INTRODUCTION

Breast cancer is the most frequently reported and diagnosed cancer in women worldwide and is principal cause of cancer related death among females. In Pakistan, the Age-standardized rate/100,000 is highest in the world and probability of having breast cancer is one out of nine women, and is likely for 40,000 deaths every year out of the 90,000 cases detected. Accordingly Pakistani women have the highest risk of breast cancer among all Asian populations which is already reported by several authors. The situation become worst when patients with breast cancer have metastasis, a situation which considerably elevates the tumor load frequently resulting in serious result.
diagnosis and accordingly management of breast cancer can improve the five year survival rate as well as the quality of life.5

MiRNAs are small, 18–24 nucleotide long specific class of non-coding RNAs that are preserved across species and contribute in gene silencing at post-transcriptional level.6 A lot of studies have reported that miRNAs play important roles in many human biological and pathological pathways such as growth, apoptosis, development and tumorigenesis.7 The role of tumor-associated miRNAs is now established as tumor suppressors or oncogenic miRNAs.8

These findings offer experimental support for using miR-155 as a therapeutic intervention for the treatment of breast carcinoma.9 MiR-146 a/b is found to acts as a tumor suppressor gene and can also be useful as a biomarker for identification of breast cancer. It is reported to be dysregulated in different pathways leading to the development of breast cancer.10 Another miRNA miR-485 is found to be down-regulated in breast cancer indicating its tumor suppressor role in BC. It’s down regulation play an important role in development and progression of breast cancer and may serve as potential biomarker.11 Similarly many miRNAs can act as oncogenic in breast cancer. The constancy of miRs and their occurrence in blood and in body fluids, such as serum and plasma, open up the likelihood of using miRNA as biomarkers for detection of cancers including breast cancer.12 We are interested to focus on miR-195, which has been reported to be down-regulated in a wide range of malignant tumors, including hepatocellular carcinoma,13 colorectal cancer,14 gastric cancer15 and breast cancer.16

We carried out Real Time PCR assays initially on tissues followed by on plasma to detect the expression of miR-195 in BC patients and controls. Moreover, the correlations of miR-195 expression with clinicopathological features of BC patients were statistically analyzed. Our data showed that miR-195 was significantly down regulated in plasma of BC patient and could be served as a potential non-invasive molecular biomarker for the early detection of BC.

METHODS

Patients and blood samples: The study and the data collection were carried out at Liaquat University Hospital (LUH) Jamshoro, Isra University Hospital Hyderabad and Karachi Institute of Radiotherapy and Nuclear Medicine (KIRAN), Karachi. The study lasted for a period of one year. The cases were selected randomly for age, parity and social class. Patients having any other cancer beside breast cancer were not included in the study. Patient consent was taken on proforma from all study participants. Plasma was separated from each EDTA bottle after two hours in 2 ml Eppendorf tubes and stored at - 40°C and processed for the extraction of RNA. Patient’s demographic data, history, biopsy and grading of the tumors were documented from the laboratory reports and clinical data were recorded from the hospital HIMS record.

Extraction of RNA: Total RNA (including MiRNAs) from all the plasma samples was extracted by TRIZOL LS method according to the protocol provided by the suppliers (invitrogen).

Reverse transcriptase reactions: The cDNA was synthesized from total RNA as per cDNA kit instructions of Thermo Scientific. Total RNA from each sample was reverse transcribed into cDNA with an oligo (dT) primer. PCR primers already reported14 were synthesized by IDT and each sample were analyzed for each specific gene with Sybr Green I Master mix on the Bio-Rad CFX system according to manufacturer protocols (Bio-Rad USA). The average Ct value of the endogenous control (GAPDH) for every sample was subtracted from the Ct value for each target gene, resulting in the ΔCt value. MiRNA expression levels were calculated using ΔΔCt method.17

MiRNA-specific real time PCR (miR-RT-qPCR): Total RNA was poly(A) tailed using poly(A) polymerase (NEB) at 37°C for one hour, then terminated by heating at 65°C for 20 min. Poly(A)-tailed RNA (1.2 μg) was then reverse-transcribed into first-strand cDNA using reverse transcriptase with miRNA specific stem-looped RT primer.14

Quantitative reverse transcription (qRT)-PCR: Thermo Scientific Maxima SYBR green/ROX qPCR Master Mix (2x) was used for PCR. Real Time PCR amplification in the form of CT (Threshold cycle) was noted and quantification was done by ΔΔCt cycle threshold method after normalization to that of U6 (used as internal control).

