1 Introduction

The purpose of this paper is to study algebras of singular integral operators on $\mathbb{R}^n$ and nilpotent Lie groups that arise when one considers the composition of Calderón-Zygmund operators with different homogeneities, such as operators that occur in sub-elliptic problems and those arising in elliptic problems. For example, one would like to describe the algebras containing the operators related to the Kohn-Laplacian for appropriate domains, or those related to inverses of Hörmander sub-Laplacians, when these are composed with the more standard class of pseudo-differential operators. The algebras we study can be characterized in a number of different but equivalent ways, and consist of operators that are pseudo-local and bounded on $L^p$ for $1 < p < \infty$. While the usual class of Calderón-Zygmund operators is invariant under a one-parameter family of dilations, the operators we study fall outside this class, and reflect a multi-parameter structure.

This paper is the second in the series begun with [NRSW12].

1.1 Background

An initial impetus for the study of composition of singular integral operators of different types came from the study of the $\bar{\partial}$-Neumann problem in complex analysis. In the case of domains in $\mathbb{C}^n$ where matters are sufficiently well understood, the relevant “Calderón operator” for this boundary-value problem can be viewed as a composition of a sub-elliptic type operator with a standard pseudo-differential operator of order 0. Early studies of such compositions in the context of the Heisenberg group can be found [GS77] and in [PS82]. In [MRS95] more general such operators appear as singular integrals with “flag kernels”. The corresponding algebra was broad enough to contain, for example, all operators of the form $m(L, iT)$, where $L$ is the sub-Laplacian and $T$ is the central invariant vector field, with $m$ a multiplier of Marcinkiewicz-type. The notion of flag kernels (having singularities on appropriate flag varieties) and the properties of the corresponding singular integrals were then extended to the higher step case in [NRS01], largely in the Euclidean setting, and then in [NRSW12] in the context of automorphic flags on a general homogeneous group. In this connection we should mention the general theory of Brian Street [Str14] which treats aspects of both singular integrals and singular Radon transforms in the context of multi-parameter analysis.

However, the general nature of these results did not provide an entirely satisfactory answer to a main question that arises when composing singular integrals of different homogeneities: that of characterizing the resulting class of kernels. It turns out that the class in question is indeed narrower than the class of flag kernels: the kernels satisfy stricter differential inequalities, and in particular they are all smooth away from the origin, and the corresponding operators are thus pseudo-local.

A different approach to the study of flag kernels can be found in the work of Glowacki; see [Glo10a], [Glo10b], [Glo13]. There has been recent interest in the study of Hardy spaces associated to flags and flag kernels (see for example [HL10], [HLL10], [Rua11], [HLL13], [HLS14], [Wu14a]) and in the study of weighted norm inequalities (see for example [Wu14b]). Further recent references that deal with flag kernels include [Yan09], [DLM10] [Rua10], [WL12], [LZ13], [SY13], [Wu14b], and [MPR15].
1.2 Some motivating examples

We begin by describing a particularly simple situation occurring in studying the heat equation on \(\mathbb{R}^n \times \mathbb{R}\), or in studying convolution of operators arising on the non-Abelian Heisenberg group \(\mathbb{H}^n = \{(z, t) : z = (z_1, \ldots, z_n) \in \mathbb{C}^n, t \in \mathbb{R}\}\). In the latter case, Calderón-Zygmund kernels adapted to the automorphic dilations \(\delta \cdot (z, t) = (\delta z, \delta^2 t)\) are distributions \(K\) on \(\mathbb{H}^n\) which, away from the origin, are given by integration against a smooth function \(\mathcal{K}\) satisfying
\[
\left| \partial_t \partial_{z, \bar{z}} K(z, t) \right| \lesssim (|z| + |t|^2)^{-2n-2-|\alpha|-2\beta}
\] (1.1)
and which satisfy appropriate cancellation conditions. Similarly the isotropic variants of these kernels (the building blocks of the standard pseudodifferential operators) satisfy instead the inequalities
\[
\left| \partial_t \partial_{\bar{z}, z} K(z, t) \right| \lesssim (|z| + |t|)^{-2n-1-|\alpha|-\beta}.
\] (1.2)

If we consider kernels with compact support, it turns out that the relevant algebra of kernels (the building blocks of the standard pseudodifferential operators) satisfy instead the inequalities
\[
\left| \partial_t \partial_{z, \bar{z}} K(z, t) \right| \lesssim (|z| + |t|)^{-2n-|\alpha|} (|z|^2 + |t|)^{-1-\beta}
\] (1.3)
for \((z, t)\) in the unit ball, in addition to cancellation conditions.

There are several ways of thinking about the estimates in equation (1.3). One notices that the inequalities in (1.3) are the best that can be satisfied on the unit ball for kernels \(K\) that are assumed to be either of type (1.1) or of type (1.2), but this rather simple situation is not repeated in the higher step case \(^1\). However, one can make two more productive observations.

a) Operators satisfying (1.3) can be understood in terms of the theory of flag kernels studied in \(\textit{NRS01}\) and \(\textit{NRSW12}\). Consider the following two sets of differential inequalities:
\[
\left| \partial_t \partial_{z, \bar{z}} K(z, t) \right| \lesssim |z|^{-2n-|\alpha|} (|z|^2 + |t|)^{-1-\beta},
\] (1.4)
\[
\left| \partial_t \partial_{\bar{z}, z} K(z, t) \right| \lesssim (|z| + |t|)^{-2n-|\alpha|} |t|^{-1-\beta}.
\] (1.5)
Equation (1.4) gives the differential inequalities satisfied by flag kernels for the flag \(0\) \(\subset \mathbb{C}^n \subset \mathbb{C}^n \oplus \mathbb{R}\), while equation (1.5) gives the differential inequalities for the opposite flag \(0^{\perp} \subset \mathbb{C}^n \subset \mathbb{C}^n \oplus \mathbb{R}\). Operators of type (1.1) satisfy (1.4), operators of type (1.2) satisfy (1.5), and locally (for \((z, t)\) in compact sets), operators of type (1.1) or (1.2) satisfy both (1.4) and (1.5). Moreover, we will see that a kernel satisfying both (1.4) and (1.5) automatically satisfies (1.3). Thus one is led to the study of two-flag kernels which locally are simultaneously flag kernels for two opposite flags.

b) A second related perspective is to view kernels \(K\) satisfying the conditions of (1.3) as satisfying differential inequalities appropriate to two different families of dilations on \(\mathbb{R}^N\). Derivatives in \(z\) or \(\bar{z}\) are controlled by the dilations \((z, t) \rightarrow (\delta z, \delta t)\), while derivatives with respect to \(t\) are controlled by the dilations \((z, t) \rightarrow (\delta z, \delta^2 t)\). This suggests that, more generally, we should study operators whose kernels satisfy differential inequalities in which different derivatives are controlled by different families of dilations.

\(^1\)See Subsection (1.3.8) below for an interesting example, and Section 7 for a more complete discussion.
In this paper we begin by adopting the second point of view. It will then turn out that the resulting class of distributions includes the class which belong to two flags. One of the main goals of this paper is the study the composition of convolution operators with kernels of this form. In the Euclidean context this reduces to the study of the product of the Fourier multipliers, but in the non-Abelian situation the composition becomes a more serious issue.

A second goal of this paper is to establish regularity of two-flag kernels. The inequalities in equations (1.4) and (1.5) are the differential inequalities for a kernel belonging simultaneously to two opposite 2-step flags, and it is easy to see that these imply the inequalities in equation (1.3). However in the case of higher step, the results are not so simple, and in fact are rather surprising. Consider, for example, the case of two opposite 3-step flags in (1.3). However in the case of higher step, the results are not so simple, and in fact are rather surprising. Consider, for example, the case of two opposite 3-step flags in $\mathbb{R}^3$:

$$\mathcal{F} : \{0\} \subset \{(x, y, z) : y = z = 0\} \subset \{(x, y, z) : z = 0\} \subset \mathbb{R}^3,$$

$$\mathcal{F} : \{0\} \subset \{(x, y, z) : x = y = 0\} \subset \{(x, y, z) : x = 0\} \subset \mathbb{R}^3.$$

A flag kernel $K$ for the flag $\mathcal{F}$ with homogeneity $\lambda \cdot (x, y, z) = (\lambda x, \lambda y, \lambda z)$ satisfies the differential inequalities

$$|\partial_z^a \partial_y^b \partial_x^c K(x, y, z)| \leq C_{a,b,c} |x|^{-1-a} (|x| + |y|)^{-1-b} (|x| + |y| + |z|)^{-1-c}. \quad (1.6)$$

A flag kernel $K$ for the flag $\mathcal{F}^-$ with homogeneity $\lambda \cdot (x, y, z) = (\lambda x, \lambda^2 y, \lambda^2 z)$ satisfies the differential inequalities

$$|\partial_z^a \partial_y^b \partial_x^c K(x, y, z)| \leq C_{a,b,c} (|x| + |y|^2 + |z|^3)^{-1-a} (|y| + |z|^2)^{-1-b} |z|^{-1-c}. \quad (1.7)$$

Suppose that $K$ is a distribution with compact support which is a flag kernel for both flags. Looking only at the inequalities in equations (1.6) and (1.7), these estimates provide no information about $K(x, y, z)$ if $x = z = 0$ and $y \neq 0$; in terms of the assumed size estimates alone, the distribution $K$ could be singular away from the origin. Unexpectedly, it turns out that

$$|\partial_z^a \partial_y^b \partial_x^c K(x, y, z)| \leq C_{a,b,c} (|x| + |y|^2 + |z|^3)^{-1-a} (|x| + |y| + |z|^2)^{-1-b} (|x| + |y| + |z|)^{-1-c},$$

and the distribution $K$ is indeed pseudo-local. It is important to note that this is a consequence of both the differential inequalities and the cancellation conditions.

### 1.3 Plan of the paper

Our results can be divided roughly into two kinds: those concerning properties of the kernels and those concerning the resulting convolution operators.

1. We begin by studying a class $\mathcal{P}(E)$ of distributions on $\mathbb{R}^N$ given away from the origin by integration against a smooth function. These functions are required to satisfy differential inequalities adapted to a set of $n \leq N$ families of dilations on $\mathbb{R}^N$ prescribed by an $n \times n$ matrix $E$. Distributions $K \in \mathcal{P}(E)$ must also satisfy appropriate cancellation conditions.

2. We are primarily interested in the local behavior of these distributions, and it will be convenient to modify the class of kernels outside the unit ball so that they and all their derivatives are rapidly decreasing at infinity. Under these hypotheses, we shall denote the class of modified kernels by $\mathcal{P}_0(E)$.

---

\footnote{We will see below in Section 7 that if the rank of the matrix $E$ is greater than 1, then the kernels $K \in \mathcal{P}(E)$ are integrable at infinity.}
3. We then characterize these distributions in terms of their Fourier transform, and also in terms of decompositions as infinite dyadic sums of dilates of normalized bump functions. This material is discussed in Sections 2-6. In Section 7, we show that these distributions fall outside the class of standard Calderón-Zygmund kernels. In Section 10, we find the smallest class $P_0(E)$ containing the convolution of Calderón-Zygmund kernels with different homogeneities. In Section 11, we show that two-flag kernels provide examples of the classes $P(E)$.

After establishing the basic properties of the distributions $K \in P_0(E)$, we fix a homogeneous nilpotent Lie group $G$ whose underlying space is $\mathbb{R}^N$ and thus has a given automorphic family of dilations. (Of course this includes the special case in which the group $G$ is the abelian $\mathbb{R}^n$.)

4. If the $n$ families of dilations on $\mathbb{R}^N$ given by the matrix $E$ are compatible with the automorphic dilations, we show that convolution on $G$ with a distribution $K \in P(E)$ defines a bounded operator on $L^p(G)$ for $1 < p < \infty$, and that the collection of these convolution operators form an algebra under composition. This material is discussed in Sections 8-9.

5. We also characterize the smallest algebra of convolution operators which arise when one composes Calderón-Zygmund operators of different homogeneities. This material appears in Section 10.

6. Finally, we describe a generalization of the class $P(E)$ to allow variable coefficients, and we investigate the commutation properties of these operators. In particular, we study the role of the classical pseudo-differential operators. This material is considered in Sections 12 and 13.

In the following subsections we provide a more detailed summary of the results in this paper.

1.3.1 Section 2: The class of kernels

In Section 2, we provide a precise definition of a class of distributions and their associated multipliers. We start with a fixed decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$. Write $x \in \mathbb{R}^N$ as $(x_1, \ldots, x_n)$ with $x_j = (x_k : k \in C_j) \in \mathbb{R}^{C_j}$. (Throughout this paper we use boldface, such as $x_j$, to indicate a tuple of coordinates, and standard type, such as $x_k$, to indicate a single coordinate.) Each component $\mathbb{R}^{C_j}$ is equipped with a family of dilations, denoted by $\lambda \cdot x_j$ for $\lambda > 0$. For simplicity of exposition in this Introduction, we assume that these are the standard isotropic dilations $\lambda \cdot x_j = (\lambda x_k : k \in C_j)$ although we will allow more general non-isotropic dilations in Section 2 below. If $Q_j$ is the homogeneous dimension of $\mathbb{R}^{C_j}$, then for isotropic dilations, $Q_j$ is the dimension of $\mathbb{R}^{C_j}$. Let $n_j$ be a smooth homogeneous norm on $\mathbb{R}^{C_j}$ so that $n_j(\lambda \cdot x_j) = \lambda n_j(x_j)$. Thus for isotropic dilations, we can take $n_j$ to be the standard Euclidean norm on $\mathbb{R}^{C_j}$.

The homogeneities on each component $\mathbb{R}^{C_j}$ can be weighted in various ways to give a global family of dilations on $\mathbb{R}^N$. Let $E = \{\epsilon(j,k)\}$ be an $n \times n$ matrix with strictly positive entries, and for $1 \leq j \leq n$, define a family of dilations on $\mathbb{R}^N$ by setting

$$\delta_j(\lambda)[x] = (\lambda^{1/\epsilon(j,1)} \cdot x_1, \ldots, \lambda^{1/\epsilon(j,j)} \cdot x_j, \ldots, \lambda^{1/\epsilon(j,n)} \cdot x_n). \quad (1.8)$$

$^3$A precise definition is given in Subsection 8.1 below.

$^4$If $\lambda \cdot x_j = \exp[A_j \log \lambda](x_j)$ the homogeneous dimension of $\mathbb{R}^{C_j}$ is the trace of $A_j$. 
and the homogeneous dimension of $\mathbb{R}_\lambda^H$ is a distribution in the cellation conditions on the distributions product kernels or flag kernels. Roughly speaking, they require that if $K$ family of dilations $\in \mathcal{P}$ different dilation structures. We require that the components of the matrix $E$ satisfy

$$e(j, j) = 1 \quad 1 \leq j \leq n,$$

$$e(j, k) \leq e(j, l)e(l, k) \quad 1 \leq j, k, l \leq n.$$  \hfill (1.10)

We study a family $\mathcal{P} = \mathcal{P}(E)$ of distributions $K$ on $\mathbb{R}^N$ which are given away from the origin $0 \in \mathbb{R}^N$ by integration against a smooth function $K$ satisfying the following differential inequality:~\footnote{This is standard terminology, although we only have $N_j(x + y) \leq A_j(N_j(x) + N_j(y))$ for some constant $A_j$ instead of the usual triangle inequality.}

$$|\partial_{x_1}^{\alpha_1} \cdots \partial_{x_n}^{\alpha_n} K(x)| \lesssim \prod_{j=1}^n N_j(x)^{-Q_j - |\alpha_j|}. \hfill (1.11)$$

(Note that derivatives of $K$ with respect to any of the variables in $x_j$ are controlled by the family of dilations $\delta_j(\lambda)$ and the homogeneous norm $N_j$.) In addition, we impose certain cancellation conditions on the distributions $K$. These are analogous to cancellation conditions for product kernels or flag kernels. Roughly speaking, they require that if $x = (x', x'')$ is a decomposition of the coordinates $x_1, \ldots, x_n$ into two subsets, then $K(x') = \int K(x', x'')\psi(x'') \, dx''$ is a distribution in the $x''$ variables of the same type. The precise conditions are specified in part 1.3 of Definition 2.2 below.

Note that in the example of the Heisenberg group given above, we have the natural decomposition $\mathbb{H}^n = \mathbb{C}^n \oplus \mathbb{R} \cong \mathbb{R}^{2n} \oplus \mathbb{R}$. The isotropic dilations on each component are given by $\lambda \cdot (z_1, \ldots, z_n) = (\lambda z_1, \ldots, \lambda z_n)$ and $\lambda \cdot t = \lambda t$, so that the homogeneous dimension of $\mathbb{C}^n$ is $2n$ and the homogeneous dimension of $\mathbb{R}$ is $1$. Set $n_1(z) = |z| = [\sum_{j=1}^n |z_j|^2]^{\frac{1}{2}}$ and $n_2(t) = |t|$, so that $n_1(\lambda \cdot z) = \lambda n_1(z)$ and $n_2(\lambda \cdot t) = \lambda n_2(t)$. If we take $E = \begin{bmatrix} 1 & 1 \\ 2 & 1 \end{bmatrix}$ then

$$N_1(z, t) = n_1(z) + n_2(t) \approx |z| + |t|,$$

$$N_2(z, t) = n_1(z)^2 + n_2(t) \approx |z|^2 + |t|,$$  \hfill (1.12)

and the corresponding dilations are given by

$$\delta_1(\lambda)(z, t) = (\lambda z, \lambda t),$$

$$\delta_2(\lambda)(z, t) = (\lambda^2 z, \lambda t).$$

The differential inequalities required by (1.11) are then

$$|\partial_{z}^\alpha \partial_t^\beta K(z, t)| \lesssim N_1(z, t)^{-2n-|\alpha|}N_2(z, t)^{-1-\beta} \approx (|z| + |t|)^{-2n-|\alpha|}(|z|^2 + |t|)^{-1-\beta}$$

which is in agreement with (1.3).

