COISOTROPIC SUBMANIFOLDS IN b-SYMPLECTIC GEOMETRY

STEPHANE GEUDENS AND MARCO ZAMBON

Abstract. We study coisotropic submanifolds of b-symplectic manifolds. We prove that b-coisotropic submanifolds (those transverse to the degeneracy locus) determine the b-symplectic structure in a neighborhood, and provide a normal form theorem. This extends Gotay’s theorem in symplectic geometry. Further, we introduce strong b-coisotropic submanifolds and show that their coisotropic quotient, which locally is always smooth, inherits a reduced b-symplectic structure.

Introduction

In symplectic geometry, an important and interesting class of submanifolds are the coisotropic ones. They are the submanifolds C satisfying TCΩ ⊂ TC, where TCΩ denotes the symplectic orthogonal of the tangent bundle TC. They arise for instance as zero level sets of moment maps, and in mechanics as those submanifolds that are given by first class constraints (see Dirac’s theory of constraints). The notion of coisotropic submanifolds extends to the wider realm of Poisson geometry, and it plays an important role there too: for instance, a map is a Poisson morphism if and only if its graph is coisotropic, and coisotropic submanifolds admit canonical quotients which inherit a Poisson structure.

The Poisson structures which are non-degenerate at every point are exactly the symplectic ones. They are the submanifolds C satisfying TCΩ ⊂ TC, where TCΩ denotes the symplectic orthogonal of the tangent bundle TC. They arise for instance as zero level sets of moment maps, and in mechanics as those submanifolds that are given by first class constraints (see Dirac’s theory of constraints). The notion of coisotropic submanifolds extends to the wider realm of Poisson geometry, and it plays an important role there too: for instance, a map is a Poisson morphism if and only if its graph is coisotropic, and coisotropic submanifolds admit canonical quotients which inherit a Poisson structure.

This paper is devoted to coisotropic submanifolds of log-symplectic manifolds. We single out two classes, which we call \( b \)-coisotropic and strong \( b \)-coisotropic. We prove that certain properties of coisotropic submanifolds in symplectic geometry – properties which certainly do not carry over to arbitrary coisotropic submanifolds of log-symplectic manifolds – do carry over to the above classes. Moreover, we show that these classes of submanifolds enjoy some properties that are \( b \)-geometric enhancements of well-known facts about coisotropic submanifolds in Poisson geometry. We now elaborate on this.

**Main results.** Let \((M, Z, \omega)\) be a \( b \)-symplectic manifold, and denote by \( \Pi \) the corresponding Poisson tensor on \( M \). We consider two classes of submanifolds which are coisotropic (in the sense of Poisson geometry) with respect to \( \Pi \).

A submanifold of \( M \) is called \( b \)-coisotropic if it is coisotropic and a \( b \)-submanifold (i.e. transverse to \( Z \)). An equivalent characterization is the following: a \( b \)-submanifold \( C \) such that \((b TC)^{\omega} \subset b TC \). The latter formulation makes apparent that this notion is very natural in \( b \)-symplectic geometry. Section 2 is devoted to the class of \( b \)-coisotropic submanifolds.

We show that the \( b \)-conormal bundle of a \( b \)-coisotropic submanifold is a Lie subalgebroid. We also show that for Poisson maps between log-symplectic manifolds compatible with the corresponding hypersurfaces, the graphs are \( b \)-coisotropic submanifolds, once "lifted" to a suitable blow-up [9]. Both of these statements are \( b \)-geometric analogs of well-known facts about coisotropic submanifolds in Poisson geometry. Next, in Theorem 2.13 we show that Gotay’s theorem in symplectic geometry [8] extends to \( b \)-coisotropic submanifolds in \( b \)-symplectic geometry. The main consequence is a normal form theorem for the \( b \)-symplectic structure around such submanifolds:

**Theorem.** A neighborhood of a \( b \)-coisotropic submanifold \( C \hookrightarrow (M, Z, \omega) \) is \( b \)-symplectomorphic to the following model:

\[
(a \text{ neighborhood of the zero section in } E^*, \Omega),
\]

where the vector bundle \( E := \ker(b^{i*} \omega) \) denotes the kernel of the pullback of \( \omega \) to \( C \), and \( \Omega \) is a \( b \)-symplectic form which is constructed out of the pullback \( b^{i*} \omega \) and is canonical up to neighborhood equivalence (see equation (15) for the precise formula).

Such a normal form allows to study effectively the deformation theory of \( C \) as a coisotropic submanifold [7]. Another possible application is the construction of \( b \)-symplectic manifolds using surgeries, as done for instance in [6, Theorem 6.1]. We point out that in the special case of Lagrangian submanifolds, the above result is a version of Weinstein’s tubular neighborhood theorem, and was already obtained by Kirchhoff-Lukat [13, Theorem 5.18].

In Section 3 we consider the following subclass of the \( b \)-coisotropic submanifolds. A submanifold \( C \) is called strong \( b \)-coisotropic if it is coisotropic and transverse to all the symplectic leaves of \((M, \Pi)\) it meets. We remark that Lagrangian submanifolds intersecting the degeneracy hypersurface \( Z \) never satisfy this definition.

The main feature of strong \( b \)-coisotropic submanifolds is that the characteristic distribution

\[
D := \Pi^2(TC^{\omega}),
\]

is regular, with rank equal to \( \text{codim}(C) \). Recall the following fact in Poisson geometry: when the quotient of a coisotropic submanifold by its characteristic distribution is a smooth manifold, then it inherits a Poisson structure, called the reduced Poisson structure. We show (see Proposition 3.6 for the full statement):
Proposition. Let $C$ be a strong $b$-coisotropic submanifold of a $b$-symplectic manifold. If the quotient $C/D$ by the characteristic distribution is smooth, then the reduced Poisson structure is again $b$-symplectic.

Instances of the above proposition arise when a connected Lie group acts on a $b$-symplectic manifold with equivariant moment map, in the sense of Poisson geometry, and $C$ is the zero level set of the latter, see Corollary 3.10. At the end of the paper we provide examples of $b$-symplectic quotients, and – by reversing the procedure – in Corollary 3.16 we realize any $b$-symplectic structure on the 2-dimensional sphere as such a quotient.

In order to state and prove these results, in Section 1 we collect some facts about $b$-geometry. A few of them are new, to the best of our knowledge, and are of independent interest. More specifically, in Lemma 1.10 we show that, while the anchor map of the $b$-tangent bundle does not admit a canonical splitting, distributions tangent to $Z$ do have a canonical lift to the $b$-tangent bundle. In Proposition 1.19 we provide a version of the $b$-Moser theorem relative to a $b$-submanifold, which we could not find elsewhere in the literature.

1. Background on $b$-geometry

In this section, we address the formalism of $b$-geometry, which originated from work of Melrose [18] in the context of manifolds with boundary. We review some of the main concepts, including $b$-symplectic structures, and we prove some preliminary results that will be used in the body of this paper.

1.1. $b$-manifolds and $b$-maps.

We first introduce the objects and morphisms of the $b$-category, following [11].

Definition 1.1. A $b$-manifold is a pair $(M, Z)$ consisting of a manifold $M$ and a codimension-one submanifold $Z \subset M$.

Given a $b$-manifold $(M, Z)$, we denote by $\mathcal{X}(M)$ the set of vector fields on $M$ that are tangent to $Z$. Note that $\mathcal{X}(M)$ is a locally free $C^\infty(M)$-module, with generators
\[
x_1 \partial_{x_1}, \partial_{x_2}, \ldots, \partial_{x_n}
\]
in a coordinate chart $(x_1, \ldots, x_n)$ adapted to $Z = \{x_1 = 0\}$. Thanks to the Serre-Swan theorem, these $b$-vector fields give rise to a vector bundle $bTM$.

Definition 1.2. Let $(M, Z)$ be a $b$-manifold. The $b$-tangent bundle $bTM$ is the vector bundle over $M$ satisfying $\Gamma(bTM) = \mathcal{X}(M)$.

The natural inclusion $\mathcal{X}(M) \subset \mathfrak{X}(M)$ induces a vector bundle map $\rho : bTM \to TM$, which is an isomorphism away from $Z$. Restricting to $Z$, we get a bundle epimorphism $\rho|_Z : bTM|_Z \to TZ$, which gives rise to a trivial line bundle $\mathbb{L} := \ker(\rho|_Z)$. Indeed, $\mathbb{L}$ is canonically trivialized by the normal $b$-vector field $\xi \in \Gamma(\mathbb{L})$, which is locally given by $x \partial_x$ where $x$ is any local defining function for $Z$. So at any point $p \in Z$, we have a short exact sequence
\[
0 \to \mathbb{L}_p \to bT_p M \xrightarrow{\rho_p} T_p Z \to 0,
\]
but this sequence does not split canonically.

Since $^b\mathfrak{x}(M)$ is a Lie subalgebra of $\mathfrak{x}(M)$, it inherits a natural Lie bracket $[\cdot,\cdot]$. The data $(\rho, [\cdot,\cdot])$ endow $^bT\mathfrak{m}$ with a Lie algebroid structure. The map $\rho$ is called the anchor of $^bT\mathfrak{m}$.

**Definition 1.3.** Let $(M, Z)$ be a $b$-manifold. The $b$-cotangent bundle $^bT^*\mathfrak{m}$ is the dual bundle of $^bT\mathfrak{m}$.

In coordinates $(x_1, \ldots, x_n)$ adapted to $Z = \{x_1 = 0\}$, the $b$-cotangent bundle $^bT^*\mathfrak{m}$ has local frame

$$\frac{dx_1}{x_1}, dx_2, \ldots, dx_n.$$ 

We will denote the set $\Gamma(\wedge^k(\,^bT^*\mathfrak{m}))$ of Lie algebroid $k$-forms by $^b\Omega^k(M)$, and we refer to them as $b$-$k$-forms. The space $^b\Omega^*(M)$ is endowed with the Lie algebroid differential $^bd$, which is determined by the fact that the restriction $^b\Omega^k(M),^bd \to (\Omega^k(M \setminus Z), d)$ is a chain map. Note that the anchor $\rho$ induces an injective map $\rho^*: \Omega^k(M) \to ^b\Omega^k(M)$, which allows us to view honest de Rham forms as $b$-forms.

**Definition 1.4.** Given $b$-manifolds $(M_1, Z_1)$ and $(M_2, Z_2)$, a $b$-map $f : (M_1, Z_1) \to (M_2, Z_2)$ is a smooth map $f : M_1 \to M_2$ such that $f$ is transverse to $Z_2$ and $f^{-1}(Z_2) = Z_1$.

Given a $b$-map $f : (M_1, Z_1) \to (M_2, Z_2)$, the usual pullback $f^* : \Omega^*(M_2) \to \Omega^*(M_1)$ extends to an algebra morphism $^bf^* : ^b\Omega^*(M_2) \to ^b\Omega^*(M_1)$, see [14, Proof of Proposition 3.5.2]. That is, we have a commutative diagram

$$\begin{array}{ccc}
^b\Omega^*(M_2) & \xrightarrow{\quad^bf^*\quad} & ^b\Omega^*(M_1) \\
\downarrow{\rho^*_2} & & \downarrow{\rho^*_1} \\
\Omega^*(M_2) & \xrightarrow{\quad f^*\quad} & \Omega^*(M_1)
\end{array}$$

This $b$-pullback has the expected properties; for instance, the assignment $f \mapsto ^bf^*$ is functorial, and the $b$-pullback $^bf^*$ commutes with the $b$-differential $^bd$.

We can now define the Lie derivative of a $b$-form $\omega \in ^b\Omega^k(M)$ in the direction of a $b$-vector field $X \in ^b\mathfrak{x}(M)$ by the usual formula

$$\mathcal{L}_X\omega = \left. \frac{d}{dt} \right|_{t=0} ^b\rho^*_t\omega,$$

where the $b$-pullback is well-defined since the flow $\{\rho_t\}$ of $X$ consists of $b$-diffeomorphisms. Cartan’s formula is still valid

$$\mathcal{L}_X\omega = ^bd_X\omega + \iota_X^bd\omega.$$ 

Dual to the $b$-pullback $^bf^*$, a $b$-map $f : (M_1, Z_1) \to (M_2, Z_2)$ induces a $b$-derivative $^bf_* : ^bT\mathfrak{m}_1 \to ^bT\mathfrak{m}_2$, which is the unique morphism of vector bundles $^bT\mathfrak{m}_1 \to ^bT\mathfrak{m}_2$ that makes the following diagram commute [14, Proposition 3.5.2]:
At each point $p \in M_1$, the derivative $(f_*)_p$ and the $b$-derivative $(b f_*)_p$ have the same rank, by the next result proved in [5].

**Lemma 1.5.** Let $f : (M_1, Z_1) \to (M_2, Z_2)$ be a $b$-map. The anchor $\rho_1$ of $bT M_1$ restricts to an isomorphism $(\rho_1)_p : \text{Ker} (b f_*)_p \to \text{Ker} (f_*)_p$ for all $p \in M_1$.

We finish this subsection by observing that, if a $b$-submanifold $X$, then its lift to a section of the $b$-tangent bundle can be pushed forward by the $b$-derivative $b f_*$. 

**Lemma 1.6.** Let $f : (M_1, Z_1) \to (M_2, Z_2)$ be a surjective $b$-map, and let $Y \in \Gamma(b T M_1)$ be such that $Y := \rho_1(Y)$ pushes forward to some element $W \in \mathfrak{X}(M_2)$. Then $b f_*(Y)$ is a well-defined section of $b T M_2$, and it equals the unique element $\overline{W} \in \Gamma(b T M_2)$ satisfying $\rho_2(\overline{W}) = W$.

