Asymptotic results for the absorption time of telegraph processes with a non-standard barrier at the origin

Antonella Iuliano∗  Claudio Macci†

October 24, 2022

Abstract

A telegraph process with an elastic barrier at the origin was studied in [5]; in particular the number of visits of the origin before the absorption is a geometric distributed random variable $M$. Some asymptotic results (large and moderate deviations) for that model were obtained in [17]. In this paper we study large and moderate deviations for a generalized model where $M$ is a light-tailed distributed random variable.

Keywords: finite velocity, random motion, large deviations, moderate deviations.

2000 Mathematical Subject Classification: 60F10, 60J25, 60K15.

1 Introduction

The (integrated) telegraph process describes an alternating random motion of a particle on the real line with finite velocity; see e.g. the seminal papers [13] and [14], and the quite recent books [15] and [20]. This model has been widely studied, and it is possible to find several non-standard versions in the literature (generalizations, modifications, etc.). Among the more recent references with some generalizations, we recall [2] for a model driven by certain random trials, [6] for a telegraph process perturbed by a Brownian motion, and [11] for certain multivariate extensions. Finally, since in this paper we prove results on large deviations, we also recall [16] (see also some references cited therein). This kind of processes deserves interest for many possible applications in different fields.

A large class of (possibly non-standard) telegraph processes concern random motions on the real line subject to barriers; see e.g. [18], [10], [19] (for results and other references the interested reader can see Chapter 3 in [15]). There is a wide literature on stochastic processes subject to the presence of barriers of different kinds. In particular in some references the barriers exhibit a hard reflection, with random switching to full absorption, and they are called elastic barriers (see e.g. the old paper [9] and the book [11]); in this paper we use this term even if nowadays it is used for different purposes. In general the number of visits of an elastic barrier is a geometric distributed random variable $M$ (say), independent of all the rest. Among the references on stochastic processes subject to elastic barriers, here we recall [5] and [4] (which deal with some versions of telegraph processes), and [12], [7] and [8] (which deal with diffusion processes).

In this paper we consider a generalization of the random motion in [5], i.e. a telegraph process on $[0, \infty)$, which starts at $x > 0$, and with an elastic barrier at the origin. The dynamic of this model depends on two parameters $\lambda, \mu > 0$ such that $\lambda > \mu$. More precisely we consider a non-standard barrier at the origin such that the number of visits before the absorption is a light-tailed

distributed random variable $M$ (thus, in particular, $M$ could be geometric distributed as happens for the case of elastic barriers); we are not aware of any other work with models having this kind of barriers. Our aim is to generalize the large (and moderate) deviation results in [17] for the model in [5], and more precisely for the absorption time at the origin $A_x(\lambda, \mu)$. The theory of large deviations provides a collection of techniques which allow to give an asymptotic evaluation of the probabilities of rare events on an exponential scale (see e.g. [3] as a reference on this topic). The asymptotic results concern two scalings:

- Scaling 1: $x \to \infty$ for $A_x(\lambda, \mu)$;
- Scaling 2: $\mu \to \infty$ for $A_x(\beta \mu, \mu)$ (for some $\beta > 1$).

We conclude with the outline of the paper. We start with Section 2 in which we present some preliminaries on the model, some examples, some preliminaries on large deviations and a brief description of the results. In Sections 3 and 4 we present the results for scalings 1 and 2, respectively. Finally, in Section 5 we present some numerical estimates based on an asymptotic Normality result under the scaling 2 when $M$ is a shifted Poisson distributed random variable (see Example 2.1).

2 Preliminaries

In this section we present the model (with some useful related formulas) and some examples; moreover we present some preliminaries on large deviations, and a brief description of the results.

2.1 The model, some formulas and examples

Let $\lambda, \mu > 0$ be such that $\lambda > \mu$. We consider a random motion of a particle that starts at $x > 0$, moves on $[0, \infty)$, and we are interested in the absorption time $A_x = A_x(\lambda, \mu)$ at the origin. We refer to eq. (2) in [5] (even if here the distribution of the random variable $M$ could be more general than the one in [5]), and the absorption time can expressed as follows

$$A_x = C_x + 1_{\{M > 1\}} \sum_{i=1}^{M-1} C_{0,i},$$

where $C_x, M, \{C_{0,i} : i \geq 1\}$ are independent random variables. More precisely $C_x$ is the random time until the first arrival at the origin, and $\{C_{0,i} : i \geq 1\}$ are i.i.d. random variables such that, for every integer $i \geq 1$, $C_{0,i}$ is the (possible) $i$-th interarrival time between two consecutive visits of the origin after the time $C_x$; moreover the particle is absorbed at the origin after $M$ visits of the origin. In view of what follows it is useful to recall that the moment generating function of $C_x$ is

$$G_{C_x}(\lambda, \mu)(s) = G_{C_0(\lambda, \mu)}(s)e^{x\Lambda(s; \lambda, \mu)} \quad \text{(for all } s \in \mathbb{R}),$$

where

$$G_{C_0(\lambda, \mu)}(s) = \begin{cases} \frac{\lambda+\mu-2s-\sqrt{(\lambda+\mu-2s)^2-4\lambda\mu}}{2\mu} & \text{if } s \leq \frac{(\sqrt{\lambda}-\sqrt{\mu})^2}{2} \\ \infty & \text{if } s > \frac{(\sqrt{\lambda}-\sqrt{\mu})^2}{2} \end{cases}$$

is the (common) moment generating function of the random variables $\{C_{0,i} : i \geq 1\}$, and

$$\Lambda(s; \lambda, \mu) := \frac{\lambda - \mu - \sqrt{(\lambda + \mu - 2s)^2 - 4\lambda\mu}}{2}$$

(see eqs. (25)-(41) in [5]; see also eq. (3) in [17]). In what follows we use the symbols $\Lambda'(s; \lambda, \mu)$ and $\Lambda''(s; \lambda, \mu)$ for the first and the second derivative of $\Lambda(s; \lambda, \mu)$ with respect to $s$. 

2
Proposition 2.1. Assume that Condition 2.1 holds. Then we have

Remark 2.2. discussed in the next remark.

Proof. Firstly we have

\[ M \text{ in } \mathbb{R} \] where Condition 2.1. Such a condition allows to generalize the case studied in the literature (see eq. (1) in [5]) where \( M \) is a geometric distributed random variable; for more details on this case see also Example 2.3 presented below.