Statistical analysis: Data analysis was done on SPSS version 21.0 for windows release (IBM, incorporation, USA). Variables were analyzed using students t-test and Chi-square test. A P value of ≤ 0.05 was defined as significant.

RESULTS

Demography of patients: All 139 females with biopsy confirmed BC was included in this study.
Mean age was 41.3±5.13 years. Most of the BC patients 99 (71.22%) belonged to 5th decade of life, after that 6th decade noted in 31 (22.30%) of cases. Only two (1.43%) patients were in 3rd decade (p=0.001). Marital status (married to unmarried) ratio was 33.75:1, only four patients (2.9%) were unmarried while 135 (97.1%) were married. Out of 139 cases 38 (27.3%) were post-menopausal and 101 (72.66%) were pre-menopausal female (Table-I).

Clinical examination: Eighty two (58.9%) cases had cancerous lumps in their right breast followed by 57 (41%) in left breast, bilateral breast lumps were not observed in present study. Only 4.3% cases had more than one lump and majority of cases (95.6% of cases) had one lump. Lump size of more than five cm was noted in 91.3% of cases, while small sized lumps i.e., less than two cm were found only in 0.71% of cases (Table-II).

Histological examination: Invasive Ductal carcinoma was in 138 (99.2%) of patients while invasive lobular carcinoma was observed only in one case (carcinoma in situ was not observed in our study (Table-III).

Majority of cases 92 (66.18%) consist of Grade II. Grade I and III were noted in 27 (19.4%) and 20 (14.3%) cases respectively (p=0.001). Clinical staging was done according to AJCC. Majority of breast cancer were found in stage III i.e. 77 (55.39%), followed by Stage II, I and IV respectively (p=0.001) (Table-III).

Down regulation of miR-195: Out of 139 breast cancer cases, 38 (27.3%) showed high expression and 101(72.6%) showed low expression. On the contrary, controls (n=70) showed higher and low expression in 59(84.2%) and 11(15.7%) of cases respectively (Table- IV).

Association of clinicopathological features with miR-195 expression: Out of 89 BC patients who were presented with axillary lymph node involvement, 71.9% showed downregulation of miR-195 with highly significant p-value i.e., 0.001. In contrast out of 50 cases with no axillary lymph nodes, 74% of the cases showed downregulation of miR-195 with same highly significant p-value i.e., 0.001 (Table-IV).

Table-I: Demography of study population (n=139).

| No. of Pt. | %  | p-value |
|-----------|----|---------|
| 1. Age Distribution |    |         |
| a 25-29.9 years | 2  | 1.4     | 0.001 |

| g Underlying structure | 61(43.8%) | 78(56.1%) |       |
Out of 19.4% of grade I, 66.1% of grade II and 14.38% of grade III cases of BC, 62.96% ($p=0.001$), 75% ($p=0.001$) and 75% ($p=0.001$) of the cases revealed down regulation of MiR-195 respectively (Table-IV).

Out of 15.1% of stage I, 28.05% of stage II, 55.39% of stage III and 1.43% of stage IV cases of BC, 80.95%, 64.1%, 74% and 100% ($p=0.001$) of the cases showed down regulation of MiR-195 (Table-IV).