**Proof.** Since $f$ is a $b$-map, we have that $W \in \mathfrak{X}(M_2)$ is tangent to $Z_2$, so indeed $W = \rho_2(\overline{W})$. Now, first consider $p \in M_1 \setminus Z_1$. Commutativity of the diagram (2) implies that

$$
\rho_2 \left( (b f)_* (Y_p) \right) = (f_*)_p (\rho_1 (Y_p)) = (f_*)_p (Y_p) = W_{f(p)}.
$$

But we also have $\rho_2 (\overline{W}_{f(p)}) = W_{f(p)}$, so that injectivity of $\rho_2$ at $f(p) \in M_2 \setminus Z_2$ implies $(b f)_* (Y_p) = \overline{W}_{f(p)}$. Next, we choose $p \in Z_1$. Since $f$ is a $b$-map, we can take a (one-dimensional) slice $S$ through $p$ transverse to $Z_1$, such that the restriction $f|_S : S \to f(S)$ is a diffeomorphism. Since $(b f)_*|_S$ is a vector bundle map covering the diffeomorphism $f|_S$, the expression $(b f)_*|_S (Y|_S)$ is well-defined and smooth. Moreover, it is equal to $\overline{W}|_{f(S)}$ on the dense subset $f(S) \setminus (f(S) \cap Z_2) \subset f(S)$, as we just proved. By continuity, the equality $(b f)_*|_S (Y|_S) = \overline{W}|_{f(S)}$ holds on all of $f(S)$, so that in particular $(b f)_* (Y_p) = \overline{W}_{f(p)}$. This concludes the proof. 

\[ \square \]

1.2. $b$-submanifolds.

Given a $b$-manifold $(M, Z)$, a submanifold $C \subset M$ transverse to $Z$ inherits a $b$-manifold structure with distinguished hypersurface $C \cap Z$. Such submanifolds are therefore the natural subobjects in the $b$-category.

**Definition 1.7.** A $b$-submanifold $C$ of a $b$-manifold $(M, Z)$ is a submanifold $C \subset M$ that is transverse to $Z$.

Let $C \subset (M, Z)$ be a $b$-submanifold. The inclusion $i : (C, C \cap Z) \hookrightarrow (M, Z)$ of $b$-manifolds induces a canonical map $b i_* : b T C \to b T M$ that is injective by Lemma 1.5. This allows us to view $b T C$ as a Lie subalgebroid of $b T M$. In particular, we have the following fact.

**Lemma 1.8.** If $C \subset (M, Z)$ is a $b$-submanifold, then $\mathbb{L}_p \subset b T_p C$ for all $p \in C \cap Z$. 

Proof. Fixing some notation, we have anchor maps $\tilde{\rho}: bTC \to TC$ and $\rho: bTM \to TM$, and we put $\tilde{L} := \text{Ker}(\tilde{\rho}|_{C \cap Z})$ and $L = \text{Ker}(\rho|_{Z})$ as before. If $i: (C, C \cap Z) \hookrightarrow (M, Z)$ denotes the inclusion, then we get a commutative diagram with exact rows, for points $p \in C \cap Z$:

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathbb{L}_p & \longrightarrow & bT_pM & \longrightarrow & bT_pZ & \longrightarrow & 0 \\
& & \downarrow{(b,i)_p} & & \downarrow{(i|_{C \cap Z})_p} & & & \\
0 & \longrightarrow & \tilde{\mathbb{L}}_p & \longrightarrow & bT_pC & \longrightarrow & bT_p(C \cap Z) & \longrightarrow & 0
\end{array}
\] (3)

We obtain $(b,i)_p(\tilde{\mathbb{L}}_p) = \mathbb{L}_p$: the inclusion “$\subset$” holds by the above diagram, and the equality follows by dimension reasons since $(b,i)_p$ is injective. In particular, $\mathbb{L}_p$ is contained in the image of $(b,i)_p$, as we wanted to show. \hfill \Box

The notions of $b$-map and $b$-submanifold are compatible, as the next lemma shows.

Lemma 1.9. Let $f: (M_1, Z_1) \to (M_2, Z_2)$ be a $b$-map, and assume that we have $b$-submanifolds $C_1 \subset (M_1, Z_1)$ and $C_2 \subset (M_2, Z_2)$ such that $f(C_1) \subset C_2$.

a) Restricting $f$ gives a $b$-map

$$f|_{C_1}: (C_1, C_1 \cap Z_1) \to (C_2, C_2 \cap Z_2).$$

b) Further, $(b\iota)_*{(f|_{C_1})} = (b\iota)_*$. 

Proof. a) We first note that

$$(f|_{C_1})^{-1}(C_2 \cap Z_2) = C_1 \cap f^{-1}(C_2 \cap Z_2) = C_1 \cap f^{-1}(C_2) \cap f^{-1}(Z_2) = C_1 \cap f^{-1}(C_2) \cap Z_1 = C_1 \cap Z_1,$$

since $f$ is a $b$-map and $C_1 \subset f^{-1}(C_2)$. Next, choosing $p \in C_1 \cap Z_1$, we have to show that

$$(f\iota)_p(T_pC_1) + T_{f(p)}(C_2 \cap Z_2) = T_{f(p)}C_2.$$ (4)

We clearly have the inclusion “$\subset$”.$^*$ For the reverse, we choose $v \in T_{f(p)}C_2$. By transversality $f \pitchfork Z_2$, we know that $(f\iota)_p(T_pM_1) + T_{f(p)}Z_2 = T_{f(p)}M_2$. So we have $v = (f\iota)_p(x) + y$ for some $x \in T_pM_1$ and $y \in T_{f(p)}Z_2$. Next, since $C_1 \pitchfork Z_1$, we have $T_pC_1 + T_pZ_1 = T_pM_1$ so that $x = x_1 + x_2$ for some $x_1 \in T_pC_1$ and $x_2 \in T_pZ_1$. So we have

$$v = (f\iota)_p(x_1) + [(f\iota)_p(x_2) + y].$$ (5)

The term in square brackets clearly lies in $T_{f(p)}Z_2$, and being equal to $v - (f\iota)_p(x_1)$ it also lies in $T_{f(p)}C_2$. So it lies in $T_{f(p)}(C_2 \cap Z_2)$, using the transversality $C_2 \pitchfork Z_2$. Hence the decomposition (5) is as required in (4).

b) Denoting the inclusions $i_1: (C_1, C_1 \cap Z_1) \hookrightarrow (M_1, Z_1)$ and $i_2: (C_2, C_2 \cap Z_2) \hookrightarrow (M_2, Z_2)$, we have $f \circ i_1 = i_2 \circ f|i_{C_1}$. Hence by functoriality, $(b\iota)_* = b(i_2)_* \circ b(f|i_{C_1})_*$, which implies the claim. \hfill \Box
1.3. Distributions on $b$-manifolds.

We saw that the short exact sequence (1) does not split canonically. However, its restriction to suitable distributions does split.

**Lemma 1.10.** Let $(M, Z)$ be a $b$-manifold with anchor map $\rho : bTM \to TM$.

a) Given a distribution $D$ on $M$ that is tangent to $Z$, there exists a canonical splitting $\sigma : D \to bTM$ of the anchor $\rho$.

b) Let $\mathcal{D}$ denote the set of distributions on $M$ tangent to $Z$, and let $\mathcal{S}$ consist of the subbundles of $bTM$ intersecting trivially $\ker(\rho)$. Then there is a bijection $\mathcal{D} \to \mathcal{S} : D \mapsto \sigma(D)$, where the splitting $\sigma$ is as in a). The inverse map reads $D' \mapsto \rho(D')$.

**Proof.** a) One checks that the inclusion $\Gamma(D) \subset \Gamma(bTM)$ induces a well-defined vector bundle map $\sigma : D \to bTM : v \mapsto X_\rho$, where $X \in \Gamma(D)$ is any extension of $v \in D_p$. This map $\sigma$ satisfies $\rho \circ \sigma = \text{Id}_D$, so in particular $\rho(\sigma(D)) = D$.

b) We only have to show that if $D'$ is a subbundle of $bTM$ intersecting trivially $\ker(\rho)$, then $\sigma(\rho(D')) = D'$. Denote $D := \rho(D')$, a distribution on $M$ tangent to $Z$. The canonical splitting $\sigma : D \to bTM$ is injective, and $D$ and $D'$ have the same rank, hence it suffices to show that $\sigma(D) \subset D'$. If $X$ is a section of $D$, then $X = \rho(Y)$ for unique $Y \in \Gamma(D')$. We get $\rho(\sigma(X)) = X = \rho(Y)$, and since the anchor $\rho$ is injective on sections, this implies that $\sigma(X) = Y$. $\square$

**Corollary 1.11.** Let $f : (M_1, Z_1) \to (M_2, Z_2)$ be a $b$-map of constant rank. Notice that $\text{Ker}(f_*)$ is a distribution on $M_1$ that is tangent to $Z_1$. It satisfies $\sigma(\text{Ker}(f_*)) = \text{Ker}(b_{f_*})$, where $\sigma : \text{Ker}(f_*) \to bTM_1$ denotes the canonical splitting of the anchor $\rho_1$.

**Proof.** Under the bijection of Lemma 1.10 b), $\text{Ker}(f_*)$ corresponds to $\text{Ker}(b_{f_*})$, as a consequence of Lemma 1.5. $\square$

1.4. Vector bundles in the $b$-category.

If $(M, Z)$ is a $b$-manifold and $\pi : E \to M$ a vector bundle, then $(E, E|_Z)$ is naturally a $b$-manifold and the projection $\pi : (E, E|_Z) \to (M, Z)$ is a $b$-map. Along the zero section $M \subset E$, the $b$-tangent bundle $bTE$ splits canonically as follows.

**Lemma 1.12.** Let $(M, Z)$ be a $b$-manifold and $\pi : E \to M$ a vector bundle. Then at points $p \in M$ we have a canonical decomposition $b_{T_p}E \cong b_{T_p}M \oplus E_p$.

**Proof.** Denote by $VE := \text{Ker}(\pi_*)$ the vertical bundle. By Corollary 1.11 there is a canonical lift $\sigma : VE \hookrightarrow bTE$ such that $\sigma(VE) = \text{Ker}(b_{\pi_*})$. So we get a short exact sequence of vector bundles over $E$

$$0 \to VE \xrightarrow{\sigma} bTE \xrightarrow{b_{\pi_*}} \pi^*(bTM) \to 0.$$ (6)
Here
\[ \pi^* \left( b^{TM} \right) = \left\{ (e, v) \in E \times b^{TM} : \pi(e) = pr(v) \right\} \]
is the pullback of the vector bundle \( pr : b^{TM} \to M \) by \( \pi \), and the surjective vector bundle map
\[ b\tilde{\pi}_* : b^{TE} \to \pi^* \left( b^{TM} \right), \quad (e, v) \mapsto \left( e, \left( b\tilde{\pi}_* \right)_e(v) \right) \]
is induced by the \( b \)-map \( \pi : (E, E|Z) \to (M, Z) \).

Restricting (6) to the zero section \( M \subset E \) gives a short exact sequence of vector bundles over \( M \):
\[ 0 \to E \hookrightarrow b^{TE}|_M \xrightarrow{b\pi} b^{TM} \to 0. \]
This sequence splits canonically through the map \( b\iota_* : b^{TM} \to b^{TE}|_M \) induced by the inclusion \( i : (M, Z) \hookrightarrow (E, E|Z) \).

The following result makes use of the decomposition introduced in Lemma 1.12.

**Lemma 1.13.**

a) Let \( \pi : (E, E|Z) \to (M, Z) \) be a vector bundle over the \( b \)-manifold \((M, Z)\). Denote by \( \rho \) and \( \tilde{\rho} \) the anchor maps of \( b^{TM} \) and \( b^{TE} \) respectively. Under the decomposition of Lemma 1.12, we have that the map
\[ \tilde{\rho}|_M : b^{TE}|_M \cong b^{TM} \oplus E \to TE|_M \cong TM \oplus E \]
equals \( \rho \oplus Id_E \).

b) Consider a morphism \( \varphi \) of vector bundles over \( b \)-manifolds covering a \( b \)-map \( f \):
\[ \begin{array}{ccc}
(E_1, E_1|Z_1) & \xrightarrow{\varphi} & (E_2, E_2|Z_2) \\
\pi_1 \downarrow & & \downarrow \pi_2 \\
(M_1, Z_1) & \xrightarrow{f} & (M_2, Z_2) \end{array} \]
(7)

Then \( \varphi \) is a \( b \)-map, and its \( b \)-derivative along the zero section
\[ b\varphi_*|_M : b^{TE}|_M \cong b^{TM} \oplus E_1 \to b^{TE}|_M \cong b^{TM} \oplus E_2 \]
equals \( b\iota_* \oplus \varphi \).