Remark 2.1. Note that in general \( G_M \) is an increasing function such that \( G_M(0) = 1 \), and therefore we have \((-\infty, 0] \subset \mathcal{D}(G_M)\). Then, if Condition 2.1 holds, we have

\[ s_M := \sup \mathcal{D}(G_M) > 0 \text{ (possibly with } s_M = \infty). \]

Moreover we can have \( \mathcal{D}(G_M) = (-\infty, s_M) \), possibly with \( s_M = \infty \), or \( \mathcal{D}(G_M) = (-\infty, s_M] \) with \( s_M < \infty \). For the first case see Example 2.1 (where \( s_M = \infty \)) and Example 2.3 where \( s_M = -\log(1 - \alpha) \) for \( \alpha \in (0, 1] \) (and therefore \( s_M = \infty \) if and only if \( \alpha = 1 \)); for the second case see Example 2.2 where \( s_M = \log \left( 1 + \frac{\phi}{2\theta} \right) \) for some \( \theta, \xi > 0 \).

Now we present a formula for the moment generating function \( G_{A_x}(\lambda, \mu) \) of \( A_x = A_x(\lambda, \mu) \).

Proposition 2.1. Assume that Condition 2.1 holds. Then we have

\[ G_{A_x}(\lambda, \mu)(s) = \begin{cases} G_M(\log G_{C_0}(\lambda, \mu)(s))e^{x\lambda(s;\lambda, \mu)} & \text{if } s \leq \frac{(X - \sqrt{\mu})^2}{2} \\ \infty & \text{if } s > \frac{(X - \sqrt{\mu})^2}{2} \end{cases} \]

Proof. Firstly we have

\[ G_{A_x}(\lambda, \mu)(s) = \mathbb{E} \left[ e^{s(C_x+1(M > 1) \sum_{i=1}^{M-1} C_{0,i})} \right] = G_{C_x}(\lambda, \mu)(s) \mathbb{E} \left[ e^{s1(M > 1) \sum_{i=1}^{M-1} C_{0,i}} \right] \]

and, by (1), we get

\[ G_{A_x}(\lambda, \mu)(s) = G_{C_0}(\lambda, \mu)(s)e^{x\lambda(s;\lambda, \mu)} \mathbb{E} \left[ e^{s1(M > 1) \sum_{i=1}^{M-1} C_{0,i}} \right]. \]

Moreover we have

\[ \mathbb{E} \left[ e^{s1(M > 1) \sum_{i=1}^{M-1} C_{0,i}} \right] = \mathbb{E} \left[ e^{s1(M > 1) \sum_{i=1}^{M-1} C_{0,i}} | M \right] \]

\[ = P(M = 1) + \sum_{m=2}^{\infty} (G_{C_0}(\lambda, \mu)(s))^{m-1} P(M = m) = \sum_{m=1}^{\infty} (G_{C_0}(\lambda, \mu)(s))^{m-1} P(M = m) \]

\[ = \frac{\sum_{m=1}^{\infty} (G_{C_0}(\lambda, \mu)(s))^{m-1} P(M = m)}{G_{C_0}(\lambda, \mu)(s)} = \frac{G_M(\log G_{C_0}(\lambda, \mu)(s))}{G_{C_0}(\lambda, \mu)(s)}. \]

Then we conclude by combining the above equalities.

It is worth noting that we can have \( G_{A_x}(\lambda, \mu)(s) = \infty \) for some \( s \in \left( 0, \frac{\sqrt{\mu} - \sqrt{\phi}}{2} \right] \). This issue is discussed in the next remark.

Remark 2.2. Assume that Condition 2.1 holds. Then, if we consider the set

\[ \mathcal{D}(G_{A_x}(\lambda, \mu)) := \{ r \in \mathbb{R} : G_{A_x}(\lambda, \mu)(r) < \infty \}, \]
we have
\[ (-\infty, 0] \subset \mathcal{D}(G_{A_0(\lambda,\mu)}) \subset \left(-\infty, \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}\right), \]
and the first inclusion is strict. Moreover \( \log G_{C_0(\lambda,\mu)} \) is an increasing function; then we can consider its inverse \( [\log G_{C_0(\lambda,\mu)}]^{-1}(s) \). In particular we have
\[
G_{C_0(\lambda,\mu)} \left(\frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}\right) = \sqrt{\lambda} \mu, \text{ which yields } [\log G_{C_0(\lambda,\mu)}]^{-1} \left(\log \frac{\lambda}{\mu}\right) = \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}.
\]
Then, by Proposition 2.1, we have two cases.

- **Case A.** If \( s_M \geq \log \sqrt{\frac{\lambda}{\mu}}, \) possibly with \( s_M = \infty \), we have:
  
  \[
  \begin{cases}
  s_M = \log \sqrt{\frac{\lambda}{\mu}} \text{ and } \mathcal{D}(G_M) = (-\infty, s_M), \text{ then } \mathcal{D}(G_{A_0(\lambda,\mu)}) = \left(-\infty, \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}\right); \\
  \text{otherwise}
  
  \mathcal{D}(G_{A_0(\lambda,\mu)}) = \left(-\infty, \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}\right).
  \end{cases}
  \]

- **Case B.** If \( s_M < \log \sqrt{\frac{\lambda}{\mu}} \), then we set
  
  \[
  \hat{s}(\lambda, \mu, s_M) := [\log G_{C_0(\lambda,\mu)}]^{-1}(s_M)
  \]
  and we have
  \[
  \mathcal{D}(G_{A_0(\lambda,\mu)}) = \left\{ \begin{array}{ll}
  (-\infty, \hat{s}(\lambda, \mu, s_M)) & \text{if } \mathcal{D}(G_M) = (-\infty, s_M) \\
  (-\infty, \hat{s}(\lambda, \mu, s_M)] & \text{if } \mathcal{D}(G_M) = (-\infty, s_M].
  \end{array} \right.
  \]

Now we present three examples.

**Example 2.1.** Assume that \( M \) is a shifted Poisson distributed random variable; thus, for some \( \theta > 0 \),
\[
P(M = m) = \frac{\theta^{m-1}}{(m - 1)!} e^{-\theta} \text{ (for all } m \geq 1).\]
Then we can easily check that
\[
G_M(s) = e^{s+\theta(e^s-1)} \text{ for all } s \in \mathbb{R};
\]
thus \( s_M = \infty \) and \( \mathcal{D}(G_M) = \mathbb{R} \) (so this example obviously concerns the Case A in Remark 2.2). Then, by Proposition 2.1, we can easily check that
\[
G_{A_0(\lambda,\mu)}(s) = \left\{ \begin{array}{ll}
G_{C_0(\lambda,\mu)}(s)e^{\theta(C_0(\lambda,\mu)(s)-1)}e^{\lambda(s;\lambda,\mu)} & \text{if } s \leq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\
\infty & \text{if } s > \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}.
  \end{array} \right.
  \]

