (see [14], (2.27), or [6], (14.23)):

$$b^2, c^2, bc, (a - 1)b, (a - 1)c, q^2a + d - (q^2 + 1).$$

The three 1-forms $\omega_0 := \omega_1(b), \omega_2 := \omega_1(c), \omega_1 := \omega_1(a)$ form a basis of the vector space $\text{inv}\Gamma$ and the bimodule structure of $\Gamma$ is determined by the following commutation relations (see [14], p.135, or [6], p.499):

$$q^j\omega_ja = a\omega_j, q^j\omega_jb = qb\omega_j, q^j\omega_jc = c\omega_j, \omega_jd = qd\omega_j \text{ for } j = 0, 2,$$

$$q^2\omega_1b = ab_1, \omega_1b = q^2b\omega_1, q^2\omega_1c = c\omega_1, \omega_1d = q^2d\omega_1.$$ (7)

3.3. The 4D$_{\pm}$-calculus

In order to describe the 4D$_{\pm}$-calculus $\Gamma_{\pm}$, we first restate some facts developed in Subsection 14.2.4 in [6]. The quantum tangent space $T_{\pm}$ of the 4D$_{\pm}$-calculus is expressed therein in terms of the generators $E, F, K, K^{-1}$ of the Hopf algebra $U_q(sl_2)$ (see [6], p.57). Let $\varepsilon_\pm := \varepsilon$ and let $\varepsilon_\mp$ be the character of the algebra $\mathcal{O}(SU_q(2))$ such that $\varepsilon_-(a) = \varepsilon_-(d) = -1$ and $\varepsilon_-(b) = \varepsilon_-(c) = 0$. Then $T_{\pm}$ is spanned by the four linear functionals

$$X_1 = \varepsilon_\pm K^{-2} - \varepsilon, X_2 = q^{1/2}\varepsilon_\pm FK^{-1}, X_3 = q^{-1/2}\varepsilon_\pm EK^{-1}, X_4 = \varepsilon_\pm K^2 + \lambda q^{-1}\varepsilon_\pm FE - \varepsilon$$

and we have

$$\Delta(X_1) = \varepsilon \otimes X_1 + X_1 \otimes \varepsilon_\pm K^{-2},$$

$$\Delta(X_j) = \varepsilon \otimes X_j + X_j \otimes \varepsilon_\pm + X_1 \otimes X_j, \quad j = 2, 3,$$

$$\Delta(X_4) = \varepsilon \otimes X_1 + \lambda^2 q^{-1}X_1 \otimes \varepsilon_\pm FE + X_4 \otimes \varepsilon_\pm K^2 + \lambda^2 q^{-1/2}(X_2 \otimes \varepsilon_\pm EK + X_3 \otimes \varepsilon_\pmKF).$$

There is a dual pairing of Hopf algebras $U_q(sl_2)$ and $\mathcal{O}(SU_q(2))$ determined on the generators by the equations

$$\langle K, a \rangle = q^{-1/2}, \langle K, d \rangle = q^{1/2}, \langle E, c \rangle = \langle F, b \rangle = 1 \text{ and zero otherwise}.$$ (11)
Let \( \{\omega_1, \omega_2, \omega_3, \omega_4\} \) be a basis of the vector space \( \text{inv}\Gamma \) such that \( (X_i, \omega_j) = \delta_{ij}, i, j = 1, \ldots, 4 \). We set \( \epsilon = +1 \) for the \( 4D_{+} \)-calculus and \( \epsilon = -1 \) for the \( 4D_{-} \)-calculus. From (11) we derive
\[
\langle X_1, a \rangle = eq - 1, \quad \langle X_1, d \rangle = eq^{-1} - 1, \quad \langle X_2, b \rangle = \langle X_3, c \rangle = \epsilon, \\
\langle X_4, a \rangle = eq^{-1} - 1 + \epsilon \lambda^2 q^{-1}, \quad \langle X_4, d \rangle = eq - 1.
\]
(12)
(13)

The other pairings of \( X_i \) with matrix generators \( a, b, c, d \) vanish. Since \( \langle X, x \rangle = (X, \omega(x)) \) for \( X \in T_\pm \) and \( X \in A \) (see [6], formula (14.9)), we therefore obtain
\[
\omega_1(a) = (eq - 1)\omega_1 + (eq^{-1} - 1 + \epsilon \lambda^2 q^{-1})\omega_4, \quad \omega_1(b) = \omega_2, \\
\omega_1(d) = (eq^{-1} - 1)\omega_1 + (eq - 1)\omega_4, \quad \omega_1(c) = \epsilon \omega_3. 
\]
(14)
(15)

From the general theory of left-covariant FODC we recall that
\[
\omega_i x = \sum_j x_{(1)} f^j_i(x_{(2)}) \omega_j, \quad x \in A,
\]
(16)
where the functionals \( f^j_i \) are determined by the equation \( \Delta(X_i) = \epsilon \otimes X_i + \sum_j X_j \otimes f^j_i \). From the formulas (8)–(11) we therefore read off that the non-zero functionals \( f^j_i \) are
\[
f^1_1 = \epsilon K^{-2}, \quad f^1_2 = X_2, \quad f^1_3 = X_3, \quad f^1_4 = \lambda^2 q^{-1} \epsilon FE, \quad f^2_2 = f^3_2 = \epsilon, \\
f^1_2 = \lambda^2 q^{-1/2} \epsilon K, \quad f^2_3 = \lambda^2 q^{-1/2} \epsilon K, \quad f^4_1 = \epsilon k^2.
\]

Inserting these functionals into (14)–(15) and using the dual pairing (11) we obtain the following list of commutation relations which described the bimodule structure of the \( 4D_{\pm} \)-calculus:
\[
\omega_1 a = eq \omega_1 + eb \omega_3 + \epsilon \lambda^2 q^{-1} aw_4, \quad \omega_1 b = eq^{-1} b \omega_1 + e \omega_2, \\
\omega_1 c = eq \omega_1 + ed \omega_3 + \lambda \epsilon q^{-1} cw_4, \quad \omega_1 d = eq^{-1} d \omega_1 + e \omega_2, \\
\omega_2 a = ea \omega_2 + \epsilon \lambda^2 q^{-1} dw_4, \quad \omega_2 b = eb \omega_2, \quad \omega_2 c = ec \omega_2 + \lambda \epsilon q^{-1} dw_4, \quad \omega_2 d = ed \omega_2, \\
\omega_3 a = ea \omega_3, \quad \omega_3 b = eb \omega_3 + \epsilon \lambda^2 q^{-1} aw_4, \quad \omega_3 c = ec \omega_3, \quad \omega_3 d = ed \omega_3 + \epsilon \lambda^2 q^{-1} cw_4, \\
\omega_4 a = eq^{-1} aw_4, \quad \omega_4 b = eq \omega_4, \quad \omega_4 c = eq^{-1} cw_4, \quad \omega_4 d = eqd\omega_4.
\]

Further, we note that
\[
\omega^*_1 = -\omega_1, \quad \omega^*_2 = -\omega_3, \quad \omega^*_3 = -\omega_4
\]
(17)
and that the right ideal \( R_{\Gamma_{\pm}} \) admits the following nine generators (see [15], p.132, or [6], p.504):
\[
b^2, \quad c^2, \quad b(a-d), \quad c(a-d), \quad a^2 + q^2 d^2 - (1+q^2)(ad+q^{-1}bc), \quad z_{\pm} b, \quad z_{\pm} c, \quad z_{\pm} (a-d), \quad z_{\pm} (q^2 a + d - (q^2+1)),
\]
(18)
where
\[
z_{\pm} := q^2 a + d - \epsilon (q^3 + q^{-1}).
\]

Let \( R_{\Gamma_{\pm,3}} \) denote the right ideal of \( A \) generated by \( R_{\Gamma_{\pm}} \) and the single element \( a + eqd \). Since \( S(x)^* \in R_{\Gamma_{\pm,3}} \) for \( x \in R_{\Gamma_{\pm,3}} \), there exists a left-covariant \(*\)-FODC \( \Gamma_{\pm,3} \) of \( A \) which is a quotient of the \( 4D_{\pm} \)-calculus \( \Gamma_{\pm} \) and has the associated right ideal \( R_{\pm,3} \) (by Proposition 14.6 in [6]). Since \( \langle X_1, a + eqd \rangle = 0 \) by (12)–(13), it is not difficult to check that the quantum tangent space of \( \Gamma_{\pm,3} \)
is spanned by the three functionals $X_1, X_2, X_3$. Hence the FODC $\Gamma_{\pm,3}$ has dimension 3. If we set $\omega_4 = 0$ in the above formulas for the $4D\pm$-calculus $\Gamma_{\pm}$, then we obtain the corresponding formulas for the FODC $\Gamma_{\pm,3}$. In particular, we see that the $*\text{-FODC} \Gamma_{\pm,3}$ gives the classical first order differential calculus on $SU(2)$ in the limit $q \to 1$. Thus the $*\text{-FODC} \Gamma_{\pm,3}$ on $SU_q(2)$ seems to be of interest in itself.