**Proof.**

a) Since \( M \) is a \( b \)-submanifold of \((E, E|Z)\), we have that \( b^{TM} \) is a Lie subalgebroid of \( b^{TE} \). In particular, \( \tilde{\rho} \) and \( \rho \) agree on \( b^{TM} \). Next, we know that \( \tilde{\rho} \) takes \( E \subset b^{TE}|_M \) isomorphically to \( E \subset TE|_M \), thanks to Lemma 1.5 applied to \( \pi \). To see that \( \tilde{\rho}|_E = Id_E \), we choose \( v \in E_p \) and extend it to \( V \in \Gamma(VE) \). Denote by \( \sigma : VE \hookrightarrow b^{TE} \) the canonical splitting of \( \tilde{\rho} \), as in the proof of Lemma 1.12. Then \( \tilde{\rho}(v) = [\tilde{\rho}(\sigma(V))]_p = V_p = v \).

b) It is routine to check that \( \varphi \) is a \( b \)-map, so we only prove the second statement. Taking the \( b \)-derivative of both sides of the equality \( \pi_2 \circ \varphi = f \circ \pi_1 \) at a point \( p \in M_1 \), we know that \( \left( b\pi_2 \right)_*(b\varphi_*)(E_1)_p = b\iota_* \left( \left( b\pi_1 \right)_*(E_1)_p \right) = 0 \), since \( (E_1)_p = \text{Ker} \left( \left( b\pi_1 \right)_* \right)_p \). Hence \( b\varphi_* (E_1)_p \subset \text{Ker} \left( \left( b\pi_2 \right)_* \right)_{f(p)} = (E_2)_{f(p)} \) by the proof of Lemma 1.12. Using a) and the
diagram (2), we have a commutative diagram
\[ \begin{array}{ccc}
\mathbb{T}_pE_1 \cong \mathbb{T}_pM_1 \oplus (E_1)_p & \xrightarrow{\mathbb{b}\psi} & \mathbb{T}_{f(p)}E_2 \cong \mathbb{T}_{f(p)}M_2 \oplus (E_1)_{f(p)} \\
\rho_1 \oplus \text{Id} & & \rho_2 \oplus \text{Id} \\
\mathbb{T}_pE_1 \cong \mathbb{T}_pM_1 \oplus (E_1)_p & \xrightarrow{\psi} & \mathbb{T}_{f(p)}E_2 \cong \mathbb{T}_{f(p)}M_2 \oplus (E_2)_{f(p)}
\end{array} \] (8)

It implies that
\[ \mathbb{b}\varphi_\ast_{(E_1)_p} = \varphi_\ast_{(E_1)_p} = \varphi_{(E_1)_p}. \]

Finally, \( \mathbb{b}\varphi_\ast_{\mathbb{T}M_1} = \mathbb{b}f_\ast \) holds by Lemma 1.9 b).

1.5. Log-symplectic and \( b \)-symplectic structures.

The \( b \)-geometry formalism can be used to describe a certain class of Poisson structures, called log-symplectic structures. These can indeed be regarded as symplectic structures on the \( b \)-tangent bundle.

**Definition 1.14.** A Poisson structure on a manifold \( M \) is a bivector field \( \Pi \in \Gamma(\wedge^2 TM) \) such that the bracket \( \{ f, g \} = \Pi(df, dg) \) is a Lie bracket on \( C^\infty(M) \). Equivalently, the bivector field \( \Pi \) must satisfy \( [\Pi, \Pi] = 0 \), where \( [\cdot, \cdot] \) is the Schouten-Nijenhuis bracket of multivector fields. A smooth map \( f : (M_1, \Pi_1) \rightarrow (M_2, \Pi_2) \) is a Poisson map if the pullback \( f^* : (C^\infty(M_2), \{\cdot, \cdot\}_2) \rightarrow (C^\infty(M_1), \{\cdot, \cdot\}_1) \) is a Lie algebra homomorphism.

The bivector \( \Pi \) induces a bundle map \( \Pi^T : T^* M \rightarrow TM \) by
\[ \left< \Pi^T_p(\alpha), \beta \right> = \Pi_p(\alpha, \beta) \quad \forall \alpha, \beta \in T^*_pM, \]
and the rank of \( \Pi \) at \( p \in M \) is defined to be the rank of the linear map \( \Pi^T_p \). Poisson structures of full rank correspond with symplectic structures via \( \omega \leftrightarrow -\Pi^{-1} \).

For every \( f \in C^\infty(M) \), the operator \( \{ f, \cdot \} \) is a derivation of \( C^\infty(M) \). The corresponding vector field \( X_f = \Pi^T(df) \) is the Hamiltonian vector field of \( f \). Any Poisson manifold \((M, \Pi)\) comes with a (singular) distribution \( \text{Im} \left( \Pi^T \right) \), generated by the Hamiltonian vector fields. This distribution is integrable (in the sense of Stefan-Sussman) and each leaf \( \mathcal{O} \) of the associated foliation has an induced symplectic structure \( \omega_\mathcal{O} := -\left( \Pi\big|_{\mathcal{O}} \right)^{-1} \).

**Definition 1.15.** A Poisson structure \( \Pi \) on a manifold \( M^{2n} \) is called log-symplectic if \( \wedge^n \Pi \) is transverse to the zero section of the line bundle \( \wedge^{2n} TM \).

Note that a log-symplectic structure \( \Pi \) is of full rank everywhere, except at points lying in the set \( Z := (\wedge^n \Pi)^{-1}(0) \), called the singular locus of \( \Pi \). If \( Z \) is nonempty, then it is a smooth hypersurface by the transversality condition, and we call \( \Pi \) bona fide log-symplectic. In that case, \( Z \) is a Poisson submanifold of \((M, \Pi)\) with an induced Poisson structure that is regular of corank-one. If \( Z \) is empty, then \( \Pi \) defines a symplectic structure on \( M \).

Since log-symplectic structures come with a specified hypersurface, it seems plausible that they have a \( b \)-geometric interpretation. As it turns out, log-symplectic structures are exactly the symplectic structures of the \( b \)-category.

**Definition 1.16.** A \( b \)-symplectic form on a \( b \)-manifold \((M^{2n}, \mathbb{Z})\) is a \( \mathbb{b}d \)-closed and non-degenerate \( b \)-two-form \( \omega \in \mathbb{b}\Omega^2(M) \).
Here, non-degeneracy means that the bundle map $\omega^b : bTM \to bT^*M$ is an isomorphism, or equivalently that $\wedge^n \omega$ is a nowhere vanishing element of $b\Omega^{2n}(M)$.

**Example 1.17.** [11, Example 9] In analogy with the symplectic case, the $b$-cotangent bundle $bT^*M$ of a $b$-manifold $(M, Z)$ is $b$-symplectic in a canonical way. Note that $(bT^*M, bT^*M|_Z)$ is naturally a $b$-manifold, and that the bundle projection $\pi : (bT^*M, bT^*M|_Z) \to (M, Z)$ is a $b$-map. The tautological $b$-one-form $\theta \in b\Omega^1(bT^*M)$ is defined by

$$\theta_\xi(v) = \left< \xi, (b\pi^*_{\xi})_\xi (v) \right>,$$

where $\xi \in bT^*_\pi(\xi)M$ and $v \in bT^*_\xi(bT^*M)$. Its differential $-b d\theta$ is a $b$-symplectic form on $bT^*M$. To see this, choose coordinates $(x_1, \ldots, x_n)$ on $M$ adapted to $Z = \{x_1 = 0\}$, and let $(y_1, \ldots, y_n)$ denote the fiber coordinates on $bT^*M$ with respect to the local frame $\{dx_1, dx_2, \ldots, dx_n\}$. The tautological $b$-one form is then given by

$$\theta = y_1 \frac{dx_1}{x_1} + \sum_{i=2}^n y_i dx_i,$$

with exterior derivative

$$-b d\theta = \frac{dx_1}{x_1} \wedge dy_1 + \sum_{i=2}^n dx_i \wedge dy_i.$$

A log-symplectic structure on $M$ with singular locus $Z$ is nothing else but a $b$-symplectic structure on the $b$-manifold $(M, Z)$, see [11, Proposition 20]. Indeed, given a $b$-symplectic form $\omega$ on $(M, Z)$, its negative inverse $b\Pi^\omega := - (\omega\rho)^{-1} : bT^*M \to bTM$ defines a $b$-bivector field $b\Pi \in \Gamma (\wedge^2 (bTM))$, and applying the anchor map $\rho$ to it yields a bivector field $\Pi := \rho (b\Pi) \in \Gamma (\wedge^2 TM)$ that is log-symplectic with singular locus $Z$. Conversely, a log-symplectic structure $\Pi$ on $M$ with singular locus $Z$ lifts uniquely under $\rho$ to a non-degenerate $b$-bivector field $b\Pi$, whose negative inverse is a $b$-symplectic form on $(M, Z)$. These processes are summarized in the following diagram:

$$
\begin{array}{c}
\begin{array}{c}
bT^*M \\ \downarrow \rho^\ast
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
bTM \\ \downarrow \rho
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
bT^*M \\
\Pi\downarrow
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
T^*M \\ \Pi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
TM
\end{array}
\end{array}

(9)

We will switch between the $b$-symplectic and the log-symplectic (i.e. Poisson) viewpoint, depending on which one is the most convenient.

1.6. **A relative $b$-Moser theorem.**

We will need a relative Moser theorem in the $b$-symplectic setting. First, we prove the following $b$-geometric version of the relative Poincaré lemma [3, Proposition 6.8].

**Lemma 1.18.** Let $(M, Z)$ be a $b$-manifold and $C \subset (M, Z)$ a $b$-submanifold. Denote by $i : (C, C \cap Z) \hookrightarrow (M, Z)$ the inclusion. If $\beta \in b\Omega^k(M)$ is $b$-closed and $b\iota^*\beta = 0$, then there
exist a neighborhood $U$ of $C$ and $\eta \in b\Omega^{k-1}(U)$ such that
\[
\begin{cases}
b\eta = \beta|_U \\
\eta|_C = 0
\end{cases}.
\]

**Proof.** We adapt the proof of [3, Proposition 6.8]. We first choose a suitable tubular neighborhood of $C$ that is compatible with the hypersurface $Z$. Due to transversality $C \pitchfork Z$, we can pick a complement $V$ to $TC$ in $TM|_{C}$ such that $V_p \subset T_pZ$ for all $p \in C \cap Z$. Fix a Riemannian metric $g$ for which $Z \subset (M,g)$ is totally geodesic (e.g. [19, Lemma 6.8]). The associated exponential map then establishes a $b$-diffeomorphism between a neighborhood of $C$ in $(V,V|_{C\cap Z})$ and a neighborhood of $C$ in $(M,Z)$.

So we may work instead on the total space of $\pi : (V,V|_{C\cap Z}) \to (C, C \cap Z)$. Consider the retraction of $V$ onto $C$ given by $r : V \times [0,1] \to V : (p,v,t) \mapsto (p,tv)$, and notice that the $r_t$ are $b$-maps. The associated time-dependent vector field $X_t$ is given by $X_t(p,v) = \frac{1}{t}v$, which is a $b$-vector field that vanishes along $C$. It follows that we get a well-defined $b$-de Rham homotopy operator
\[
I : b\Omega^k(V) \to b\Omega^{k-1}(V) : \alpha \mapsto \int_0^1 b^*_{r_t}(\iota_{X_t}\alpha)dt,
\]
which satisfies
\[
b^*_{r_1}\alpha - b^*_{r_0}\alpha = b^*dI(\alpha) + I(b^*d\alpha).
\]
(10)
Since $r_1 = \text{Id}$ and $r_0 = \pi \circ \iota$, the formula (10) gives $\beta = b^*dI(\beta)$. Now set $\eta := I(\beta)$. □

**Proposition 1.19 (Relative $b$-Moser theorem).** Let $(M, Z)$ be a $b$-manifold and $C \subset (M, Z)$ a $b$-submanifold. If $\omega_0$ and $\omega_1$ are $b$-symplectic forms on $(M, Z)$ such that $\omega_0|_C = \omega_1|_C$, then there exists a $b$-diffeomorphism $\varphi$ between neighborhoods of $C$ such that $\varphi|_C = \text{Id}$ and $b^*\varphi \omega_1 = \omega_0$.

**Proof.** Consider the convex combination $\omega_t := \omega_0 + t(\omega_1 - \omega_0)$ for $t \in [0,1]$. There exists a neighborhood $U$ of $C$ such that $\omega_t$ is non-degenerate on $U$ for all $t \in [0,1]$. Shrinking $U$ if necessary, Lemma 1.18 yields $\eta \in b\Omega^1(U)$ such that $\omega_1 - \omega_0 = b^*\eta$ and $\eta|_C = 0$. As in the usual Moser trick, it now suffices to solve the equation
\[
\iota_{X_t}\omega_t + \eta = 0
\]
for $X_t \in b\mathfrak{X}(U)$, which is possible by non-degenearcy of $\omega_t$. The $b$-vector fields $X_t$ thus obtained vanish along $C$ since $\eta|_C = 0$. Further shrinking $U$ if necessary, we can integrate the $X_t$ to an isotopy $\{\phi_t\}_{t \in [0,1]}$ defined on $U$. Note that the $\phi_t$ are $b$-diffeomorphisms that restrict to the identity on $C$. By the usual Moser argument, we have $b^*\phi_t \omega_1 = \omega_0$, so setting $\varphi := \phi_1$ finishes the proof. □

**Remark 1.20.** We learnt from Ralph Klaasse that the work in progress [15] contains a version of Proposition 1.19 that holds in the more general setting of symplectic Lie algebroids.

2. **$b$-coisotropic submanifolds and the $b$-Gotay theorem**

This section is devoted to coisotropic submanifolds of $b$-symplectic manifolds that are transverse to the degeneracy hypersurface. The main result is Theorem 2.13, a $b$-symplectic version of Gotay’s theorem, which implies a normal form statement around such submanifolds. This can be used, for instance, to study the deformation theory of $b$-coisotropic submanifolds [7].
2.1. \( b \)-coisotropic submanifolds.

In this subsection we introduce \( b \)-coisotropic submanifolds and we discuss some of their main features. First recall the definition of a coisotropic submanifold in Poisson geometry.

**Definition 2.1.** Let \((M, \Pi)\) be a Poisson manifold with associated Poisson bracket \(\{\cdot, \cdot\}\). A submanifold \(C \subset M\) is coisotropic if the following equivalent conditions hold:

a) \(\Pi^f(TC^0) \subset TC\), where \(TC^0 \subset T^*M|_C\) denotes the annihilator of \(TC\).

b) \(\{\mathcal{I}_C, \mathcal{I}_C\} \subset \mathcal{I}_C\), where \(\mathcal{I}_C := \{ f \in C^\infty(M) : f|_C = 0 \}\) denotes the vanishing ideal of \(C\).

c) \(T_pC \cap T_pO\) is a coisotropic subspace of the symplectic vector space \(\left( T_pO, -\Pi|_O(p)^{-1} \right) \)

for all \(p \in C\), where \(O\) denotes the symplectic leaf through \(p\).