**Example 2.2.** Assume that \( M \) is a shifted Poisson inverse Gaussian distributed random variable. Then, for some \( \theta, \xi > 0 \), the moment generating function of \( M \) is
\[
G_M(s) = \left\{ \begin{array}{ll}
e^{s+\xi-\sqrt{\xi^2-2\theta(s^2-1)}} & \text{if } \theta(e^s - 1) \leq \frac{\xi^2}{2}, \text{ i.e. } s \leq \log \left(1 + \frac{\xi^2}{2\theta}\right) \\
\infty & \text{if } \theta(e^s - 1) > \frac{\xi^2}{2}, \text{ i.e. } s > \log \left(1 + \frac{\xi^2}{2\theta}\right);\end{array} \right.
\]
thus \( \mathcal{D}(G_M) = (-\infty, s_M] \) with \( s_M = \log \left(1 + \frac{\xi^2}{2\theta}\right) \). As far as Case A in Remark 2.2 is concerned, we have \( s_M \geq \log \sqrt{\frac{\lambda}{\mu}} \) if and only if \( 1 + \frac{\xi^2}{2\theta} \geq \sqrt{\frac{\lambda}{\mu}} \) or, equivalently, if and only if \( \frac{\xi^2}{2\theta} \geq \sqrt{\frac{\lambda}{\mu}} - 1 \). Then, by Proposition 2.1, we can easily check that we have the following two cases (which correspond to Cases A and B in Remark 2.2 respectively).
If $\frac{\xi^2}{2\theta} \geq \sqrt{\frac{\lambda}{\mu}} - 1$, then

$$G_{A_\alpha}(\lambda, \mu)(s) = \begin{cases} G_{C_0}(\lambda, \mu)(s)e^{\xi - \sqrt{\frac{\lambda^2 - 2\theta \lambda}{\mu}}} & \text{if } s \leq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\ \infty & \text{otherwise.} \end{cases}$$

If $\frac{\xi^2}{2\theta} < \sqrt{\frac{\lambda}{\mu}} - 1$, then

$$G_{A_\alpha}(\lambda, \mu)(s) = \begin{cases} G_{C_0}(\lambda, \mu)(s)e^{\xi - \sqrt{\frac{\lambda^2 - 2\theta \lambda}{\mu}}} & \text{if } s \leq \hat{s}(\lambda, \mu, s_M) \\ \infty & \text{otherwise.} \end{cases}$$

Note that (see Case B in Remark 2.2), since $\mathcal{D}(G_M) = (-\infty, s_M]$ with $s_M = \log \left(1 + \frac{\xi^2}{2\theta}\right)$, we have $\mathcal{D}(G_{A_\alpha}(\lambda, \mu)) = (-\infty, \hat{s}(\lambda, \mu, s_M)]$. In particular we can check that

$$G_{A_\alpha}(\lambda, \mu, \lambda, \mu, s_M)) = \left(1 + \frac{\xi^2}{2\theta}\right)e^{\xi + \sqrt{\lambda}(\lambda, \mu, s_M)} < \infty$$

since $G_{C_0}(\lambda, \mu)(\hat{s}(\lambda, \mu, s_M)) = 1 + \frac{\xi^2}{2\theta}$.

**Example 2.3.** Assume that $M$ is a geometric distributed random variable; thus, for some $\alpha \in (0, 1]$,

$$P(M = m) = (1 - \alpha)^{m-1}\alpha \text{ (for all } m \geq 1)$$

as in eq. (1) in [3]. Then we can easily compute the moment generating function of $M$, and we have

$$G_M(s) = \begin{cases} \frac{e^{se\alpha}}{1 - (1 - \alpha)e^s} & \text{if } (1 - \alpha)e^s < 1, \text{ i.e. } s < -\log(1 - \alpha) \\ \infty & \text{if } (1 - \alpha)e^s \geq 1, \text{ i.e. } s \geq -\log(1 - \alpha); \end{cases}$$

thus $\mathcal{D}(G_M) = (-\infty, s_M]$ with $s_M = -\log(1 - \alpha)$, and we have $s_M = \infty$ if and only if $\alpha = 1$ (because we consider the rule $\log 0 = -\infty$). As far as Case A in Remark 2.2 is concerned, we have $s_M \geq \log \sqrt{\frac{\lambda}{\mu}}$ if and only if $\frac{1}{1 - \alpha} \geq \sqrt{\frac{\lambda}{\mu}}$ or, equivalently, if and only if $\alpha \geq 1 - \sqrt{\frac{\mu}{\lambda}}$. Then, by Proposition 2.1, we can easily check that we have the following two cases (which correspond to Cases A and B in Remark 2.2 respectively).

If $\alpha \geq 1 - \sqrt{\frac{\mu}{\lambda}}$, then

$$G_{A_\alpha}(\lambda, \mu)(s) = \begin{cases} \frac{\alpha G_{C_0}(\lambda, \mu)(s)e^{\lambda s}}{1 - (1 - \alpha)G_{C_0}(\lambda, \mu)(s)} & \text{if } s \leq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\ \infty & \text{otherwise.} \end{cases}$$

In particular, if $\alpha = 1 - \sqrt{\frac{\mu}{\lambda}}$, we can write down

$$G_{A_\alpha}(\lambda, \mu)(s) = \begin{cases} \frac{\alpha G_{C_0}(\lambda, \mu)(s)e^{\lambda s}}{1 - (1 - \alpha)G_{C_0}(\lambda, \mu)(s)} & \text{if } s < \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\ \infty & \text{otherwise} \end{cases}$$

because $G_{A_\alpha}(\lambda, \mu)\left(\frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2}\right) = \infty$, and therefore $\mathcal{D}(G_{A_\alpha}(\lambda, \mu)) = (-\infty, \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2})$.  

5
If $\alpha < 1 - \frac{\mu}{\sqrt{\lambda}}$, then

$$G_{A_{\alpha}}(\lambda, \mu)(s) = \begin{cases} \frac{\alpha G_{C_0(\lambda, \mu)}(s) e^{x_\alpha(\lambda, \mu)}}{1 - (1 - \alpha)G_{C_0(\lambda, \mu)}(s)} & \text{if } s \leq \hat{s}(\lambda, \mu, s_M) \\ \infty & \text{otherwise} \end{cases}$$

where the second equality holds noting that $D(G_{A_{\alpha}}(\lambda, \mu)) = (-\infty, \hat{s}(\lambda, \mu, s_M))$ because $D(G_M) = (-\infty, s_M)$ (see Case B in Remark 2.1 in [17] and, moreover, since $s_M = -\log(1 - \alpha)$, we have $s < \hat{s}(\lambda, \mu, s_M)$ if and only if $G_{C_0(\lambda, \mu)}(s) < e^{s_M} = \frac{1}{1 - \alpha}$. Finally we remark that the equality $G_{A_{\alpha}}(\lambda, \mu)(\hat{s}(\lambda, \mu, s_M)) = \infty$ can be checked noting that $\alpha G_{C_0(\lambda, \mu)}(\hat{s}(\lambda, \mu, s_M)) = \frac{\alpha}{1 - \alpha}$ and $1 - (1 - \alpha)G_{C_0(\lambda, \mu)}(\hat{s}(\lambda, \mu, s_M)) = 0$.