**Remark 1.** As noted in [4], the $4D\pm$-calculus $\Gamma_{\pm}$ is an irreducible bicovariant FODC, because it is derived from the fundamental corepresentation of $SL_q(2)$ which is irreducible. By definition this means that $\Gamma_{\pm}$ has no non-trivial *bicovariant* quotient FODC. However, as we have seen, $\Gamma_{\pm,3}$ is a non-trivial *left-covariant* quotient FODC of $\Gamma_{\pm}$.

### 3.4 The 2-dimensional calculus on the quantum sphere $S^2_q$

The considerations of this subsection are only needed in Section 6 below.

Let $\mathcal{O}(S^2_q)$ denote the unital *-subalgebra of $A = \mathcal{O}(SU_q(2))$ generated by the elements

$$x_+ := ba, \quad x_- := cd, \quad y_0 := bc.$$ 

In order to shorten some formulas it is occasionally convenient to replace $y_0$ by the element

$$x_0 := \lambda_+ bc + 1 = \lambda_+ y_0 + 1.$$ 

From the formulas for the comultiplication of the generators $a, b, c, d$ in $\mathcal{O}(SU_q(2))$ we get

$$\Delta(x_+) = a^2 \otimes x_+ + q^{-1} b^2 \otimes x_- + \lambda_+ ba \otimes y_0 + ba \otimes 1,$$

$$\Delta(x_-) = q c^2 \otimes x_+ + d^2 \otimes x_- + \lambda_+ cd \otimes y_0 + cd \otimes 1,$$

$$\Delta(y_0) = ac \otimes x_+ + db \otimes x_- + x_0 \otimes y_0 + be \otimes 1.$$ 

That is, we have $\Delta(\mathcal{O}(S^2_q)) \subseteq A \otimes \mathcal{O}(S^2_q)$ and hence $\mathcal{O}(S^2_q)$ is a left quantum space of $A$ (that is, a left $A$-comodule algebra) with coaction given by the restriction of the comultiplication. It is well-known that that $\mathcal{O}(S^2_q)$ is the coordinate algebra of the Podles’ quantum 2-sphere $S^2_q$ in the case $c = 0$ [9]. (Note that the quantum 2-spheres in [9], [10] and [1] are right quantum spaces, while we consider the corresponding left quantum spaces here.) The generators $x_+, x_-, y_0$ satisfy the relations

$$x_+ x_- - q^2 x_- x_+ = (q^2 - 1) y_0^2, \quad x_+ x_- - q^4 x_- x_+ = (1 - q^2) q y_0,$$

$$x_+ y_0 = q^2 x_+ y_0, \quad q^2 x_- y_0 = y_0 x_-.$$

In fact, the algebra $\mathcal{O}(S^2_q)$ can be also characterized as the abstract unital algebra with generators $x_+, x_-, y_0$ and defining relations (22) and (23). Since $q$ is real, the algebra $\mathcal{O}(S^2_q)$ is a *-algebra with involution determined by $(x_+)^* = x_-$ and $(y_0)^* = y_0$.

As shown by P. Podles [10], the quantum space $S^2_q$ carries a unique 2-dimensional *-FODC. For the application given in Section 6 it is crucial that this calculus is induced from the 3D-calculus of the quantum group $SU_q(2)$. This fact has been known to the author since several years (in fact, since the writing of [1]) and also to others (S. Majid, P. Podles). Since I could not find this result in the literature, we shall derive it in this subsection. In order to do so we first repeat some more facts on the 3D-calculus from Subsection 14.1.3 in [6]. Let $(\Gamma, d)$ be the 3D-calculus on $\mathcal{O}(SU_q(2))$ and let $\Gamma_2$ denote the induced *-FODC of $\Gamma$ on the *-subalgebra $\mathcal{O}(S^2_q)$.
The quantum tangent space \( \mathcal{T} \) of the 3D-calculus has the three basis elements
\[
X_0 := q^{-1/2} FK, \quad X_2 := q^{1/2} EK, \quad X_1 := (1 - q^{-2})^{-1}(\varepsilon - K^4)
\]
satisfying
\[
\Delta X_j = \varepsilon \otimes X_j + X_j \otimes K_2 \quad \text{for } j = 0, 2 \quad \text{and} \quad \Delta X_1 = \varepsilon \otimes X_1 + X_1 \otimes K^4.
\] (24)
The basis \( \{\omega_0, \omega_1, \omega_2\} \) of the vector space \( \text{inv}\Gamma \) is dual to the basis \( \{X_0, X_1, X_2\} \) of \( \mathcal{T} \). Therefore, by the general theory of left-covariant differential calculi we have
\[
dx = \sum_{j=0}^2 x(j) \langle X_j, x(2) \rangle \omega_j, \quad x \in A.
\] (25)
From (24) and the relations \( \langle X_0, b \rangle = \langle X_2, c \rangle = \langle X_1, a \rangle = 1 \) and \( \langle X_0, a \rangle = \langle X_0, c \rangle = \langle X_2, a \rangle = \langle X_1, b \rangle = \langle X_1, c \rangle = 0 \) by (11), we obtain
\[
\langle X_0, x_+ \rangle = \langle X_2, x_- \rangle = q^{-1},
\]
\[
\langle X_0, x_- \rangle = \langle X_0, y_0 \rangle = \langle X_2, x_+ \rangle = \langle X_2, y_0 \rangle = \langle X_1, x_+ \rangle = \langle X_1, x_- \rangle = \langle X_1, y_0 \rangle = 0.
\]
Inserting these facts and equations (19)–(21) into (22) we get
\[
dx_+ = q^{-1}a^2 \omega_0 + b^2 \omega_2, \quad dx_- = c^2 \omega_0 + q d^2 \omega_2, \quad dy_0 = ca \omega_0 + bd \omega_2.
\] (26)
Some lengthy but straightforward computations using the formulas (26), (21) and (7) yield the following commutation relations for the FODC \( \Gamma_2 \) on \( \mathcal{O}(S^2_q) \):
\[
dx_+ x_+ = x_+ dx_+ - q^{-1}x^2 d_+ x_0 + q x_+ x_0 dx_+,
\]
\[
dx_+ x_- = q^2 x_- d_+ + q x_+ x_- dx_0 - q^{-1}x_+ (x_0-1) dx_-,
\]
\[
dx_+ x_0 = x_0 dx_+ + q x_+ (x_0+q^{-2}) dx_0 - q^{-1}x_+^2 x_- dx_-,
\]
\[
dx_- x_+ = q^{-2} x_+ dx_- - q^{-1}x_- x_+ dx_0 - q x_- (x_0-1) dx_+,
\]
\[
dx_- x_- = x_- dx_- + q x_-^2 dx_0 - q^{-1}x_- x_0 dx_-,
\]
\[
dx_- x_0 = x_0 dx_- - q^{-1}x_- (x_0+q^2) dx_0 + q x_-^2 x_+^2 dx_+,
\]
\[
dx_0 x_+ = q^{-2} x_+ dx_0 + q^{-1}x_+ (x_0+q^{-2}) dx_0 - q^{-1}x_+ (x_0-1) dx_+ - q^3 x_+^2 x_+^2 dx_-,
\]
\[
dx_0 x_- = q^2 x_- dx_0 + q x_+ (x_0-1) dx_- - q x_- (x_0+q^2) dx_0 + q^3 x_-^2 x_-^2 dx_+,
\]
\[
dx_0 x_0 = x_0 dx_0 - q^{-1}x_+^2 (x_0-1) x_+ dx_- + q x_0 (x_0-1) dx_0.
\]
Moreover, from (26) it follows also that
\[
x_+ dx_- + q^2 x_- dx_+ - qx_0 dy_0 = 0.
\] (27)

**Lemma 4.** The FODC \( \Gamma_2 \) is the left counter-part of the unique 2-dimensional left-covariant \(*\)-FODC on \( \mathcal{O}(S^2_q) \) characterized in [10].