**DISCUSSION**

Worldwide breast cancer (BC) has reached the top most position amongst the cancers in women.$^{18}$ Early detection of cancer is vital for saving the lives of patients. This could be achieved by screening programs, self examination, and awareness about it. Studies have revealed that regardless of the high incidence and death ratio related to BC, early detection is still not possible because of lack of knowledge and wakefulness about it even among the educated females like students of medical and non-medical universities.$^5$

| e Stage IV        | 2          | 1.43|           |

Out of 19.4% of grade I, 66.1% of grade II and 14.38% of grade III cases of BC, 62.96% ($p=0.001$), 75% ($p=0.001$) and 75% ($p=0.001$) of the cases revealed down regulation of MiR-195 respectively (Table-IV).

Out of 15.1% of stage I, 28.05% of stage II, 55.39% of stage III and 1.43% of stage IV cases of BC, 80.95%, 64.1%, 74% and 100% ($p=0.001$) of the cases showed down regulation of MiR-195 (Table-IV).
MiRNAs signify a new biological entity with impending role as tumor biomarkers, which can helpful in diagnosis. Several studies about role of MiRNA and cancers highlighted the possible function of miRNAs as molecular biomarkers in many human cancers as well as BC.

A large number of miRNA show dysregulation in BC. These miRNAs are useful in diagnosis of cancers as well as in their prognosis as reported by Tang and colleagues that the increase in expression of miR-27 in breast cancer patients was associated with overall poor survival, signifying that miR-27a could be an important marker of development of carcinoma of breast.

Reason of selecting MiR-195 for this study was that miR-195 is highly conserved small non coding RNAs clustered at the same Chromosomal region 17p13.1 which play key role as tumor suppressors in BC.

In this study we have reported expression of MiR-195 in BC which has been found deregulated in a large number of malignant tumors, including hepatocellular carcinoma, colorectal cancer, gastric cancer and breast cancer. The results of the present study showed that the relative expression level of miR-195 in BC was considerably lower than in non-cancerous plasma samples. These results are supported by the findings of Dan Li et al. who reported that expression levels of miR-195 and miR-497 are inversely correlated with BC. Such expression pattern may well identify malignant tumors from normal or benign tumors.

Analysis of association of miR-195 with clinicopathological features showed that status of miR-195 expression in plasma samples of BC patients was significantly correlated with tissue differentiation grade, lymph node metastasis and clinical stage of BC patients. Zhao et al. has observed two fold reductions in the status of miR-195 level in BC patients as compared to healthy control group. He has reported the usefulness of MiRNAs for early detection of tumor but has not found any significant relationship of it with TNM staging and clinicopathological parameters. We have highlighted the importance of expression of MiR-195 in BC patients with weak differentiation grade, higher occurrence of lymph node metastasis and advanced clinical stage, suggesting that down regulation of miR-195 played an important role in BC development. We have also found that although low miR-195 expression is significantly correlated with advanced clinical stage but its expression start decreasing from the stage II and even in stage I. These results highlights another fact that level of MiR-195 is significantly down regulated in all grades and stages of BC, even in lymph node negative patients with a highly significant p-value in all of these parameters. This property makes this miRNA a potential marker for diagnosis of BC in early stages.

CONCLUSION

It was found that there is noticeably significant relationship of low miR-195 expression with higher differentiation grade and lymph node metastasis and clinical stage with significant p-value. Moreover, there were significant association between miR-195 expression and some clinicopathological features. Majority of BC patients from SINDH present in 5th decade of life and most of these patients were married, pre-menopausal signifying the occurrence of BC in young age group. Breast cancer in first degree relative was present in small number of patients. All the BC females have breast fed their children. Very small numbers of BC patients have taken exogenous hormones in the form of pills or have had any mode of contraception. All the patients were having unilateral breast cancer. The main bulk of the BC patients presented with one lump with the size more than 5 cm. Majority of the patients had axillary lymph node involvement at the time of presentation; a fact highlighting late presentation and diagnosis of BC. All the cases were invasive ductal carcinoma at grade II differentiation and in stage III at the time of presentation.