1.3.2 Section 3 Marked partitions

Our analysis of the distributions $K \in \mathcal{P}_0(E)$ is based on the decomposition of the unit ball into the regions where one summand in each norm $N_j(x) = n_1(x_1)^{e(j, 1)} + \cdots + n_n(x_n)^{e(j, n)}$ is strictly larger than all the others. (There is an analogous decomposition of the Fourier

\footnote{We use standard multi-index notation; see Section 2 for more details.}
transform $\xi$-space for $\xi$ large, which is needed to understand the differential inequalities of the multiplier $m = \hat K$.) Matters are simplest in the case when $n = 2$ exemplified by the Heisenberg group, where the two norms are given in equation (1.12). In this case there are three regions near the origin.

1. The set $|z|^2 \geq |t| \geq |t|^2$, where the isotropic dilations are controlling. Here $N_1(z, t) \approx |z| \approx |z| + |t|$ and $N_2(z, t) \approx |z|^2 \approx (|z| + |t|)^2$.

2. The set $|z| \lesssim |t| \lesssim |t|^{1 \over 2}$, where the automorphic dilations are controlling. Here $N_1(z, t) \approx |t| \approx |z|^2 + |t|$ and $N_2(z, t) \approx |t| \approx |z|^2 + |t|$.

3. The intermediate region where $|t| \lesssim |z| \lesssim |t|^{1 \over 2}$ where kernels of the type (1.3) behave like “product kernels”. Here $N_1(z, t) \approx |z|$ and $N_2(z, t) \approx |t|$.

The case $n \geq 3$ is more intricate. The required systematic decomposition of the $x$-space depends on the notion of a ‘marked partition’ of the set $\{1, \ldots, n\}$, which is a collection of disjoint non-empty subsets $I_1, \ldots, I_r$ of $\{1, \ldots, n\}$ with $\bigcup_{r=1}^s I_r = \{1, \ldots, n\}$, together with a ‘marked’ element $k_r$ in each subset $I_r$. This concept arises as follows.

Suppose the matrix $E$ satisfies the conditions given in equation (1.10), and let $x$ be a point in the unit ball such that no two terms in any norm $N_j(x)$ are equal. We will see in Proposition 13 below that if $n_{k_r}(x_{k_r})$ is the dominant term in $N_j(x)$ for some $j \neq k$ then $n_{k}(x)$ is also the dominant term in $N_k(x)$. Thus given such a point $x$, there is a well-defined set $\{k_1, \ldots, k_s\}$ of indices such that $n_{k_r}(x_{k_r})$ is the dominant term in $N_{k_r}(x)$. For $1 \leq r \leq s$, we let $I_r$ be the set of indices $j$ such that $n_{k_r}(x_{k_r})$ is dominant in $N_j(x)$. Then $k_r \in I_r$ and this produces a marked partition. The details are given below in Section 3.

One may note that the decomposition given via marked partitions is somewhat akin to what happens in the theory of “resolutions of singularities”, here applied to (say) a smooth version of a power of the function $F(x) = \prod_{j=1}^n N_j(x)$. Using that theory (see e.g. [CGP13]) one would be led to decompose a neighborhood of the origin into a number of parts, and in each part make an appropriate change of variables so that $F$ becomes essentially a monomial in the new variables. However, in our situation the decomposition by marked partitions is much more explicit and tractable, and no auxiliary change of variables is required.

### 1.3.3 Section 4 Characterization by Fourier transforms

For $\xi \in \mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$ write $\xi = (\xi_1, \ldots, \xi_n)$ with $\xi_k \in \mathbb{R}^{C_k}$ and set

$$\hat N_j(\xi) = |\xi_1|^{1/e(1,j)} + \cdots + |\xi_j| + \cdots + |\xi_n|^{1/e(j,n)}.$$

This is the ‘dual norm’ to $N_j(x)$. Denote by $\mathcal{M}_\infty(E)$ the class of multipliers $m \in C^\infty(\mathbb{R}^N)$ satisfying

$$\left| \partial^{\alpha_1}_{\xi_1} \cdots \partial^{\alpha_n}_{\xi_n} m(\xi) \right| \lesssim \prod_{j=1}^n \left[ 1 + \hat N_j(\xi) \right]^{-|\alpha_j|}.$$  

On page 6 we introduced the subclass $\mathcal{P}_0(E)$ of proper distributions. In Section 4 we show that $\mathcal{K} \in \mathcal{P}_0(E)$ if and only if its Fourier transform $m = \hat K \in \mathcal{M}_\infty(E)$.

### 1.3.4 Sections 5 and 6 Characterization by dyadic decompositions
In Section 5 we show that kernels \( K \in \mathcal{P}_0(E) \) can be characterized by their dyadic decomposition into dilates of bump functions. Let \( \{\varphi^I\} \) be a uniformly bounded family of \( C^\infty \)-functions supported in the unit ball, where \( I \) runs over the set of all \( n \) -tuples \( I = (i_1, \ldots, i_n) \in \mathbb{Z}^n \). Let

\[
[\varphi^I](x) = 2^{-\sum_{j=1}^{n} Q_j i_j} \varphi(2^{-i_1} x_1, \ldots, 2^{-i_n} x_n)
\]

be the \( L^1 \)-invariant dilation of \( \varphi^I \), and let

\[
\Gamma_Z(E) = \left\{ I = (i_1, \ldots, i_n) \in \mathbb{Z}^n : e(j,k) i_k \leq i_j < 0 \right\}.
\]

If

\[
\int_{\mathbb{R}^n} \varphi^I(x_1, \ldots, x_j, \ldots, x_n) \, dx_j = 0
\]

for each \( I \in \Gamma_Z(E) \) and for all \( 1 \leq j \leq n \), then the infinite series \( \sum_{I \in \Gamma_Z(E)} [\varphi^I]_f \) converges in the sense of distributions to a distribution \( K \in \mathcal{P}_0(E) \). More generally, we show that the ‘strong’ cancellation condition given in (1.17) can be replaced by a variant of the weak cancellation condition that was introduced in [NRSW12]. Roughly speaking, if \( \varphi^I \) does not have cancellation in a variable \( x_j \), then there is a compensating gain in the size of \( \varphi^I \).

This more general result is then used in our study of convolutions of distributions in Section 9. In this study we also need a converse statement: if \( K \in \mathcal{P}_0(E) \), it can be written, modulo distributions corresponding to coarser decompositions of \( \mathbb{R}^N \), as a sum \( \sum_{I \in \Gamma_Z(E)} [\varphi^I]_f \). This is the subject of Section 6.

1.3.5 Section 7: Significance of the rank of \( E \)

In Section 7 we show that the class of classical Calderón-Zygmund kernels corresponds exactly to the case in which the rank of the matrix \( E \) is equal to 1. If the rank is greater than 1, distributions \( K \in \mathcal{P}(E) \) differ from Calderón-Zygmund kernels in two ways:

1) The distribution \( K \) is integrable at infinity, and so we can write \( K = K_0 + K_\infty \) with \( K_0, K_\infty \in \mathcal{P}(E) \), where \( K_0 \) has support in the unit ball, and where \( K_\infty \) is given by integration against a function \( K_\infty \in C^\infty(\mathbb{R}^N) \cap L^1(\mathbb{R}^N) \). Thus for \( \text{rank}(E) \geq 2 \), we focus on the local behavior of distributions \( K \in \mathcal{P}(E) \). We generally restrict our attention to the class of proper distributions \( \mathcal{P}_0(E) \subset \mathcal{P}(E) \) such that all derivatives are rapidly decreasing at infinity.

2) If \( K \) is a Calderón-Zygmund kernel, then \( \left| \{ x \in \mathbb{R}^N : |K(x)| > \lambda \} \right| \lesssim \lambda^{-1} \). If \( K \in \mathcal{P}(E) \) and the rank of \( E \) is greater than 1, such weak type estimates may no longer be true. We show, for example, that if \( \text{rank}(E) = n \) there exist distributions \( K \in \mathcal{P}(E) \) such that \( \left| \{ x \in \mathbb{R}^N : |K(x)| > \lambda \} \right| \approx \lambda^{-1} \left[ \log \lambda \right]^{n-1} \).

3) In general, there is a notion of ‘reduced rank’ which determines optimal bounds for estimates of the sort considered in 2). This is discussed in Section 7.3.

\footnote{The precise statement is given in Definition 5.9.}
1.3.6 Sections 8 and 9: Convolution operators on a Lie group

In Sections 8 and 9 we turn to the second part of our analysis dealing with convolution operators $T_K f = f * K$ on a homogeneous nilpotent Lie group $G \cong \mathbb{R}^N$. Our two main results are the following:

(A) If $K \in \mathcal{P}_0(E)$ then each operator $T_K$ extends to a bounded operator on $L^p(G)$ for $1 < p < \infty$.

(B) If $K, L \in \mathcal{P}_0(E)$ then there exists $M \in \mathcal{P}_0(E)$ such that $T_L \circ T_K = T_M$. Formally $M = K * L$, although the convolution of tempered distributions is not always defined. Thus the space $\mathcal{P}_0(E)$ is an algebra under composition (or convolution).

The first result follows rather easily from the observation that every distribution $K \in \mathcal{P}_0(E)$ is a flag kernel, since it was established in [NRSW12] that convolution with a flag kernel extends to a bounded operator on $L^p$. The second result is analogous to the result in the same paper that the space of kernels is closed under convolution. However this case is more difficult and requires additional ideas.

We remark that both results are quite simple for Euclidean convolution, since $\hat{T_K f}(\xi) = m(\xi) \hat{f}(\xi)$ where $m$ is the Fourier transform of $K$ and hence $m \in \mathcal{M}_\infty(E)$. It is not hard to check that a multiplier $m \in \mathcal{M}_\infty(E)$ satisfies the conditions of the Marcinkiewicz multiplier theorem, and the $L^p$-boundedness of the operator $T_K$ follows immediately. Since the product of two such multipliers is again a multiplier of the same class, the result on composition of operators also follows easily in this case.

To prove the results on a more general group, we rely very heavily on the decomposition of distributions $K \in \mathcal{P}(E)$ as dyadic sums of dilates of bump functions. The heart of the argument is then a careful analysis of sums of the form $\sum_{I,J} [\varphi_I]_I * [\psi_J]_J$.

1.3.7 Section 10: Convolution of Calderón-Zygmund kernels

In Section 10 we study the convolution of Calderón-Zygmund kernels $K_1, \ldots, K_m$ with compact support having different homogeneities. If the homogeneities are suitably adapted to the decomposition on $\mathbb{R}^N$ we show that there is an $s \times s$ matrix $E$ so that the algebra $\mathcal{P}_0(E)$ contains each $K_j$. We also establish a kind of converse result: If $E$ is an $n \times n$ matrix satisfying the basic hypothesis given in (1.10), then there are finitely many different homogeneities on $\mathbb{R}^N$ so that $\mathcal{P}_0(E)$ is the minimal algebra of the above type containing compactly supported Calderón-Zygmund kernels of each homogeneity.

1.3.8 Section 11: Regularity of two-flag kernels

In Section 11 we return to the study of kernels belonging to two opposite flags, and show that these belong to $\mathcal{P}_0(E)$ for an appropriate matrix $E$. In the example studied in section 11.2 where the kernel satisfied the two estimates

$$|\partial_x^a \partial_y^b \partial_z^c K(x, y, z)| \leq C_{a,b,c} \left\{ \begin{array}{ll}
|x|^{1-a} (|x|^2 + |y|)^{-1-b}(|x|^3 + |y|^{3/2} + |z|)^{-1-c} \\
(|x| + |y|)^2 + |z|^3)^{-1-a} (|y| + |z|^{3/2})^{-1-b} |z|^{-1-c}
\end{array} \right.,$$
it turns out that $K \in \mathcal{P}_0(\mathbf{E})$ where

$$
\mathbf{E} = \begin{bmatrix}
1 & 1 & 1 \\
2 & 1 & 1 \\
3 & \frac{3}{2} & 1
\end{bmatrix}
$$

and

$$
\begin{align*}
N_1(x, y, z) &= |x| + |y| + |z|, \\
N_2(x, y, z) &= |x|^2 + |y| + |z|, \\
N_3(x, y, z) &= |x|^3 + |y|^{3/2} + |z|
\end{align*}
$$

1.3.9 Sections 12 and 13: Operators with variable coefficients

In Sections 12 and 13 we describe a wider class of operators with “variable coefficients”. An operator $T$ belongs to this extended class if it is of the form

$$
T[f](x) = \int_G K(x, z) f(x \cdot z^{-1}) dz
$$

(1.18)

where for each $x$, the distribution $K(x, \cdot)$ is a kernel of the type we have been considering that depends in an appropriately smooth way on $x$. One can then assert:

a) Operators of that type form an algebra, and each is bounded on $L^p(G)$ for $1 < p < \infty$.

b) The standard pseudo-differential operators of order 0 belong to this algebra, and the subalgebra of these operators is “central” in the sense that an operator of the extended algebra commutes with a standard pseudo-differential operator of order 0, up to an error which is an appropriate “smoothing operator.”

2 The Classes $\mathcal{P}(\mathbf{E})$ and $\mathcal{M}(\mathbf{E})$

In this section we define a class of distributions $\mathcal{P}(\mathbf{E})$ and the corresponding class of Fourier multipliers $\mathcal{M}(\mathbf{E})$ on the space $\mathbb{R}^N$ and its dual. We begin by introducing notation that will be used throughout the paper.

2.1 Notation

2.1.1 Decompositions of $\mathbb{R}^N$

We begin with an initial decomposition of $\mathbb{R}^N$ into direct sums of subspaces where only some of the coordinates $x_1, \ldots, x_N$ are non-zero. Thus if $C \subset \{1, \ldots, N\}$ is non-empty, set

$$
\mathbb{R}^C = \left\{ x = (x_1, \ldots, x_N) \in \mathbb{R}^N : x_j = 0 \text{ for all } j \notin C \right\} \subset \mathbb{R}^N.
$$

(2.1)

We will abuse of this notation by allowing $\mathbb{R}^C$ to also indicate the set of $c$-tuples ($c$ being the cardinality of $C$) with entries indexed by elements of $C$. We assume that an initial decomposition of $\mathbb{R}^N$ is given,

$$
\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n},
$$

(2.2)

where $C_1, \ldots, C_n \subset \{1, \ldots, N\}$ are disjoint non-empty subsets with $\bigcup_{j=1}^n C_j = \{1, \ldots, N\}$. Given the decomposition (2.2), if $x = (x_1, \ldots, x_N) \in \mathbb{R}^N$ we write $x = (x_1, \ldots, x_n)$ where $x_j = \{x_l : l \in C_j\}$. 
Unfortunately there are further notational complications. We shall sometimes need to consider the direct sum of only a subset of the subspaces $\mathbb{R}^{C_1}, \ldots, \mathbb{R}^{C_n}$, and we will also need to partition the set $\{C_1, \ldots, C_n\}$ into a union of disjoint subsets and consider the corresponding coarser decomposition of $\mathbb{R}^N$. We shall then use the following notation.

(a) If $L = \{l_1, \ldots, l_r\} \subset \{1, \ldots, n\}$, write

$$\mathbb{R}^L = \mathbb{R}^{C_{l_1}} \oplus \cdots \oplus \mathbb{R}^{C_{l_r}} = \left\{ x \in \mathbb{R}^N : x_j = 0 \text{ for all } j \notin \bigcup_{k=1}^r C_{l_k} \right\}. \quad (2.3)$$

An element of $\mathbb{R}^L$ can then be written $x_L = \{x_k : k \in L\}$.

(b) Let $I_1, \ldots, I_s \subset \{1, \ldots, n\}$ be disjoint, non-empty subsets with $\bigcup_{r=1}^s I_r = \{1, \ldots, n\}$. Write

$$\mathbb{R}^{I_r} = \bigoplus_{k \in I_r} \mathbb{R}^{C_k} = \left\{ x \in \mathbb{R}^N : x_j = 0 \text{ for all } j \notin \bigcup_{k \in I_r} C_k \right\}. \quad (2.4)$$

We then have the coarser decomposition $\mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s}$. If $x \in \mathbb{R}^N$ we write $x = (x_{I_1}, \ldots, x_{I_s})$ where $x_{I_r} \in \mathbb{R}^{I_r}$.

Note that we have slightly abused notation since the symbols $\mathbb{R}^L$ and $\mathbb{R}^{I_r}$ in equations (2.3) and (2.4) have a different meaning than the symbol $\mathbb{R}^C$ in equation (2.1). However $C$ is a subset of $\{1, \ldots, N\}$ while $L$ and $I_r$ are subsets of $\{1, \ldots, n\}$.