The singular distribution \(\Pi^f(TC^0)\) on \(C\) appearing above is called the characteristic distribution. If \(\Pi = -\omega^{-1}\) is symplectic, the coisotropcity condition becomes \(TC^\omega \subset TC\).

**Definition 2.2.** Let \((M, Z, \omega)\) be a \(b\)-symplectic manifold, and denote by \(\Pi\) the corresponding Poisson bivector field on \(M\). A submanifold \(C\) of \(M\) is called \(b\)-coisotropic if it is coisotropic with respect to \(\Pi\) and a \(b\)-submanifold (i.e. transverse to \(Z\)).

**Remark 2.3.** A \(b\)-coisotropic submanifold \(C^0 \subset (M^{2n}, Z, \Pi)\) of middle dimension is necessarily Lagrangian, i.e. \(T_pC \cap T_pO\) is a Lagrangian subspace of the symplectic vector space \(\left( T_pO, -\Pi|_O(p)^{-1} \right) \) for all \(p \in C\), where \(O\) denotes the symplectic leaf through \(p\). Indeed, at points away from \(Z\) there is nothing to prove. At points \(p \in C \cap Z\), we have

\[
\dim(T_pC \cap T_pO) \leq \dim(T_pC \cap T_pZ) = n - 1,
\]

where the last equality follows from transversality \(C \cap Z\). On the other hand, \(T_pC \cap T_pO\) is at least \((n - 1)\)-dimensional, being a coisotropic subspace of the \((2n - 2)\)-dimensional symplectic vector space \(T_pO\). Hence \(\dim(T_pC \cap T_pO) = n - 1\), which proves the claim.

Definition 2.2 can be rephrased in terms of the \(b\)-symplectic form \(\omega\): a \(b\)-coisotropic submanifold is precisely a \(b\)-submanifold \(C\) such that \((bTC)^\omega \subset bTC\).

**Proposition 2.4.** Let \(C\) be a \(b\)-submanifold of a \(b\)-symplectic manifold \((M, Z, \omega)\). Then \(C\) is coisotropic if and only if \((bTC)^\omega \subset bTC\).

Notice that the latter condition states that \(bTC\) is a coisotropic subbundle of the symplectic vector bundle \((bTM)(C; \omega|_{C})\).

**Proof.** If \(C\) is coisotropic, then at points of \(C \cap (M \setminus Z)\) we have that \(TC^\omega \subset TC\), i.e. \((bTC)^\omega \subset bTC\). By continuity, this inclusion of subbundles holds at all points of \(C\). Conversely, if this inclusion holds on \(C\), it follows that \(C \cap (M \setminus Z)\) is coisotropic in \(M \setminus Z\), and using characterization b) in Definition 2.1 we see that \(C\) is coisotropic in \(M\). \(\square\)

We give an alternative description of the characteristic distribution of a \(b\)-coisotropic submanifold.

**Lemma 2.5.** Let \(C\) be any \(b\)-submanifold of a \(b\)-symplectic manifold \((M, Z, \omega)\), and let \(\rho : bTM \to TM\) denote the anchor of \(bTM\) so that \(\Pi = \rho(-\omega^{-1})\) is the Poisson bivector corresponding with \(\omega\). Then

\[
\rho\left( (bTC)^\omega \right) = \Pi^f(TC^0).
\] (11)
Proof. At points $p \in C \setminus (C \cap Z)$, the equality (11) holds by symplectic linear algebra. So let $p \in C \cap Z$. Denote by $b\Pi := -\omega^{-1} \in \Gamma (b^2 (bTM))$ the lift of $\Pi$ as a $b$-bivector field. Note that

$$\left( bT_pC \right)^{\omega_p} = \left( \omega_p^{-1} \right) \left( \left( bT_pC \right)^0 \right) = b\Pi^\sharp \left( \left( bT_pC \right)^0 \right), \quad (12)$$

where the annihilator is taken in $b^*T_pM$. We now assert:

Claim: $(bT_pC)^0 = \rho_p^* (T_pC^0)$.

To prove the claim, we first note that the dimensions of both sides agree since

$$\text{Ker} (\rho_p^* \cap T_pC^0 = \text{Im} (\rho_p)^0 \cap T_pC^0 = T_pZ^0 \cap T_pC^0 = (T_pZ + T_pC)^0 = \{0\},$$

where the last equality holds by transversality $C \bowtie Z$. Now it is enough to show that the inclusion "⊃" holds, which is clearly the case since $\rho_p(bT_pC) \subset T_pC$.

We thus obtain

$$\rho_p \left( \left( bT_pC \right)^{\omega_p} \right) = \left( \rho_p \circ b\Pi^\sharp \circ \rho_p^* \right) (T_pC^0) = \Pi_p^\sharp (T_pC^0),$$

where in the first equality we used (12) and the claim just proved, and in the second we used the diagram (9).

A general fact in Poisson geometry is that the conormal bundle of any coisotropic submanifold is a Lie subalgebroid of the cotangent Lie algebroid. We now show that the $b$-geometry version of this fact holds for $b$-coisotropic submanifolds.

**Proposition 2.6.** Let $(M, Z, \omega)$ be a $b$-symplectic manifold with corresponding Poisson bivector field $\Pi$. Recall that $b^*T M$ is a Lie algebroid (endowed with the Lie bracket induced by $b\Pi$), fitting in the diagram of Lie algebroids (9). Let $C$ be a $b$-coisotropic submanifold.

a) $(bTC)^0$ is a Lie subalgebroid of $b^*T M$.

b) $(bTC)^0$ fits in the following diagram of Lie subalgebroids of the diagram (9):

$$\begin{array}{ccc}
(bTC)^0 & \xleftarrow{\omega_p} & (bTC)^\omega \\
\rho^* & \downarrow & \Pi^\sharp \\
T(C^0) & \xrightarrow{\rho} & T(C)
\end{array} \quad (13)
$$

**Proof.** Diagram (13) is a diagram of vector subbundles of diagram (9), by the claim in the proof of Lemma 2.5 and by equation (12).

For a), since the morphism $b\Pi^\sharp$ in diagram (9) is an isomorphism of Lie algebroids, it suffices to show that $(bTC)^0$ is a Lie subalgebroid of $b^*T M$. Since $(bTC)^\omega$ is the kernel of the closed $b$-2-form $b^i \omega$, a standard Cartan calculus computation shows that this is indeed the case. It is well-known that $T(C^0)$ and $T(C)$ are also Lie subalgebroids, proving b). □

2.2. Examples of $b$-coisotropic submanifolds.

We now exhibit some examples of $b$-coisotropic submanifolds. The main result of this subsection is Proposition 2.8, which shows that graphs of suitable Poisson maps between log-symplectic manifolds give rise to $b$-coisotropic submanifolds, once lifted to a certain blow-up.
Examples 2.7. a) Given a log-symplectic manifold \((M, Z, \Pi)\), any hypersurface of \(M\) transverse to \(Z\) is \(b\)-coisotropic.

b) Let \((M, \Omega)\) be a symplectic manifold, whose non-degenerate Poisson structure we denote \(\Pi_M := -\Omega^{-1}\), and let \((N, \Pi_N)\) be a log-symplectic manifold with singular locus \(Z\). Then \((M \times N, \Pi_M - \Pi_N)\) is log-symplectic with singular locus \(M \times Z\). Given a Poisson map \(\phi: (M, \Pi_M) \rightarrow (N, \Pi_N)\) transverse to \(Z\), we have that \(\text{Graph}(\phi) \subset (M \times N, \Pi_M - \Pi_N)\) is \(b\)-coisotropic. As a concrete example, consider for instance

\[
\phi: \left(\mathbb{R}^4, \sum_{i=1}^2 \partial_{x_i} \wedge \partial_{y_i}\right) \rightarrow \left(\mathbb{R}^2, x \partial_x \wedge \partial_y\right); (x_1, y_1, x_2, y_2) \mapsto (y_1, x_2 - x_1 y_1).
\]

We will now prove Proposition 2.8. We start recalling some facts from [9, §2.1]. Given a manifold \(M\) and a closed submanifold \(L\) of codimension \(\geq 2\), one can construct a new manifold by replacing \(L\) with the projectivization of its normal bundle. The resulting manifold \(\text{Bl}_L(M)\), the real projective blow-up of \(M\) along \(L\), comes with a map

\[
p: \text{Bl}_L(M) \rightarrow M
\]

which restricts to a diffeomorphism \(\text{Bl}_L(M) \setminus p^{-1}(L) \rightarrow M \setminus L\). Further, let \(S \subset M\) be a submanifold which intersects cleanly \(L\), i.e. \(S \cap L\) is a submanifold with \(T(S \cap L) = TS \cap TL\). Then \(S\) can be “lifted” to a submanifold of \(\text{Bl}_L(M)\), namely the closure of the inverse image of \(S \setminus L\) under \(p\):

\[
\overline{S} := p^{-1}(S \setminus L).
\]

Now let \((M_i, Z_i, \Pi_i)\) be log-symplectic manifolds, for \(i = 1, 2\). The product \(M_1 \times M_2\) is not log-symplectic in general\(^1\), but [20], [9, §2.2]

\[
X := \text{Bl}_{Z_1 \times Z_2}(M_1 \times M_2) \setminus (M_1 \times Z_2 \cup Z_1 \times M_2) \quad (14)
\]

is log-symplectic with singular locus the exceptional divisor \(p^{-1}(Z_1 \times Z_2)\), and the blow-down map \(p: X \rightarrow M_1 \times M_2\) is Poisson, where \(M_2\) denotes \((M_2, -\Pi_2)\).

Proposition 2.8. Let \(f : (M_1, Z_1, \Pi_1) \rightarrow (M_2, Z_2, \Pi_2)\) be a Poisson map with \(f(Z_1) \subset Z_2\). Then

\[
\overline{\text{graph}(f)}
\]

is a \(b\)-coisotropic submanifold of the log-symplectic manifold \(X\) defined in (14).

Proof. The intersection \(\overline{\text{graph}(f)} \cap Z_1 \times Z_2\) is clean, since it coincides with \(\overline{\text{graph}(f|Z_1)}\) thanks to the assumption \(f(Z_1) \subset Z_2\). Hence \(\overline{\text{graph}(f)}\) can be “lifted” to \(X\).

The resulting submanifold \(\overline{\text{graph}(f)}\) is coisotropic: \(\overline{\text{graph}(f)}\) is coisotropic in \(M_1 \times M_2\) because \(f\) is a Poisson map, so \(p^{-1}(\overline{\text{graph}(f)} \setminus Z_1 \times Z_2)\) is coisotropic in \(X\) (since \(p\) is a Poisson diffeomorphism away from the exceptional divisor), and the same holds for its closure.

\(^1\)However it fits in a slight generalization of the notion of log-symplectic structure used in this note: indeed \((M_1 \times Z_2) \cup (Z_1 \times M_2)\) is a normal crossing divisor, and vector fields tangent to it give rise to a Lie algebroid to which the Poisson structure on \(M_1 \times M_2\) lifts in a non-degenerate way (we thank Aldo Witte for pointing this out to us). One can check that if \(f: M_1 \rightarrow M_2\) is a Poisson map transverse to \(Z_2\), then \(\overline{\text{graph}(f)}\) intersects transversely both \(M_1 \times Z_2\) and \(Z_1 \times M_2\). This statement generalizes Example 2.7 b) and can be viewed as an analogue of Proposition 2.8.
To finish the proof, we have to show that \( \text{graph}(f) \) is transverse to the exceptional divisor \( E := p^{-1}(Z_1 \times Z_2) \). Let \((x_1^{(1)})\) be local coordinates on \( M_1 \) such that \( Z_1 = \{ x_1^{(1)} = 0 \} \), and similarly let \((x_2^{(2)})\) be local coordinates on \( M_2 \) such that \( Z_2 = \{ x_2^{(2)} = 0 \} \). Then
\[
(x_1^{(1)}, f^*(x_2^{(2)}) - x_2^{(2)})
\]
are local coordinates on \( M_1 \times M_2 \) that are adapted to both submanifolds. Lemma 2.9 then implies that, with the notation of the beginning of this subsection, \( S \) intersects transversely the hypersurface \( p^{-1}(L) \) of \( Bl_L(M) \).

For every point \( S \in \text{graph}(f) \), we are adding exactly the exceptional divisor \( E \), where \( E = \{ (x,y) \in \mathbb{R}^n \times \mathbb{R}^m : x \in \mathbb{R}^n, y \in \mathbb{R}^m \} \subset \mathbb{R}^{n+m} \times \mathbb{R}P^{m-1} \).

The proof of Proposition 2.8 uses the following statement, for which we could not find a reference in the literature.

**Lemma 2.9.** Let \( m, n \) be non-negative integers. Consider \( \mathbb{R}^{n+m} \) with standard coordinates \( x_1, \ldots, x_n, y_1, \ldots, y_m \), and the subspaces
\[
Z := \{ 0 \} \times \mathbb{R}^m,
\]
\[
S := (\mathbb{R}^k \times \{ 0 \}) \times (\mathbb{R}^l \times \{ 0 \})
\]
where \( k \leq n \) and \( l \leq m \). Then, in the blow-up \( Bl_Z(\mathbb{R}^{n+m}) \), the submanifold \( \overline{S} \) intersects transversely the exceptional divisor \( E \).