Note that, in both cases $\alpha \geq 1 - \frac{\mu}{\sqrt{\lambda}}$ and $\alpha < 1 - \frac{\mu}{\sqrt{\lambda}}$, for some values of $s$ we have

$$G_{A_{\alpha}}(\lambda, \mu)(s) = \frac{\alpha G_{C_0(\lambda, \mu)}(s) e^{x_\alpha(\lambda, \mu)}}{1 - (1 - \alpha)G_{C_0(\lambda, \mu)}(s)} = \frac{\alpha G_{C_0(\lambda, \mu)}(s)}{1 + (\alpha - 1)G_{C_0(\lambda, \mu)}(s)}$$

(for the second equality see eq. (11)). In this way we recover the first displayed formula in the proof of Proposition 9 in [3]. Actually one should consider the correct version of Proposition 9 in [3] discussed in Remark 2.1 in [17]; in particular, for the case $\alpha < 1 - \frac{\mu}{\sqrt{\lambda}}$, $\hat{s}(\lambda, \mu, \alpha) = \frac{\alpha((1 - \alpha)\lambda - \mu)}{2(1 - \alpha)\mu}$ in Remark 2.1 in [17] corresponds to $\hat{s}(\lambda, \mu, s_M)$ in Remark 2.2 (Case B) in this paper.

### 2.2 Preliminaries on large deviations, and a brief description of the results

We start with some basic definitions (see e.g. [3], pages 4-5). Let $\mathcal{Z}$ be a topological space equipped with its completed Borel $\sigma$-field. A family of $\mathcal{Z}$-valued random variables $\{Z_r : r > 0\}$ (defined on the same probability space $(\Omega, \mathcal{F}, P)$) satisfies the large deviation principle (LDP for short) with speed function $v_r$ and rate function $I$ if: $\lim_{r \to \infty} v_r = \infty$; the function $I : \mathcal{Z} \to [0, \infty]$ is lower semi-continuous;

$$\limsup_{n \to \infty} \frac{1}{v_r} \log P(Z_r \in F) \leq -\inf_{z \in F} I(z)$$

and

$$\liminf_{r \to \infty} \frac{1}{v_r} \log P(Z_r \in G) \geq -\inf_{z \in G} I(z).$$

A rate function $I$ is said to be good if its level sets $\{\{z \in \mathcal{Z} : I(z) \leq \eta\} : \eta \geq 0\}$ are compact.

Throughout this paper we prove LDPs with $\mathcal{Z} = \mathbb{R}$. In view of what follows we recall a well-known result (specified for real-valued random variables) which provides (4) and a weak form of (5) with $I = \Lambda^*$.

**Theorem 2.2** (Gärtner Ellis Theorem (on $\mathbb{R}$)). Let $\{Z_r : r > 0\}$ be a family of real valued random variables (defined on the same probability space $(\Omega, \mathcal{F}, P)$). Assume that the function $\Lambda : \mathbb{R} \to (-\infty, \infty]$ defined by

$$\Lambda(s) := \lim_{r \to \infty} \frac{1}{v_r} \log \mathbb{E} [e^{v_r s Z_r}] \quad \text{(for all } s \in \mathbb{R})$$

exists, and it is finite in a neighborhood of the origin $s = 0$. Moreover let $\Lambda^* : \mathbb{R} \to [0, \infty] \text{ defined by}$

$$\Lambda^*(z) := \sup_{s \in \mathbb{R}} \{sz - \Lambda(s)\}$$

(6)
(it is the Legendre transform of \( \Lambda \)). Then: (1) holds with \( I = \Lambda^* \);

\[
\lim_{r \to \infty} \frac{1}{v_r} \log P(Z_r \in G) \geq - \inf_{z \in G \cap E} \Lambda^*(z) \text{ for all open sets } G
\]

where \( E \) is the set of exposed points of \( I \) (namely the points in which \( I \) is finite and strictly convex); if \( \Lambda \) is essentially smooth and lower semi-continuous, then the LDP holds with good rate function \( I = \Lambda^* \).

We also recall that \( \Lambda \) in the above statement is essentially smooth (see e.g. Definition 2.3.5 in [3]) if:

- the interior of the set \( \mathcal{D}_\Lambda := \{ s \in \mathbb{R} : \Lambda(s) < \infty \} \) is non-empty;
- the function \( \Lambda \) is differentiable throughout the interior of \( \mathcal{D}_\Lambda \);
- the function \( \Lambda \) is a steep (namely \( |\Lambda'(s)| \) tends to infinity when \( s \) in the interior of \( \mathcal{D}_\Lambda \) approaches any finite point of its boundary).

For instance the function \( \Lambda(\cdot; \lambda, \mu) \) in (2) is essentially smooth because \( \Lambda'(s; \lambda, \mu) \uparrow \infty \) as \( s \uparrow \frac{(\sqrt{\lambda}-\sqrt{\mu})^2}{2} \) (this can be checked with some computations and we omit the details).

Now, in view of what follows, we present some formulas for Legendre transforms (see (6)). This is the analogue of Lemma 2.1 in [17] (in some parts we have exactly the same formulas, in other cases some notation are suitably changed) and we omit the proof. Note that the two cases presented in the following lemma correspond to Cases A and B in Remark 2.2, respectively.

**Lemma 2.1.** Let \( \Lambda(\cdot; \lambda, \mu) \) be the function in (2).

(i) Let \( H_A(z; \lambda, \mu) \) be defined by

\[
H_A(z; \lambda, \mu) := \sup_{s \leq \frac{(\sqrt{z-1})\lambda - (\sqrt{z+1})\mu}{2}} \{ sz - \Lambda(s; \lambda, \mu) \},
\]

or equivalently

\[
H_A(z; \lambda, \mu) := \sup_{s < \frac{(\sqrt{z-1})\lambda - (\sqrt{z+1})\mu}{2}} \{ sz - \Lambda(s; \lambda, \mu) \}.
\]

Then we have

\[
H_A(z; \lambda, \mu) = \begin{cases} \frac{1}{2} \left( \sqrt{z - 1} \lambda - \sqrt{z + 1} \mu \right)^2 & \text{if } z \geq 1 \\ \infty & \text{otherwise.} \end{cases}
\]

(ii) For \( s_M < \log \frac{\lambda}{\mu} \), let \( \hat{s}(\lambda, \mu, s_M) \) be defined by (3) (see Case B in Remark 2.2), and set

\[
\tilde{z}(\lambda, \mu, s_M) := \Lambda'(\hat{s}(\lambda, \mu, s_M); \lambda, \mu).
\]