### 2.1.2 Dilations on $\mathbb{R}^N$

The underlying space $\mathbb{R}^N$ is equipped with a family of dilations given by

$$\lambda \cdot x = \lambda \cdot (x_1, \ldots, x_N) = (\lambda^{d_1} x_1, \ldots, \lambda^{d_N} x_N) \quad (2.5)$$

where each $d_j > 0$. We can restrict these dilations in equation (2.5) to each subspace $\mathbb{R}^{C_j}$ and write $\lambda \cdot x_j = \{\lambda^{d_1} x_l : l \in C_j\}$. The homogeneous dimension of the subspace $\mathbb{R}^{C_j}$ is then $Q_j = \sum_{l \in C_j} d_l$. Let $n_j : \mathbb{R}^{C_j} \rightarrow [0, \infty)$ be a smooth homogeneous norm for this family of dilations so that

$$n_j(x_j) \approx \sum_{l \in C_j} |x_l|^{1/d_l}. \quad (2.6)$$

Thus $n_j(\lambda \cdot x_j) = n_j(x_j)$ for $\lambda > 0$. Put

$$E(\rho) = \left\{ x \in \mathbb{R}^N : n_j(x_j) < \rho, 1 \leq j \leq n \right\}.$$

We use standard multi-index notation for derivatives. If $\gamma = (\gamma_1, \ldots, \gamma_N) \in \mathbb{N}^N$ then $\partial^\gamma = \prod_{i=1}^N \partial_{x_i}^{\gamma_i}$ and $|\gamma| = \sum_{i=1}^N \gamma_i$. Using the decomposition (2.2), we can also write $\gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n}$. When estimating derivatives $\partial^\gamma f(x)$ in terms of homogeneous norms on each subspace $\mathbb{R}^{C_j}$ we need to use an appropriately weighted length. Thus put

$$[\gamma_j] = \sum_{l \in C_j} \gamma_l d_l \quad \text{and} \quad [\gamma] = \sum_{j=1}^n [\gamma_j] = \sum_{l=1}^N \gamma_l d_l. \quad (2.7)$$

The space of infinitely differentiable real-valued functions on $\mathbb{R}^N$ with compact support is denoted by $C_0^\infty(\mathbb{R}^N)$ and the space of Schwartz functions is denoted by $\mathcal{S}(\mathbb{R}^N)$. The basic semi-norms on these spaces are given by

$$||\varphi||_{(m)} = \sup_{x \in \mathbb{R}^N} \left\{ |\partial^\gamma x \varphi(x)| : |\gamma| \leq m \right\} \quad \text{for } \varphi \in C_0^\infty(\mathbb{R}^N),$$

$$||\psi||_M = \sup_{x \in \mathbb{R}^N} \left\{ (1 + |x|^\alpha) |\partial^\beta x \psi(x)| : |\alpha| + |\beta| \leq M \right\} \quad \text{for } \psi \in \mathcal{S}(\mathbb{R}^N).$$
Let $\mathcal{A}$ be an index set. We use the following terminology from Section 4 in [NRSW12].

1) If $\{\varphi_\alpha : \alpha \in \mathcal{A}\} \subset C_0^\infty(\mathbb{R}^N)$, then the family $\{\varphi_\alpha\}$ is normalized in terms of a function $\Phi \in C_0^\infty(\mathbb{R}^N)$ if there are constants $C, C_m > 0$ and integers $p_m$ with the following properties.

a) If the support of $\Phi$ is contained in the ball $B(\rho)$ then the support of each $\varphi_\alpha$ is contained in the ball $B(C\rho)$.

b) For every $m \in \mathbb{N}$ and every $\alpha \in \mathcal{A}$, $||\varphi_\alpha||_{(m)} \leq C_m||\Phi||_{(m+p_m)}$.

2) A family $\{\varphi_\alpha : \alpha \in \mathcal{A}\} \subset C_0^\infty(\mathbb{R}^N)$ is uniformly bounded if all the members are supported in a fixed ball $B(\rho)$ and if there are constants $C_m > 0$ so that $||\varphi_\alpha||_{(m)} \leq C_m$ for all $\alpha \in \mathcal{A}$.

3) If $\{\psi_\alpha : \alpha \in \mathcal{A}\} \subset \mathcal{S}(\mathbb{R}^N)$, then the family $\{\psi_\alpha\}$ is normalized in terms of a function $\Psi \in \mathcal{S}(\mathbb{R}^N)$ if there are constants $C_M > 0$ and integers $p_M \in \mathbb{N}$ so that $||\psi_\alpha||_{(M)} \leq C_M||\Psi||_{(M+p_M)}$ for every $M \in \mathbb{N}$.

4) A family $\{\psi_\alpha : \alpha \in \mathcal{A}\} \subset \mathcal{S}(\mathbb{R}^N)$ is uniformly bounded if there are constants $C_M > 0$ so that $||\psi_\alpha||_{M} \leq C_M$ for all $\alpha \in \mathcal{A}$.

Given the decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$, define an $n$-parameter family of dilations by setting $(\lambda_1, \ldots, \lambda_n) \cdot x = (\lambda_1 x_1, \ldots, \lambda_n x_n)$. If $(\lambda_1, \ldots, \lambda_n) = (2^{-t_1}, \ldots, 2^{-t_n})$ with $t = (t_1, \ldots, t_n) \in \mathbb{R}^n$ then for $f \in L^1(\mathbb{R}^N)$, we define

$$
(f)_t(x) = f(2^{-t_1} \cdot x_1, \ldots, 2^{-t_n} \cdot x_n),
$$

$$
[f]_t(x) = 2^{-\sum_{j=1}^n t_j} f(2^{-t_1} \cdot x_1, \ldots, 2^{-t_n} \cdot x_n).
$$

Note that $||(f)_t||_{L^\infty(\mathbb{R}^N)} = ||f||_{L^\infty(\mathbb{R}^N)}$ while $|[f]_t||_{L^1(\mathbb{R}^N)} = ||f||_{L^1(\mathbb{R}^N)}$.

### 2.2 Global norms

The classes $\mathcal{P}(\mathbf{E})$ and $\mathcal{M}(\mathbf{E})$ of distributions and multipliers are defined using families of norms $\{N_1, \ldots, N_n\}$ and dual norms $\{\tilde{N}_1, \ldots, \tilde{N}_n\}$. These in turn are defined in terms of an $n \times n$ matrix $\mathbf{E} = \{e(j, k)\}$, where each entry $e(j, k) \in (0, \infty)$. For $1 \leq j \leq n$ set

$$
N_j(t_1, \ldots, t_n) = n_1(t_1)^{e(j, 1)} + \cdots + n_n(t_n)^{e(j, n)} \approx \sum_{k=1}^n \sum_{t \in C_k} |t_l|^{e(j, k)/d_l},
$$

$$
\tilde{N}_j(t_1, \ldots, t_n) = n_1(t_1)^{-e(j, 1)} + \cdots + n_n(t_n)^{-e(j, n)} \approx \sum_{k=1}^n \sum_{t \in \tilde{C}_k} |t_l|^{-e(k, j)/d_l}.
$$

The entries of $\mathbf{E}$ are usually subject to certain natural constraints.

**Definition 2.1.** The matrix $\mathbf{E}$ satisfies the basic hypothesis if :\footnote{The motivation for these constraints is discussed in Section 4 below.}

$$
e(j, j) = 1, \quad \text{for } 1 \leq j \leq n,
$$

$$
e(j, l) \leq e(j, k)e(k, l) \quad \text{for } 1 \leq j, k, l \leq n.
$$

In particular, $1 \leq e(j, k)e(k, j)$ for $1 \leq j, k \leq n$.\footnote{The motivation for these constraints is discussed in Section 4 below.}
We will need to restrict the norms \( \{N_j\} \) to certain subspaces of \( \mathbb{R}^N \). Thus if \( L = \{l_1, \ldots, l_s\} \subset \{1, \ldots, n\} \), we use the notation introduced on page 12 and set \( \mathbb{R}^L = \bigoplus_{l \in L} \mathbb{R}^{C_l} \).

For \( t_L = (t_{l_1}, \ldots, t_{l_s}) \in \mathbb{R}^L \), and for each \( l \in L \), put

\[
N_l(t_L) = \sum_{m \in L} n_m(t_m)e^{(l,m)}.
\]

If \( R = \{R_1, \ldots, R_s\} \) are positive real numbers and if \( \psi \in C_0(\mathbb{R}^L) \), define \( \psi_R \in C_0(\mathbb{R}^L) \) by setting

\[
\psi_R(t_L) = \psi(R_1 \cdot t_{l_1}, \ldots, R_s \cdot t_{l_s}).
\]

### 2.3 Classes of distributions and multipliers

Let \( \mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_r} \), let \( E = \{e(j, k)\} \) be an \( n \times n \) matrix satisfying (2.10), and let \( \{N_1, \ldots, N_n\} \) and \( \{\tilde{N}_1, \ldots, \tilde{N}_n\} \) be the norms and dual defined in (2.9).

**Definition 2.2.** A distribution \( \mathcal{K} \) on \( \mathbb{R}^N \) belongs to the class \( \mathcal{P}(E) \) if it satisfies the following differential inequalities and cancellation conditions.

(a) **[Differential Inequalities]** Away from the origin the distribution \( \mathcal{K} \) is given by integration against a \( C^\infty \)-function \( K \), and for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \), there is a constant \( C_\gamma \) so that

\[
|\partial^\gamma K(x)| \leq C_\gamma \prod_{j=1}^n N_j(x)^{(Q_j)_{\gamma_j} + |\gamma_j|}.
\]

(b) **[Cancellation Conditions]** Let \( L = \{l_1, \ldots, l_s\} \) and \( M = \{m_1, \ldots, m_s\} \) be any pair of complementary subsets of \( \{1, \ldots, n\} \), let \( R = \{R_1, \ldots, R_s\} \) be any positive real numbers, and let \( \psi \in C_0^\infty(\mathbb{R}^M) \) have support in the unit ball. Define a distribution \( \mathcal{K}_{\psi, R} \) on \( \mathbb{R}^L \) by setting

\[
\langle \mathcal{K}_{\psi, R}, \varphi \rangle = \langle \mathcal{K}, \varphi \otimes \psi \rangle
\]

for every \( \varphi \in C_0^\infty(\mathbb{R}^L) \). Then \( \mathcal{K}_{\psi, R} \) uniformly satisfies the analogue of the estimates in (13) on the space \( \mathbb{R}^L \): precisely, this means that away from the origin of \( \mathbb{R}^L \) the distribution \( \mathcal{K}_{\psi, R} \) is given by integration against a smooth function \( K_{\psi, R} \) and for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \) there is a constant \( C'_\gamma \) depending only on the constants \( \{C_\gamma\} \) in (13) and the norms \( \{||\psi||_{(m)}\} \) (but independent of \( R \)) so that

\[
|\partial^\gamma K_{\psi, R}(x)| \leq C'_\gamma \prod_{i=1}^r N_i(x_L)^{(Q_i)_{\gamma_i} + |\gamma_i|}.
\]

In particular, if \( L = \emptyset \) then \( |\langle \mathcal{K}, \psi \rangle| \) is bounded independently of \( R \).

**Remark 2.3.** Since \( N_j(x)^{-|\gamma_j|} \leq |x_j|^{-|\gamma_j|} \), it follows that a distribution \( \mathcal{K} \in \mathcal{P}(E) \) is a product kernel on \( \mathbb{R}^N = \bigoplus_{i=1}^r \mathbb{R}^{C_i} \) in the sense of [NRS01]. (The cancellation conditions follow from the Fourier transform characterization. See [NRS01], Remark 2.16.) However, the distributions in \( \mathcal{P}(E) \) are in general more regular; they are singular only at the origin.

**Definition 2.4.** If \( m \in C_0^\infty(\mathbb{R}^N \setminus \{0\}) \) then \( m \) belongs to the class of multipliers \( M(E) \) if for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \) there is a constant \( C_\gamma \) so that

\[
|\partial^\gamma m(\xi)| \leq C_\gamma \prod_{j=1}^n \hat{N}_j(\xi)^{-|\gamma_j|}.
\]
We shall see in Lemma 2.5 that unless \( c(j, k) = c(j, l) e(l, k) \) for all \( j, k, l \in \{1, \ldots, n\} \), the distribution \( K \in \mathcal{P}(E) \) is integrable at infinity. We are primarily interested in the local behavior of these kernels and the following restricted classes of distributions and multipliers.

**Definition 2.5.** Let \(|x|\) denote the usual Euclidean norm of a vector \( x \in \mathbb{R}^N \).

(a) A distribution \( K \) on \( \mathbb{R}^N \) belongs to the class \( \mathcal{P}_0(E) \) if it belongs to the class \( \mathcal{P}(E) \) and away from the origin it is given by a smooth function \( K \) satisfying the differential inequalities

\[
|\partial^K K(x)| \leq C_{M, \gamma} \prod_{j=1}^n N_j(x)^{(Q_j + \|\gamma_j\|)} (1 + |x|)^{-M}
\]

for every multi-index \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \) and every \( M \geq 0 \). Moreover the quotient distributions \( K_{\psi, R} \) defined in part (b) of Definition 2.2 satisfy

\[
|\partial^\gamma K_{\psi, R}(x)| \leq D_{M, \gamma} (1 + |x|)^{-M} \prod_{l=1}^r N_l(x)^{(Q_l + \|\gamma_l\|)},
\]

(b) A function \( m \in C^\infty(\mathbb{R}^N) \) belongs to \( \mathcal{M}_\infty(E) \) if there is a constant \( C_\gamma \) so that

\[
|\partial^\gamma m(x)| \leq C_\gamma \prod_{j=1}^n (1 + \tilde{N}_j(x))^{-|\gamma_j|}
\]

for every multi-index \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \).

We will see in Section 4 below that the multipliers \( m \in \mathcal{M}_\infty(E) \) are precisely the Fourier transforms of the distributions \( K \in \mathcal{P}_0(E) \), and conversely, that distributions \( K \in \mathcal{P}_0(E) \) are the inverse Fourier transforms of multipliers \( m \in \mathcal{M}_\infty(E) \). The family of norms

\[
|K|_M = \sum_{|\gamma|, |\gamma'| \leq M} \inf \left\{ C_{M, \gamma} + D_{M, \gamma'} : \text{ (2.11) and (2.12) hold} \right\}
\]

with \( M \in \mathbb{N} \) induces a Fréchet space topology on the space \( \mathcal{P}_0(E) \).

### 3 Marked partitions and decompositions of \( \mathbb{R}^N \)

#### 3.1 Dominant terms in \( N_j(t) \) and \( \tilde{N}_j(t) \)

To study the kernels and multipliers introduced in Section 2 we need to partition the space \( \mathbb{R}^N \) into regions where the norms \( N_j(t) = \sum_{k=1}^n n_k(t_k)^{e(j,k)} \) or \( \tilde{N}_j(t) = \sum_{k=1}^n n_k(t_k)^{1/e(k,j)} \) are comparable to a single term \( n_k(t_k)^{e(j,k)} \) or \( n_k(t_k)^{1/e(k,j)} \). We begin by introducing the notion of strict dominance and A-dominance.

**Definition 3.1.** Let \( A \geq 1 \).

(a) Let \( t \in \mathbb{B}(1) \). The term \( t_k \) is A-dominant in \( N_j(t) \) if \( n_l(t_l)^{e(j,l)} < [A n_k(t_k)]^{e(j,k)} \) for every \( l \neq k \). The term \( t_k \) is strictly dominant in \( N_j(t) \) if we can take \( A = 1 \).

(b) Let \( t \in \mathbb{B}(1)^C \). The term \( t_k \) is A-dominant in \( \tilde{N}_j(t) \) if \( n_l(t_l)^{1/e(l,j)} < [A n_k(t_k)]^{1/e(k,j)} \) for every \( l \neq k \). The term \( t_k \) is strictly dominant in \( \tilde{N}_j(t) \) if we can take \( A = 1 \).
Remarks 3.2.

1) If \( t \in \mathbb{B}(1) \) and if \( t_k \) is \( A \)-dominant in \( N_j(t) \) then \( N_j(t) \approx n_k(t_k)^{e(j,k)} \) where the implied constant depends only on \( A, E \), and \( n \).

2) If \( t \in \mathbb{B}(1)^c \) and if \( t_k \) is \( A \)-dominant in \( \hat{N}_j(t) \) then \( \hat{N}_j(t) \approx n_k(t)^{1/e(k,j)} \) where the implied constant depends only on \( A, E \), and \( n \).

3) If \( t \in \mathbb{B}(1)^c \) then each \( \hat{N}_j(t) \geq 1 \).

4) If \( t \in \mathbb{B}(1)^c \) and if \( t_k \) is \( A \)-dominant in any \( \hat{N}_j(t) \) then \( A n_k(t_k) > 1 \).

The following is a simple but key fact about dominance.

**Proposition 3.3.** Suppose the matrix \( E \) satisfies the basic hypothesis \([2,10]\).

(a) Let \( t \in \mathbb{B}(1) \). If \( t_k \) is \( A \)-dominant in \( N_j(t) \) then \( t_k \) is also \( A \)-dominant in \( N_k(t) \). In particular, if \( t_k \) is strictly dominant in \( N_j(t) \), then \( t_k \) is strictly dominant in \( N_k(t) \).

(b) Let \( t \in \mathbb{B}(1)^c \). If \( t_k \) is \( A \)-dominant in \( \hat{N}_j(t) \) then \( t_k \) is also \( A \)-dominant in \( \hat{N}_k(t) \). In particular if \( t_k \) is strictly dominant in \( \hat{N}_j(t) \) then \( t_k \) is also strictly dominant in \( \hat{N}_k(t) \).