**Proof.** We have
\[
Bl_Z(\mathbb{R}^{n+m}) = \left\{ \left( (x, y), [x] \right) : x \in \mathbb{R}^n \setminus \{ 0 \}, y \in \mathbb{R}^m \right\} \subset \mathbb{R}^{n+m} \times \mathbb{R}P^{m-1},
\]
where \( [\cdot] \) denotes the class in projective space. Notice that by taking the closure we are adding exactly the exceptional divisor
\[
E = \{ 0 \} \times \mathbb{R}^m \times \mathbb{R}P^{m-1}.
\]
We have
\[
\overline{S} = \left\{ \left( (x_1, 0, y_1, 0), [(x_1, 0)] \right) : x_1 \in \mathbb{R}^k \setminus \{ 0 \}, y_1 \in \mathbb{R}^l \right\}.
\]
By taking the closure we are adding exactly
\[
\{ 0 \} \times (\mathbb{R}^l \times \{ 0 \}) \times \mathbb{R}P^{k-1} = \overline{S} \cap E.
\]
For every point \( p \in \overline{S} \cap E \) there is a curve of the form
\[
\gamma : t \mapsto \left( (tx_1, 0, y_1, 0), [(x_1, 0)] \right)
\]
lying in \( \overline{S} \) with \( \gamma(0) = p \), and clearly \( \frac{d}{dt}[\gamma](t) \notin T_p E \). Since \( \frac{d}{dt}[\gamma](t) \in T_p \overline{S} \) and \( E \) has codimension 1, we obtain \( T_p E + T_p \overline{S} = T_p Bl_Z(\mathbb{R}^{n+m}) \).

**Remark 2.10.** One can show that for any pair of submanifolds \( L \) and \( S \) intersecting cleanly, around any point of the intersection there exist local coordinates of the ambient manifold \( M \) that are simultaneously adapted to both submanifolds. Lemma 2.9 than implies that, with the notation of the beginning of this subsection, \( \overline{S} \) intersects transversely the hypersurface \( p^{-1}(L) \) of \( Bl_L(M) \).
2.3. $b$-coisotropic embeddings and the $b$-Gotay theorem.

If $C \xrightarrow{i} (M, Z, \omega)$ is $b$-coisotropic, then Proposition 2.4 implies that $(C, C \cap Z, b^i \ast \omega)$ is $b$-presymplectic, i.e. the $b$-two-form $b^i \ast \omega \in b^4 \Omega^2(C)$ is closed of constant rank. Conversely, in this subsection we prove that any $b$-presymplectic manifold embeds $b$-coisotropically into a $b$-symplectic manifold, which is unique up to neighborhood equivalence. In other words, we show a version of Gotay’s theorem for $b$-coisotropic submanifolds. For Lagrangian submanifolds, this becomes a version of Weinstein’s tubular neighborhood theorem, which was already obtained in [13], Theorem 5.18.

As a consequence, a $b$-coisotropic submanifold $C \subset (M, Z, \omega)$ determines $\omega$ (up to $b$-symplectomorphism) in a neighborhood of $C$. Notice that arbitrary coisotropic submanifolds of the log-symplectic manifold $(M, Z, \Pi)$ do not satisfy this property: for instance $Z$ is a coisotropic (even Poisson) submanifold, and by [11] the additional data consisting of a certain element of $H^2_{1b}(Z)$ is necessary in order to determine the $b$-symplectic structure in a neighborhood of $Z$.

**Definition 2.11.** A $b$-presymplectic form on a $b$-manifold is a $b$-two-form which is closed and of constant rank.

**Definition 2.12.** Let $(M_1, Z_1, \omega)$ be a $b$-manifold endowed with a $b$-presymplectic form $\omega \in b \Omega^2(M_1)$. A $b$-coisotropic embedding of $M_1$ into a $b$-symplectic manifold $(M_2, Z_2, \Omega)$ is a $b$-map $\phi : (M_1, Z_1) \rightarrow (M_2, Z_2)$ such that $\phi$ is an embedding and

1) $b^\phi \ast \Omega = \omega$.

2) $\phi(M_1)$ is $b$-coisotropic in $(M_2, Z_2, \Omega)$.

We will prove the following Gotay theorem in the $b$-symplectic setting.

**Theorem 2.13 (The $b$-Gotay theorem).** Let $(C, Z_C, \omega_C)$ be a $b$-manifold with a $b$-presymplectic form $\omega_C \in b^4 \Omega^2(C)$. We then have the following:

a) $C$ embeds $b$-coisotropically into a $b$-symplectic manifold,

b) the embedding is unique up to $b$-symplectomorphism in a tubular neighborhood of $C$, fixing $C$ pointwise.

We divide the proof of Theorem 2.13 into several steps. We roughly follow the reasoning from the symplectic case, presented in [8]. We start by constructing a $b$-symplectic thickening of the $b$-presymplectic manifold $C$, from which item a) of Theorem 2.13 will follow.

**Proposition 2.14.** Denote by $E$ the vector bundle $\text{Ker}(\omega_C) \subset b^4 T^* C$. Then there is a $b$-symplectic structure $\Omega_G$ on a neighborhood of the zero section $C \subset E^*$. 

**Proof.** Fix a complement $G$ to $E$ in $b^4 T^* C$, and let $j : E^* \hookrightarrow b^4 T^* C$ be the induced inclusion. It is clear that $j(E^*) = G^d$. Since both the bundle projection $\pi : (E^*, E^*|_{Z_C}) \rightarrow (C, Z_C)$ and the inclusion $j : (E^*, E^*|_{Z_C}) \rightarrow (b^4 T^* C, b^4 T^* C|_{Z_C})$ are $b$-maps, we can define a $b$-two-form $\Omega_G$ on $(E^*, E^*|_{Z_C})$ by

$$\Omega_G := b^\pi \ast \omega_C + b^j \omega_{\text{can}}.$$ \hfill (15)

Here $\omega_{\text{can}}$ denotes the canonical $b$-symplectic form on $b^4 T^* C$ as in Example 1.17, and the subscript $G$ is used to stress that the definition depends on the choice of complement $G$.

We want to show that $\Omega_G$ is $b$-symplectic on a neighborhood of $C \subset (E^*, E^*|_{Z_C})$. As $\Omega_G$ is clearly $b$-closed, it suffices to prove that $\Omega_G$ is non-degenerate at points $p \in C$.

**Claim:** Under the decomposition

\[ T_p \left( b^4 T^* C \right) \cong b^4 T^*_p C \oplus b^4 T^*_p C, \]
of Lemma 1.12, the canonical $b$-symplectic form is the usual pairing

$$\langle \omega_{can} \rangle_p (v + \alpha, w + \beta) = \langle v, \beta \rangle - \langle w, \alpha \rangle.$$  

(16)

This claim can be checked writing in cotangent coordinates $\omega_{can} = \frac{dx}{\pi_1} \wedge dy_1 + \sum_{i=2}^{n} dx_i \wedge dy_i$, and noticing that $y_i$ is a linear coordinate on each fiber $bT^*_p C$, i.e. $y_i \in (bT^*_p C)^* \cong bT_p C$. \triangle

Consider now the decomposition

$$bT_p E^* \cong bT_p C \oplus E^*_p = E_p \oplus G_p \oplus E^*_p$$

(17)
given by Lemma 1.12. Using Lemma 1.13 b) we have $(b,j_*)_p = \text{Id}_{bT_p C} \oplus j|_{E^*_p}$. Hence under the decomposition (17) we have

$$\left( b^* j^\ast \omega_{can} \right)_p (v + w + \alpha, x + y + \beta) = \langle \omega_{can} \rangle_p (v + w + j(\alpha), x + y + j(\beta))$$

$$= \langle v + w, j(\beta) \rangle - \langle x + y, j(\alpha) \rangle$$

$$= \langle v, j(\beta) \rangle - \langle x, j(\alpha) \rangle,$$

using the above claim and recalling that $j(E^*_p) = G^0_p$. In matrix notation,

$$\left( b^* j^\ast \omega_{can} \right)_p = \begin{pmatrix} E_p & G_p & E^*_p \\ 0 & 0 & A \\ G^*_p & 0 & 0 \\ E^*_p & -A & 0 & 0 \end{pmatrix}$$

(18)

for some matrix $A$ of full rank. Similarly we have $(b^* \pi)_p = \text{Id}_{bT_p C} \oplus 0$, applying Lemma 1.13 b) to $\pi$ (regarded as a vector bundle map). Therefore, under (17) we get

$$\left( b^* \pi^\ast \omega_C \right)_p (v + w + \alpha, x + y + \beta) = \langle \omega_C \rangle_p (v + w, x + y),$$

so that we get a matrix representation of the form

$$\left( b^* \pi^\ast \omega_C \right)_p = \begin{pmatrix} E_p & G_p & E^*_p \\ 0 & 0 & 0 \\ G_p^* & 0 & B & 0 \\ E^*_p & 0 & 0 & 0 \end{pmatrix}$$

(19)

where we also use that $E = \text{Ker}(\omega_C)$. Note that the matrix $B$ in (19) is of full rank since the restriction of $\langle \omega_C \rangle_p$ to $G_p$ is non-degenerate. Combining (18) and (19), we have that

$$\langle \Omega_C \rangle_p = \left( b^* \pi^\ast \omega_C \right)_p + \left( b^* j^\ast \omega_{can} \right)_p = \begin{pmatrix} E_p & G_p & E^*_p \\ 0 & 0 & A \\ G^*_p & 0 & B & 0 \\ E^*_p & -A & 0 & 0 \end{pmatrix},$$

(20)

which is of maximal rank. Therefore, $\Omega_C$ is non-degenerate at points $p \in C \subset E^*$. \hfill \Box

Proof of item a) of Theorem 2.13. We show that the inclusion $(C, Z_C, \omega_C) \hookrightarrow (E^*, E^*|_{Z_C}, \Omega_C)$ is indeed a $b$-coisotropic embedding, i.e.

i) $b^\ast \Omega_C = \omega_C$.

ii) $b^TC \omega_C \subset b^TC$. 

We have $\iota^*\Omega_G = b(\pi \circ i)^*\omega_C + b(j \circ i)^*\omega_{can} = \omega_C + b(j \circ i)^*\omega_{can}$. Note that $j \circ i$ is the inclusion of $C$ into $bT^*C$, so that $b(j \circ i)^*\omega_{can} = 0$ since $C$ is $b$-Lagrangian in $(bT^*C, \omega_{can})$. To check ii), we let $p \in C$ and choose $v + w + \alpha \in E_p \oplus G_p \oplus E_p^* \cong bT_pE^*$ lying in $bT_pC \Omega_G$. Let $x \in E_p \subset bT_pC$ be arbitrary. Thanks to (20), we then have
\[
0 = (\Omega_G)_p (x, v + w + \alpha) = (\Omega_G)_p (x, \alpha),
\]
which forces that $\alpha = 0$ due to non-degeneracy of $(\Omega_G)_p$ on $E_p \times E_p^*$. Hence $v + w + \alpha = v + w$ lies in $E_p \oplus G_p = bT_pC$, as desired. \(\square\)

The uniqueness statement b) of Theorem 2.13 is an immediate consequence of the following proposition, to which we devote the rest of this subsection.

**Proposition 2.15.** Let $(M, Z, \omega)$ be a $b$-symplectic manifold and $C$ a $b$-coisotropic submanifold, with induced $b$-presymplectic form $\omega_C \in \Omega^2(C)$. Let $E := \text{Ker}(\omega_C)$ and fix a splitting $bTC = E \oplus G$. Then there is a $b$-symplectomorphism $\tau$ between a neighborhood of $C \subset (M, Z, \omega)$ and a neighborhood of $C \subset (E^*, E^{|C}\cap Z, \Omega_G)$, with $\tau|_C = \text{Id}_C$.

**Proof.** Since $\omega|_{C \times G}$ is non-degenerate, we have a decomposition $bTM|_C = G \oplus G^\omega$ as symplectic vector bundles. Note that $E$ is a Lagrangian subbundle of $(G^\omega, \omega)$, since
\[
E^\omega \cap G^\omega = (E \oplus G)^\omega = bTC^\omega = bTC^\omega \cap TC = E.
\]
We fix a Lagrangian complement $V$ to $E$ in $(G^\omega, \omega)$, i.e. $G^\omega = E \oplus V$.

The idea of the proof is to construct a $b$-diffeomorphism between neighborhoods of $C$ in $M$ and $E^*$ obtained as a composition of $b$-diffeomorphisms to a neighborhood in $V$ -- whose $b$-derivative at points of $C$ pulls back $\Omega_G$ to $\omega$, and then apply a Moser argument.

We start by establishing a $b$-geometry version of the tubular neighborhood theorem, in which $V$ plays the role of the normal bundle to $C$.

**Claim 1:** There is a $b$-diffeomorphism $\phi$ between a neighborhood of $C$ in $(V, V|_{C\cap Z})$ and a neighborhood of $C$ in $(M, Z)$, satisfying $b\phi|_C = \text{Id}_{bTM|_C}$.

We will construct this map in two steps:

1. $V \rightarrow \rho(V) \rightarrow M$

**Step 1.** Let $\rho : bTM \rightarrow TM$ denote the anchor map of $bTM$ and notice that its restriction to $V$ is injective. To see this, recall the decomposition
\[
bTM|_C = G \oplus G^\omega = G \oplus E \oplus V = bTC \oplus V
\]
and the fact that $\text{Ker}(\rho|_C) \subset bTC$ by Lemma 1.8, so that $\text{Ker}(\rho)$ intersects $V$ trivially. As such, we get a $b$-diffeomorphism $\rho : (V, V|_{C\cap Z}) \rightarrow (\rho(V), \rho(V)|_{C\cap Z})$.