Moreover let \( H_B(z; \lambda, \mu, s_M) \) be defined by

\[
H_B(z; \lambda, \mu, s_M) := \sup_{s \leq \hat{s}(\lambda, \mu, s_M)} \{ sz - \Lambda(s; \lambda, \mu) \},
\]

or equivalently

\[
H_B(z; \lambda, \mu, s_M) := \sup_{s < \hat{s}(\lambda, \mu, s_M)} \{ sz - \Lambda(s; \lambda, \mu) \}.
\]

Then we have

\[
H_B(z; \lambda, \mu, s_M) = \begin{cases} \frac{1}{2} \left( \sqrt{z - 1} \lambda - \sqrt{z + 1} \mu \right)^2 & \text{if } z \leq \tilde{z}(\lambda, \mu, s_M) \\ \hat{s}(\lambda, \mu, s_M) z - \Lambda(\hat{s}(\lambda, \mu, s_M); \lambda, \mu) & \text{if } 1 \leq z \leq \tilde{z}(\lambda, \mu, s_M) \\ \infty & \text{if } z > \tilde{z}(\lambda, \mu, s_M). \end{cases}
\]
Remark 2.3. One can check with some computations that
\[ \tilde{z}(\lambda, \mu, s_M) := \frac{\lambda + \mu - 2\hat{s}(\lambda, \mu, s_M)}{\sqrt{(\lambda + \mu - 2\hat{s}(\lambda, \mu, s_M))^2 - 4\lambda\mu}}, \]
which is the analogue of \( \tilde{z}(\lambda, \mu, \alpha) \) in Lemma 2.1 in \([17]\).

Our aim is to present a generalization of some large and moderate deviation results in \([17]\). These asymptotic results concern the random variables \( \{A_x(\lambda, \mu) : x > 0\} \) as the initial position \( x \) go to infinity (scaling 1), and the random variables \( \{A_x(\beta\mu, \mu) : \mu > 0\} \) as the switching rates \( \lambda = \beta\mu \) and \( \mu \) go to infinity simultaneously (scaling 2).

Lemma 2.1 will be used in Proposition 3.1 and Remark 3.1 for scaling 1 (Cases A and B respectively) with speed \( x \), and in Proposition 4.1 and Remark 4.1 for scaling 2 (Cases A and B respectively) with speed \( \mu \). Some other results concern moderate deviations for which we do not have to distinguish between Cases A and B: Proposition 3.2 for scaling 1, and Proposition 4.2 for scaling 2. Actually, for scaling 2, we also present a non-central moderate deviation result, i.e. Proposition 4.3 together with Lemma 4.1.

The moderate deviation results in Propositions 3.2 and 4.2 fill the gap between a convergence to a constant (governed by a suitable LDP) and a weak convergence to a Normal distribution; for more details see Remarks 3.1 and 4.2 in \([17]\), respectively. We can also say that the non-central moderate deviation result in Proposition 4.3 fill the gap between a convergence to a constant (governed by a suitable LDP) and the weak convergence of \( \mu A_x/\mu(\beta\mu, \mu) \) to \( A_x(\beta, 1) \) as \( \mu \to \infty \), which is a consequence of Lemma 4.1.

3 Large and moderate deviation results under the scaling 1

We start with the analogue of Proposition 3.1 and Remark 3.2 in \([17]\); in the first case we have a full LDP, in the second case we have a weak formulation of the lower bound for open sets in term of the exposed points (as illustrated in Theorem 2.2).

Proposition 3.1. Assume that \( s_M \geq \log \sqrt{\frac{\lambda}{\mu}} \). Then the family \( \{A_x(\lambda, \mu) : x > 0\} \) satisfies the LDP with speed \( x \), and good rate function \( I_1 \) defined by \( I_1(z) := H_A(z; \lambda, \mu) \), where \( H_A(z; \lambda, \mu) \) is the function in Lemma 2.1(i).

Proof. We consider Proposition 2.1, Remark 2.2 (Case A) and Lemma 2.1(i). If \( s_M = \log \sqrt{\frac{\lambda}{\mu}} \) and \( D(G_M) \) is open, then
\[
\lim_{x \to \infty} \frac{1}{x} \log \mathbb{E}[e^{sA_x(\lambda, \mu)}] = \begin{cases} 
\Lambda(s; \lambda, \mu) & \text{if } s < \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\
\infty & \text{if } s \geq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} .
\end{cases}
\]
otherwise
\[
\lim_{x \to \infty} \frac{1}{x} \log \mathbb{E}[e^{sA_x(\lambda, \mu)}] = \begin{cases} 
\Lambda(s; \lambda, \mu) & \text{if } s \leq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} \\
\infty & \text{if } s \geq \frac{(\sqrt{\lambda} - \sqrt{\mu})^2}{2} .
\end{cases}
\]
Then the desired LDP holds by a straightforward application of Theorem 2.2.

Remark 3.1. If \( s_M < \log \sqrt{\frac{\lambda}{\mu}} \), then we have to consider Remark 2.3 (Case B) and the function \( H_B(z; \lambda, \mu, s_M) \) in Lemma 2.1(ii). Then, by Theorem 2.2 we have
\[
\limsup_{x \to \infty} \frac{1}{x} \log P \left( \frac{A_x(\lambda, \mu)}{x} \in F \right) \leq - \inf_{z \in F} H_B(z; \lambda, \mu, s_M) \text{ for all closed sets } F .
\]
and
\[ \liminf_{x \to \infty} \frac{1}{x} \log P \left( \frac{A_x(\lambda, \mu)}{x} \in G \right) \geq - \inf_{z \in G \cap \mathcal{E}} H_B(z; \lambda, \mu, s_M) \] for all open sets \( G \) where \( \mathcal{E} = (\tilde{\varepsilon}(\lambda, \mu, s_M), \infty) \) is the set of exposed points of \( H_B(\cdot; \lambda, \mu, s_M) \).

We conclude with moderate deviations, i.e. with the analogue of Proposition 3.2 in [17].

**Proposition 3.2.** For every family of positive numbers \( \{\varepsilon_x : x > 0\} \) such that
\[ \varepsilon_x \to 0 \text{ and } x\varepsilon_x \to \infty, \] the family \( \left\{ \frac{A_x(\lambda, \mu) - \mathbb{E}[A_x(\lambda, \mu)]}{\sqrt{\varepsilon_x}} : x > 0 \right\} \) satisfies the LDP with speed \( 1/\varepsilon_x \), and good rate function \( \tilde{I}_1 \) defined by \( \tilde{I}_1(z) := \frac{z^2}{2\Lambda''(0; \lambda, \mu)} \), where \( \Lambda''(0; \lambda, \mu) = \frac{8\lambda\mu}{(\lambda - \mu)^3} \).