**Proof.** The assertion will follow from the first statement of the main theorem in [10]. Hence it suffices to check that \( \Gamma_2 \) fulfills the assumptions made there. Being induced from the left-covariant \(*\)-FODC \( \Gamma \) on \( \mathcal{O}(SU_q(2)) \), \( \Gamma_2 \) is obviously a left-covariant \(*\)-FODC on \( \mathcal{O}(S^2_q) \). The above commutation
rules show that the differentials $dx_+, dx_-, dx_0$ generate $\Gamma_2$ as a left $O(S^3_2)$-module. Thus it remains to verify assumption 7) in [10], Section 1. In the present context this condition means that for arbitrary elements $z_+, z_-, z_0 \in O(S^3_2)$ an equation

$$z_+ dx_+ + z_- dx_- + z_0 dy_0 = 0$$

(28)
in $\Gamma_2$ is valid if and only if there is an element $z \in O(S^3_2)$ such that

$$z_+ = q^2 z x_-, \quad z_- = z x_+, \quad z_0 = -q z x_0.$$  

(29)

Clearly, (28) implies (29) because of the relation (27). (By modifying the uniqueness proofs given in [10] or [1] the proof of the converse direction can be avoided in the present case, but we prefer to carry out it here.) Conversely, suppose now that (28) holds. Inserting this into (26) and comparing the coefficients of $\omega_0$ and $\omega_2$ we obtain

$$q^{-1} z_+ a^2 + z_- c^2 + z_0 ca = 0,$$

(30)

$$z_+ b^2 + q z_- d^2 + z_0 bd = 0.$$  

(31)

The equations (31) $q^2 ac - (30) db$, (31) $a^2 - (30) q^{-3} b^2$ and (31) $d^2 - (111) q^3 c^2$ can be written as

$$q^2 z_- x_+ - z_+ x_+ + q \lambda z_0 y_0 = 0,$$

(32)

$$z_-(q^{-1} \lambda_+ y_0 + q) + z_0 x_+ = 0,$$

(33)

$$z_+(q \lambda_+ y_0 + q^{-1}) + z_0 x_- = 0.$$  

(34)

respectively. Define now an element $z \in O(S^3_2)$ by

$$z := -\lambda_+^2 z_+ x_+ - z_0(q\lambda y_0 + q^{-1}) = -q^{-2} \lambda_+^2 z_+ x_+ - z_0(q^{-3} \lambda_+ y_0 + q^{-1}),$$

(35)

where the second equality follows from (32). From the algebra relations (22)–(23) and the formulas (33) and (34) it then follows that the relations (29) are fulfilled. For instance, let us explain how to get the first equality of (29). First we multiply the second representation of $z$ in (33) by $x_-$ from the right, then we symplify the terms by means of the algebra relations $x_+ x_- = q^2 y_0^2 + q y_0$ and $y_0 x_- = q^2 x_- y_0$ and finally we insert the expression of $z_0 x_-$ from (34). This in turn yields the desired relation $z x_- = q^2 z_+$. The second and third equalities in (33) can be derived in similar manner from the first expression of $z$ in (35) and formula (33).

4. Main results

The first main theorem describes all possible admissible commutator representations of the 3D-calculus on $SU_q(2)$. In order to formulate this result some further preliminaries are needed.

Let $\pi$ be a $*$-representation of $A = O(SU_q(2))$ as described by the model in the preceding section. Suppose that are a linear operator $T$ and a symmetric linear operator $R$ on $H_0$ and a dense linear subspace $D_0 \subseteq D(T) \cap D(T^*) \cap D(R)$ of $H_0$ such that $wD_0 = D_0$,

$$w T \pi^* \eta = q T \eta \quad \text{for} \quad \eta \in D_0,$$

(36)

$$w^2 R \pi^* \eta + q^2 R \eta = (1 + q^2) w R \pi^* \eta \quad \text{for} \quad \eta \in D_0.$$  

(37)
From the assumptions \( w \mathcal{D}_0 = \mathcal{D}_0 \) and (36) one easily derives that
\[
\begin{align*}
wT \eta &= qTw \eta, \\
w^* \eta &= qT^* w \eta, \\
T w^* \eta &= qw^* T \eta, \\
T^* w^* \eta &= qw^* T^* \eta 
\end{align*}
\] for \( \eta \in \mathcal{D}_0 \).

Further, assume that there are a symmetric linear operator \( Q \) on \( \mathcal{G} \) and a dense linear subspace \( \mathcal{E} \) of \( \mathcal{G} \) such that \( v \mathcal{D}_0 = \mathcal{D}_0 \) and
\[
v^2 Qv^2 \eta + q^2 Q \eta = (1 + q^2)vQv \eta \quad \text{for} \quad \eta \in \mathcal{D}_0.
\]

Let \( F \) be a linear operator on the Hilbert space \( \mathcal{G} \oplus \mathcal{H} \) which has the dense linear subspace \( \mathcal{D}_F := \mathcal{E} \oplus \text{Lin}\{\eta_n : \eta \in \mathcal{D}_0, n \in \mathbb{N}_0\} \) as a core and is defined by
\[
F \eta_n = \lambda_n T \eta_{n-1} + w^n Rw^* \eta_n + \lambda_{n+1} T^* \eta_{n+1}, \quad \eta \in \mathcal{D}_0,
\]
(40)
\[
F \eta = Q \eta, \quad \eta \in \mathcal{E}.
\]
(41)

Clearly, \( F \) is a symmetric operator.

**Theorem 1.** Under the above assumptions, the pair \((\pi, F)\) is an admissible commutator representation of the 3D-calculus on \( SU_q(2) \). Up to unitary equivalence any admissible commutator representation of the 3D-calculus is of this form.

We shall see in the next section that by appropriate choice of the above operators \( T \) and \( R \) one obtains a faithful admissible commutator representation of the 3D-calculus. In contrast to this the 4D\( \pm \)-calculus has no faithful admissible commutator representation.

**Theorem 2.** Let \((\pi, F)\) be an admissible commutator representation of the 4D\( \pm \)-calculus \( \Gamma_{\pm} \). Then the corresponding \(*\)-FODC homomorphism \( \rho : \Gamma_{\pm} \to \Gamma_{\pi, F} \) passes to a homomorphism of the quotient \(*\)-FODC \( \Gamma_{\pm, 3} \) to \( \Gamma_{\pi, F} \), so \((\pi, F)\) becomes a commutator representation of \( \Gamma_{\pm, 3} \).

The next theorem shows in particular that none of the three calculi can be given by a spectral triple in the sense of A. Connes.

**Theorem 3.** If \((\pi, F)\) is a commutator representation of the 3D-calculus or the 4D\( \pm \)-calculus such that all operators \( d_{\pi, F}(x), x \in \mathcal{A} \), are bounded, then we have \( d_{\pi, F}(x) = 0 \) for all \( x \in \mathcal{A} \).

5. Commutator representations of the 3D-calculus on \( SU_q(2) \)

In this section we investigate admissible commutator representations \((\pi, F)\) of the 3D-calculus \( \Gamma \) more in detail. Throughout this section we retain the notation of Sections 3 and 4 and suppose that \( \pi \) is a \(*\)-representation of \( \mathcal{A} = \mathcal{O}(SU_q(2)) \) such that \( \mathcal{G} = \{0\} \). If not specified otherwise all operator equations containing the operators \( R, T \) and \( F \) are meant on the domains \( \mathcal{D}_0 \) and \( \mathcal{D}_F = \text{Lin}\{\eta_n : \eta \in \mathcal{D}_0\} \), respectively. Further, we will denote an operator on \( \mathcal{H}_0 \) and the corresponding diagonal operator on \( \mathcal{H} = \bigoplus_n \mathcal{H}_n \) by the same symbol.

Let us first look at the operator relation (37). It can be rewritten in the form
\[
w(wRw^* - R)w^* = q^2 (wRw^* - R).
\]
(42)

Therefore, if \( R' \) and \( R'' \) satisfies the operator equations
\[
wR'w^* = q^2 R' \quad \text{and} \quad wR''w^* = R'',
\]
(43)
respectively, then \( R := R' + R'' \) is a solution of equation (39). Conversely, suppose that \( R \) is a solution of (37) and put
\[
R' := (1 + q^2)^{-1}(R - wRw^*) \quad \text{and} \quad R'' = (1 + q^2)^{-1}(q^2 R + wRw^*).
\]
Then \( R' \) and \( R'' \) satisfy the equations (34) and we have \( R := R' + R'' \). From this decomposition and Lemma 6 below it follows in particular that the only bounded solutions of (37) are the bounded operators commuting with \( w \). Further, we obtain that
\[
R_n\eta_n = w^n R w^* \eta_n = q^{2n} R' \eta_n + R'' \eta_n, \quad \eta \in D_0. \tag{44}
\]

If \((\pi, F)\) is a commutator representation of \( \Gamma \) with \(*\)-FODC homomorphism \( \rho : \Gamma \rightarrow \Gamma_{\pi, F} \), we let \( \Omega_j = \rho(-\imath \omega_j) \) denote the image of the left-invariant 1-form \(-\imath \omega_j, j = 0, 1, 2\). Then we have
\[
\Omega_0 = \Omega_{\pi, F}(b), \quad \Omega_2 = \Omega_{\pi, F}(c), \quad \Omega_1 = \Omega_{\pi, F}(a) = -q^{-2} \Omega_{\pi, (d)}.
\]
The next theorem gives a reformulation of admissible commutator representations in terms of the representation \( \pi \). It shows that the operators \( \Omega_0, \Omega_2, \Omega_1 \) can be nicely expressed in terms of the operators \( T \) and \( R' \). Note that \( \pi(c)^{-1} \) is a well-defined bounded operator mapping \( D_F \) into itself, because we assumed that \( G = \{0\} \).