**Step 2.** The distribution $\rho(V)$ is complementary to $TC$, i.e.
\[
TM|_C = TC \oplus \rho(V).
\]

Indeed, by Step 1, we have at any point $p \in C$
\[
dim(T_pM) = \dim(T_pC) + \dim(V_p) = \dim(T_pC) + \dim(\rho(V_p)),
\]
and moreover, if $v \in V_p$ is such that $\rho(v) \in T_pC$, then $v \in bT_pC \cap V_p = \{0\}$. Now fix a Riemannian metric $g$ on $M$ such that $Z \subset (M, g)$ is totally geodesic (e.g. [19, Lemma 6.8]). The corresponding exponential map $\exp_p$ takes a neighborhood of $C \subset \rho(V)$ diffeomorphically onto a neighborhood of $C \subset M$. Moreover the fibers of $\rho(V)$ over $C \cap Z$ are mapped
COISOTROPIC SUBMANIFOLDS IN $b$-SYMPLECTIC GEOMETRY

into $Z$, since $\rho(V_p) \in T_pZ$ for $p \in C \cap Z$ and $Z$ is totally geodesic. Therefore, the map\(^2\) $\exp_g : (\rho(V), \rho(V)|_{C \cap Z}) \rightarrow (M, Z)$ is a $b$-diffeomorphism between neighborhoods of $C$.

We now show that $\phi := \exp_g \circ \rho : V \rightarrow M$ has the claimed property. That is, we show that $[b(\exp_g \circ \rho)]_C$ is the identity map on $bTV|_C \cong bTC \oplus V = bTM|_C$, by checking that it acts as the identity on sections. We will need the commutative diagram

$$
\begin{array}{ccc}
\rho \circ \text{Id}_V & \xrightarrow{\rho \circ \text{Id}_V} & bTM|_C \\
\uparrow & & \uparrow \\
TC \oplus V & \xrightarrow{\rho \circ \text{Id}_V} & TM|_C
\end{array}
$$

(23)

which implicitly uses a) of Lemma 1.13. We will also use that for all $q \in C$ the ordinary derivative reads

$$(\exp_g \circ \rho)_q : T_q V \cong T_q C \oplus V_q \rightarrow T_q M = T_q C \oplus \rho(V_q) : w + v \mapsto w + \rho(v).$$

(24)

For a section $X + Y \in \Gamma(bTC \oplus V)$ we now compute

$$\rho \left([b(\exp_g \circ \rho)_* (X + Y)]\right) = (\exp_g \circ \rho)_*(\rho(X) + Y) = \rho(X) + \rho(Y) = \rho(X + Y)$$

using (23) in the first equality and (24) in the second. Since the anchor $\rho$ is injective on sections, this implies that $[b(\exp_g \circ \rho)_* (X + Y)] = X + Y$, as desired. Claim 1 is proved. △

Next, the map

$$\psi : V \rightarrow E^*, \ v \mapsto -\iota_v \omega|_E$$

is an isomorphism of vector bundles covering $\text{Id}_C$, whence a $b$-diffeomorphism between the total spaces (For the injectivity, note that $\iota_v \omega|_E = 0$ implies that $v \in E^w \cap C^w = E$ as in (21), so that $v \in V \cap E = \{0\}$). The composition $\psi \circ \phi^{-1} : (M, Z) \rightarrow (E^*, E^*|_{C \cap Z})$ is a $b$-diffeomorphism between neighborhoods of $C$, with $(\psi \circ \phi^{-1})|_C = \text{Id}_C$.

Claim 2: This $b$-diffeomorphism satisfies $[b(\psi \circ \phi^{-1})^* \Omega_G]_C = \omega|_C$.

As before, let $\pi : E^* \rightarrow C$ denote the bundle projection, and let $j : E^* \hookrightarrow bT^*C$ be the inclusion induced by the splitting $bTC = E \oplus G$. Since $\psi : V \rightarrow E^*$ is a vector bundle morphism covering $\text{Id}_C$, by Lemma 1.13 b) we have that

$$b\psi|_C : bTV|_C \cong bTC \oplus V \rightarrow bTE^*|_C \cong bTC \oplus E^*$$

equals $\text{Id}_{bTC} \oplus \psi$. Furthermore $b\phi|_C = \text{Id}_{bTM|_C}$ by Claim 1. Therefore, for $p \in C$ and $x_1 + v_1 \in bT_pC \oplus V_p = bT_pM$, we have

$$[b(\psi \circ \phi^{-1})^* \Omega_G]_p(x_1 + v_1, x_2 + v_2) = (\Omega_G)_p(x_1 + \psi(v_1), x_2 + \psi(v_2)).$$

(25)

\(^2\)Alternatively, one can apply [2, Example 3.3.9, p. 88-89] (see also [21, Theorem 2]).
Recalling equation (15) and applying Lemma 1.13 b) as in the proof of Proposition 2.14, we expand the right hand side of (25) as follows:

\[(\Omega_G)_p (x_1 + \psi(v_1), x_2 + \psi(v_2)) = \omega_p(x_1, x_2) + (\omega_{can})_p (x_1 + j(\psi(v_1)), x_2 + j(\psi(v_2)))
\]
\[= \omega_p(x_1, x_2) + (x_1, j(\psi(v_2))) - (x_2, j(\psi(v_1)))
\]
\[= \omega_p(x_1, x_2) + \omega_p(e_1, v_2) + \omega_p(v_1, e_2)
\]
\[= \omega_p(x_1 + v_1, x_2 + v_2),
\]

using equation (16) in the second equality, writing \(x_i = e_i + g_i \in E_p \oplus G_p = bT_p C\), and using in the last equality that \(V\) is a Lagrangian subbundle of \((G^\omega, \omega)\). This finishes the proof of Claim 2. \(\triangle\)

Applying Proposition 1.19 (relative \(b\)-Moser) yields a \(b\)-diffeomorphism \(\rho\), defined on a neighborhood of \(C \subset (M, Z)\), such that \(b^\rho \ast (b(\psi \circ \phi^{-1})^\ast \Omega_G) = \omega\) and \(\rho|_C = \text{Id}_C\). So setting \(\tau := \psi \circ \phi^{-1} \circ \rho\) finishes the proof.

3. Strong \(b\)-coisotropic submanifolds and \(b\)-symplectic reduction

We consider a subclass of \(b\)-coisotropic submanifolds in \(b\)-symplectic manifolds, namely, the coisotropic submanifolds that are transverse to the symplectic leaves they meet. The main observation is that their characteristic distribution has constant rank, and the quotient (whenever smooth) by this distribution inherits a \(b\)-symplectic form (Proposition 3.6).

3.1. Strong \(b\)-coisotropic submanifolds.

In Subsection 2.1 we have seen that a \(b\)-coisotropic submanifold \(C \subset (M, Z, \omega)\) comes with a characteristic distribution

\[D := \rho \left( bTC^\omega \right) = \Pi^\sharp\left( TC^0 \right).
\]

In general, \(D\) fails to be regular. To force that \(D\) has constant rank, we have to impose a condition on \(C\) that is stronger than \(b\)-coisotropcity.

Definition 3.1. A submanifold \(C\) of a log-symplectic manifold \((M, Z, \Pi)\) is called strong \(b\)-coisotropic if it is coisotropic (with respect to \(\Pi\)) and transverse to all the symplectic leaves of \((M, \Pi)\) it meets.

To justify this definition, we note that

\[\Pi^\sharp_p|_{T_p C^0}\]

is injective \(\iff\) \(\text{Ker}\left(\Pi^\sharp_p\right) \cap T_p C^0 = \{0\}\)

\(\iff\) \(T_p C^0 \cap T_p C^0 = \{0\}\)

\(\iff\) \((T_p O + T_p C)^0 = \{0\}\)

\(\iff\) \(T_p O + T_p C = T_p M,\)

where \(O\) denotes the symplectic leaf through \(p\). The last equation is exactly the transversality condition of Definition 3.1. Consequently, we have:

Proposition 3.2. Let \(C \subset (M, Z, \Pi)\) be a coisotropic submanifold. Then \(C\) is strong \(b\)-coisotropic iff the characteristic distribution of \(C\) is regular, with rank equal to \(\text{codim}(C)\).

Lemma 2.5 immediately implies:
**Corollary 3.3.** Let $C \subset (M, Z, \omega)$ be strong $b$-coisotropic. Then its characteristic distribution is tangent to $Z$, and corresponds to $bTC^{\omega}$ under the bijection of Lemma 1.10 b).

**Remark 3.4.** If $C$ is a strong $b$-coisotropic submanifold of $(M^{2n}, Z, \Pi)$ intersecting $Z$, then necessarily $\dim(C) \geq n + 1$. Indeed, if $O$ denotes the symplectic leaf through $p \in C \cap Z$, then we have

$$\dim(C) = \dim(T_pO + T_pC) + \dim(T_pO \cap T_pC) - \dim(O) = \dim(T_pO \cap T_pC) + 2 \geq n + 1,$$

where the last inequality holds since $T_pO \cap T_pC$ is a coisotropic subspace of the $(2n - 2)$-dimensional vector space $T_pO$. Alternatively, one can observe that a middle-dimensional $b$-coisotropic submanifold $C'' \subset (M^{2n}, Z, \omega)$ is $b$-Lagrangian (i.e. $bTC^{\omega} = bTC$). Its characteristic distribution satisfies

$$\dim(D_p) = \begin{cases} \dim(C) - 1 & \text{if } p \in C \cap Z, \\ \dim(C) & \text{else,} \end{cases}$$

so that $C$ cannot be strong $b$-coisotropic whenever it intersects $Z$, due to Proposition 3.2.

### 3.2. Coisotropic reduction in $b$-symplectic geometry.

In this subsection we adapt coisotropic reduction to the $b$-symplectic category. It is well-known that, given a coisotropic submanifold $C$ of a Poisson manifold $M$, its quotient $\overline{C}$ by the characteristic distribution is again a Poisson manifold, provided it is smooth. More precisely, the vanishing ideal $I_C$ is a Poisson subalgebra of $(C^{\infty}(M), \{\cdot, \cdot\})$, and denoting by $N(I_C) := \{f \in C^{\infty}(M) : \{f, I_C\} \subset I_C\}$ its Poisson normalizer, we have that $N(I_C)/I_C$ is a Poisson algebra. As an algebra it is canonically isomorphic to the algebra of smooth functions on the quotient $\overline{C}$, so it endows the latter with a Poisson structure, called the **reduced Poisson structure**.

**Remark 3.5.** When the Poisson structure on $M$ is non-degenerate, i.e. corresponds to a symplectic form $\omega \in \Omega^2(M)$, the reduced Poisson structure on $\overline{C}$ is also non-degenerate. Indeed [22], it corresponds to the symplectic form $\omega_{\text{red}}$ on $\overline{C}$ obtained by symplectic coisotropic reduction, i.e. the unique one that satisfies $q^*\omega_{\text{red}} = \tilde{\iota}^*\omega$, where $q : C \to \overline{C}$ is the projection and $\tilde{\iota} : C \to M$ is the inclusion.

**Proposition 3.6 (Coisotropic reduction).** Let $C$ be a strong $b$-coisotropic submanifold of a $b$-symplectic manifold $(M, Z, \omega, \Pi)$. Then $D := \Pi^2(\overline{TC^{\omega}})$ is a (constant rank) involutive distribution on $C$. Assume that $\overline{C} := C/D$ has a smooth manifold structure, such that the projection $q : C \to \overline{C}$ is a submersion. Then $\overline{C}$ inherits a $b$-symplectic structure $\overline{\Omega}$, determined by

$$b_\eta^*\overline{\Omega} = b_i^*\omega, \quad (27)$$

where $i : C \hookrightarrow M$ is the inclusion. Its corresponding log-symplectic structure is exactly the reduced Poisson structure on $\overline{C}$ obtained from $\Pi$.

**Proof.** We know that $D$ has constant rank, by Proposition 3.2. As for involutivity, first note that $D$ is generated by Hamiltonians $X_{h_1}|_{\overline{C}}$ of functions $h \in I_C$. On such generators, we have

$$[X_{h_1}|_{\overline{C}}, X_{h_2}|_{\overline{C}}] = [X_{h_1}, X_{h_2}]|_{\overline{C}} = X_{\{h_1, h_2\}}|_{\overline{C}},$$

where $\{h_1, h_2\} \in I_C$ due to coisotropicity of $C$. Hence $D$ is involutive.
The quotient $C \cap Z := (C \cap Z) / D$ is a smooth submanifold of $C$, since for every slice $S$ in $C$ transverse to $D$, the intersection $S \cap Z$ is a smooth slice in $C \cap Z$ transverse to $D$. The leaf space $(\overline{C}, C \cap Z)$ is a $b$-manifold, and the projection $q : (C, C \cap Z) \to (\overline{C}, C \cap Z)$ is a $b$-map. For $p \in C$, we have an exact sequence
\[ 0 \to D_p \hookrightarrow T_p C \xrightarrow{(q_p)_*} T_{q(p)} \overline{C} \to 0, \]
which corresponds with an exact sequence on the level of $b$-tangent spaces
\[ 0 \to \left( bT_p C \right)^{\omega_p} \hookrightarrow bT_p C \xrightarrow{(q_p)_*} bT_{q(p)} \overline{C} \to 0. \tag{28} \]
To see this, consider the canonical splitting $\sigma : D \to \mathcal{B} C$ of the anchor $\rho : bTC \to TC$, as constructed in Lemma 1.10 a), and notice that
\[ \ker \left( \left( b \alpha \right)_p \right) = \sigma \left( \ker \left( q_* \right)_p \right) = \sigma (D_p) = \left( bT_p C \right)^{\omega_p}, \]
where the first equality holds by Corollary 1.11 and the third by Corollary 3.3.