**Proof.** Let \( t \in \mathbb{B}(1) \) and \( A \geq 1 \). By the basic hypothesis, \( e(k,l) \geq e(j,l)/e(j,k) \), and since \( n_i(t_i) \leq 1 \) it follows that \( n_i(t_i)^{e(k,l)} \leq n_i(t_i)^{e(j,l)/e(j,k)} \). If \( t_k \) is \( A \)-dominant in \( N_j(t) \) and if \( l \neq k \), then \( n_i(t_i)^{e(j,l)} < [A n_k(t_k)]^{e(j,k)} \), and so

\[
n_i(t_i)^{e(k,l)} \leq n_i(t_i)^{e(j,l)/e(j,k)} < A n_k(t_k).
\]

Thus \( t_k \) is \( A \)-dominant in \( N_k(t) \). On the other hand, if \( t \in \mathbb{B}(1)^c \) and \( t_k \) is \( A \)-dominant in \( \hat{N}_j(t) \), then every \( l \neq k \) we have \( n_i(t_i)^{1/e(l,k)} < [A n_k(t_k)]^{1/e(k,j)} \). Since \( e(l,j) \leq e(l,k)/e(k,j) \) and \( A n_k(t_k) > 1 \) we have

\[
n_i(t_i)^{1/e(l,k)} = [n_i(t_i)^{1/e(l,j)}]^{e(l,j)/e(l,k)} < [A n_k(t_k)]^{e(l,j)/e(l,k)/e(k,j)} \leq A n_k(t_k).
\]

Thus \( t_k \) is \( A \)-dominant in \( \hat{N}_k(t) \).

\[\square\]

### 3.2 Marked partitions and the sets \( E_S \) and \( \hat{E}_S \)

The notion of strict dominance allows us to decompose (up to a closed set of measure zero) the ball \( \mathbb{B}(1) = \{ t \in \mathbb{R}^n : n_j(t_j) \leq 1 \} \) into sets where one term in each \( N_j \) is strictly dominant. The same is true for the complement \( \mathbb{B}(1)^c \) and the norms \( \hat{N}_j \). The decomposition depends on the notion of a marked partition.

**Definition 3.4.**

(a) A **marked partition** \( S = \{(I_1; k_1); \ldots; (I_s; k_s)\} \) of the set \( \{1, \ldots, n\} \) is a collection \( \{I_1, \ldots, I_s\} \) of disjoint non-empty subsets of \( \{1, \ldots, n\} \) such that \( \bigcup_{r=1}^s I_r = \{1, \ldots, n\} \), together with a choice of a particular element \( k_r \in I_r \) in each subset.

(b) The partition \( S_0 = \{\{(1), 1\}; \ldots; \{(n), n\}\} \) is called the **principal partition** of \( \{1, \ldots, n\} \).

(c) Any marked partition \( S = \{(I_1; k_1); \ldots; (I_s; k_s)\} \) with \( s < n \) is called a **non-principal partition**.
(d) The set of all marked partitions of \(\{1, \ldots, n\}\) is denoted by \(S(n)\).

We want to associate a unique marked partition to every point \(t \in \mathbb{R}^N\), but to do this we need to exclude the closed set of measure zero where two different terms in \(N_j(t)\) or \(\hat{N}_j(t)\) can be equal. Let

\[
\Xi = \left\{ t \in \mathbb{R}^N : (\exists j)(\forall l \neq m) \ n_l(t_j)^{e(j,l)} = n_m(t_m)^{e(j,m)} \text{ or } n_l(t_j)^{1/e(j,l)} = n_m(t_m)^{1/e(m,j)} \right\}.
\]

The set \(\Xi\) is closed and has measure zero, and \(\mathbb{R}^N \setminus \Xi\) is dense in \(\mathbb{R}^N\). Note that if \(t \notin \Xi\), all the summands in \(N_j(t)\) and \(\hat{N}_j(t)\) are distinct.

We associate to every point \(t \in \mathbb{R}^N \setminus \Xi\) a marked partition \(S(t) \in S(n)\). There are two cases, depending on whether the point \(t\) belongs to \(\mathbb{B}(1)\) or to \(\mathbb{B}(1)^c\).

**Case 1:** If \(t \in \mathbb{B}(1) \setminus \Xi\) then for every \(j\) the terms \(n_1(t_1)^{e(j,1)}, \ldots, n_n(t_n)^{e(j,n)}\) in \(N_j(t)\) are distinct. Thus for each \(j \in \{1, \ldots, n\}\) there exists a unique integer \(k(j) \in \{1, \ldots, n\}\) such that \(t_{k(j)}\) is strictly dominant in \(N_j(t)\). Let \(\{k_1, \ldots, k_s\}\) be the set of distinct integers \(k(j)\) which arise in this way. For \(1 \leq r \leq s\) set

\[
I_r = \left\{ j \in \{1, \ldots, n\} : t_{k_r} \text{ is strictly dominant in } N_j(t) \right\}.
\]

Every \(j\) belongs to a unique \(I_r\) since there is only one term in \(N_j(t)\) which is dominant, and according to Proposition 3.3 we have \(k_r \in I_r\). Thus \(S(t) = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)\).

**Case 2:** If \(t \in \mathbb{B}(1)^c \setminus \Xi\), the terms \(n_1(t_1)^{1/e(j,1)}, \ldots, n_n(t_n)^{1/e(j,n)}\) in \(\hat{N}_j(t)\) are distinct, and again for each \(j\) there exists a unique integer \(k(j) \in \{1, \ldots, n\}\) such that \(t_{k(j)}\) is strictly dominant in \(\hat{N}_j(t)\). Let \(\{k_1, \ldots, k_s\}\) be the set of distinct integers that arise, and again set

\[
I_r = \left\{ j \in \{1, \ldots, n\} : t_{k_r} \text{ is strictly dominant in } \hat{N}_j(t) \right\}.
\]

We have \(k_r \in I_r\) by Proposition 3.3 and thus \(S = S(t) = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)\).

**Definition 3.5.** Let \(S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)\), and let \(A \geq 1\). Then

\[
E^A_S = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{B}(1) : \forall r \in \{1, \ldots, s\}, \forall j \in I_r, \ t_{k_r} \text{ is A-dominant in } N_j(t) \right\}
\]

\[
= \left\{ t \in \mathbb{B}(1) : \forall r \in \{1, \ldots, s\}, \forall j \in I_r, \forall l \neq k_r, n_l(t_j)^{e(j,l)} < [A n_{k_r}(t_{k_r})]^{e(j,k_r)} \right\}.
\]

\[
\hat{E}^A_S = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{B}(1)^c : \forall r \in \{1, \ldots, s\}, \forall j \in I_r, \ t_{k_r} \text{ is A-dominant in } \hat{N}_j(t) \right\}
\]

\[
= \left\{ t \in \mathbb{B}(1)^c : \forall r \in \{1, \ldots, s\}, \forall j \in I_r, \forall l \neq k_r, n_l(t_j)^{1/e(j,l)} < [A n_{k_r}(t_{k_r})]^{1/e(k_r,j)} \right\}.
\]

When \(A = 1\) we write \(E^1_S = E_S\) and \(\hat{E}^1_S = \hat{E}_S\).

**Proposition 3.6.** The set \(E^A_S\) and \(\hat{E}^A_S\) are open. Moreover,

\[
\mathbb{B}(1) \setminus \Xi = \bigcup_{S \in S(n)} E_S, \quad \mathbb{B}(1)^c \setminus \Xi = \bigcup_{S \in S(n)} \hat{E}_S.
\]

If \(A > 1\) then

\[
\mathbb{B}(1) \subset \bigcup_{S \in S(n)} E^A_S, \quad \mathbb{B}(1)^c \subset \bigcup_{S \in S(n)} \hat{E}^A_S.
\]

**Proof.** The first line follows from the construction of \(E_S\) and \(\hat{E}_S\). The second line follows since the closure of \(\mathbb{R}^N \setminus \Xi\) is all of \(\mathbb{R}^N\), and if \(A > 1\) then \(E^A_S\) is an open neighborhood of the closure of \(E_S\), and \(\hat{E}^A_S\) is an open neighborhood of the closure of \(\hat{E}_S\). □
3.3 Characterizing the sets $E_S^A$ and $\hat{E}_S^A$

Let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)$. The definitions of the sets $E_S^A$ and $\hat{E}_S^A$ involve inequalities between the norms $n_j(t_j)$ and $n_k(t_k)$ for all $r \in \{1, \ldots, s\}$ and all $j \neq r$. In this section we show that the sets are characterized by a smaller number of inequalities relating, for given $r$, $n_k(t_k)$ to $n_j(t_j)$ only for $j \in I_r \cup \{k_1, \ldots, k_s\}$.

**Definition 3.7.** Let $\{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)$. For $1 \leq r \leq s$ and $1 \leq l \leq n$ set

$$\sigma_S(k_r, l) = \min_{j \in I_r} \frac{e(j, l)}{e(j, k_r)}, \quad \tau_S(l, k_r) = \min_{j \in I_r} \frac{e(l, j)}{e(k_r, j)}.$$

**Proposition 3.8.** Suppose that the matrix $E = \{e(j, k)\}$ satisfies the basic hypothesis (2.10) and that $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)$.

(a) If $1 \leq r \leq s$ and if $l \in I_r$ then

$$\sigma_S(k_r, l) = e(l, k_r)^{-1}, \quad \tau_S(l, k_r) = e(k_r, l)^{-1}.$$

(b) Let $1 \leq r, p \leq s$. If $m \in I_p$ then

$$\sigma_S(k_r, m) \geq \sigma_S(k_r, k_p) \sigma_S(k_p, m), \quad \tau_S(m, k_r) \geq \tau_S(m, k_p) \tau_S(k_p, k_r).$$

**Proof.** It suffices to prove the statements about $\sigma_S$; the statements about $\tau_S$ follow in the same way. If $l \in I_r$ we can take $j = l$ in the definition of $\sigma_S(k_r, l)$ to see that $\sigma_S(k_r, l) \leq e(l, k_r)^{-1}$. On the other hand it follows from the basic assumption (2.10) that $e(j, l)/e(j, k_r) \geq e(l, k_r)^{-1}$ for any $l$, and this gives the opposite inequality and establishes the first equality in (a).

Next let $m \in I_p$. Then using (a) and the basic hypothesis, if $j_0 \in I_r$

$$\sigma_S(k_r, m) \sigma_S(k_r, k_p) = e(m, k_p)^{-1} \sigma_S(k_r, k_p) = e(m, k_p)^{-1} \min_{j \in I_r} \frac{e(j, k_p)}{e(j, k_r)} \leq e(m, k_p)^{-1} \frac{e(j_0, k_p)}{e(j_0, k_r)} \leq \frac{e(j_0, m)}{e(j_0, k_r)}.$$

Taking the minimum over $j_0 \in I_r$ it follows that $\sigma_S(k_r, m) \geq \sigma_S(k_r, k_p) \sigma_S(k_p, m)$, which establishes the first inequality in (b) and completes the proof.  

**Lemma 3.9.** Let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)$.

(a) Let $t \in \mathbb{B}(1)$. If $t \in E_S^A$ then for every $r \in \{1, \ldots, s\}$

$$n_{k_r}(t_{k_r}) > A^{-1} n_j(t_j)^{1/e(j, k_r)} = A^{-1} n_j(t_j)^{\sigma_S(k_r, j)} \quad \forall j \in I_r, j \neq k_r, \text{ and}$$

$$n_{k_r}(t_{k_r}) > A^{-1} n_{k_p}(t_{k_p})^{e(k_r, k_p)} \quad \forall p \in \{1, \ldots, s\}, \ p \neq r. \quad (3.1)$$

Conversely, if $t \in \mathbb{B}(1)$ satisfies (3.1) then $t \in E_S^A$ where $\eta$ is a constant that depends only on the matrix $E$.

(b) Let $t \in \mathbb{B}(1)^c$. If $t \in \hat{E}_S^A$ then for every $r \in \{1, \ldots, s\}$

$$n_{k_r}(t_{k_r}) > A^{-1} n_j(t_j)^{e(k_r, j)} = A^{-1} n_j(t_j)^{1/\tau_S(j, k_r)} \quad \forall j \in I_r, j \neq k_r, \text{ and}$$

$$n_{k_r}(t_{k_r}) > A^{-1} n_{k_p}(t_{k_p})^{1/\tau_S(k_p, k_r)} \quad \forall p \in \{1, \ldots, s\}, \ p \neq r. \quad (3.2)$$

Conversely, if $t \in \mathbb{B}(1)^c$ satisfies (3.2) then $t \in E_S^A$ where $\eta$ is a constant that depends only on the matrix $E$. 
Letting $A = A^n = 1$, we obtain the following characterization of the sets $E_S$ and $\hat{E}_S$.

**Corollary 3.10.** Let $S = ((I_1, k_1); \ldots; (I_s, k_s)) \in S(n)$.

(a) If $t \in B(1)$ then $t \in E_S$ if and only if
\[
\begin{align*}
n_k(t_{k_r}) &> n_j(t_j)^{1/(j,k_r)} = n_j(t_j)^{\sigma_S(j,k_r)} \quad \text{for every } j \in I_r \text{ with } j \neq k_r, \text{ and} \\
n_k(t_{k_r}) &> n_{k_p}(t_{k_p})^{\sigma_S(k_r,k_p)} \quad \text{for every } p \in \{1, \ldots, s\} \text{ with } p \neq r.
\end{align*}
\]

(b) If $t \in B(1)^c$ then $t \in \hat{E}_S$ if and only if
\[
\begin{align*}
n_k(t_{k_r}) &> n_j(t_j)^{\sigma_S(k_r,j)} = n_j(t_j)^{1/\tau_S(j,k_r)} \quad \text{for every } j \in I_r \text{ with } j \neq k_r, \text{ and} \\
n_k(t_{k_r}) &> n_{k_p}(t_{k_p})^{1/\tau_S(k_p,k_r)} \quad \text{for every } p \in \{1, \ldots, s\} \text{ with } p \neq r.
\end{align*}
\]

**Proof of Lemma 3.2.**

If $t \in B(1)$ then $t \in E_S^2(1)$ if and only if $n_k(t_{k_r}) > A^{-1} n_{l_p}(t_l)^{\sigma_S(j,l)/\sigma_S(j,k_r)}$ for $1 \leq r \leq s$, for $l \neq k_r$, and for all $j \in I_r$. But since $n_k(t_l) \leq 1$ this is equivalent to saying that
\[
n_k(t_{k_r}) > A^{-1} \max_{j \in I_r} n_l(t_l)^{\sigma_S(j,l)/\sigma_S(j,k_r)} = A^{-1} n_l(t_l)^{\min_j \tau_S(j,l)/\sigma_S(j,k_r)} = A^{-1} n_l(t_l)^{\sigma_S(k_r,l)},
\]
and this establishes both inequalities in (3.1). To prove the converse, let $l \in \{1, \ldots, n\}$ with $l \neq k_r$. Then there exists an index $p \in \{1, \ldots, s\}$ so that $l \in I_p$, and by the first inequality in (3.1) it follows that $n_l(t_l)^{\sigma_S(k_r,l)} < A n_{k_p}(t_{k_p})$. On the other hand, the second inequality in (3.1) says that $n_{k_p}(t_{k_p})^{\sigma_S(k_r,k_p)} \leq A n_k(t_{k_r})$. Also, Proposition 3.8 part (b) says that $\sigma_S(k_r,l) \geq \sigma_S(k_r,k_p) \sigma_S(k_p,l)$. Since $n_k(t_l) < 1$, it follows that
\[
n_l(t_l)^{\sigma_S(k_r,l)} \leq n_l(t_l)^{\sigma_S(k_r,l)} \leq [A n_{k_p}(t_{k_p})]^{\sigma_S(k_r,k_p)} < A^{1+\tau_S(k_r,k_p)} n_k(t_{k_r}).
\]

But then if $j \in I_r$ and $l \neq k_r$,
\[
n_l(t_l)^{\sigma_S(j,l)} = \begin{cases} n_l(t_l)^{\sigma_S(j,l)/\sigma_S(j,k_r)} \leq n_l(t_l)^{\sigma_S(k_r,l)} & \text{if } j \in I_r, \\
\leq [A^{\eta} n_k(t_{k_r})]^{\sigma_S(k_r,j)} & \text{if } j \notin I_r,
\end{cases}
\]
where we take $\eta = 1 + \sup_{r \neq p} \sigma_S(k_r,k_p) + \sup_{r \neq p} \tau_S(k_r,k_p)^{-1}$. This shows that $t_k$ is $A^n$-dominant in $N_j(t)$, and completes the proof of (3.2).