**Theorem 4.** Suppose that \((\pi, F)\) is an admissible commutator representation of the 3D-calculus and let \( F \) be of the form (44) with operators \( T \) and \( R = R' + R'' \) satisfying (30) and (34), respectively. Then we have
\[
\pi(c)T = qT \pi(c) \quad \text{and} \quad \pi(c)R' = q^2 R' \pi(c), \tag{45}
\]
\[
R'' \pi(x) = \pi(x) R'' \quad \text{for all} \quad x \in A, \tag{46}
\]
\[
F \eta_n = T \pi(a) \eta_n + \pi(c)^n R \pi(c)^{n-2} \eta_n + R^* \eta_n + T^* \pi(d)(\eta_n, \eta \in D_0, \tag{47}
\]
\[
\Omega_0 = \lambda \pi(b) T, \quad \Omega_2 = -\lambda \pi(c) T^*, \quad \Omega_1 = q^{-2} \lambda \pi(bc) R'. \tag{48}
\]

Conversely, if \( R' \) and \( R'' \) are symmetric linear operators and \( T \) is a linear operator defined on common dense linear subspace \( D_0 \subseteq D(T) \cap D(T^*) \cap D(R) \) of the Hilbert space \( \mathcal{H}_0 \) such that (32) and (34) are valid, then the pair \((\pi, F)\) with \( F \) defined by (44) is an admissible commutator representation of the 3D-calculus.

**Proof.** Most of the assertions are only reformulations of the conditions occuring in Section 4. Therefore we do not carry out all details of proof. For instance, (39) and (37) are equivalent to the equations (37) and (34). Since \( R'' = wR''w^* \) as noted above, \( R'' \) commutes with \( \pi(b) \) and \( \pi(c) \) and hence with all representation operators \( \pi(x), x \in A \). Formula (47) follows from (40) and (44).

As a sample, we prove the formula for \( \Omega_0 \) and compute
\[
\Omega_0 \eta_n = (\pi(d) F \pi(b) - q^{-1} \pi(b) F \pi(d)) \eta_n
= -q^{n+1} \pi(d)(\lambda_n T w^* \eta_n + w^n R w^* \eta_n + \lambda_{n+1} T^* w^* \eta_{n+1}) - q^{-1} \pi(b) \lambda_{n+1} T \eta_n + w^{n+1} R w^* \eta_{n+1} + \lambda_{n+2} T^* \eta_{n+2})
= -q^{n+1} (\lambda_n T w^* \eta_n + \lambda_{n+1} w^n R w^* \eta_n + \lambda_{n+1} \lambda_{n+2} T^* w^* \eta_{n+2})
+ q^n \lambda_{n+1} T w^* \eta_n + q^{n+1} \lambda_{n+1} w^n R w^* \eta_{n+1} + q^{n+2} \lambda_{n+1} \lambda_{n+2} w^* T^* \eta_{n+2}
= (-q^{n+1} \lambda_{n+1} + q^{n+1} \lambda_{n+1} \lambda_{n+2}) T w^* \eta_n
= q^n (q^{-1} - q) T w^* \eta_n = \lambda \pi(b) T \eta_n.
\]
for $\eta \in D_0$. In similar manner, one shows that

$$\Omega_2 \eta_n = (-q \pi(c) F \pi(a) + \pi(a) F \pi(c)) \eta_n = q^{n-1}(q^{-1} - q) w T^* \eta_n,$$

$$\Omega_1 \eta_n = (\pi(d) F \pi(a) - q^{n-1} \pi(b) F \pi(c) - F) \eta_n = (R_{n-1} - R_n) \eta_n$$

$$= w^{n-1}(R - w Rw^*) w^{*n-1} \eta_n = (1 - q^2) w^{n-1} R' w^{*n-1} \eta_n = (1 - q^2)q^{2n-2} R' \eta_n.$$  

These relations imply the two other formulas of (48).

By the preceding, for a given $*$-representation $\pi$ of $A$ such that $G = \{0\}$ the operators $F$ of admissible pairs $(\pi, F)$ are parametrized by the three operators $T, R'$ and $R''$ on the Hilbert space $H_0$ satisfying the relations

$$wT w^* = qT, \ wR' w^* = q^2 R' \text{ and } wR'' w^* = R''.$$

(49)

It is now easy to construct admissible pairs $(\pi, F)$. We shall do this for the faithful $*$-representation $\pi$ of the $*$-algebra $A$ given in [14]. In this case $w$ is the backward shift on the Hilbert space $H_0 = l_2(\mathbb{Z})$. That is, if we identify $H$ with $l_2(\mathbb{N}_0 \times \mathbb{Z})$ and denote by $\{e_{nk}: n \in \mathbb{N}_0, k \in \mathbb{Z}\}$ the standard orthonormal basis of $l_2(\mathbb{N}_0 \times \mathbb{Z})$, then the operators $w, \pi(a)$ and $\pi(c)$ act as

$$we_{nk} = e_{n-1,k}, \ \pi(a)e_{nk} = \lambda_ne_{n-1,k}, \ \pi(c)e_{nk} = q^ne_{n,k-1}.$$  

(50) Define linear operators $T$ and $R'$ on the domain $D_F := \text{Lin}\{e_{nk}: n \in \mathbb{N}_0, k \in \mathbb{Z}\}$ by

$$Te_{nk} = q^k e_{n-k-1}, \ R'e_{nk} = q^{2k} e_{nk}.$$  

(51) Let $R''$ by a symmetric linear operator on $D_F$ such that $wR'' w^* = R''$. The conditions [13] are obviously fulfilled. By [14], [51] and [17], the action of the operator $F$ on the basis vectors $e_{nk}$ is given by

$$F e_{nk} = \lambda_n q^k e_{n-1,k-1} + q^{2n+2k} e_{nk} + \lambda_{n+1} q^{k+1} e_{n+1,k+1} + R'' e_{nk}.$$  

Then the pair $(\pi, F)$ is an admissible commutator representation of the 3D-calculus $\Gamma$ on $SU_q(2)$. For instance, one may take $R''$ of the form $R'' e_{nk} = \sum_r \alpha_r e_{n,r-k}$, where $\{\alpha_r: \Gamma \to \mathbb{Z}\}$ is a real sequence such that $\alpha_r = 0$ for $|r| \geq r_0$. In this case it is straightforward to prove that then the corresponding FODC homomorphism $\rho: \Gamma \to \Gamma_{\pi,F}$ is faithful. (Indeed, using the vector space basis $\{a^n b^m c^r, b^m c^r d^*; m, n, s \in \mathbb{N}_0, n \in \mathbb{N}\}$ of $A$ and the formulas [18] one verifies that any relation $\pi(x_0) \Omega_0 + \pi(x_1) \Omega_1 + \pi(x_2) \Omega_2 = 0$ with $x_0, x_1, x_2 \in A$ implies that $x_0 = x_1 = x_2 = 0$.)

Note that the operators $d_{\pi,F}(x) = [iF, \pi(x)], x \in A$, of the FODC $\Gamma_{\pi,F}$ are unbounded. This stems from the fact that $T$ and $R''$ and hence the basis elements $\Omega_j, j = 0, 1, 2,$ of the vector space of left-invariant 1-forms of $\Gamma_{\pi,F}$ are unbounded operators. The reason are the sequences $(q^k)$ resp. $(q^{2k})$ in [51] as $k \to -\infty$, so this unboundedness is rather well controlled.

Commutator representations can be used to construct extensions of $*$-FODC to larger algebras. We explain this for the 3D-calculus. It is clear that the set $S := \{b^n c^m; n, m \in \mathbb{N}_0\}$ is a left Ore subset of the algebra $A$. That is, for any $(s, x) \in S \times A$ there exists $(t, y) \in S \times A$ such that $ys = tx$. Moreover, the algebra $A$ has no zero divisors. Therefore, as it is well-known in ring theory, there exists a $*$-algebra $\tilde{A}$ which contains $A$ as a $*$-subalgebra such that the elements of $S$ are invertible and $\tilde{A}$ is generated by $A$ and the inverses of $S$. Since the Hilbert space $G$ is zero, the $*$-representation
Let $\pi$ of $\mathcal{A}$ extends uniquely to a $*$-representation $\hat{\pi}$ of the $*$-algebra $\hat{\mathcal{A}}$. Hence $(\Gamma_{\pi, F}, d_{\pi, F})$ is a $*$-FODC of the $*$-algebra $\hat{\mathcal{A}}$. If we take a faithful commutator representation $(\pi, F)$ of the $3D$-calculus, the we obtain an extension of the $3D$-calculus to the larger $*$-algebra $\hat{\mathcal{A}}$ in this manner.