Since $q$ is a surjective submersion, it admits sections, hence for every sufficiently small open subset $U \subset \overline{C}$ there is a submanifold $S \subset C$ transverse to $D$ such that $q|S : S \to U$ is a diffeomorphism. At points $p \in S$ we have
\[ bT_p C = \left( bT_p C \right)^{\omega_p} \oplus bT_p S \]
due to the sequence (28). This implies that $b_i^* \omega_C$ is a $b$-symplectic form on $S$, where $i_S : S \hookrightarrow C$ is the inclusion and $\omega_C$ is the restriction of $\omega$ to $C$. Denote by $\tau : U \to S$ the inverse of $q|S : S \to U$. Then $\Omega := b^* \left( b_i^* \omega_C \right)$ is $b$-symplectic on $U$. Away from $C \cap Z$, this $b$-2-form agrees with the symplectic form obtained by symplectic coisotropic reduction from $\omega|_{M \setminus \overline{C}}$. Denote by $-\Omega^{-1}$ the non-degenerate $b$-bivector on $U$ corresponding to $\Omega$.

Away from $C \cap Z$, the log-symplectic structure $\rho (-\Omega^{-1})$ agrees with the reduced Poisson structure, by Remark 3.5. By continuity, the same is true on the whole of $U$. As $U$ was arbitrary, the reduced Poisson structure on $\overline{C}$ is log-symplectic, and the above reasoning shows that the corresponding $b$-symplectic form satisfies equation (27). \hfill $\Box$

**Examples 3.7.** a) Let $i : B \hookrightarrow (M, Z)$ be a $b$-submanifold. A quick check in coordinates shows\(^3\) that $b^* T^* M|B$ is strong $b$-coisotropic in $b^* T^* M$. Its quotient $b^* T^* M|B$ is canonically $b$-symplectomorphic to $b^* T^* B$. To see this, consider the surjective submersion
\[ \varphi : b^* T^* M|B \to b^* T^* B : \alpha_p \mapsto \left( b_i^* \right)_p \alpha_p \]
and notice that the fibers of $\varphi$ coincide with the leaves of the characteristic distribution on $b^* T^* M|B$. So we get a $b$-diffeomorphism $\overline{\varphi} : b^* T^* M|B \to b^* T^* B$. To see that this is in fact a $b$-symplectomorphism, we note that the tautological $b$-one-forms on $b^* T^* M$ and $b^* T^* B$ are related by
\[ b^* \varphi \theta_B = b^* j^* \theta_M, \tag{29} \]
where $j : b^* T^* M|B \hookrightarrow b^* T^* M$ is the inclusion. Recall that the $b$-symplectic form $\overline{\Omega}$ on $b^* T^* M|B$ is determined by the relation $b^* q^* \overline{\Omega} = b^* j^* \omega_M$, where $q : b^* T^* M|B \to b^* T^* M|B$ is the projection (cf. (27)). Hence to conclude that $\overline{\varphi}$ is $b$-symplectic, we have to show that $b^* q^* (b^* \varphi^* \omega_M) = b^* j^* \omega_M$. But this is immediate from (29) since $\overline{\varphi} \circ q = \varphi$.

---

\(^3\)The converse is also true. If $b^* T^* M|B$ is strong $b$-coisotropic in $b^* T^* M$, then $b^* T^* M|B$ is transverse to $b^* T^* M|Z$, which implies that $B$ is transverse to $Z$, i.e. that $B$ is a $b$-submanifold.
b) Given a $b$-manifold $(M, Z)$, let $K$ be a distribution on $M$ tangent to $Z$. Thanks to Lemma 1.10 a) we can view $K$ as a subbundle $\sigma(K)$ of $bT^*M$. Its annihilator $\sigma(K)^0$ is strong $b$-coisotropic in $bT^*M$, and the quotient $\sigma(K)^0$ is $bT^*(M/K)$, whenever $M/K$ is smooth. We give a proof of this fact in the particular case of a Hamiltonian group action, see Corollary 3.13.

3.3. Moment map reduction in $b$-symplectic geometry.

Recall that, given an action of a Lie group $G$ on a Poisson manifold $(M, \Pi)$, a moment map is a Poisson map $J : M \rightarrow g^*$ satisfying

$$\Pi^*(dJ^p) = v_x \quad \forall x \in g.$$ (30)

Here $J^p : M \rightarrow \mathbb{R} : p \mapsto \langle J(p), x \rangle$ is the $x$-component of $J$, the vector field $v_x$ is the infinitesimal generator of the action corresponding with $x \in g$, i.e.

$$v_x(p) = \frac{d}{dt} \bigg|_{t=0} \exp(-tx) \cdot p,$$

and $g^*$ is endowed with its canonical Lie-Poisson structure [4, Section 3]. A $G$-equivariant map $J : M \rightarrow g^*$ satisfying (30) is automatically Poisson [23, Proposition 7.30].

In view of Proposition 3.6, we recall a general fact about equivariant moment maps.

**Lemma 3.8.** Let $G$ be a Lie group acting on a Poisson manifold $(M, \Pi)$ with equivariant moment map $J : M \rightarrow g^*$. Assume the action is free on $J^{-1}(0)$. Then

a) $J^{-1}(0)$ is a coisotropic submanifold of $(M, \Pi)$.

b) $J^{-1}(0)$ is transverse to all symplectic leaves of $(M, \Pi)$ it meets.

c) the characteristic distribution $\Pi^*(T(J^{-1}(0))^0)$ on $J^{-1}(0)$ coincides with the tangent distribution to the orbits of $G \ltimes J^{-1}(0)$.

**Remark 3.9.** (i) When $(M, \Pi)$ is a log-symplectic manifold, Lemma 3.8 implies that the level set $J^{-1}(0)$ is a strong $b$-coisotropic submanifold.

(ii) When $G$ a torus, there is a more flexible notion of moment map [12, Definition 22] for log-symplectic manifolds. The smooth level sets of such moment maps are not strong $b$-coisotropic submanifolds in general. Indeed they can even fail to be transverse to the degeneracy locus $Z$ (see [12, Example 23] for an instance where $Z$ itself is such a level set).

For the sake of for completeness we provide a proof of Lemma 3.8. Items a) and c) also follow from well-known facts in symplectic geometry, by restricting the $G$-action to each symplectic leaf (whenever $G$ is connected) and using item b).

**Proof.** a) We show that 0 is a regular value of $J$. Choosing $p \in J^{-1}(0)$, it is enough to prove that the restriction $d_p J : \text{Im}(\Pi^p_\mathfrak{g}) \subset T_p M \rightarrow g^*$ is surjective. To this end, assume that $\xi \in g$ annihilates $d_p J(\text{Im}(\Pi^p_\mathfrak{g}))$. We then get for all $\alpha \in T^*_p M$ that

$$\left\langle \xi, (d_p^* J\xi) \right\rangle = \left\langle \alpha, \Pi^p_\mathfrak{g} \left( d_p J^p \xi\right) \right\rangle = - \left\langle d_p J^p \Pi^p_\mathfrak{g} (\alpha), \xi \right\rangle = 0,$$

and therefore $v_\xi(p) = 0$. Since the action $G \ltimes J^{-1}(0)$ is free, this implies that $\xi = 0$. It follows that $d_p J(\text{Im}(\Pi^p_\mathfrak{g})) = g^*$, so 0 is indeed a regular value of $J$. In particular, $J^{-1}(0)$ is a submanifold of $M$. The coisotropicity of $J^{-1}(0)$ follows since it is the preimage of a symplectic leaf $\{0\} \subset g^*$ under a Poisson map.
b) Let $\mathcal{O}$ denote the symplectic leaf through $p \in J^{-1}(0)$. By the computation (26), it suffices to prove that $\Pi_p^x|_{[T_pJ^{-1}(0)]^0}$ is injective. Since $0$ is a regular value, this annihilator is given by $[T_pJ^{-1}(0)]^0 = \{d_pJ^x : x \in \mathfrak{g}\}$. We now have a composition of maps

$$\mathfrak{g} \rightarrow [T_pJ^{-1}(0)]^0 \rightarrow \Pi_p^x([T_pJ^{-1}(0)]^0)$$

$$x \mapsto d_pJ^x \mapsto \Pi_p^x(d_pJ^x) = (v_x)_p,$$

that is injective by freeness of $G \cdot J^{-1}(0)$. In particular, $\Pi_p^x|_{[T_pJ^{-1}(0)]^0}$ is injective.

Corollary 3.10 (Moment map reduction). Consider an action of a connected Lie group $G$ on a $b$-symplectic manifold $(M, Z, \Pi)$ with equivariant moment map $J : M \to \mathfrak{g}^*$. Assume the action is free and proper on $J^{-1}(0)$. Then $J^{-1}(0)$ is a strong $b$-coisotropic submanifold, and its reduction $J^{-1}(0)/G$ is $b$-symplectic.

Remark 3.11. The fact that $J^{-1}(0)/G$ is $b$-symplectic follows already from [16, Theorem 3.11], taking $A = \mathit{TM}$ there. (The hypothesis made there, that $(J_x)_\circ \rho_x : bTM \to \mathfrak{g}^*$ has constant rank for all $x \in J^{-1}(0)$, is satisfied since $J^{-1}(0)$ is transverse to $Z$). In that reference the authors develop a reduction theory for level sets of arbitrary regular values $\mu \in \mathfrak{g}^*$ satisfying the constant rank hypothesis, their statement is thus more general than the reduction statement in our Corollary 3.10.

3.3.1. Exact $b$-symplectic forms.

As a particular case of the previous construction, we consider the $b$-symplectic analog of a well-known fact in symplectic geometry. Recall that, if a Lie group $G$ acts on an exact symplectic manifold $(M, -d\theta)$ and $\theta$ is invariant under the action, then $J : M \to \mathfrak{g}^*$ defined by

$$J^x = -\iota_{\omega^x}\theta$$

(31)

is an equivariant moment map for the action (in the sense of (30)). For a proof, see for instance [1, Theorem 4.2.10]. A similar result holds in $b$-symplectic geometry.

Lemma 3.12 (Exact $b$-symplectic forms). Suppose $(M, Z)$ is a $b$-manifold with exact $b$-symplectic form $\omega = -b\text{d}\theta$. If $\phi : G \times M \to M$ is a Lie group action preserving $Z$ and $\theta \in \Omega^1(M)$, then an equivariant moment map $J : M \to \mathfrak{g}^*$ is given by $J^x = -\iota_{V_x}\theta$. Here $V_x \in \Gamma(bTM)$ is the lift of the infinitesimal generator $v_x \in \Gamma(TM)$ under the anchor $\rho$.

Proof. Clearly $J : M \to \mathfrak{g}^*$ is a smooth map. Restricting the action to the symplectic manifold $(M \setminus Z, \omega|_{M \setminus Z})$, we know that $G \cdot (M \setminus Z, -d\theta|_{M \setminus Z})$ admits a moment map given by $J|_{M \setminus Z}$. Hence the equality $\Pi^x(dJ^x) = v_x$ holds on the dense subset $M \setminus Z$, and as both sides are smooth on $M$, it holds on the whole of $M$. Similarly, since $J|_{M \setminus Z}$ is equivariant, it follows that $J$ itself is equivariant. □
An example of Corollary 3.10 and Lemma 3.12 is \( b \)-cotangent bundle reduction. Let us recall the picture in symplectic geometry: given an action \( G \acts M \), its cotangent lift \( G \acts (T^*M, -d\theta_{can}) \) preserves the tautological one-form \( \theta_{can} \) and therefore it comes with an equivariant moment map \( J : T^*M \to \mathfrak{g}^* \) given by (31)
\[
\langle J(\alpha_q), x \rangle = -\langle \alpha_q, v_x(q) \rangle.
\]
Here \( v_x \) is the infinitesimal generator of \( G \acts M \) corresponding with \( x \in \mathfrak{g} \). If the action \( G \acts M \) is free and proper, then symplectic reduction gives \( J^{-1}(0)/G \cong T^*(M/G) \). Indeed, in some detail, there is a well-defined map
\[
\varphi : J^{-1}(0) \to T^*(M/G), \quad \alpha_q \mapsto \tilde{\alpha}_{pr(q)},
\]
where \( pr : M \to M/G \) denotes the projection and
\[
\tilde{\alpha}_{pr(q)} : T_{pr(q)}(M/G) \cong \frac{T_qM}{T_qG \cdot q} \to \mathbb{R}, \quad [v] \mapsto \alpha_q(v).
\]
Since the fibers of \( \varphi \) coincide with the orbits of \( G \acts J^{-1}(0) \), there is an induced bijection \( \overline{\varphi} : J^{-1}(0)/G \to T^*(M/G) \), which is in fact a symplectomorphism (see [17, Theorem 2.2.2]).

**Corollary 3.13** (Group actions on \( b \)-cotangent bundles). Given a \( b \)-manifold \((M, Z)\) and a connected Lie group \( G \), assume that \( \phi : G \times M \to M \) is a free and proper action that preserves \( Z \). Denote by \( \Phi : G \times \overset{b}{T}^*M \to \overset{b}{T}^*M \) the \( b \)-cotangent lift of this action, that is
\[
\langle \Phi_{(g)}(\alpha_q), v \rangle = \left\langle \alpha_q, \left[ b\phi_g^{-1}\right]_{\phi_g(q)} v \right\rangle
\]
for \( \alpha_q \in \overset{b}{T}^*_qM \) and \( v \in \overset{b}{T}_{\phi_g(q)}M \). Note that the action \( \Phi \) is also free and proper, and that it preserves the hypersurface \( \overset{b}{T}^*M|_Z \). The action \( \Phi \) has a canonical equivariant moment map \( J \), and \( J^{-1}(0)/G \) is canonically \( b \)-symplectomorphic to \( T^*(M/G) \).