The proof of (3.3) is very similar. Suppose that $t \in B(1)^c$. Then $t \in \hat{E}_S^2(1)$ if and only if $n_k(t_{k_r}) > A^{-1} n_l(t_l)^{\sigma_S(j,l)/\sigma_S(j,k_r)}$ for $1 \leq r \leq s$, for $l \neq k_r$, and for all $j \in I_r$. Suppose first that $n_l(t_l) \geq 1$. In this case it follows that
\[
n_k(t_{k_r}) > A^{-1} \max_{j \in I_r} n_l(t_l)^{\sigma_S(j,l)/\sigma_S(j,k_r)} = A^{-1} n_l(t_l)^{\tau_S(l,k_r)}.
\]

On the other hand, if $n_l(t_l) < 1$ then we still have $n_k(t_{k_r}) > A^{-1} n_l(t_l)^{1/\tau_S(l,k_r)}$ since $n_k(t_{k_r}) > A^{-1}$ by Remarks 3.2. In either case, this establishes both inequalities of (3.3). To prove the converse, let $l \in \{1, \ldots, n\}$ with $l \neq k_r$. If $n_l(t_l) < 1$, then since $n_k(t_{k_r}) > A^{-1}$ it follows that $n_l(t_l)^{1/\tau_S(l,k_r)} < 1 < [A n_{k_p}(t_{k_p})]^{1/\tau_S(l,k_r)}$. If $n_l(t_l) \geq 1$. There exists $p \in \{1, \ldots, s\}$ so that $l \in I_p$, and by the first inequality in (3.2) it follows that $n_l(t_l)^{1/\tau_S(l,k_p)} < A n_{k_p}(t_{k_p})$. On the other hand, the second inequality in (3.2) says that $n_{k_p}(t_{k_p}) \leq A^{\tau_S(k_p,k_r)} n_{k_r}(t_{k_r})$. Also, Proposition 3.8 part (b) says that $\tau_S(l,k_r) \geq \tau_S(l,k_p) \tau_S(k_p,k_r)$. It follows that
\[
n_l(t_l)^{1/\tau_S(l,k_r)} \leq n_l(t_l)^{1/\tau_S(l,k_p) \tau_S(k_p,k_r)} < [A n_{k_p}(t_{k_p})]^{1/\tau_S(k_p,k_r)} < A^{1+1/\tau_S(k_p,k_r)} n_{k_r}(t_{k_r}).
\]
If \( j \in I_r \) and \( l \neq k_r \),

\[
n_t(t_l)^{1/\epsilon(l,j)} \leq \left[ n_t(t_l)^{1/\tau_x(l,k_r)} \right]^{1/\epsilon(k_r,j)} \leq \left[ A^{1+1/\tau_x(k_r,k_r)} n_{k_r}(t_{k_r}) \right]^{1/\epsilon(k_r,j)}.
\]

Thus in all cases we have \( n_t(t_l)^{1/\epsilon(l,k_r)} \leq \left[ A^{1+1/\epsilon(k_r,j)} n_{k_r}(t_{k_r}) \right]^{1/\epsilon(k_r,j)} \), and this says that \( t_{k_r} \) is \( A^n \)-dominant in \( \tilde{N}_j(t) \), which completes the proof of (b) and of Lemma 3.9. \( \square \)

### 3.4 Estimates of kernels and multipliers on \( E_S \) and \( \hat{E}_S \)

The differential inequalities for kernels and multipliers take simpler forms on the sets \( E_S \) and \( \hat{E}_S \). First consider the principal marked partition \( S_0 = \{ \{1\}, \ldots, \{n\} \} \). If \( x \in B(1) \cap E_{S_0} \) then \( N_k(x) \approx n_k(x_k) \), and if \( \xi \in \hat{E}_{S_0} \) then \( \hat{N}_k(\xi) \approx n_k(\xi_k) \). Thus the differential inequalities for \( K \in P(E) \) and \( m \in M(E) \) take the following form on the sets \( E_{S_0} \) and \( \hat{E}_{S_0} \):

\[
x \in E_{S_0} \implies |\partial^\gamma K(x)| \leq C_\gamma \prod_{k=1}^n n_k(x_k)^{-\sum_{j \in I_r} e_{(j,k_r)}(Q_j + [\gamma_j])},
\]

\[
\xi \in \hat{E}_{S_0} \implies |\partial^\gamma m(\xi)| \leq C_\gamma \prod_{k=1}^n n_k(\xi_k)^{-\sum_{j \in I_r} e_{(j,k_r)}[\gamma_j]}.
\]

Note that these are precisely the differential inequalities satisfied by product kernels or product multipliers on \( \mathbb{R}^N = \bigoplus_{j=1}^n \mathbb{R}^{C_j} \). (See [NRS01], page 34 and page 37.) Thus although a distribution \( K \in P(E) \) is pseudo-local, if the set \( E_{S_0} \neq \emptyset \) the function \( K \) satisfies nothing better than the estimates for a product kernel on this set.

We have the following extension for non-empty sets \( E_S \) and \( \hat{E}_S \).

**Proposition 3.11.** Let \( S = \{ (I_1, k_1); \ldots; (I_s, k_s) \} \in S(n) \).

1. If \( E_S \cap B(1) \neq \emptyset \), if \( K \in P(E) \), and if \( K \in C^\infty(\mathbb{R}^N \setminus \{0\}) \) is the associated smooth function, then for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \), there is a constant \( C_\gamma \) so that for \( x \in E_S \cap B(1) \) the inequality in Definition 2.3 part (a) is equivalent to

\[
|\partial^\gamma K(x)| \leq C_\gamma \prod_{r=1}^s n_{k_r}(x_{k_r})^{-\sum_{j \in I_r} e_{(j,k_r)}(Q_j + [\gamma_j])}.
\]

2. If \( \hat{E}_S \cap B(1)^c \neq \emptyset \) and if \( m \in M(E) \) then for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \) there is a constant \( C_\gamma \) so that for \( \xi \in \hat{E}_S \) the inequality in Definition 2.3 is equivalent to

\[
|\partial^\gamma m(\xi)| \leq C_\gamma \prod_{r=1}^s n_{k_r}(\xi_{k_r})^{-\sum_{j \in I_r} e_{(j,k_r)}[\gamma_j]}.
\]

**Proof.** If \( x \in E_S \), then \( N_j(x) \approx n_{k_r}(x_{k_r})e_{(j,k_r)} \) for every \( j \in I_r \). Thus if \( x \in E_S \)

\[
|\partial^\gamma K(x)| \leq C_\gamma \prod_{j=1}^n N_j(x)^{-(Q_j + [\gamma_j])} \approx C_\gamma \prod_{r=1}^s \prod_{j \in I_r} n_{k_r}(x_{k_r})^{-e_{(j,k_r)}(Q_j + [\gamma_j])}.
\]

This establishes part (a), and again part (b) is done the same way. \( \square \)
3.5 A coarser decomposition of $\mathbb{R}^N$ associated to $S \in \mathcal{S}(n)$

Proposition 3.11 suggests that, on each non-empty set $E_S$, a kernel $K \in \mathcal{P}_0(E)$ satisfies the same differential inequalities of a product kernel adapted to a coarser decomposition of $\mathbb{R}^N$ depending on $S$ and, in a similar way, that on each non-empty set $\hat{E}_S$, a multiplier $m \in \mathcal{M}_\infty(E)$ behaves like a product multiplier.

For each $1 \leq r \leq s$ we gather the coordinates $\{t_j : j \in I_r\}$ into a single subspace as discussed on page 12. Thus for $1 \leq r \leq s$ set

$$\mathbb{R}^{I_r} = \bigoplus_{j \in I_r} \mathbb{R}^{C_j}$$

so that $\mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s}$. Note that if $s < n$, this decomposition is strictly coarser than the original decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$. If $t \in \mathbb{R}^N$ write $t = (t_{I_1}, \ldots, t_{I_s})$ where $t_{I_r} = \{t_j : j \in I_r\}$.

Next we introduce two new families of dilations $x_{I_r} \to \lambda_S x_{I_r}$ and $\xi_{I_r} \to \lambda^*_S \xi_{I_r}$ on each component $\mathbb{R}^{I_r}$. These should have the property that if $x \in E_S$ then the associated norm of $x_{I_r}$ should be comparable to $n_{k_r}(x_{k_r})$, and if $\xi \in \hat{E}_S$, then the associated norm of $\xi_{I_r}$ should be comparable to $n_{k_r}(\xi_{k_r})$. Recall from Corollary 3.10 that

$$\exists \in \mathbb{R}^N \quad \Rightarrow \quad n_j(x_j)^{1/\epsilon(j,k_r)} < n_{k_r}(x)$$

and from Proposition 3.12 that if $j \in I_r$ then $e(j,k_r) = \sigma_S(k_r,j)^{-1}$ and $e(k_r,j) = \tau(j,k_r)^{-1}$.

**Definition 3.12.** Let $S = \{(I_1,k_1); \ldots; (I_s,k_s)\} \in \mathcal{S}(n)$.

(a) If $x = (x_{I_1}, \ldots, x_{I_r}) \in \mathbb{R}^N$ with $x_{I_r} = \{x_j : j \in I_r\} \in \mathbb{R}^{I_r}$ set

$$\lambda_S x_{I_r} = \left(\lambda^{(j,k_r)} x_j : j \in I_r\right) = \left(\lambda^{1/\sigma_S(k_r,j)} x_j : j \in I_r\right).$$

Let $n_{S,r}$ be a smooth homogeneous norm on $\mathbb{R}^{I_r}$ for this dilation.

(b) If $\xi = (\xi_{I_1}, \ldots, \xi_{I_r}) \in \mathbb{R}^N$ with $\xi_{I_r} = \{\xi_j : j \in I_r\}$ let

$$\lambda^*_S \xi_{I_r} = \left(\lambda^{1/\epsilon(k_r,j)} \xi_j : j \in I_r\right) = \left(\lambda^{\tau_S(j,k_r)} \xi_j : j \in I_r\right).$$

Let $\hat{n}_{S,r}$ be a smooth homogeneous norm on $\mathbb{R}^{I_r}$ for this dilation.

Observe that

$$n_{S,r}(x_{I_r}) \approx \sum_{j \in I_r} n_j(x_j)^{1/\epsilon(j,k_r)} = \sum_{j \in I_r} n_j(x_j)^{\sigma_S(k_r,j)},$$

$$\hat{n}_{S,r}(\xi_{I_r}) \approx \sum_{j \in I_r} n_j(\xi_j)^{\epsilon(k_r,j)} = \sum_{j \in I_r} n_j(\xi_j)^{1/\tau_S(j,k_r)},$$

and that the homogeneous dimensions of $\mathbb{R}^{I_r}$ under the dilations $\lambda_S$ and $\lambda^*_S$ are given by

$$Q_{S,r} = \sum_{j \in I_r} Q_j e(j,k_r) = \sum_{j \in I_r} Q_j \sigma_S(k_r,j)^{-1},$$

$$\hat{Q}_{S,r} = \sum_{j \in I_r} Q_j e(k_r,j)^{-1} = \sum_{j \in I_r} Q_j \tau_S(j,k_r).$$
Moreover, it follows directly from and (2.9) and (3.5) that, for $1 \leq r \leq s$,

$$n_{S,r}(t_i) \lesssim \hat{N}_{k_r}(t),$$

$$\hat{n}_{S,r}(t_i) \lesssim N_{k_r}(t),$$

for all $t \in \mathbb{R}^N$.

## 4 Fourier transform duality of kernels and multipliers

In this section we show that the Fourier transforms of kernels $K \in \mathcal{P}_0(E)$ are multipliers $m \in \mathcal{M}_\infty(E)$, and conversely, that the inverse Fourier transform of multipliers $m \in \mathcal{M}_\infty(E)$ are kernels $K \in \mathcal{P}_0(E)$. Such results are well known for Calderón-Zygmund kernels and multipliers, and more generally, for product kernels and product multipliers or for flag kernels and flag multipliers. (See [NRS01] for details.)

### 4.1 Fourier transforms of multipliers

Let $m \in L^\infty(\mathbb{R}^N)$ and let $K = \hat{m}$ be its Fourier transform in the sense of tempered distributions. Thus if $\varphi \in \mathcal{S}(\mathbb{R}^N)$ we have $\langle K, \varphi \rangle = \langle m, \hat{\varphi} \rangle = \int_{\mathbb{R}^N} m(\xi) \hat{\varphi}(\xi) \, d\xi$. Let $\chi \in \mathcal{C}_c^\infty(\mathbb{R}^N)$ be identically equal to one in a neighborhood of the origin, and let $\chi_r(\xi) = \chi(\epsilon \xi)$. Then

$$\langle K, \varphi \rangle = \int_{\mathbb{R}^N} m(\xi) \hat{\varphi}(\xi) \, d\xi = \lim_{\epsilon \to 0} \int_{\mathbb{R}^N} \chi_r(\xi) m(\xi) \hat{\varphi}(\xi) \, d\xi = \lim_{\epsilon \to 0} \langle \chi_r m, \varphi \rangle$$

so $K = \lim_{\epsilon \to 0} \chi_r m$ in the sense of distributions. Thus in making estimates of the Fourier transform $\hat{m}$, we can assume that $m$ has compact support (and hence can freely integrate by parts) provided that we do not use any information about the size of this support in our estimates.

**Theorem 4.1.** Let $m \in \mathcal{M}_\infty(E)$. Then the Fourier transform $\hat{m}$ is a distribution $K$ belonging to the class $\mathcal{P}_0(E)$.

**Proof.** Assume as discussed above that $m$ has compact support. The Fourier transform is given by $K(x) = \hat{m}(x) = \int_{\mathbb{R}^N} e^{2\pi i x \cdot \xi} m(\xi) \, d\xi$, and for every $\gamma \in \mathbb{N}^N$

$$\partial^\gamma K(x) = (2\pi i)^\gamma \int_{\mathbb{R}^N} e^{2\pi i x \cdot \xi} \xi^\gamma m(\xi) \, d\xi.$$ (4.1)

To show that $K = \hat{m} \in \mathcal{P}_0(E)$, we must verify the differential inequalities of Definition 2.5 and Definition 2.2 as well as the the cancellation conditions of Definition 2.2. We begin with the differential inequalities.

If $\gamma \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n}$ and $M \geq 0$, we must show that there are constants $C_\gamma, C_{\gamma,M} > 0$ (independent of the support of $m$) so that

$$|\partial^\gamma K(x)| \leq C_\gamma \prod_{j=1}^n N_j(x)^{-Q_j + \gamma_j} \quad \text{if } x \in \mathbb{B}(1),$$

$$|\partial^\gamma K(x)| \leq C_{\gamma,M} (1 + |x|)^{-M} \quad \text{if } x \notin \mathbb{B}(1),$$

where $|x|$ is the ordinary Euclidean norm of $x \in \mathbb{R}^N$. 

The second inequality in (4.2) follows from a standard integration by parts. Let $\Delta$ denote the ordinary Laplace operator. Then

$$
\int_{\mathbb{R}^N} e^{2\pi i \langle x, \xi \rangle} \xi^\gamma m(\xi) \, d\xi = (4\pi^2 |x|)^{-2M} \int_{\mathbb{R}^N} (-\Delta)^M \left[ e^{2\pi i \langle x, \xi \rangle} \right] \xi^\gamma m(\xi) \, d\xi
= (4\pi^2 |x|)^{-2M} \int_{\mathbb{R}^N} e^{2\pi i \langle x, \xi \rangle} (-\Delta)^M \xi^\gamma m(\xi) \, d\xi.
$$

If $M$ is large enough, $|(-\Delta)^M \xi^\gamma m(\xi)| \leq C_M (1 + |\xi|)^{-N-1}$, so the last integral converges absolutely independently of the support of $m$.

We turn to the heart of the matter which is the first estimate in (4.2). Suppose that $x \in \mathbb{B}(1) \cap E_S$ where $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S(n)$. By (3.4), for $1 \leq r \leq s$, if $j \in I_r$ we have

$$
N_j(x) \approx n_{k_s}(x_{k_s})^e(j,k_r) \approx n_{S,r}(x_{I_r}),
$$

where $n_{S,r}(x_{I_r}) \approx \sum_{j \in I_r} n_j(x_j)^{1/e(j,k_r)}$ is the norm defined in (3.3). Hence, for $x \in \mathbb{B}(1) \cap E_S$, the estimate (4.2) is equivalent to the estimate

$$
|\partial^\gamma K(x)| \lesssim \prod_{r=1}^s n_{k_r}(x_{k_r})^{-\sum_{j \in I_r} e(j,k_r)(Q_j + |\gamma_j|)},
$$

which, by (4.3), may also be interpreted as the differential inequality of a product kernel for the decomposition $\mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s}$ with the dilations of $S$ such that $\lambda \cdot S x_{I_r} = \{ \chi^{e(j,k_r)} \cdot x_j : j \in I_r \}$.

To obtain (4.3) we adapt the standard method used for proving that product kernels and multipliers are related via the Fourier transform, cf. Theorem 2.1.11 in [NRS01]. This consists in splitting the Fourier integral (1.1) into $2^s$ regions depending on whether $n_{S,r}(\xi_{I_r})$ is larger or smaller than $n_{k_r}(x_{k_r})^{-1}$ for $1 \leq r \leq s$. For any $r$, we take advantage of the smallness of the domain of integration if we are considering $n_{S,r}(\xi_{I_r}) < n_{k_r}(x_{k_r})^{-1}$, while we integrate by parts in $\xi_{k_r}$ in the other case.

Let $\varphi_0$ and $\varphi_1$ be smooth functions on the positive half-line with $\varphi_0(t) + \varphi_1(t) \equiv 1$, $\varphi_0(t) \equiv 1$ for $t \leq \frac{1}{2}$ and $\varphi_0(t) \equiv 0$ for $t \geq 2$. For $e = (\epsilon_1, \ldots, \epsilon_s) \in \{0, 1\}^s$ set

$$
m_e(\xi) = m(\xi) \prod_{r=1}^s \varphi_{\epsilon_r} \left( n_{S,r}(\xi_{I_r}) n_{k_r}(x_{k_r}) \right),
$$

$$
K_e(x) = \int_{\mathbb{R}^N} e^{2\pi i \langle x, \xi \rangle} m_e(\xi) \, d\xi.
$$

Note that $m(\xi) = \sum_{e \in \{0, 1\}^s} m_e(\xi)$ and $K(x) = \sum_{e \in \{0, 1\}^s} K_e(x)$, so it will suffice to show that

$$
|\partial^\gamma K_e(x)| \lesssim \prod_{r=1}^s n_{k_r}(x_{k_r})^{-\sum_{j \in I_r} e(j,k_r)(Q_j + |\gamma_j|)}.
$$

9It may seem strange that we measure the size of $\xi_{I_r}$ with $n_{S,r}(\xi_{I_r})$ instead of $\hat{n}_{S,r}(\xi_{I_r})$. The point is that we have estimates of derivatives of $m$ in terms of $\hat{N}_{k_r}(\xi)$ and we want a bound from below on this quantity that involves a norm on $\mathbb{R}^{I_r}$. By (3.7), we need to use $n_{S,r}(\xi_{I_r})$.