For the study of harmonic analysis and metric noncommutative geometry on $SU_q(2)$ it is more important to work with the direct sum $\pi_{\text{reg}}$ of $N_0$ copies of the $*$-representation $\pi$. That is, we take the Hilbert space $\mathcal{H}_{\text{reg}} = l_2(N \times \mathbb{Z} \times N_0)$ with standard orthonormal basis $\{e_{nkl}; n, l, k \in \mathbb{N}_0, k \in \mathbb{Z}\}$ and let the operators $\pi_{\text{reg}}(x), x \in \mathcal{A}$, and $w$ act on the first two indices as stated above. Then $\pi_{\text{reg}}$ is just the GNS representation of $\mathcal{A}$ associated with the Haar state $h$ of the compact quantum group algebra $\mathcal{A} = \mathcal{O}(SU_q(2))$. Indeed, if $\varphi_h$ denotes the vector

$$\varphi_h := (1 - q^2)^{-1/2} \sum_{n=0}^{\infty} q^n e_{n00}$$

then it follows at once from the explicit formulas for the Haar state [14,13,8,6] that

$$h(x) = \langle \pi_{\text{reg}}(x) \varphi_h, \varphi_h \rangle, \quad x \in \mathcal{A}.$$ 

Let $\alpha$ and $\beta$ be positive reals. Define operators $T, R'$ and $R''$ on the span of basis vectors $e_{nkl}$ by

$$T e_{nkl} = \alpha(1 + q^2)^{1/2} q^k e_{n,k-1,l-1}, \quad R' e_{nk} = \beta q^2(1 + q^2 + q^4)^{1/2} q^{2k} e_{nkl}, \quad R'' = 0.$$ 

Let $F_{\text{reg}}$ denote the corresponding operator given by (47). Then the pair $(\pi_{\text{reg}}, F_{\text{reg}})$ is another admissible commutator representation of the $3D$-calculus. It is natural to use the state vector $\varphi_h$ to define a scalar product on the $1$-forms of the $3D$-calculus $\Gamma$ by

$$\langle \omega, \omega' \rangle := \langle \rho(\omega) \varphi_h, \rho(\omega') \varphi_h \rangle, \quad \omega, \omega' \in \Gamma,$$

where $\rho : \Gamma \to \pi_{\text{reg}}, F_{\text{reg}}$ is the corresponding $*$-FODC homomorphism. Using the formulas (52), (53) and (54) we compute

$$\langle \omega_0, \omega_0 \rangle = \langle \omega_2, \omega_2 \rangle = \alpha^2, \quad \langle \omega_1, \omega_1 \rangle = \beta^2 \text{ and } \langle \omega_k, \omega_l \rangle = 0 \text{ if } k \neq l.$$ 

6. Commutator representations of the $2$-dimensional calculus on $S^2_q$

By Lemma 4 we have shown that the $3D$-calculus $\Gamma$ on the quantum group $SU_q(2)$ induces the $2$-dimensional calculus $\Gamma_2$ on the quantum $2$-sphere $S^2_q$. Thus any commutator representation of the $3D$-calculus gives obviously a commutator representation of the $*$-FODC $\Gamma_2$ on the $*$-subalgebra $\mathcal{O}(S^2_q)$ of $\mathcal{O}(SU_q(2))$. In this brief section we shall make this more explicit.

Let $(\pi, F)$ be an admissible commutator representation of the $3D$-calculus as described in Section 4, where the $*$-representation $\pi$ is as in Subsection 3.1. Using the condition $wT w^* = qT$ by (36) and the formulas (3) and (4) we compute the differentials of the generators $x_-, x_+, y_0$ and obtain

$$d_{\pi, F}(x_+) = i q^{-1} \lambda \pi(a) T \pi(x_+) - i \lambda \pi(b) T^* \pi(y_0), \quad d_{\pi, F}(x_-) = -i q \lambda \pi(d) T \pi(x_-) + i \lambda \pi(c) T^* \pi(y_0),$$

$$d_{\pi, F}(y_0) = i q^{-1} \lambda \pi(a) T \pi(y_0) - i q \lambda \pi(d) T \pi(y_0) = i \lambda \pi(c) T \pi(x_-) - i \lambda \pi(b) T^* \pi(x_-).$$

These formulas describe the corresponding commutator representation of the $*$-FODC $\Gamma_2$ of $\mathcal{O}(S^2_q)$. In particular we see that the operator $R$ does not occur in these formulas and that $d_{\pi, F}(x) = 0$ on the subspace $\mathcal{G}$ for all $x \in \mathcal{O}(S^2_q)$.
Conversely, let $\pi$ be a $\ast$-representation of $\mathcal{O}(SU_q(2))$ on the Hilbert space $\mathcal{H} = \oplus_n \mathcal{H}_n$ as in Subsection 3.1 and let $T$ be a linear operator on the Hilbert space $\mathcal{H}_0$. If there exists a dense linear subspace $\mathcal{D}_0 \subseteq \mathcal{D}(T) \cap \mathcal{D}(T^*)$ of $\mathcal{H}_0$ such that $w\mathcal{D}_0 = \mathcal{D}_0$ and $wT^*w = qT\eta$ for $\eta \in \mathcal{D}_0$, then the above formulas describe a commutator representation of the $\ast$-FODC $\Gamma_2$ of $\mathcal{O}(S^2_q)$. Examples can be constructed similarly as in the case of the 3D-calculus.

Using the $\ast$-FODC $(\Gamma_\pi,F,d_{\Gamma_\pi,F})$ of the Ore extension $\hat{\mathcal{A}}$ of the $\ast$-algebra $\mathcal{A}$ defined in the preceding section, the operators $T$ and $T^*$ can be expressed by the formulas

$$T = i\lambda^{-1}bd_{\pi,F}(db^{-1}) \quad \text{and} \quad T^* = -i\lambda^{-1}cd_{\pi,F}(ac^{-1}).$$ (55)

**Remark 2.** Let $z := ac^{-1}$. In the $\ast$-algebra $\hat{\mathcal{A}}$ we then have $z^* = -db^{-1}$ and

$$z^*z - q^2zz^* = q^2 - 1.$$ (56)

The $\ast$-subalgebra $\mathcal{Z}$ of $\hat{\mathcal{A}}$ generated by the element $z := ac^{-1}$ is just the abstract $\ast$-algebra with a single generator $z$ and defining relation (56). It is well-known that this $\ast$-algebra $\mathcal{Z}$ has a $\ast$-FODC with commutation relations

$$d_zz = q^2zd_z, \quad dz\cdot z = q^{-2}z^*dz, \quad dz^*z = q^2zdz^*, \quad dz^*z^* = q^{-2}z^*dz^*.$$ These relations can be found (for instance) in [11]. As a byproduct of the preceding consideration we obtain a commutator representation $(\pi,F)$ of this $\ast$-FODC, where $\pi$ denotes the restriction to $\mathcal{Z}$ of the above $\ast$-representation $\hat{\pi}$ of $\hat{\mathcal{A}}$ and $F$ is the operator given by (40) with $R = 0$ and $wTw^* = qT$. That is, we have

$$\pi(z)\eta_n = q^{-n}w^*\lambda_n\eta_{n-1}, \quad \pi(z^*)\eta_n = q^{-n-1}w\lambda_{n+1}\eta_{n+1},$$

$$F\eta_n = \lambda_nT\eta_{n-1} + \lambda_{n+1}T^*\eta_{n+1}.$$ (58)

From formula (58) we see that then the operators of the differentials $d_{\pi,F}(z)$ and $d_{\pi,F}(z^*)$ act as

$$d_{\pi,F}(z)\eta_n = i\lambda q^{-n}w^*T^*\eta_n, \quad d_{\pi,F}(z^*)\eta_n = -i\lambda q^{-n-1}wTw\eta_n.$$ (59)

### 7. Proofs of Theorems 1, 2 and 3

Let us begin with some notation. For simplicity we write $x$ for the representation operator $\pi(x)$ of an algebra element $x \in \mathcal{A}$. Further, we shall omit the symbols $[\mathcal{D}_0$ and $\mathcal{D}$ denoting the restrictions of the operators to $\mathcal{D}_0$ and $\mathcal{D}$, respectively. Moreover, we write simply $\Omega(\cdot)$ instead of $\Omega_{\pi,F}(\cdot)$.