**Proof.** We follow the lines of the proof of Proposition 3.2 in [17] and we have to prove that
\[ \lim_{x \to \infty} \frac{1}{1/\varepsilon_x} \log \mathbb{E} \left[ e^{\frac{A_x(\lambda, \mu) - \mathbb{E}[A_x(\lambda, \mu)]}{\sqrt{\varepsilon_x}}} \right] = \frac{\Lambda''(0; \lambda, \mu)}{2} s^2 \] (for all \( s \in \mathbb{R} \)).

Firstly we note that
\[ \frac{1}{1/\varepsilon_x} \log \mathbb{E} \left[ e^{\frac{A_x(\lambda, \mu) - \mathbb{E}[A_x(\lambda, \mu)]}{\sqrt{\varepsilon_x}}} \right] = \varepsilon_x \left( \log G_{A_x(\lambda, \mu)} \left( \frac{s}{\sqrt{\varepsilon_x}} \right) - \mathbb{E}[A_x(\lambda, \mu)] \frac{s}{\sqrt{\varepsilon_x}} \right) = \varepsilon_x \left( \frac{1}{x} \log G_{A_x(\lambda, \mu)} \left( \frac{s}{\sqrt{x/\varepsilon_x}} \right) - \frac{\mathbb{E}[A_x(\lambda, \mu)]}{x} - \frac{s}{\sqrt{1/\varepsilon_x}} \right), \]
where \( \frac{s}{\sqrt{1/\varepsilon_x}} \) is close to zero if \( x \) is large enough. Moreover
\[ \mathbb{E}[A_x(\lambda, \mu)] = [\log G_{A_x(\lambda, \mu)}]'(0) = G_M'(0)G_{C_0(\lambda, \mu)}(0) + x\Lambda'(0; \lambda, \mu) \] (the second equality can be checked with some computations). Then, by Proposition 2.1, eq. (8) and the Taylor formula of order 2 for the function \( \Lambda(s; \lambda, \mu) \), for \( x \) large enough we have
\[ \frac{1}{1/\varepsilon_x} \log \mathbb{E} \left[ e^{\frac{A_x(\lambda, \mu) - \mathbb{E}[A_x(\lambda, \mu)]}{\sqrt{\varepsilon_x}}} \right] = \varepsilon_x \left( \frac{1}{x} \log G_M \left( \frac{s}{\sqrt{x/\varepsilon_x}} \right) - \frac{\mathbb{E}[A_x(\lambda, \mu)]}{x} - \frac{s}{\sqrt{1/\varepsilon_x}} \right) + \varepsilon_x \left( \frac{\Lambda''(0; \lambda, \mu)}{2} \frac{s^2}{x/\varepsilon_x} + o \left( \frac{1}{x/\varepsilon_x} \right) \right), \]
and we conclude by taking the limit as \( x \to \infty. \)

**4 Large and moderate deviation results under the scaling 2**

We start with the analogue of Proposition 4.1 and Remark 4.1 in [17]; in the first case we have a full LDP, in the second case we have a weak formulation of the lower bound for open sets in term of the exposed points (as illustrated in Theorem 2.2).
The family \( \{A_x(\beta \mu, \mu) : \mu > 0\} \) satisfies the LDP with speed \( \mu \), and good rate function \( I_2 \) defined by \( I_2(z) := x H_A(z/x; \beta, 1) \), where \( H_A(z; \lambda, \mu) \) is the function in Lemma \( 2.1(i) \).

**Proof.** We consider Proposition 2.1 (note that Proposition 4.2). For every family of positive numbers \( \{s \mu \} \), Remark 2.2 (Case A) and Lemma 2.1(i). If \( s \mu = \log \beta \) and \( D(G_M) \) is open, then

\[
\lim_{\mu \to \infty} \frac{1}{\mu} \log \mathbb{E} \left[ e^{s \mu A_x(\beta \mu, \mu)} \right] = \begin{cases} x \Lambda(s; \beta, 1) & \text{if } s < \frac{(\sqrt{\beta}-1)^2}{2} \\ \infty & \text{if } s \geq \frac{(\sqrt{\beta}-1)^2}{2} \end{cases}
\]

otherwise

\[
\lim_{\mu \to \infty} \frac{1}{\mu} \log \mathbb{E} \left[ e^{s \mu A_x(\beta \mu, \mu)} \right] = \begin{cases} x \Lambda(s; \beta, 1) & \text{if } s \leq \frac{(\sqrt{\beta}-1)^2}{2} \\ \infty & \text{if } s > \frac{(\sqrt{\beta}-1)^2}{2} \end{cases}
\]

Then the desired LDP holds by a straightforward application of Theorem 2.2.  

**Remark 4.1.** If \( s \mu < \log \sqrt{\beta} \) for \( \beta > 1 \), then we have to consider Remark 2.2 (Case B) and the function \( H_B(z; \beta, 1, s \mu) \) in Lemma 2.1(ii). Then, by Theorem 2.2, we have

\[
\limsup_{\mu \to \infty} \frac{1}{\mu} \log \mathbb{P}(\mu A_x(\beta \mu, \mu) \in F) \leq -\inf_{z \in F} x H_B(z/x; \beta, 1, s \mu)
\]

and

\[
\liminf_{\mu \to \infty} \frac{1}{\mu} \log \mathbb{P}(\mu A_x(\beta \mu, \mu) \in G) \geq -\inf_{z \in G \cap \mathcal{E}} x H_B(z/x; \beta, 1, s \mu)
\]

where \( \mathcal{E} = (x \hat{\varepsilon}(\beta, 1, s \mu), \infty) \) is the set of exposed points of \( x H_B(\cdot/x; \beta, 1, s \mu) \).

Now we study moderate deviations, i.e. with the analogue of Proposition 4.2 in [17].

**Proposition 4.2.** For every family of positive numbers \( \{\varepsilon \mu : \mu > 0\} \) such that

\[
\varepsilon \mu \to 0 \text{ and } \mu \varepsilon \mu \to \infty,
\]

the family \( \{\sqrt{\varepsilon \mu} A_x(\beta \mu, \mu) - \mathbb{E}[A_x(\beta \mu, \mu)] : \mu > 0\} \) satisfies the LDP with speed \( 1/\varepsilon \mu \), and good rate function \( \tilde{I}_2 \) defined by \( \tilde{I}_2(z) := \frac{z^2}{2 \Lambda''(0; \beta, 1)} \), where \( \Lambda''(0; \beta, 1) = \frac{s \beta}{(\beta - 1)} \).