10We are not claiming that $m$ is a product multiplier for the coarser decomposition. If it were so, the estimate

$$
|\partial^\gamma K(x)| \lesssim \prod_{r=1}^s n_{S,r}(x_{I_r})^{-\sum_{j \in I_r} e(j,k_r)(Q_j + |\gamma_j|)},
$$

would hold for every $x \in \mathbb{R}^N$, which is not true. Also notice that formula (4.10) below, which gives a differential inequality typical of a product multiplier, only holds for derivatives in $\xi_{k_r}$.
Since \( m \in \mathcal{M}(E) \), and since \( \tilde{N}_{k}(\xi) \gtrsim n_{S,r}(\xi_{L}) \) by (3.7), we have

\[
|\partial_{\xi_{k_{1}}}^{\delta_{k_{1}}} \cdots \partial_{\xi_{k_{s}}}^{\delta_{k_{s}}} m(\xi)| \lesssim \prod_{r=1}^{s} \tilde{N}_{k_{r}}(\xi)^{-|\delta_{k_{r}}|} \lesssim \prod_{r=1}^{s} n_{S,r}(\xi_{L})^{-|\delta_{k_{r}}|}. \tag{4.6}
\]

Since \( n_{S,r}(\xi_{L}) \) is homogeneous of degree one under the dilations \( \lambda \cdot S \cdot \xi_{L} \), and since \( \epsilon(k_{r}, r_{r}) = 1 \), it follows from Proposition 4.4 in Appendix II that \( |\partial_{\xi_{k_{r}}}^{\gamma_{r}} n_{S,r}(\xi_{L})| \lesssim C \cdot n_{S,r}(\xi_{L})^{-1-|\gamma_{r}|} \) for all multi-indices \( \gamma_{r} \). Using the chain rule, we see that \( \partial_{\xi_{k_{r}}}^{\delta_{k_{r}}} \left[ \varphi_{r}(n_{S,r}(\xi_{L}) n_{k_{r}}(x_{k_{r}})) \right] \) is a sum of terms of the form

\[
\varphi_{r}^{(m)}(n_{S,r}(\xi_{L}) n_{k_{r}}(x_{k_{r}})) n_{k_{r}}(x_{k_{r}})^{m} \partial_{\xi_{k_{r}}}^{\alpha_{1}} n_{S,r}(\xi_{L}) \cdots \partial_{\xi_{k_{r}}}^{\alpha_{m}} n_{S,r}(\xi_{L})
\]

where \( 1 \leq m \leq |\delta_{k_{r}}| \) and \( \alpha_{1} + \cdots + \alpha_{m} = \delta_{k_{r}} \). Since \( n_{k_{r}}(x_{k_{r}}) \approx n_{S,r}(\xi_{L})^{-1} \) on the support of \( \varphi_{r}^{(m)} \), \( m \geq 1 \), it follows that

\[
|\varphi_{r}^{(m)}(n_{S,r}(\xi_{L}) n_{k_{r}}(x_{k_{r}})) n_{k_{r}}(x_{k_{r}})^{m} \partial_{\xi_{k_{r}}}^{\alpha_{1}} n_{S,r}(\xi_{L}) \cdots \partial_{\xi_{k_{r}}}^{\alpha_{m}} n_{S,r}(\xi_{L})| \lesssim n_{S,r}(\xi_{L})^{-|\delta_{k_{r}}|}.
\]

Combining these estimates gives \( |\partial_{\xi_{k_{1}}}^{\delta_{k_{1}}} \cdots \partial_{\xi_{k_{s}}}^{\delta_{k_{s}}} m(\xi)| \leq C \cdot \prod_{r=1}^{s} n_{S,r}(\xi_{L})^{-|\delta_{k_{r}}|} \).

Now for each \( \epsilon = (\epsilon_{1}, \ldots, \epsilon_{s}) \in \{0,1\}^{s} \) let \( A(\epsilon) = \{ r \in \{1, \ldots, s\} : \epsilon_{r} = 1 \} \). Note that \( m_{r} \) is supported where

\[
n_{S,r}(\xi_{L}) \leq 2n_{k_{r}}(x_{k_{r}})^{-1} \quad \text{if} \quad r \notin A(\epsilon),
\]

\[
n_{S,r}(\xi_{L}) \geq \frac{1}{2}n_{k_{r}}(x_{k_{r}})^{-1} \quad \text{if} \quad r \in A(\epsilon).
\]

Choose \( \delta = (\delta_{1}, \ldots, \delta_{n}) \in \mathbb{N}^{C_{1}} \times \cdots \times \mathbb{N}^{C_{n}} \) with \( \delta_{j} = 0 \) unless \( j = k_{r} \) for some \( r \in A(\epsilon) \). If \( r \in A(\epsilon) \), we will choose the entries of each \( \delta_{k_{r}} = (\delta_{k_{r},1}, \ldots, \delta_{k_{r},C_{k_{r}}}) \) to be much larger than the corresponding entries of \( \gamma_{k_{r}} = (\gamma_{k_{r},1}, \ldots, \gamma_{k_{r},C_{k_{r}}}) \). Using (4.1) we integrate by parts to obtain

\[
\left( \prod_{r \in A(\epsilon)} \xi_{k_{r}}^{\delta_{k_{r}}} \right) \partial_{\xi_{k_{r}}}^{\gamma_{r}} K_{r}(x) = (2\pi i)^{|\gamma_{r}|} \int_{\mathbb{R}^{N}} \left( \prod_{r \in A(\epsilon)} \xi_{k_{r}}^{\delta_{k_{r}}} \right) e^{2\pi i \langle x, \xi \rangle} \xi^{\gamma_{r}} m_{r}(\xi) \, d\xi
\]

\[
= (2\pi i)^{|\gamma_{r}| - |\delta|} \int_{\mathbb{R}^{N}} \left[ \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\gamma_{r}} \right] \left( e^{2\pi i \langle x, \xi \rangle} \xi^{\gamma_{r}} m_{r}(\xi) \right) \, d\xi \tag{4.7}
\]

\[
= (-1)^{|\delta|}(2\pi i)^{|\gamma_{r}| - |\delta|} \int_{\mathbb{R}^{N}} e^{2\pi i \langle x, \xi \rangle} \left[ \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\gamma_{r}} \right] \left( \xi^{\gamma_{r}} m_{r}(\xi) \right) \, d\xi.
\]

The product rule shows that \( \left[ \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\gamma_{r}} \right] \left( \xi^{\gamma_{r}} m_{r}(\xi) \right) \) can be written as a finite sum of terms of the form

\[
\left( \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\mu_{r}} \right) [\xi^{\gamma_{r}}] \left( \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\delta_{k_{r}} - \mu_{k_{r}}} \right) [m_{r}] (\xi)
\]

where \( \mu = (\mu_{1}, \ldots, \mu_{n}) \leq (\delta_{1}, \ldots, \delta_{n}) \). The first factor is zero if the entries of \( \mu_{k_{r}} \) are larger than the corresponding terms \( \gamma_{k_{r}} \). Thus our choice of \( \delta_{k_{r}} \) guarantees that the entries of \( \delta_{k_{r}} - \mu_{k_{r}} \) are large enough to make the integrals below converge independently of the compact support of \( m \). Note that \( \mu_{j} = 0 \) unless \( j = k_{r} \) for some \( r \in A(\epsilon) \). Then

\[
\left( \prod_{r \in A(\epsilon)} \partial_{\xi_{k_{r}}}^{\mu_{r}} \right) [\xi^{\gamma_{r}}] = C_{\mu, \gamma} \prod_{r \in A(\epsilon)} \left( \prod_{j \in I_{r}} \xi_{k_{r}}^{j_{r} - \mu_{j}} \right) \prod_{r \notin A(\epsilon)} \left( \prod_{j \in I_{r}} \xi_{k_{r}}^{j_{r}} \right)
\]
According to (4.6) we also have

$$\left| \left( \prod_{r \in A(\varepsilon)} \partial_{\xi_{k_r}}^{\delta_{k_r} - \mu_{k_r}} \right) \left[ m_r(\xi) \right] \right| \leq C_{\delta, \mu} \prod_{r \in A(\varepsilon)} n_{S,r}(\xi_{l_r})^{-[\delta_{l_r}]+[\mu_{l_r}]}$$

Thus

$$\left| \left( \prod_{r \in A(\varepsilon)} \partial_{\xi_{k_r}}^{\delta_{k_r} - \mu_{k_r}} \right) \left[ \xi^\gamma \right] \left( \prod_{r \in A(\varepsilon)} \partial_{\xi_{k_r}}^{\delta_{k_r} - \mu_{k_r}} \right) \left[ m_r(\xi) \right] \right|$$

$$\leq C_{\delta, \gamma} \prod_{r \in A(\varepsilon)} n_{S,r}(\xi_{l_r})^{-[\delta_{l_r}]+[\mu_{l_r}]} \prod_{j \in I_r} \left( \prod_{r \in A(\varepsilon)} \left( \prod_{j \in I_r} \left( \prod_{j \in I_r} |\xi_{l_r}^\gamma| \right) \right) \right).$$

(4.9)

Now using (4.7), (4.8), and (4.9), we can estimate $$\left| \left( \prod_{r \in A(\varepsilon)} x_{k_r}^{\delta_{k_r}} \right) \partial_x^\gamma K(x) \right|$$ by a finite sum of terms of the form

$$\prod_{r \in A(\varepsilon)} \left[ \int_{n_{S,r}(\xi_{l_r}) \geq n_{k_r}(x_{k_r})^{-1}} \left( \prod_{j \in I_r} |\xi_{l_r}^\gamma| \right) n_{S,r}(\xi_{l_r})^{-[\delta_{l_r}]+[\mu_{l_r}]} d\xi_{l_r} \right]$$

$$\times \prod_{r \notin A(\varepsilon)} \left[ \int_{n_{S,r}(\xi_{l_r}) < n_{k_r}(x_{k_r})^{-1}} \left( \prod_{j \in I_r} |\xi_{l_r}^\gamma| \right) d\xi_{l_r} \right].$$

According to Proposition 15.3 in the appendix, this last expression is bounded by

$$\prod_{r \notin A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]} \prod_{r \in A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]} = \prod_{r \in A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]} \prod_{r \in A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]} = \prod_{r \in A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]} \prod_{r \in A(\varepsilon)} n_{k_r}(x_{k_r})^{-[\delta_{l_r}]}.$$

Comparing with (4.7), this shows that $$|\partial_x^\gamma K(x)|$$ satisfies (4.4), so the kernel K satisfies the correct differential inequalities.

We also need to verify the cancellation conditions given in Definition 2.24, part (b). Let $$x = (x', x'') \in \mathbb{R}^N_1 \times \mathbb{R}^N_2$$ be a decomposition of the variables into two subsets, with $$x' = (x_{p_1}, \ldots, x_{p_m})$$ and $$x'' = (x_{q_1}, \ldots, x_{q_l})$$. Let $$\psi$$ be a normalized bump function in the $$x''$$ variables. Then

$$K_{\psi,R}(x') = \int_{\mathbb{R}^N_2} K(x', x'') \psi(R \cdot x'') dx''$$

$$= \int_{\mathbb{R}^N_1} \int_{\mathbb{R}^N_2} e^{2\pi i \cdot x' \cdot \xi'} m(\xi') \psi(R \cdot x'') d\xi'' d\xi'$$

$$= \int_{\mathbb{R}^N_1} \int_{\mathbb{R}^N_2} \left[ \int_{\mathbb{R}^N_2} e^{2\pi i \cdot x'' \cdot \xi''} \psi(R \cdot x'') d\xi'' \right] m(\xi', \xi'') d\xi'' e^{2\pi i \cdot x' \cdot \xi'} d\xi'$$

$$= \int_{\mathbb{R}^N_1} \int_{\mathbb{R}^N_2} \left[ R^{-Q''} \hat{\psi}(R^{-1} \cdot \xi'') \right] m(\xi', \xi'') d\xi'' e^{2\pi i \cdot x' \cdot \xi'} d\xi'$$

$$= \int_{\mathbb{R}^N_1} \int_{\mathbb{R}^N_2} e^{2\pi i \cdot x' \cdot \xi'} m_{\psi,R}(\xi') d\xi'$$

where

$$m_{\psi,R}(\xi') = \int_{\mathbb{R}^N_2} \left[ R^{-Q''} \hat{\psi}(R^{-1} \cdot \xi'') \right] m(\xi', \xi'') d\xi'' = \int_{\mathbb{R}^N_2} \hat{\psi}(\xi'') m(\xi', \xi'') d\xi''.$$
Since \( ||\hat{\psi}_R||_{L^1} \) is finite and independent of \( R \), it is easy to see that \( m_{\psi,R} \) belongs to the class \( \mathcal{M}_\infty(\tilde{\mathcal{N}}_{p_1}, \ldots, \tilde{\mathcal{N}}_{p_r}) \) on the space \( \mathbb{R}^{N_1} \). Thus the estimates for \( K_{\psi,R} \) follow from the same arguments. This completes the proof of Theorem 4.1.

4.2 Fourier transforms of kernels

**Theorem 4.2.** Let \( K \in \mathcal{P}_0(\mathbf{E}) \). Then the Fourier transform of \( K \) is a smooth function belonging to the class \( \mathcal{M}_\infty(\mathbf{E}) \).

**Proof.** Suppose that \( K \in \mathcal{P}_0(\mathbf{E}) \). According to Definition 2.3 we can write \( K = K_0 + \psi \) where \( K_0 \in \mathcal{P}_0(\mathbf{E}) \) has compact support in \( \mathbb{B}(1) \) and \( \psi \in \mathcal{S}(\mathbb{R}^N) \). Since \( \hat{\psi} \in \mathcal{M}_\infty(\mathbf{E}) \), it suffices to show that \( K_0 \in \mathcal{M}_\infty(\mathbf{E}) \). Thus without loss of generality we can assume that \( K \) has compact support in the ball \( \mathbb{B}(1) \). The distribution \( K \) then acts on \( C^\infty(\mathbb{R}^N) \), and in particular, we set \( m(\xi) = \langle K, \exp[2\pi i \cdot \xi] \rangle \). From general principles, this is a smooth function and

\[
\hat{\partial}_\xi^\gamma m(\xi) = (2\pi i)^{\gamma/1}(K, \exp[2\pi i \cdot \xi]) = (2\pi i)^{\gamma/1}(\mathbf{x}^\gamma K, \exp[2\pi i \cdot \xi])
\]

\[(4.10)\]

Note that if \( |\gamma| \geq 1 \), the distribution \( \mathbf{x}^\gamma K \) coincides with integration against the locally integrable function \( \mathbf{x}^\gamma K(\mathbf{x}) \), (see Remark 2.1.7 on page 36 of [NRS01]), and this justifies the last equality.

We want to show

\[
|\hat{\partial}_\xi^\gamma m(\xi)| \leq C_\gamma \prod_{j=1}^{n}(1 + \hat{\mathcal{N}}_j(\xi))^{-[\gamma_j]}.
\]

(4.11)

Since \( K \) has compact support, this inequality follows if \( \xi \in \mathbb{B}(1) \). Thus we only need to consider \( \xi \in \mathbb{B}(1)^c \). Suppose \( \xi \) belongs to \( \hat{E}_S \) where \( S = \{ (I_1, k_1); \ldots; (I_s, k_s) \} \in \mathcal{S}(n) \). Then for \( j \in I_\epsilon, 1 + \hat{\mathcal{N}}_j(\xi) \approx n_{\epsilon_j}(\xi_{k_j})^{1/\epsilon(k_j,j)} \) and we want to prove

\[
|\hat{\partial}_\xi^\gamma m(\xi)| \leq C_\gamma \prod_{r=1}^{s} \prod_{j \in I_\epsilon} (1 + \hat{\mathcal{N}}_j(\xi))^{-[\gamma_j]} \approx C_\gamma \prod_{r=1}^{s} n_{\epsilon_j}(\xi_{k_j})^{-\sum_{j \in I_\epsilon} [\gamma_j]/\epsilon(k_j,j)}.
\]

(4.12)

The proof now follows the same pattern as the proof of Theorem 4.1. To establish (4.12) we split the integral in (4.10) into \( 2^s \) regions depending on whether \( \hat{n}_{S,\epsilon}(\mathbf{x}_{I_\epsilon,s}) \) is larger or smaller than \( n_{\epsilon_j}(\xi_{k_j})^{-1} \).