First let $\Gamma$ be the 3D-calculus on $SU_q(2)$. We want to prove that the pair $(\pi,F)$ defined at the beginning of Section 5 is indeed a commutator representation of $\Gamma$. By Lemma 3, if suffices to show that $\Omega(x) = 0$ for the six generators $x$ of the right ideal $\mathcal{R}_1$ listed by formula (1). Computing the corresponding expressions of $\Omega(x)$ by using formula (1), we obtain the relations

$$\Omega(q^2b^2) = q^2d^2Fb^2 + b^2Fd^2 - (q^2 + 1)bdFdb = 0,$$ (57)

$$\Omega(c^2) = q^2c^2Fa^2 + a^2Fc^2 - (q^2 + 1)acFca = 0,$$ (58)

$$\Omega(qbc) = -q^2cdFba + (q^2 + 1)bcFbc - abFdc + qFbc + qbcF = 0,$$ (59)

$$\Omega(q^2(a - 1)b) = q^2d^2Fab - (q^2 + 1)bdFb + b^2Fcd - q^2dFb - qbdF + qFbd = 0,$$ (60)

$$\Omega((a - 1)c) = -qcdFca^2 + (q^2 + 1)bcFca - baFc^2 + Fac + qcFa - aFc = 0,$$ (61)

$$\Omega((q^2a + d - q^2 - 1)) = q^2dFa + aFd - qbFc - qcFb - (1 + q^2)F = 0.$$ (62)
The relations (57) and (60) follows from (58) and (61), respectively, by applying the adjoint operation and using the equations (2) and the fact that the operator $F$ is symmetric. Therefore it is sufficient to check (58), (59), (61) and (62). We omit these boring straightforward computations. In the course of these verifications the formulas (3)–(4) and (40)–(41) for the definition of the representation $\pi$ and of the operator $F$ and the relations (36)–(39) are essentially used. Thus, $(\pi, F)$ is indeed a commutator representation of $\Gamma$. The admissibility of $(\pi, F)$ is obvious from its definition. This completes the proof of the first assertion of Theorem 1.

The next part of this section is devoted to the proofs of the second assertion of Theorem 1 and of Theorem 2. For this we suppose that $\Gamma$ is either the $3D$-calculus, the $4D_+\text{-}\text{calculus}$ or the $4D_-\text{-}\text{calculus}$ on $SU_q(2)$ and that $(\pi, F)$ is an arbitrary admissible commutator representation of $\Gamma$. Let $D_0$, $E$ and $D$ be corresponding subspaces.

**Lemma 5.** (i) If $\Gamma$ is the $3D$-calculus, then we have
\begin{align*}
q^2c^2Fa^2 + a^2Fc^2 - (q^2 + 1)acFca &= 0, \quad (63) \\
qc^2Fa + gaFc^2 - q^2cFac - caFc &= 0, \quad (64) \\
-q^2cdFba + (q^2 + 1)bcFbc - abFdc + qFbc + qbcF &= 0, \quad (65) \\
q^2dFa + aFd - qbFc - qcFb - (q^2 + 1)F &= 0. \quad (66)
\end{align*}

(ii) If $\Gamma$ is the $4D_+\text{-}\text{calculus}$, then we have equations (63) and
\begin{align*}
-\frac{q^2cdFba + (q^2 + 1)bcFbc - abFdc + qFbc + qbcF}{q^2dFa + aFd - qbFc - qcFb - (q^2 + 1)F} &= 0, \quad (67) \\
-q^2dcFah + qacFba - q^2c^2Fh - qabcF &= 0. \quad (68)
\end{align*}

**Proof.** (i): By (3), the right ideal $R_\Gamma$ associated with the $3D$-calculus contains the elements $c^2, bc, qa^2 + a - (q^2 + 1)$ and $a - 1c$. Therefore, by Lemma 2 we have $\Omega_{\pi,F}(c^2) = 0, \Omega_{\pi,F}(bc) = 0, \Omega_{\pi,F}(qa^2 + a - (q^2 + 1)) = 0$ and $\Omega_{\pi,F}(a - 1c) = 0$. Computing these expressions by using (1) leads to the equations (63), (65), (66) and
\begin{align*}
(q^2 + 1)bcFca - qcdFba - Fdc - qacFca - aFc &= 0, \quad (69)
\end{align*}
respectively. It remains to derive equation (64). If we subtract equation $a(66)$ from $q^2(61)$, we obtain
\begin{align*}
q^2bcFca + qacFbc - q^3cdFh - a^2Fdc + q^3cFa + aFc &= 0. \quad (70)
\end{align*}
Adding (70) and $qc(66)$, we get the equation
\begin{align*}
(q^2 + 1)caFbc - q^2c^2Fba - a^2Fdc + qcaF + aFc - qcFca &= 0. \quad (71)
\end{align*}
Inserting the relation $a^2Fc^2 = -q^2c^2Fa^2 + (q^2 + 1)acFca$ by (63) into (71), we finally get equation (64) as asserted.
(ii): Since the three elements \( x = e^2, q(e(a - d)), z \in C \) belong to the right ideal associated with the \( 4D_+ \)-calculus (see (18)), the corresponding operators \( \Omega_{\pi,F}(x) \) are zero by Lemma 2. This leads to the equations (63), (68) and

\[
\begin{align*}
- q^2 c d F a^2 + q^2 a d F a + q^2 b e F c a - q a b F c^2 + q^2 c^2 F b a - q a c F c - q c a F d a \\
+ a^2 F d c + \epsilon(q^4 + 1)c F a - \epsilon(q^3 + q^{-1})a F c = 0,
\end{align*}
\]

(72) respectively. We still have to verify equation (77). Dividing (78) by \( q^4 + 1 \) and simplifying the terms by using the commutation rules of the matrix entries \( a, b, c, d \), we obtain the equation

\[
(q^2 + 1) b c F c a - b a F c^2 - q^2 d c F a^2 + q F c a - q a F c + q^2 c c F a = 0.
\]

(73) If we substitute \( q^2 c^2 F a^2 = (q^2 + 1) a c F c a - a^2 F c^2 \) (by (74)) into \( q^{-1}c \) (73), then equation (77) follows.

Now we make use of the structure of the \(*\)-representation \( \pi \) and of the admissibility of the pair \((\pi, F)\). We freely use the notation established above. Let \( D^k \) be the direct sum of domains \( D_k = \{ \eta_k : \eta \in D_0 \}, k = 0, \ldots, n \), and let \( H^k \) denote the direct sum of subspaces \( H_k, k = 0, \ldots, n \), of \( H \). Using essentially relation (13) and the fact that \( \text{ker} \ a^k = H_k - 1 \), a straightforward induction argument shows that the operator \( F \) maps each space \( D^n \) into \( H^{n+1} \). This in turn implies that \( F \) maps the subspace \( D = \text{Lin}\{D_n : n \in \mathbb{N}_0 \} \) into \( H = \oplus \mathbb{H}_n \). Since \( F \) is symmetric, it follows that \( F \) maps the domain \( E \) into \( G \). By assumption, \( E \oplus D \) is a core for \( F \). Therefore, the operator \( F \) and hence all operators \( \Omega_{\pi,F}(x), x \in A \), leave the spaces \( G \) and \( H \) invariant. Using once more the facts that the operator \( F \) is symmetric and that \( F \) maps \( D^n \) into \( H^{n+1} \) it follows that the restriction of the operator \( F \) to the dense linear subspace \( D \) of \( H \) is of the form

\[
F \eta_n = T_n \eta_{n-1} + R_n \eta_n + T_{n+1}^* \eta_{n+1}, \quad \eta \in D_0.
\]

(74) Here \( T_n \) and \( R_n, n \in \mathbb{N}_0 \), are (possible unbounded) linear operators on the Hilbert space \( H_0 \) such that the domains of \( T_n, R_n \) and \( T_n^* \) contain \( D_0 \) and \( R_n \) is symmetric. Formula (74) will be essentially used in the sequel. For \( n \in \mathbb{N} \), we set

\[
E_n := R_n - w R_{n-1} w^*.
\]

(75) Inserting the formulas (4) and (74) for the action of the operators \( a, c \) and \( F \) into (13) and comparing the expressions occurring in the \((n-2)\)-th, \((n-1)\)-th and \( n \)-th components, we obtain the recurrence relations

\[
\begin{align*}
\lambda_{n+1} \lambda_n w^2 T_{n-1} + q^4 \lambda_n \lambda_{n-1} T_{n+1} w^2 &= (q + q^3) \lambda_{n+1} \lambda_{n-1} w T_n w, \\
w^2 R_{n-1} + q^2 R_{n+1} w^2 &= (q^2 + 1)w R_n w, \\
\lambda_{n+1} \lambda_n w^2 T_n + \lambda_{n+2} \lambda_{n+1} T_{n+2}^* w^2 &= (q + q^{-1}) \lambda_{n+1} w T_n^* w,
\end{align*}
\]