**Proof.** We follow the lines of the proof of Proposition 4.2 in [17] and we have to prove that

\[
\lim_{x \to \infty} \frac{1}{\varepsilon \mu} \log \mathbb{E} \left[ e^{\sqrt{\varepsilon \mu} (A_x(\beta \mu, \mu) - \mathbb{E}[A_x(\beta \mu, \mu)])} \right] = \frac{x \Lambda''(0; \beta, 1)}{2} s^2 \text{ for all } s \in \mathbb{R}.
\]

Firstly we note that

\[
\frac{1}{\varepsilon \mu} \log \mathbb{E} \left[ e^{\sqrt{\varepsilon \mu} (A_x(\beta \mu, \mu) - \mathbb{E}[A_x(\beta \mu, \mu)])} \right] = \varepsilon \mu \left( \log G_{A_x(\beta \mu, \mu)} \left( s \sqrt{\varepsilon \mu} - \mathbb{E}[A_x(\beta \mu, \mu)] \frac{s \sqrt{\varepsilon \mu}}{\mu} \right) - \mathbb{E}[A_x(\beta \mu, \mu)] \frac{s \sqrt{\varepsilon \mu}}{\mu} \right)
\]

\[
= \mu \varepsilon \mu \left( \frac{1}{\mu} \log G_{A_x(\beta \mu, \mu)} \left( s \sqrt{\varepsilon \mu} - \mathbb{E}[A_x(\beta \mu, \mu)] \frac{s \sqrt{\varepsilon \mu}}{\mu} \right) - \mathbb{E}[A_x(\beta \mu, \mu)] \frac{s \sqrt{\varepsilon \mu}}{\mu} \right),
\]

where \( \frac{s \sqrt{\varepsilon \mu}}{\mu} \) is close to zero if \( \mu \) is large enough. Moreover

\[
\mathbb{E}[A_x(\beta \mu, \mu)] = \left( \log G_{A_x(\beta \mu, \mu)} \right)'(0) = \frac{s \beta + 1}{\mu(\beta - 1)} + x \frac{\beta + 1}{(\beta - 1)^2} \gamma(0; \beta, 1)
\]

(10)
(the second equality can be checked with some computations). Then, by Proposition \[2.1\] eq. (10) and the Taylor formula of order 2 for the function \(\Lambda(s; \beta, 1)\), for \(\mu\) large enough we have

\[
\frac{1}{1/\varepsilon\mu} \log \mathbb{E} \left[ e^{\frac{x}{\varepsilon\mu} \sqrt{M_\mu}(A_\mu(\beta_\mu, \mu) - \mathbb{E}[A_\mu(\beta_\mu, \mu)])} \right] = \mu \varepsilon\mu \left( \frac{1}{\mu} \log G_M \left( \log G_{C_0(\beta_\mu, \mu)} \left( \frac{s}{\varepsilon\mu} \right) \right) + \frac{x}{\mu} \Lambda \left( \frac{s}{\varepsilon\mu} ; \beta_\mu, \mu \right) \right. \\
- \left( \frac{2}{\mu(\beta - 1)} + x \Lambda' \left( 0 ; \beta, 1 \right) \right) \varepsilon\mu \right) \\
= \mu \varepsilon\mu \left( \frac{1}{\mu} \log G_M \left( \log G_{C_0(\beta, 1)} \left( \frac{s}{\varepsilon\mu} \right) \right) + \frac{x}{\mu} \Lambda \left( \frac{s}{\varepsilon\mu} ; \beta, 1 \right) \right. \\
- \left( \frac{2}{\mu(\beta - 1)} + x \Lambda' \left( 0 ; \beta, 1 \right) \right) \varepsilon\mu \right) \\
= \varepsilon\mu \left( \log G_M \left( \log G_{C_0(\beta, 1)} \left( \frac{s}{\varepsilon\mu} \right) \right) - \frac{2}{\beta - 1} \varepsilon\mu \right) + x \mu \varepsilon\mu \left( \Lambda'' \left( 0 ; \beta, 1 \right) \right) \frac{s^2}{\mu^2} + o \left( \frac{1}{\varepsilon\mu} \right)
\]

and we conclude by taking the limit as \(\mu \to \infty\). \(\square\)

In the final part we present a non-central moderate deviation result. We start with the analogue of Lemma 4.1 in \[17\].

**Lemma 4.1.** For \(\beta > 1\), the random variables \(\{\mu A_x(\mu, \mu) : \mu > 0\}\) are equally distributed.

**Proof.** The result can be easily proved by taking the moment generating functions of the involved random variables, and by referring to the formulas presented in Proposition \[2.1\] (note that \(G_{C_0(\beta_\mu, \mu)}(s) = G_{C_0(\beta, 1)}(s)\) and \(\Lambda(\mu s; \beta_\mu, \mu) = \mu \Lambda(s; \beta, 1)\)). In fact these moment generating functions do not depend on \(\mu\). We omit the details. \(\square\)

Now we prove the analogue of Proposition 4.3 in \[17\].

**Proposition 4.3.** Assume that \(s_M \geq \log \sqrt{\beta}\), for \(\beta > 1\). Then, for every family of positive numbers \(\{\varepsilon\mu : \mu > 0\}\) such that \(9\) holds, the family \(\{\mu \varepsilon\mu A_x(\mu, \mu) : \mu > 0\}\) satisfies the LDP with speed \(1/\varepsilon\mu\), and good rate function \(I_2\) (see Proposition \[4.1\]).

**Proof.** We follow the lines of the proof of Proposition 4.3 in \[17\]. We consider Proposition \[2.1\] (again we note that \(G_{C_0(\beta_\mu, \mu)}(\mu s) = G_{C_0(\beta, 1)}(s)\) and \(\Lambda(\mu s; \beta_\mu, \mu) = \mu \Lambda(s; \beta, 1)\)), Remark \[2.2\] (Case A) and Lemma \[2.1\](i). We distinguish two cases.

In the first case, i.e. if \(s_M = \log \sqrt{\beta}\) and \(D(G_M)\) is open, then

\[
\frac{1}{1/\varepsilon\mu} \log \mathbb{E} \left[ e^{\frac{x}{\varepsilon\mu} \mu \varepsilon\mu A_x(\mu, \mu) (\beta_\mu, \mu)} \right] = \varepsilon\mu \log \mathbb{E} \left[ e^{\mu A_x(\mu, \mu) (\beta_\mu, \mu)} \right] \\
= \left\{ \begin{array}{ll}
\varepsilon\mu \log G_M \left( \log G_{C_0(\beta_\mu, \mu)}(s\mu) \right) + \frac{x}{\mu} \Lambda(s\mu; \beta_\mu, \mu) & \text{for } s\mu < \left( \frac{C}{2} \right) \\
\infty & \text{otherwise}
\end{array} \right.
\]