Let \( \varphi_0 \) and \( \varphi_1 \) be smooth functions on the positive half-line with \( \varphi_0(t) + \varphi_1(t) \equiv 1, \varphi_0(t) \equiv 1 \) for \( t \) near zero, and \( \varphi_0(t) \equiv 0 \) for \( t \) large. For \( \epsilon = (\epsilon_1, \ldots, \epsilon_s) \in \{0, 1\}^s \) set

\[
K_\epsilon(\mathbf{x}) = K(\mathbf{x}) \prod_{r=1}^{s} \varphi_{\epsilon_r}(n_{\epsilon_j}(\xi_{k_j})\hat{n}_{S,\epsilon}(\mathbf{x}_{I_\epsilon,s})),
\]

\[
m_\epsilon(\xi) = \int_{\mathbb{R}^N} e^{2\pi i (\mathbf{x} \cdot \xi)} K_\epsilon(\mathbf{x}) d\mathbf{x}.
\]

(4.13)

Note that \( m(\xi) = \sum_{\epsilon \in \{0, 1\}^s} m_\epsilon(\xi) \) and \( K(\mathbf{x}) = \sum_{\epsilon \in \{0, 1\}^s} K_\epsilon(\mathbf{x}) \). Recall that \( \hat{n}_{S,\epsilon}(\xi_j) = \sum_{j \in I_\epsilon} n_j(\xi_j)^{\epsilon(k_j,j)} \) so \( \hat{n}_{S,\epsilon} \) is homogeneous relative to the family of dilations \( \{ \xi_j, j \in I_\epsilon \} \rightarrow \{ \lambda^{1/\epsilon(k_j,j)} \xi_j; j \in I_\epsilon \} \). It follows from Proposition 15.4 that for \( \delta_{k_j} \in \mathbb{N}^{C_{k_j}} \) and \( \epsilon \in \{0, 1\}^s \) we have

\[
|\hat{\partial}_{\delta_{k_{j_1}}} \cdots \hat{\partial}_{\delta_{k_{j_s}}} K_\epsilon(\mathbf{x})| \leq C_\delta \prod_{j=1}^{n} N_j(\mathbf{x})^{-Q_j} \prod_{r=1}^{s} \hat{n}_{S,\epsilon}(\mathbf{x}_{k_j})^{-[\delta_{k_j}]}.
\]

(4.14)
Thus according to (4.7) and (4.16), we can estimate to make the integrals below converge independently of the compact support of \( e \) the entries of sum of terms of the form \( e \).

According to (4.14)

\[
\prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} e(x) = (-2\pi i)^{\gamma} \int_{\mathbb{R}^N} \left( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right) e^{-2\pi i(x, \xi)} x^\gamma K_r(x) \, dx
\]

\[
= (-2\pi i)^{\gamma} \int_{\mathbb{R}^N} \left[ \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right] (e^{-2\pi i(x, \xi)} x^\gamma K_r(x) \, dx
\]

\[
= (-1)^{|\xi|} \left( -2\pi i \right)^{|\xi|} \int_{\mathbb{R}^N} e^{-2\pi i(x, \xi)} \left[ \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right] (x^\gamma K_r(x) \, dx.
\]

The product rule shows that the derivative \( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \) \((x^\gamma K_r(x)\) can be written as a sum of terms of the form \( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \) \((x^\gamma) \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \)). In the first factor, the entries of \( \mu_r \) can only be as large as the corresponding terms \( \gamma_r \). Thus we will choose \( \delta_r \)

\[
\left( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right) (x^\gamma) = C_{\mu, \gamma} \prod_{r \in A(e)} \left( \prod_{j \in I_r, j \neq k_r} x_j^{\gamma_j} \right)^{\gamma_r - \mu_r} \prod_{r \notin A(e), j \in I_r} \left( \prod_{j \in I_r} x_j^{\gamma_j} \right)
\]

Note that \( e(j, l) \leq e(j, k_r) e(k_r, l) \). Thus \( r \leq l \)

\[
N_j(x) = \sum_{i=1}^n |x_i|^{e(j, l)} \geq \sum_{i \in I_r} |x_i|^{e(k_r, l)} \geq \sum_{l \in I_r} |x_i|^{e(k_r, l)} e(j, k_r)
\]

\[
\geq \sum_{l \in I_r} \sum_{l \in I_r} |x_i|^{e(k_r, l)} = \hat{n}_{S_r}(x_{I_r}) e(k_r).
\]

According to (4.14)

\[
\left| \left( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right) (x^\gamma) \right| \leq C_{\delta, \mu} \prod_{j=1}^n N_j(x)^{-Q_j} \prod_{r \in A(e)} \hat{n}_{S_r}(x_{I_r})^{-[\delta_r] + [\mu_r]}
\]

\[
\leq C_{\delta, \mu} \prod_{r \in A(e)} \hat{n}_{S_r}(x_{I_r})^{-\sum_{j \in I_r, j \neq k_r} Q_j e(k_r, j)} \prod_{r \in A(e)} \hat{n}_{S_r}(x_{I_r})^{-[\delta_r] + [\mu_r]}
\]

Thus according to (4.17) and (4.18), we can estimate \( \left| \left( \prod_{r \in A(e)} \partial_{\xi_k^r}^{\gamma} \right) (x^\gamma) \right| \) by a sum of terms of the form

\[
\prod_{r \notin A(e)} \hat{n}_{S_r}(x_{I_r})^{e(k_r, l)}
\]

\[
\prod_{r \in A(e)} \int_{\mathbb{R}^I_r} \left( \prod_{j \in I_r} x_j^{\gamma_j} \right)^{\gamma_r - \mu_r} \left[ \hat{n}_{S_r}(x_{I_r})^{-\sum_{j \in I_r, j \neq k_r} Q_j e(k_r, j)} \right] dI_r
\]

\[
\approx \prod_{r \notin A(e)} \hat{n}_{S_r}(x_{I_r})^{e(k_r, l)}
\]

\[
\prod_{r \in A(e)} \int_{\mathbb{R}^I_r} \left( \prod_{j \in I_r} x_j^{\gamma_j} \right)^{\gamma_r - \mu_r} \left[ \hat{n}_{S_r}(x_{I_r})^{-\sum_{j \in I_r, j \neq k_r} Q_j e(k_r, j)} \right] dI_r
\]

\[
\prod_{r \in A(e)} \int_{\mathbb{R}^I_r} \left( \prod_{j \in I_r} x_j^{\gamma_j} \right)^{\gamma_r - \mu_r} \left[ \hat{n}_{S_r}(x_{I_r})^{-\sum_{j \in I_r, j \neq k_r} Q_j e(k_r, j)} \right] dI_r
\]
It may happen that the integrals over the regions where \( n_{S,T}(x_{t_r}) < n_{k_r}(\xi_{k_r})^{-1} \) diverge if all the appropriate \( \gamma_j \) are equal to zero. However, for these terms, we use the cancellation properties of the kernels since \( \bar{\varphi}_{k_r}(n_{k_r}(\xi_{k_r})n_{S,T}(x_{t_r})) \) are dilates of normalized bump functions. Thus according to Proposition 15.3 this last expression is bounded by

\[
\prod_{\gamma r \in A(\epsilon)} n_{k_r}(\xi_{k_r})^{-\sum_{j \in I_r} [\gamma_j]\epsilon(j,k_r)} \prod_{\gamma r \in A(\epsilon)} n_{k_r}(\xi_{k_r})^{\sum_{j \in I_r} (-[\gamma_j]-[\delta_j])\epsilon(j,k_r)} = \prod_{\gamma r \in A(\epsilon)} n_{k_r}(\xi_{k_r})^{[\delta_r]\epsilon(j,k_r)} \prod_{s=1}^{s} n_{k_r}(\xi_{k_r})^{-\sum_{j \in I_r} [\gamma_j]\epsilon(j,k_r)}.
\]

Comparing with (4.7), this shows that \( |\partial^\gamma m(\xi)| \) satisfies (4.12), so the multiplier \( m \) satisfies the correct differential inequalities, and this completes the proof of Theorem 4.2. \( \square \)

5 Dyadic sums of Schwartz functions

In Section 4 we showed that distributions \( K \in \mathcal{P}_0(E) \) can be characterized in terms of their Fourier transforms. We now begin the study of a different kind of characterization in terms of dyadic sums of normalized bump functions. In this section we show that appropriate sums of dilates do converge to distributions \( K \in \mathcal{P}_0(E) \). In Theorem 5.14 below, we will see that, modulo ‘coarser’ kernels, every distribution \( K \in \mathcal{P}_0(E) \) can be decomposed in this way.

If \( \varphi \in \mathcal{S}(\mathbb{R}^N) \), the dilates \([\varphi]_k \) and \((\varphi)_k \) were defined in equation (2.8). In this section we show that appropriate dyadic sums of dilates \( [\varphi]_k \) of Schwartz functions having suitable cancellation properties converge to distributions \( K \in \mathcal{P}_0(E) \). Similarly we show that dyadic sums of dilates \((\varphi)_k \) of Schwartz functions with appropriate vanishing conditions converge to multipliers \( \mathcal{M}_\infty(E) \). The main results appear in subsections 5.4-5.6. However, before turning to the main results of this section, we begin with some further remarks about cones associated to matrices, and then discuss inclusions among classes of kernels and multipliers defined by different matrices.

5.1 Cones associated to a matrix \( E \)

Let \( E = \{ e(j,k) \} \) be an \( n \times n \) matrix satisfying the basic hypotheses in (5.10) and let \( \mu \geq 0 \). We introduce the following notation.

\[
\Gamma(E) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : \forall j \neq k, e(j,k)t_k < t_j < 0 \right\},
\]

\[
\Gamma_\mu(E) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : \forall j \neq k, e(j,k)t_k - \mu < t_j < 0 \right\},
\]

\[
\Gamma_\mu^\circ(E) = \text{int} (\Gamma_\mu(E)) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : \forall j \neq k, e(j,k)t_k < t_j < 0 \right\},
\]

\[
\Gamma_{\mu,0}(E) = \left\{ I = (i_1, \ldots, i_n) \in \mathbb{Z}^n : \forall j \neq k, e(j,k)i_k - \mu < i_j < 0 \right\},
\]

\[
\Gamma(E) = \Gamma_{\mu,0}(E).
\]

We will refer to properties of the cone \( \Gamma(E) \) which are proved in Appendix I (Section 14). In particular, Lemma 5.1 summarizes the content of Lemma 14.7 and Lemma 14.9.

Since \( E \) satisfies the basic hypothesis, \( \Gamma(E) \) is not empty. However its interior, which is an open convex cone, can be empty. For example, if \( E = \begin{bmatrix} 1 & 2 \\ 2 & 1 \end{bmatrix} \), \( \Gamma(E) \) is the one-dimensional
ray given by $x_1 = 2x_2$, $x_2 < 0$, which has no interior. Note that in this case $1 = e(1, 2)e(2, 1)$.

The following Lemma shows that, more generally, any such equality is the obstruction to the open cone being non-empty.

**Lemma 5.1.** Let $E$ be a matrix satisfying the basic hypotheses (2.10).

1. The interior of $\Gamma(E)$ is non-empty if and only if $E$ is reduced, i.e., $1 < e(j, k)e(k, j)$ for every pair $1 \leq j \neq k \leq n$.

2. $\Gamma(E)$ is contained in the intersection of the hyperplanes \{ $t \in \mathbb{R}^n : e(j, k)t_k = t_j$ \} for all pairs $(j, k)$ such that $e(j, k)e(k, j) = 1$ and has non-empty interior in this subspace of $\mathbb{R}^n$.

### 5.2 Inclusions among classes of kernels associated to different matrices

The cone $\Gamma(E)$ contains the relevant information on the structure of kernels and multipliers associated with the matrix $E$.

**Proposition 5.2.** Let $E, E'$ be two $n \times n$ matrices, both satisfying the basic hypotheses. The following are equivalent:

1. $\mathcal{P}_0(E) \subseteq \mathcal{P}_0(E')$;
2. $\mathcal{M}_\infty(E) \subseteq \mathcal{M}_\infty(E')$;
3. for every $j = 1, \ldots, n$ and $\xi \in B^c$, $\hat{N}_j(\xi) \leq \tilde{N}_j(\xi)$;
4. for every $j, k = 1, \ldots, n$, $e(j, k) \leq e'(j, k)$;
5. $\Gamma(E) \subseteq \Gamma(E')$.

**Proof.** The equivalence between (i) and (ii) is given by Theorems 4.1 and 4.2. The implications (v)$\Rightarrow$(iv)$\Rightarrow$(iii)$\Rightarrow$(ii) are obvious. In order to prove that (ii) implies (v), assume by contradiction that $\Gamma(E)$ in not contained in $\Gamma(E')$. Then there exists a half-line $\mathbb{R}^- \alpha \in \Gamma(E) \setminus \Gamma(E')$, where $\alpha = (\alpha_1, \ldots, \alpha_n)$ has strictly positive components.

Let $N_\alpha = \sum_{j=1}^n n_j(\xi)\frac{1}{\alpha_j}$ and consider multipliers $m$ which satisfy the inequalities

$$|\partial^\gamma m(\xi)| \lesssim (1 + N_\alpha(\xi))^{-\sum_{j} \alpha_j |\gamma_j|}$$

for all $\gamma \in \mathbb{N}^N$. We show that every such $m$ is in $\mathcal{M}_\infty(E)$ but there exist some which are not in $\mathcal{M}_\infty(E')$.

To prove the first statement it suffices to show that, for every $j$,

$$(1 + N_\alpha(\xi))^{\alpha_j} \gtrsim 1 + \tilde{N}_j(\xi).$$

This condition is equivalent to the inequalities $\alpha_k/\alpha_j \leq e(k, j)$ for every $j, k$, and in turn these are equivalent to the condition $-\alpha \in \Gamma(E)$.

Similarly, since $-\alpha \notin \Gamma(E')$, there exist $j, k$ such that $\alpha_k/\alpha_j > e'(k, j)$. Suppose in (5.2) we take $\gamma = (0, \ldots, 0, \gamma_j, \ldots, 0)$ and $\xi = (0, \ldots, 0, \xi_k, \ldots, 0)$. The inequality becomes

$$|\partial^\gamma m(0, \ldots, \xi_k, \ldots, 0)| \lesssim (1 + n_k(\xi_k)\frac{1}{\alpha_k})^{-\alpha_j |\gamma_j|}$$
where the right-hand side is not dominated by
\[
(1 + n_k(\xi_k))^{-\frac{1}{\gamma_j}} \|f_j\| \approx (1 + \tilde{N}_j^t(\xi))^{-\gamma_j}.
\]

It is then sufficient to construct \( m \) satisfying (5.2) and such that, for some \( l \in C_j \) it satisfies the opposite inequality
\[
|\partial_{\xi}^l \sum (0, \ldots, \xi_k, \ldots, 0)| \gtrsim (1 + n_k(\xi_k)^{1/\alpha_k})^{-\alpha_j d_l},
\]
e.g.,
\[
m(\xi) = \frac{\xi_l}{\tilde{N}_\alpha(\xi)^{\alpha_j d_l}},
\]
where \( \tilde{N}_\alpha \) is a smooth homogeneous norm equivalent to \( N_\alpha \) and even in \( \xi_l \). This \( m \) is not in \( \mathcal{M}_\infty(E') \).

### 5.3 Coarser decompositions and lower dimensional matrices

We will often need to consider classes \( \mathcal{P}_0(E) \) where \( E \) is a lower-dimensional (say \( s \times s \)) matrix and the variables \( x_1, x_2, \ldots, x_n \) have correspondingly been grouped together into \( s \) blocks with given dilation exponents within each block.

Precisely, consider a coarser decompositions of \( \mathbb{R}^N \),
\[
\mathbb{R}^N = \mathbb{R}^{A_1} \oplus \mathbb{R}^{A_2} \oplus \cdots \oplus \mathbb{R}^{A_s},
\]
where \( A = \{ A_1, A_2, \ldots, A_s \} \) is a partition of \( \{1, 2, \ldots, n\} \) and \( \mathbb{R}^{A_r} \) is defined according to (2.3). We also assign an \( n \)-tuple \( \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \) of positive exponents to define dilations on each \( \mathbb{R}^{A_r} \), with homogeneous norm
\[
n_{A_r}(t_{A_r}) = \sum_{j \in A_r} n_j(t_j)^{\alpha_j}, \quad r = 1, \ldots, n. \tag{5.3}
\]

Given an \( s \times s \) matrix \( E = (e(t, r))_{1 \leq t, r \leq s} \) satisfying the basic hypotheses, with \( s < n \), let \( \mathcal{P}_0(E, A, \alpha) \) be the class of associated kernels and \( \mathcal{M}_\infty(E, A, \alpha) \) the class of multipliers. The associated norms are, for \( 1 \leq t \leq s \),
\[
\tilde{N}_t(x) = \sum_{r=1}^{s} n_{A_r}(x_{A_r})^{e(t, r)} \approx \sum_{r=1}^{s} \sum_{k \in A_r} n_k(x_k)^{\alpha_k e(t, r)} \tag{5.4}
\]
\[
\tilde{N}_t^n(\xi) = \sum_{r=1}^{s} n_{A_r}(\xi_{A_r})^{e(t, r)} \approx \sum_{r=1}^{s} \sum_{k \in A_r} n_k(\xi_k)^{\frac{\alpha_k}{\alpha_j} e(t, r)}.
\]

Define the \( n \times n \) matrix \( E^d = (e^d(j, k)) \) where, for \( j \in A_t \) and \( k \in A_r \),
\[
e^d(j, k) = \frac{\alpha_k}{\alpha_j} e(t, r). \tag{5.5}
\]

Then \( E^d \) satisfies the basic assumptions and the associated dual norms are
\[
\tilde{N}_d^{\tilde{N}_t^n}(x) = \sum_{r=1}^{s} \sum_{k \in A_r} n_k(x_k)^{\frac{\alpha_k}{\alpha_j} e(t, r)} \approx N_t^n(x)^{1/\alpha_j}
\]
\[
\tilde{N}_d^{\tilde{N}_t^n}(\xi) = \sum_{r=1}^{s} \sum_{k \in A_r} n_k(\xi_k)^{\frac{\alpha_k}{\alpha_j} e(t, r)} \approx \tilde{N}_t^n(\xi)^{1/\alpha_j}.
\]
Lemma 5.3. We have the equalities $M_{\infty}(E, A, \alpha) = M_{\infty}(E')$, $P_0(E, A, \alpha) = P_0(E')$.