(76) \( (77) \) \( (78) \) respectively. Applying first the adjoint operation to (78), multiplying then by \( w^2 \) from the left and from the right, dividing by \( \lambda_{n+1} \) and replacing finally \( n \) by \( n-1 \), we get

\[
\lambda_{n-1} w^2 T_{n-1} + \lambda_{n+1} T_{n+1} w^2 = (q + q^{-1}) \lambda_n w T_n w.
\]

(79)
The equation \( \lambda_{n-1}(74) - \lambda_n \lambda_{n+1}(72) \) reads as
\[
(q^4 \lambda_n \lambda_{n-1} - \lambda_n \lambda_{n+1}^2) T_{n+1}w^2 = (q + q^3) \lambda_n \lambda_{n+1}((q + q^3) \lambda_n - (q + q^{-1}) \lambda_n \lambda_{n+1}) wT_n w.
\]
Since \( \lambda_k^2 = 1 - q^{2k} \) by (77), the latter yields \( \lambda_n T_{n+1}w^2 = q^{-1} \lambda_{n+1} wT_n w \) and so
\[
q \lambda_n T_{n+1} = \lambda_{n+1} wT_n w^*.
\] (80)

Note that the preceding formulas (74), (77) and (80) are valid for both the 3\(D_3\)-calculus and the 4\(D_{\pm}\)-calculus, because they were derived only from equation (53) and this equation holds for all three calculi according to Lemma 5.

In order to continue the proof we first specify to the 3\(D_3\)-calculus. Then, by Lemma 5(i), we have also equation (64). Inserting now (74) into (64) and comparing the \((n-1)\)-th and \(n\)-th components, we get the relations
\[
q^2 R_n w^2 + w^2 R_{n-1} = q^2 w R_{n-1} w + w R_n w, \quad (81)
\]
\[
\lambda_{n+1} T_{n+1}^* w^2 + \lambda_n w^2 T_n^* = q \lambda_n w T_n^* w + q^{-1} \lambda_{n+1} w T_{n+1}^* w, \quad (82)
\]
respectively. Multiplying (82) by \(w^*\) from the right, replacing \(n\) by \(n-1\), passing to the adjoint operators and finally applying formula (80), we derive
\[
\lambda_{n+1} T_n = \lambda_n T_{n+1}. \quad (83)
\]
Comparing (84) and (83) we conclude that \(T_n = \lambda_n \lambda_1^{-1} T_1\) and \(w T_n w^* = q T_n\). That is, setting \(T := \lambda_1^{-1} T_1\), we have
\[
T_n = \lambda_n T \quad \text{and} \quad w T_n w^* = q T_n, \quad \eta \in D_0. \quad (84)
\]

Next we investigate the diagonal terms \(R_n\) of the operator \(F\). First we note that in terms of the operators \(E_n\) defined by (73), the equations (74) and (81) are reformulated as
\[
q^2 E_{n+1} = w E_n w^* \quad \text{and} \quad q^2 E_n = w E_n w^*, \quad (85)
\]
respectively. In particular, we have \(E_{n+1} = E_n\) for all \(n\). If we compare the \(n\)-th components in (85), we get the relation
\[
q^{n+2} \lambda_n^2 w R_{n-1} w^* + (q^2 + 1) q^{2n+2} R_n + q^{n+2} \lambda_{n+1}^2 w^* R_{n+1} w - 2q^{n+2} R_n = 0. \quad (86)
\]
Putting the relations (55) into (60) we derive that \(E_n = 0\) for all \(n\). Setting \(R := R_0\), the latter means that
\[
R_n = w R_{n-1} w^* = w^n R w^{*n}. \quad (87)
\]
Further, comparing the \(n\)-th components in (60), we find that
\[
q^2 \lambda_n^2 R_{n-1} + \lambda_n^2 R_{n+1} + q^{2n+2} w^* R_n w + q^{2n+2} w R_n w^* - (q^2 + 1) R_n = 0. \quad (88)
\]
Inserting the relation \(E_n = 0\) into (58), we obtain \(R_{n+1} + q^2 R_{n-1} - (q^2 + 1) R_n = 0\). Because of (57), this means that
\[
w^2 R w^* + q^2 R = (1 + q^2) w R w^*. \quad (89)
\]
Finally, the restriction of the operator $F$ to the subspace $E$ of the Hilbert space $G$ is a symmetric linear operator, say $Q$. Since $b = c = 0$, $a = v$ and $d = w$ on $G$ by (8), equation (64) reads as

$$v^2 Q v^2 + q^2 Q = (1 + q^2) v Q v^*.$$  \hfill (90)

Summarizing the preceding, the formulas (74), (72), (55), (89) and (90) show that the operator $F$ has the required form. This completes the proof of the second assertion of Theorem 1.

Now we turn to the $4D_{\pm}$-calculus and prove Theorem 2. To begin with, we compute the $(n-1)$-th and the $n$-th components of the expressions in equation (67). Comparing coefficients we derive

$$R_n w^2 - q^{-1} w R_n w - w R_{n-1} w + q^{-1} w^2 R_{n-1} = 0,$$ \hfill (91)

$$\lambda_{n+1} T_{n+1} w^2 - \epsilon \lambda_{n+1} w T_{n+1} w - q \lambda_n w T_n w + q \epsilon \lambda_n w^2 T_n = 0.$$ \hfill (92)

Applying the adjoint operation to (92), we get

$$\lambda_{n+1} T_{n+1} - \epsilon \lambda_{n+1} w T_{n+1} w^* - q \lambda_n w T_n w^* + q \epsilon \lambda_n w^2 T_n w^* = 0.$$ \hfill (93)

Recall that formula (80) holds also for the $4D_{\pm}$-calculus, because it was derived from formula (63). Inserting (80) into (93), we derive that

$$T_{n+1} = \epsilon w T_{n+1} w^*.$$ \hfill (94)

Combining the latter with (80), we get

$$q \lambda_n T_{n+1} = \epsilon \lambda_{n+1} T_n.$$ \hfill (95)

Next we use equation (88) which holds by Lemma 5(ii). Computing the $(n-1)$-th components of (88), we obtain the relation

$$- q^2 \lambda_n^2 w R_{n-2} + q^3 \lambda_n w^* R_n w^2 + q^3 \lambda_n w^2 R_{n-1} w^* - q^{n+2} \lambda_n R_{n+1} w - (q^2 + 1) q^3 \lambda_n R_{n-1} w - (q^2 + 1) q^3 \lambda_n R_n w + q \lambda_n R_{n-1} w + q \lambda_n R_{n+1} w = 0.$$ \hfill (96)

In terms of the operator $E_n$, the formulas (74) and (71) can be written as

$$q^2 E_{n+1} = w E_n w^*$$ \hfill (97)

respectively. Inserting these formulas into (96) $w^*$, a lengthy computation shows that $E_n = 0$. That is, setting $R := R_0$, we have

$$R_n = w R_{n-1} w^* = w^n R w^2$$ for $n \in \mathbb{N}_0$. \hfill (98)

Using the formulas (74), (72) and (88) established above, we compute

$$\Omega(a) \eta_n = (\epsilon q - 1) T_n \eta_{n-1} + (R_{n-1} - R_n) \eta_n + (\epsilon q - 1) T_{n+1} \eta_{n+1},$$ \hfill (99)

$$\Omega(b) \eta_n = - \lambda q^3 \lambda_n^2 T_n \eta_n \equiv \lambda q^3 \lambda_n^2 T_n \eta_n,$$ \hfill (100)

$$\Omega(c) \eta_n = - \lambda q^3 \lambda_n \lambda_n^{-1} T_n \eta_n \equiv - \lambda q^3 \lambda_n T_n \eta_n,$$ \hfill (101)

$$\Omega(d) \eta_n = (\epsilon q^{-1} - 1) T_n \eta_{n-1} + (R_{n+1} - R_n) \eta_n + (\epsilon q^{-1} - 1) T_{n+1} \eta_{n+1},$$ \hfill (102)
for $\eta \in \mathcal{D}_0$ and $n \in \mathbb{N}$. In particular, we get
\[
\Omega(a + eqd)\eta_n = (eqR_{n+1} - (eq + 1)R_n + R_{n-1})\eta_n.
\] (103)

Put $\Omega_j = \rho(-i\omega_j)$. Since $\rho$ is bimodule homomorphism, the commutation relations between the 1-forms $\omega_j$ and the generators $a, b, c, d$ remain valid if $\omega_j$ is replaced by $\Omega_j$. In particular, the relation
\[
\omega_2a = c\omega_2 + \epsilon\lambda^2q^{-1}\omega_4
\] yields
\[
\Omega_2a = \epsilon a\Omega_2 + \epsilon\lambda^2q^{-1}b\Omega_4.
\] (104)

Since $\Omega(a + eqd) = (1 - q^2)(eq^{-3} - 1)\Omega_4$ by (14) and (15), it follows from (103) that $\Omega_4: \mathcal{H}_n \to \mathcal{H}_n$ and so $b\Omega_4 : \mathcal{H}_n \to \mathcal{H}_n$. Further, by (100) the operators $\Omega_2a$ and $\epsilon a\Omega_2$ map $\mathcal{H}_n$ into $\mathcal{H}_n$. Because of (104) this implies that $\Omega_4 = 0$ on each space $\mathcal{H}_n$ and so on $\mathcal{H}$. From the relation
\[
\omega_2c = c\omega_2 + \epsilon\lambda^2q^{-1}d\omega_4
\] we get $\Omega_2c = \epsilon\Omega_2 + \epsilon\lambda^2q^{-1}d\Omega_4$. Since $c = 0$ and $d$ is unitary on $\mathcal{G}$, this implies that $\Omega_4 = 0$ on $\mathcal{G}$.