**Proof.** Denote the infinitesimal generators of \( \phi \) by \( v_x = \rho_M(V_x) \in \mathfrak{X}(M) \) and those of \( \Phi \) by \( \tau_x = \rho_{\overset{b}{T}^*M}(\nabla_x) \in \mathfrak{X}(\overset{b}{T}^*M) \), where \( x \in \mathfrak{g} \). One checks that they are related via
\[
\pi_x(\tau_x) = v_x,
\]
where \( \pi : \overset{b}{T}^*M \to M \) denotes the projection. Since the action \( \Phi \) preserves the tautological \( b \)-one form \( \theta \in \overset{b}{\Omega}^1(\overset{b}{T}^*M) \), Lemma 3.12 gives an equivariant moment map \( J : \overset{b}{T}^*M \to \mathfrak{g}^* \) defined by \( J^* = -i_{\tau}\theta \). Explicitly, one has
\[
-\langle J(\xi_p), x \rangle = (\tau_x)(\xi_p) = \xi_{\tau_x}(\nabla_x)_{\xi_p} = \left\langle \xi_p, \left[ b\tau_x\right]_{\tau_x} \nabla_x \right\rangle = \left\langle \xi_p, (V_x)_p \right\rangle,
\]
where the last equality uses (32) and Lemma 1.6. Denoting by \( K \) the tangent distribution to the orbits of \( G \acts M \) and by \( \sigma : K \to \overset{b}{T}^M \) the splitting of the anchor \( \rho_M : \overset{b}{T}^M \to TM \) obtained via Lemma 1.10 a), the equality (33) shows that
\[
J^{-1}(0) = \sigma(K)^0.
\]
We now perform reduction on \( J^{-1}(0) \) as in Corollary 3.10. Because the projection map \( pr : (M, Z) \to (M/G, Z/G) \) is a \( b \)-submersion with kernel \( \operatorname{Ker}(pr_*) = K \), Corollary 1.11 implies that \( \operatorname{Ker}(bpr_*) = \sigma(K) \), and therefore
\[
\overset{b}{T}_{pr(q)}(M/G) \cong \frac{\overset{b}{T}_qM}{\sigma(K_q)}.
\]
It is now clear from (34) and (35) that \( b \)-covectors in \( J^{-1}(0) \) descend to \( M/G \), i.e. we get a well-defined map

\[
\varphi : J^{-1}(0) \to \mathcal{g} \mathcal{T}^* (M/G), \quad \alpha_q \mapsto \tilde{\alpha}_{pr(q)},
\]

where

\[
\tilde{\alpha}_{pr(q)} : \mathcal{g} \mathcal{T}_{pr(q)}(M/G) \cong \frac{\mathcal{T}_q M}{\sigma(R_q)} \to \mathbb{R}, \quad [v] \mapsto \alpha_q(v).
\]

It is easy to check that \( \varphi \) is a surjective submersion with connected fibers. From symplectic geometry we know that the fibers of \( \varphi \) and the orbits of the \( G \)-action \( G \cdot J^{-1}(0) \) coincide on the open dense subset \( J^{-1}(0) \setminus (J^{-1}(0) \cap \mathcal{g} \mathcal{T}^* M |_{\mathcal{Z}}) \) of \( J^{-1}(0) \). By continuity, the corresponding tangent distributions must agree on all of \( J^{-1}(0) \), and so the same holds for the foliations integrating them. Therefore, the map \( \varphi \) descends to a smooth bijective \( b \)-map

\[
\mathcal{P} : J^{-1}(0)/G \to \mathcal{g} \mathcal{H}^*(M/G).
\]

Being a bijective submersion between manifolds of the same dimension, \( \mathcal{P} \) is a diffeomorphism. The restriction of \( \mathcal{P} \) to the complement of \( (J^{-1}(0) \cap \mathcal{g} \mathcal{T}^* M |_{\mathcal{Z}})/G \), endowed with the symplectic structure obtained by symplectic (i.e. coisotropic) reduction, is a symplectomorphism onto its image. Hence, by Proposition 3.6, \( \mathcal{P} \) is a \( b \)-symplectomorphism. \( \square \)

3.3.2. Circle bundles.

We find examples for Proposition 3.6 and Corollary 3.10 by “reverse engineering”.

**Proposition 3.14.** Let \((N, \omega)\) be a \( b \)-symplectic manifold, which for simplicity we assume to be compact. Let \( q : C \to N \) be a principal \( S^1 \)-bundle, with connection \( \theta \in \Omega^1(C) \). Denote by \( \sigma \in \Omega^2(N) \) the closed 2-form satisfying \( d\theta = q^* \sigma \).

(i) The following is a is \( b \)-symplectic manifold:

\[
(C \times I, \quad \tilde{\omega} := dt \wedge p^* \theta + (t - 1)p^*q^* \sigma + \frac{b}{p^*} b^* q^* \omega).
\]

Here \( I \) is an interval around 1 with coordinate \( t \), and \( p : C \times I \to C \) the projection.

(ii) \( C \times \{1\} \) is a strong \( b \)-coisotropic submanifold, and the reduced \( b \)-symplectic manifold (as in Proposition 3.6) is isomorphic to \((N, \omega)\).

We make a few observations about \( \tilde{\omega} \). The summand of \( \tilde{\omega} \) containing \( \sigma \) is necessary to ensure that \( \tilde{\omega} \) is \( b^d \)-closed. In the special case that \( C \) is the trivial \( S^1 \)-bundle \( N \times S^1 \), choosing \( \theta = dp/\rho \) the angle “coordinate” on \( S^1 \) (so \( \sigma = 0 \)), the above lemma delivers the product of the \( b \)-symplectic manifold \((N, \omega)\) and of the symplectic manifold \((I \times S^1, dt \wedge \theta)\).

In the special case that \( \omega \) equals the closed 2-form \( \sigma \), we have \( \tilde{\omega} = d(tp^* \theta) \), which can be interpreted as the prequantization of \( \sigma \) when the latter is symplectic.

**Remark 3.15.** By the above proposition, we actually recover \((N, \omega)\) by moment map reduction, as in Corollary 3.10. Indeed, \( S^1 \) acts on \( C \times I \) (trivially on the second factor) preserving the \( b \)-symplectic form \( \tilde{\omega} \) (since \( \theta \) is \( S^1 \)-invariant). An equivariant moment map is \( J(x, t) = t = 1 \), hence \( C \times \{1\} = J^{-1}(0) \).

**Proof.** (i) To check that \( \tilde{\omega} \) is \( b^d \)-closed, notice that its first two summands can be written as \( d(tp^* \theta) - p^* q^* \sigma \), which is closed since \( \sigma \) is closed.

For every real number \( t \) sufficiently close to 1, \((t - 1) \sigma + \omega \) is a \( b \)-symplectic form on \( N \), so its \( n \)-th power (where \( \dim(N) = 2n \)) is a nowhere-vanishing element of \( b \Omega^{2n}(N) \). This implies that \( \tilde{\omega}^{n+1} \) is a nowhere-vanishing element of \( \Omega^{2(n+1)}(C \times I) \), shrinking \( I \) if necessary. Hence \( \tilde{\omega} \) is \( b \)-symplectic.
(ii) Denote by $Z \subset N$ the singular hypersurface of $\omega$. Then the singular hypersurface of $\tilde{\omega}$ is $p^{-1}(q^{-1}(Z)) \subset C \times I$, which is transverse to $C \times \{1\}$. Therefore the latter is a $b$-submanifold, and is coisotropic since it has codimension one. If $i : C \times \{1\} \to C \times I$ denotes the inclusion, then we have $b^* \tilde{\omega} = b^* \omega$. One consequence is that $b^* T(C \times \{1\}) \tilde{\omega} = \ker(b^* \omega)$. Applying the anchor $\rho$, we obtain that the characteristic distribution $\rho \left( b^* T(C \times \{1\}) \tilde{\omega} \right)$ of $C \times \{1\}$ is given by $\ker(q_\omega)$. Since the latter has constant rank one, by Proposition 3.2 we conclude that $C \times \{1\}$ is a strong $b$-coisotropic submanifold. A second consequence is that the reduced $b$-symplectic manifold is isomorphic to $(N, \omega)$.

A concrete instance of the construction of Proposition 3.14 is the following.

**Corollary 3.16.** Let $h$ be any smooth function on $\mathbb{C}P^1$ that vanishes transversely along a hypersurface. On $\mathbb{C}^2$ consider the differential forms $\Omega := i(d\bar{z}_1 \wedge dz_1 + dz_2 \wedge d\bar{z}_2)$ (twice the standard symplectic form) and $\alpha := z_1 dz_1 + z_2 d\bar{z}_2$, and denote by $r$ the radius.

(i) In a neighborhood of the unit sphere $S^3$, the following is a $b$-symplectic form:

$$\tilde{\omega} = \frac{1}{r^2} \left( -1 + \frac{1}{p^* h} \right) \left( -\frac{i}{r^2} (\alpha \wedge \bar{\alpha}) + \Omega \right) + \Omega,$$

where $P : \mathbb{C}^2 \setminus \{0\} \to \mathbb{C}P^1$ is the projection.

(ii) The unit sphere $S^3$ is a strong $b$-coisotropic submanifold, and the reduced $b$-symplectic manifold is $(\mathbb{C}P^1, \frac{1}{p^* \sigma})$ where $\sigma$ is twice the Fubini-Study symplectic form.

**Remark 3.17.** The diagonal action of $S^1$ on the above neighborhood of the unit sphere $S^3$ in $\mathbb{C}^2$ preserves $\tilde{\omega}$ and has moment map given by $v \mapsto ||v||^2 - 1$. This follows from Remark 3.15 and the proof below.

**Proof.** On $\mathbb{R}^4 = \mathbb{C}^2$ we consider the 1-form $\tilde{\theta} = \sum_{j=1}^2 x_j dy_j - y_j dx_j$. Notice that we have $d\tilde{\theta} = 2 \sum_{j=1}^2 dx_j \wedge dy_j = \Omega$. Consider the unit sphere $S^3$. Let $q : S^3 \to \mathbb{C}P^1$ be the principal bundle given by the diagonal action of $U(1)$ (the Hopf fibration). Then $\theta := \tilde{\theta} \circ q$ is a connection 1-form on $S^3$, where $i$ is the inclusion. Then $d\theta = q^* \sigma$, where $\sigma$ is the symplectic form on $\mathbb{C}P^1$ obtained from $\Omega$ by coisotropic reduction. Consider the $b$-symplectic form $\omega := \frac{1}{p^* \sigma}$ on $\mathbb{C}P^1$. Applying Proposition 3.14 to $S^3 \times I \overset{\rho}{\to} S^3 \overset{\partial}{\to} \mathbb{C}P^1$ yields a $b$-symplectic form $\tilde{\omega}$ on $S^3 \times I$, defined by

$$\tilde{\omega} = dt \wedge p^* \theta + \left( t - 1 + \frac{1}{p^* q^* h} \right) p^* q^* \sigma.$$  

(37)

We now make $\tilde{\omega}$ more explicit. Denote by $p' : \mathbb{C}^2 \setminus \{0\} \to S^3$ the projection $v \mapsto ||v||$, let $r$ denote the radius function $v \mapsto ||v||$, and let $E$ be the Euler vector field $E \circ \tilde{\theta} = 0$ and $L_E (t/r^2) = 0$. Hence, using $q^* \sigma = d\theta$ and $d\tilde{\theta} = \Omega$ we obtain

$$p^* q^* \sigma = d(\tilde{\theta}/r^2) = \frac{1}{r^2} \left( -\frac{2 dr}{r} \wedge \tilde{\theta} + \Omega \right).$$

Using $\tilde{\theta} = \text{Im}(\alpha)$ and $r^2 = z_1 \bar{z}_1 + z_2 \bar{z}_2$ we get $-2 dr/r \wedge \tilde{\theta} = -\frac{i}{r^2} (\alpha \wedge \bar{\alpha})$. If we now use the identification $(a, t) \mapsto \sqrt{t}a$ between $S^3 \times I$ and a neighborhood of $S^3$ in $\mathbb{C}^2$ (so $t = r^2$), then the expression (37) becomes (36).

**Remark 3.18.** We show directly from its definition (36) that $\tilde{\omega}$ satisfies the transversality condition required for $b$-symplectic forms. As $-\frac{i}{r^2} (\alpha \wedge \bar{\alpha}) + \Omega$ vanishes, one obtains $\tilde{\omega}^\wedge = -2(1 - \frac{1}{r^2} + \frac{1}{p^* q^* h}) dz_1 \wedge dz_1 \wedge d\bar{z}_2 \wedge d\bar{z}_2$. The dual 4-vector field is thus transverse to the zero section, in a neighborhood of the unit sphere $S^3$. 

Example 3.19. We display an example of a function \( h \) on \( \mathbb{C}P^1 \) which vanishes on the circle \( \mathbb{R}P^1 \subset C\mathbb{P}^1 \). The function \( g := \text{Im}(\bar{z}_1 z_2) = x_1 y_2 - y_1 x_2 \) on \( S^3 \) is \( U(1) \)-invariant, hence descends to a function \( h \) on \( \mathbb{C}P^1 \), which is readily seen to vanish exactly on \( \mathbb{R}P^1 \). It vanishes linearly there: using homogeneous the coordinate \( w := z_2 / z_1 \) on the open subset \( \{ [z_1 : z_2] : z_1 \neq 0 \} \) of \( \mathbb{C}P^1 \), we have \( h = \frac{\text{Im}(w)}{1+r^2} \), which vanishes with non-zero derivative on \( \{ \text{Im}(w) = 0 \} \). Since \( g \) is quadratic, we have \( p'(g) = g/r^2 \), hence the coefficient \( \frac{1}{r^2} (-1 + \frac{1}{1+r^2}) \) in equation (36) reads

\[
\left( -\frac{1}{r^2} + \frac{1}{\text{Im}(\bar{z}_1 z_2)} \right).
\]

---

4To see this, first notice that on \( S^3 \) we have \( \bar{z}_1 z_2 = (\bar{z}_1 z_2) / (\bar{z}_1 z_1 + \bar{z}_2 z_2) \), and then divide numerator and denominator by \( \bar{z}_1 z_1 \).