and therefore

\[
\lim_{\mu \to \infty} \frac{1}{1/\varepsilon\mu} \log \mathbb{E} \left[ e^{\frac{x}{\varepsilon\mu} \mu \varepsilon\mu A_x(\mu, \mu) (\beta_\mu, \mu)} \right] = \left\{ \begin{array}{ll}
x \Lambda(s; \beta, 1) & \text{if } s < \left( \frac{C}{2} \right) \\
\infty & \text{if } s \geq \left( \frac{C}{2} \right)
\end{array} \right.
\]
In the second case, i.e. if $s_M > \log \sqrt{\beta}$ and/or $D(G_M)$ is closed, then
\[
\frac{1}{1/\varepsilon_\mu} \log \mathbb{E} \left[ e^{\mu \beta_x/(\mu_\varepsilon_\mu) (\beta_\mu, \mu)} \right] = \begin{cases} 
\varepsilon_\mu \log G_M (\log G_{\varepsilon_\mu (\beta_1)} (s) + xA(s; \beta, 1) & \text{for } s \leq \frac{(\sqrt{\beta} - 1)^2}{2} \varepsilon_\mu \\
\infty & \text{otherwise}
\end{cases}
\]
and therefore
\[
\lim_{\mu \to \infty} \frac{1}{1/\varepsilon_\mu} \log \mathbb{E} \left[ e^{\mu \beta_x/(\mu_\varepsilon_\mu) (\beta_\mu, \mu)} \right] = \begin{cases} 
xA(s; \beta, 1) & \text{if } s \leq \frac{(\sqrt{\beta} - 1)^2}{2} \\
\infty & \text{if } s > \frac{(\sqrt{\beta} - 1)^2}{2}.
\end{cases}
\]

Finally, in both cases, the desired LDP (for every choice of positive numbers $\{\varepsilon_\mu : \mu > 0\}$ such that (9) holds) can be obtained as a straightforward application of Theorem 2.2.

\section{Numerical estimates by simulations}

In this section we follow the same lines of Section 5 in [17]. We refer to an asymptotic Normality result under the scaling 2, i.e. the weak convergence of $\sqrt{n} (A_x(\beta_\mu, \mu) - \mathbb{E}[A_x(\beta_\mu, \mu)])$ to the centered Normal distribution with variance $xA''(0; \beta, 1)$. The aim is to present some numerical values obtained by simulations to estimate $\beta$; actually we assume that $\beta > \beta_0$ for some known $\beta_0 > 1$.

Now we recall some formulas presented in Section 5 in [17]. Let $\Phi$ be the standard Normal distribution function. We denote the simulated sample mean of $A_x(\beta_\mu, \mu)$ for chosen values $\beta = \beta_\ast > \beta_0 > 1$ by $\overline{A}_x(\beta_\mu, \mu)$ and, when $\mu$ is large, we have:

- the confidence interval for $\beta_\ast$ at the level $\ell$, when $x < \overline{A}_x(\beta_\mu, \mu) - \sqrt{x^3/3} \overline{A}_x(\beta_\mu, \mu)$

\[
\left( \overline{A}_x(\beta_\mu, \mu) + \sqrt{x^3/3} \overline{A}_x(\beta_\mu, \mu) - x, \overline{A}_x(\beta_\mu, \mu) - \sqrt{x^3/3} \overline{A}_x(\beta_\mu, \mu) + x \right);
\]

- the point estimation of $\beta_\ast$

\[
\overline{A}_x(\beta_\mu, \mu) + x.
\]

Now we are ready to present some numerical values for Example 2.1 (instead of Example 2.3 as in [17]). In all cases we perform simulations by setting $x = 1$ and $\beta_0 = 1.50$; furthermore, the size of simulated sample paths is $10^3$ and the confidence level is $\ell = 0.95$. For each table we vary one parameter (among $\theta$, $\mu$ and $\beta_\ast$) and the other two are fixed.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|c|}
\hline
$\theta$ & $\mu$ & $\beta_\ast$ & $x^3/3$ & $\overline{A}_x(\beta_\mu, \mu)$ & Confidence Interval (11) & Point Estimation (12) \\
\hline
1.5 & 1000 & 1.75 & 3.666667 & 3.672570 & (1.657130, 1.868960) & 1.748343 \\
3 & 1000 & 1.75 & 3.666667 & 3.661619 & (1.65950, 1.873114) & 1.751422 \\
5 & 1000 & 1.75 & 3.666667 & 3.672501 & (1.657145, 1.868985) & 1.748363 \\
10 & 1000 & 1.75 & 3.666667 & 3.698365 & (1.651608, 1.859329) & 1.741190 \\
\hline
\end{tabular}
\caption{Numerical approximations for the confidence interval for $\beta$ varying $\theta$}
\end{table}

In Table 1 we consider some values of $\theta$ ($\mu$ and $\beta_\ast$ are constant). The point estimates and the length of the confidence intervals are stable for $\theta = 1.5$, $\theta = 3$ and $\theta = 5$; on the contrary, for $\theta = 10$, the point estimate is slightly less accurate, and the confidence interval is slightly narrower.
Table 2: Numerical approximations for the confidence interval for $\beta$ varying $\mu$

| $\theta$ | $\mu$ | $\beta_*$ | $x_\frac{\beta_*}{\mu}+1$ | $A_x(\beta_*\mu,\mu)$ | Confidence Interval (11) | Point Estimation (12) |
|----------|-------|-----------|----------------|----------------------|--------------------------|-----------------------|
| 3        | 1000  | 2         | 3               | 3.00749              | (1.840883,2.222106)     | 1.996271              |
| 3        | 5000  | 2         | 3               | 2.999793             | (1.923491,2.09058)      | 2.000104              |
| 3        | 10000 | 2         | 3               | 2.999903             | (1.944638,2.062365)     | 2.000048              |
| 3        | 50000 | 2         | 3               | 2.999883             | (1.974494,2.026999)     | 2.000058              |

Table 3: Numerical approximations for the confidence interval for $\beta$ varying $\beta_*$

| $\theta$ | $\mu$ | $\beta_*$ | $x_\frac{\beta_*}{\mu}+1$ | $A_x(\beta_*\mu,\mu)$ | Confidence Interval (11) | Point Estimation (12) |
|----------|-------|-----------|----------------|----------------------|--------------------------|-----------------------|
| 5        | 1000  | 1.5       | 5               | 5.018858             | (1.455599,1.548262)     | 1.497654              |

In Table 2 we consider some large values of $\mu$ ($\theta$ and $\beta_*$ are constant). Then, as one can expect, the accuracy of point estimates and confidence intervals generally improves when $\mu$ increases; indeed our formulas (11) and (12) concern the scaling where $\mu \to \infty$.

In Table 3 we consider some values of $\beta_*$ ($\theta$ and $\mu$ are constant). In this case, as $\beta_*$ increases, we have more accurate point estimates and wider confidence intervals.