Thus we have shown that $\Omega_4 = 0$ on $\mathcal{G} \oplus \mathcal{H}$ which yields that $\rho(\omega_{T_{\pm}}(a + eqd)) = 0$. Therefore, by Lemma 3 the FODC homomorphism $\rho$ passes to the quotient FODC $\Gamma_{\pm,3}$. This completes the proof of Theorem 2.

**Remark 3.** The assertions of Theorems 1 and 2 could be also derived from the commutation relations and the involution properties of the calculi thus avoiding the use of the right ideals. We prefered to give the above proof because it emphasizes the role of the corresponding right ideals and it needs only very few generators of the right ideals.

**Remark 4.** By adding a few lines to the preceding arguments one gets a complete description of all admissible commutator representations of the quotient $*$-FODC $\Gamma_{\pm,3}$. In this remark we briefly derive this result. Since $\Omega_4 = 0$ and hence $\Omega(a + eqd) = 0$, it follows from (104), (10) and (108) that
\[
\omega_2R\omega^* + eq^{-1}R = (1 + eq^{-1})wRw^* \text{ on } \mathcal{D}_0.
\] (105)

Set $T := \lambda_1^{-1}T_1$. From (14) and (15) we get $T_n = (eq)^{1-n}\lambda_n T$ and
\[
wT^* = \epsilon T \text{ on } \mathcal{D}_0.
\] (106)

Let $Q$ denote the restriction of $F$ to the domain $\mathcal{E}$ in the subspace $\mathcal{G}$. Since $b = 0$ on $\mathcal{G}$, we have $\Omega(b) \equiv dFb - q^{-1}bFd = 0$ and so $\Omega_2 = 0$ on $\mathcal{G}$. Hence the relation $\Omega_1d = eq^{-1}d\Omega_1 + \epsilon\Omega_2$ implies that $\Omega_1v^* = \epsilon q^{-1}v^*\Omega_1$ on $\mathcal{G}$. Because $\Omega_4 = 0$ as shown in the above proof, we have $\Omega(a) = (eq-1)\Omega_1$ by (14). On $\mathcal{G}$ we have $\Omega(a) = dFa - q^{-1}bFc - F = v^*Qv - Q$. Inserting the latter into the relation $\Omega(a)v^* = eq^{-1}v^*\Omega(a)$, we finally obtain that
\[
v^*Qv^* + eq^{-1}Q = (1 + eq^{-1})vQv^* \text{ on } \mathcal{E}.
\] (107)

The symmetric operator $F$ now acts as
\[
F\eta_n = (eq)^{1-n}\lambda_n T\eta_{n-1} + w^nRw^*\eta_n + (eq)^{-n}\lambda_{n+1}T^*\eta_{n+1}, \eta \in \mathcal{D}_0, \text{ and } F\eta = Q\eta, \eta \in \mathcal{E}.
\] (108)

Conversely, let $T$ be a linear operator and $R$ a symmetric linear operator on a dense domain $\mathcal{D}_0$ of $\mathcal{H}$ and let $Q$ be a symmetric linear operator on a dense domain $\mathcal{E}$ of $\mathcal{G}$ such that $\mathcal{D}_0 \subseteq$
Let \( u Au^* = \alpha A \) for some \( \alpha \in \mathbb{R}, |\alpha| \neq 1 \), then \( A = 0 \).

**Proof.** Then we also have \( u A^* u^* = \alpha A^* \). So we may assume that \( A \) is self-adjoint. The relation \( u A u^* = \alpha A \) implies that the spectrum of \( A \) is invariant under multiplication by \( \alpha \) and \( \alpha^{-1} \). Since \( |\alpha| \neq 1 \) and \( A \) is bounded, this is only possible if \( A = 0 \).

We carry out the proof for the \( 4D_+ \)-calculus. The case of the \( 3D \)-calculus is much simpler and follows easily from the relations (2) and (3) and Lemma 6.

By assumption all operators \( d_{\pi,F} (x), x \in A \), are bounded. Hence the four operators \( \Omega_1, \Omega_2, \Omega_3, \Omega_4 \) are also bounded. Recall that \( \Omega_1^* = \Omega_1, \Omega_2^* = \Omega_3 \) and \( \Omega_4^* = \Omega_4 \) by (7). From these facts and the commutation relations of the \( 4D_+ \)-calculus it is clear that the operators \( \Omega_j \) leave the spaces \( G = \ker b = \ker c \) and \( H \) invariant.

We shall show that all \( \Omega_j = 0 \) on \( H \) for \( j = 1, \ldots, 4 \). First note that \( \Omega_4 : H_n \to H_n \), because of the relation \( \Omega_4 bc = b\Omega_4 \) and the fact that \( \Omega_n = \ker (bc + q^{2n+1}I) \). Since \( \Omega_4 b = eq\Omega_4 \), we therefore obtain that \( w(\Omega_4[H_n])w^* = eq(\Omega_4[H_n]) \), so that \( \Omega_4[H_n] = 0 \) by Lemma 6 and hence \( \Omega_4 = 0 \) on \( H \). Consequently we have \( \Omega_3 bc = b\Omega_3 \) which implies that \( \Omega_3 : H_n \to H_n \). Since \( \Omega_4 = 0 \), we have the two relations

\[
\begin{align*}
\Omega_3 a &= eqa\Omega_1 + eb\Omega_3, \\
\Omega_3 b &= eq^{-1}b\Omega_1 + ea\Omega_2,
\end{align*}
\]

Using the fact that \( \Omega_3 : H^n \to H^n \) it follows from (10) by induction that \( \Omega_1 : H^n \to H^{n+1} \). Because \( \Omega_1^* = -\Omega_1 \), we have \( \Omega_1 : H_n \to H_{n-1} \oplus H_n \oplus H_{n+1} \). Hence \( \Omega_1 \) is of the form

\[
\begin{align*}
\Omega_1 \eta_n &= A_n \eta_{n-1} + B_n \eta_n + A_{n+1}^* \eta_{n+1}, 
\end{align*}
\]

where \( A_n \) and \( B_n \) are bounded linear operators on \( H_0 \). Inserting this expression into (10) and comparing the \( n \)-th components, we get \( qB_n w^* = eqw^*B \). Thus, \( wB_n w^* = eq^{-1}B_n \) and hence \( B_n = 0 \) by Lemma 6. Comparing the \((n-2)\)-th components in (10), we obtain the equation \( \lambda_n A_{n-1} = eq\lambda_{n-1} A_n \), so that we have

\[
A_n = (eq)^{1-n} \lambda_n \lambda_1^{-1} A_1
\]

Since \( \| A_n \| \leq \| \Omega_1 \| \) and \( q^{-n} \lambda_n \to +\infty \) if \( n \to \infty \) (recall that \( 0 < q < 1 \)), we conclude from (11) that \( A_n = 0 \) for all \( n \in \mathbb{N} \). Thus \( \Omega_1 = 0 \) on \( H \). Applying once more equations (10) and (11), we see that \( \Omega_2 = \Omega_3 = 0 \) on \( H \).

A much simpler reasoning shows that the operators \( \Omega_j \) are also zero on \( G \). Since the four 1-forms \( \omega_j, j = 1, \ldots, 4 \), generate the \( 4D_+ \)-calculus as a left \( A \)-module, it follows that \( d_{\pi,F} (x) = 0 \) for all \( x \in A \). This completes the proof of Theorem 3.

**Acknowledgement:** This work was completed during the authors visit at the University of Fukuoka in September 1998. I am very grateful to Professors A. Inoue and H. Kurose and Dr. H. Ogi for their warm hospitality and for the excellent working atmosphere.