Proof. Let $m \in M_{\infty}(E, A, \alpha)$. Then, for every $\gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{A_1} \times \cdots \times \mathbb{N}^{A_s}$,

$$|\partial_\gamma^2 m(\xi)| \lesssim \prod_{t=1}^s (1 + \widehat{N}_t(\xi))^{-\|\gamma_t\|},$$

where

$$\|\gamma_t\| = \sum_{j \in A_t} \frac{1}{n_j} \sum_{l \in C_j} \gamma_l d_l,$$

by (2.7), taking into account the dilations on $E_t$ which make (5.3) a homogeneous norm.

If $\gamma_t = (\gamma'_t)_{j \in A_t}$, $\gamma$ can be written as an element of $\mathbb{N}^{A_1} \times \cdots \times \mathbb{N}^{A_s}$ as $\gamma = (\gamma'_1, \ldots, \gamma'_n)$. Then

$$\sum_{l \in C_j} \gamma_l d_l = \|\gamma'_j\|$$

and therefore

$$\prod_{t=1}^s (1 + \widehat{N}_t(\xi))^{-\|\gamma_t\|} = \prod_{t=1}^s \prod_{j \in A_t} (1 + \widehat{N}_t(\xi))^{-\frac{1}{n_j} \|\gamma'_t\|} \approx \prod_{t=1}^s \prod_{j \in A_t} (1 + \widehat{N}_j^t(\xi))^{-\|\gamma'_t\|} = \prod_{t=1}^s (1 + \widehat{N}_j^t(\xi))^{-\|\gamma'_t\|}.$$

Then $m \in M_{\infty}(E)$. The opposite implication is proved in the same way. The equality $P_0(E) = P_0(E')$ follows from Theorems 4.4 and 5.2.

Notice that Lemma 5.3 implies that kernels belonging to $P_0(E, A, \alpha)$ satisfy stronger cancellation properties than those required by the definition.

Combining together Proposition 5.2 and Lemma 5.3 we obtain the following statement.

Corollary 5.4. Let $A$ and $\alpha$ be as above, and let $E$ an $s \times s$ matrix satisfying the basic hypotheses. $E'$ an $n \times n$ matrix also satisfying the basic hypotheses. We have the inclusion $P_0(E, A, \alpha) \subseteq P_0(E')$ if and only if the matrices $E'$ and $E$ satisfy the condition

$$e'(j, k) \leq e(j, k), \quad \forall j, k, \ 1 \leq j, k \leq n,$$

together with the other equivalent conditions in Proposition 5.2.

This result can be applied in particular to the case where an $n \times n$ matrix $E$ satisfying the basic hypotheses is not reduced, i.e., there exist $j \neq k$ such that $e(j, k)e(k, j) = 1$. As shown in Appendix I (Section 14.5), in this case the $j$-th row of $E$ equals $e(j, k)$ times the $k$-th row, and the same holds for the $k$-th column.

Following the notation of Lemma 14.1, we denote by $k_1, \ldots, k_s$ representatives of the equivalence classes $A_1, \ldots, A_s$ under the relation

$$j \sim k \iff e(j, k)e(k, j) = 1.$$

Then, for all $j \in A_t$,

$$N_j(x) \approx N_{k_t}(x)^{e(j, k_t)} \quad \text{and} \quad \widehat{N}_j(\xi) \approx \widehat{N}_{k_t}(\xi)^{e(j, k_t)}.$$

Moreover, for every $r \in \{1, \ldots, s\}$,

$$N_{k_r}(x) \approx \sum_{r=1}^s \left( \sum_{k \in A_r} n_k(x_k)^{e(k_r, k_r)} \right)^{e(k_r, k_r)} \quad \text{and} \quad \widehat{N}_{k_r}(\xi) \approx \sum_{r=1}^s \left( \sum_{k \in A_r} n_k(\xi_k)^{e(k_r, k_r)} \right)^{1/e(k_r, k_r)}.$$
Therefore we are in the previous situation, with \( \alpha_k = \epsilon(k_r, k) \) if \( k \in A_r \) and with the reduced matrix

\[
E^b = (\epsilon(k_t, k_r))_{1 \leq t, r \leq s}
\]
defined in Section 14.5. Notice that \((E^b)^\flat = E\). By Lemma 5.3 we have the following

**Proposition 5.5.** \( P_0(E) = P_0(E^b) \) and \( M_\infty(E) = M_\infty(E^b) \).

Proposition 5.5 makes it possible to replace, whenever it is appropriate, \( E \) by \( E^b \) and reduce matters to the case of a reduced matrix.

### 5.4 Size estimates

We now turn to the construction of the dyadic decompositions of kernels \( K \) belonging to classes \( P_0(E) \). In the rest of this section, we shall assume that \( \Gamma^o(E) \) is non-empty, and consequently that \( \Gamma^o(E) \) is non-empty, where \( \Gamma^o(E) \) and \( \Gamma^o(E) \) were defined in equation (5.4).

Let \( \{ \varphi^I : I \in \Gamma^o(E) \} \) be a uniformly bounded family in \( C^\infty_0(\mathbb{R}^N) \) or \( S(\mathbb{R}^N) \). We will show that if all the functions \( \varphi^I \) satisfy a suitable cancellation condition, then the sum

\[
K = \sum_{I \in \Gamma^o(E)} |\varphi^I|_I
\]

(5.7)

converges in the sense of distributions to an element \( K \in P_0(E) \). The precise statement is given in Theorem 5.13 below.

We first show that, even without any cancellation hypotheses on the functions \( \varphi^I \), the sum in equation (5.7) satisfies the differential inequalities of Definition 2.2 for the class \( P_0(E) \).

**Lemma 5.6.** Suppose that \( \Gamma^o(E) \) is non-empty, and let \( \{ \varphi^I : I \in \Gamma^o(E) \} \) be a uniformly bounded family of Schwartz functions. Then the series \( K(x) = \sum_{I \in \Gamma^o(E)} |\varphi^I|_I(x) \)

converges absolutely for all \( x \neq 0 \), \( K \in C^\infty(\mathbb{R}^N \setminus \{0\}) \), and

\[
\partial^\gamma K(x) = \sum_{I \in \Gamma^o(E)} 2^{-\sum_{j=1}^n i_j(Q_j + |\gamma_j|)} (\partial^\gamma \varphi^I)(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n).
\]

(5.8)

Moreover, for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^N \) and \( M \geq 0 \) there exists a constant \( C_{\gamma, M} > 0 \) so that

\[
|\partial^\gamma K(x)| \leq C_{\gamma, M} \prod_{j=1}^n N_j(x)^{- Q_j + |\gamma_j|} (1 + |x|)^{-M}.
\]

(5.9)

**Proof.** Since the family \( \{ \varphi^I \} \) is uniformly bounded in \( S(\mathbb{R}^n) \), for each \( M > 0 \) there is a constant \( C_{\gamma, M} \) so that

\[
\left| 2^{-\sum_{j=1}^n i_j(Q_j + |\gamma_j|)} (\partial^\gamma \varphi^I)(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n) \right| \leq C_{\gamma, M} \prod_{j=1}^n 2^{-i_j(Q_j + |\gamma_j|)} (1 + \sum_{j=1}^n 2^{-i_j} n_j(x_j))^{-M}.
\]

It follows from Proposition 10.3 in Appendix III that the series on the right hand side of equation (5.8) converges absolutely and is bounded by \( C \prod_{j=1}^n N_j(x)^{- Q_j + |\gamma_j|} \prod_{j=1}^n (1 + n_j(x))^{-M} \). This shows that the formal differentiation of equation (5.7) yielding (5.8) is justified, and also establishes the inequality in (5.9). \( \square \)
As an application of Lemma 5.6 we check that kernels satisfying the differential inequalities in part (ii) of Definition 2.2 just fail to be integrable near the origin. See also Lemma 7.6.

**Corollary 5.7.** Let E satisfy (2.10) and let \(N_j(x)\) be defined in equation (2.4). Suppose that \(\Gamma^o(E)\) is non-empty. Then

(a) \(\int_{B(1)} \prod_{j=1}^n N_j(x)^{-Q_j} \, dx = +\infty\);

(b) If \(\alpha > 0\) and \(1 \leq k \leq n\) then \(\int_{B(1)} N_k(x)^\alpha \prod_{j=1}^n N_j(x)^{-Q_j} \, dx < +\infty\).

**Proof.** Choose \(\varphi \in C^\infty_0(\mathbb{R}^N)\) supported in \(B(1)\) with \(\int_{\mathbb{R}^N} \varphi(x) \, dx = 1\) and \(\varphi(x) \geq 0\). Then if \(\varphi' = \varphi\) for every \(I\), the family \(\{\varphi'\}\) is normalized in \(S(\mathbb{R}^N)\). According to equation (5.9), if \(F \subset \Gamma(E)\) is a finite set with \(M\) elements, then \(\sum_{I \in F} [\varphi]_I(x) \leq C \prod_{j=1}^N N_j(x)^{-Q_j}\), and hence

\[
\int_{B(1)} \prod_{j=1}^N N_j(x)^{-Q_j} \, dx \geq C^{-1} \sum_{I \in F} \int_{\mathbb{R}^N} [\varphi]_I(x) \, dx = C^{-1} M.
\]

Letting \(M \to \infty\) gives statement (ii). To prove statement (i), observe that there is a constant \(c_{k,I} > 0\) so that if \(x \in B(1)\), then \(N_k(x) \leq N_l(x)^{c_{k,l}}\). Thus given \(\alpha > 0\) and \(1 \leq k \leq n\) there exist positive numbers \(\epsilon_1, \ldots, \epsilon_n\) so that \(N_k(x)^\alpha \leq \prod_{l=1}^n N_l(x)^{\epsilon_l}\). Then

\[
\int_{B(1)} N_k(x)^\alpha \prod_{j=1}^n N_j(x)^{-Q_j} \, dx \leq \int_{B(1)} \prod_{j=1}^n N_j(x)^{-Q_j + \epsilon_j} \, dx
\]

\[
\leq \prod_{j=1}^n \int_{n_j(x_j) \leq 1} n_j(x_j)^{-Q_j + \epsilon_j} \, dx_j < +\infty.
\]

This completes the proof. \(\square\)

### 5.5 Cancellation properties

We next turn to a discussion of cancellation properties. Let \(\mathbb{R}^N = \bigoplus_{j=1}^n \mathbb{R}^{C_j}\) and suppose \(E\) is an \(n \times n\) matrix satisfying (2.10).

**Definition 5.8.** Let \(\varphi \in S(\mathbb{R}^N)\).

(a) \(\varphi\) has cancellation in the variable \(x_j\) if \(\int_{\mathbb{R}^{C_j}} \varphi(x_1, \ldots, x_j, \ldots, x_n) \, dx_j = 0\).

(b) \(\varphi\) has strong cancellations if it has cancellation in \(x_j\) for \(1 \leq j \leq n\).

This terminology was used in Definition 5.3 of [NRSW12]. We will also need a variant of the notion of weak-cancellation that was introduced in Definition 5.5 of [NRSW12].

**Definition 5.9.** A function \(\varphi \in C^\infty(\mathbb{R}^N)\) has weak cancellation with parameter \(\epsilon > 0\) relative to the \(n\)-tuple \(I = (i_1, \ldots, i_n) \in \Gamma(\mathbb{R}^N)\) provided that one can write

\[
\varphi = \sum_{A \subset \{1, \ldots, n-1\}} \prod_{j \in A} 2^{-\epsilon(A,j)} \varphi_A
\]

where the sum is taken over all subsets \(A \subset \{1, \ldots, n-1\}\), and for each subset \(A\),
(1) \( \varphi_A \in C_0^\infty(\mathbb{R}^N) \), and is normalized relative to \( \varphi \);

(2) \( \varphi_A \) has cancellation in the variable \( x_j \) for each \( j \notin A \), and in particular for \( j = n \);

(3) \( \tau_A : A \to \{1, \ldots, n\} \) is a mapping with \( \tau_A(j) \neq j \) for all \( j \in A \);

(4) \( \Lambda(I, j) = i_j - e(j, \tau_A(j))i_{\tau_A(j)}. \)

Note that if \( I \in \Gamma(Z(E)) \), then \( i_j - e(j, \tau_A(j))\) \( i_{\tau_A(j)} \geq 0 \). Thus if \( \varphi \) has weak cancellation, it can be written as a finite sum of functions, each of which has the property that for each index \( j \), either there is cancellation in \( x_j \) or the lack of cancellation is compensated by a gain \( 2^{-e(i_j - e(j, \tau_A(j)))i_{\tau_A(j)}} \).

The following is Lemma 5.1 in [NRSW12]:

**Proposition 5.10.** If \( \varphi \in S(\mathbb{R}^N) \) and \( \{J_1, \ldots, J_r\} \) are disjoint subsets of \( \{1, \ldots, N\} \), then the following are equivalent:

(a) \( \int \varphi(x) \, dx_{J_k} = 0 \) for \( 1 \leq k \leq r \).

(b) For every \( (j_1, \ldots, j_r) \in J_1 \times \cdots \times J_r \) there is a function \( \varphi_{j_1, \ldots, j_r} \in S(\mathbb{R}^n) \), normalized with respect to \( \varphi \), so that \( \varphi(x) = \sum_{j_1 \in J_1} \cdots \sum_{j_r \in J_r} \partial_{j_1} \cdots \partial_{j_r} \varphi_{j_1, \ldots, j_r}(x) \).

Moreover, if \( \varphi \in C_0^\infty(\mathbb{R}^N) \), then we can choose the functions \( \varphi_{j_1, \ldots, j_r} \in C_0^\infty(\mathbb{R}^N) \) normalized relative to \( \varphi \).

We will also need the following result.

**Proposition 5.11.** Let \( L = \{l_1, \ldots, l_a\} \) and \( M = \{m_1, \ldots, m_b\} \) be complementary subsets of \( \{1, \ldots, n\} \), let \( A \) be a subset of \( M \), and let \( R = \{R_{l_1}, \ldots, R_{l_a}\} \) be positive real numbers. Write any \( x \in \mathbb{R}^N \) as \( x = (x', x'') \) where \( x' = (x_{l_1}, \ldots, x_{l_a}) \in \mathbb{R}^L \) and \( x'' = (x_{m_1}, \ldots, x_{m_b}) \in \mathbb{R}^M \). Let \( \varphi \in S(\mathbb{R}^N) \) and let \( \psi \in C_0^\infty(\mathbb{R}^M) \) have support in \( B(1) \). Put

\[ \Phi(x') = \int_{\mathbb{R}^M} \varphi(x', x'') \psi(R_{m_1} \cdot x_{m_1}, \ldots, R_{m_b} \cdot x_{m_b}) \, dx_{m_1} \cdots dx_{m_b}. \]

(a) \( \Phi \in S(\mathbb{R}^L) \) and is normalized relative to \( \varphi \) and \( \psi \) with constants independent of \( R \). If \( \varphi \in C_0^\infty(\mathbb{R}^N) \), then \( \Phi \in C_0^\infty(\mathbb{R}^L) \) and is normalized relative to \( \varphi \) and \( \psi \) with constants independent of \( R \).

(b) If some of the parameters \( \{R_{m_j}\} \) are large, there is an improvement over statement (a): there exists \( \epsilon > 0 \) independent of \( \varphi, \psi \) and \( R \) so that

\[ \Phi(x') = \left[ \prod_{m_j \in M} \min \{1, R_{m_j}^{\epsilon}\} \right] \Phi(x') \]

where \( \Phi \in S(\mathbb{R}^N) \) is normalized relative to \( \varphi \) and \( \psi \), with constants independent of \( R \). If \( \varphi \in C_0^\infty(\mathbb{R}^N) \) is supported in the unit ball, then \( \Phi \in C_0^\infty(\mathbb{R}^L) \) and is normalized relative to \( \varphi \) and \( \psi \) with constants independent of \( R \).

(c) If \( \varphi \) has cancellation in some of the variables in \( M \) there is an improvement over statement (b) even if \( R_{m_j} \) is small. There exists \( \epsilon > 0 \) independent of \( \varphi, \psi \) and \( R \) so that if \( \varphi \) has cancellation in \( x_j \) for each \( j \in A \) then

\[ \Phi(x') = \left[ \prod_{m_j \in M \setminus A} \min \{1, R_{m_j}^{\epsilon}\} \right] \left[ \prod_{m_j \in A} \min \{R_{m_j}^{\epsilon}, R_{m_j}^{-\epsilon}\} \right] \Phi(x'), \]

where \( \Phi \) is normalized relative to \( \varphi \) and \( \psi \), with constants independent of \( R \).
Proof. Statement (b) is clear. Next, since $\psi(x''')$ is supported where $n_{m_j}(x_{m_j}) \leq 1$, we have $n_{m_j}(x_{m_j}) \leq R_{m_j}^{-1}$ if $\psi(R_{m_1} \cdot x_{m_1}, \ldots, R_{m_k} \cdot x_{m_k}) \neq 0$. The integration in the definition of $\Phi(x')$ takes place over the set $\{(x_{m_1}, \ldots, x_{m_k}) : n_{m_j}(x_{m_j}) \leq R_{m_j}^{-1}\}$, and we can estimate the integral by the (small) size of the region of integration in the variables $\{x_{m_j}\}$ for which $R_{m_j}$ is large. This gives the estimate in part (b). To establish (c) we use Proposition 5.10: $\Phi(x')$ is a sum of terms of the form

$$\int_{R^M} \partial_{j_1} \cdots \partial_{j_a} \varphi_{j_1, \ldots, j_a}(x', x'') \psi(R_{m_1} \cdot x_{m_1}, \ldots, R_{m_k} \cdot x_{m_k}) \, dx_{m_1} \cdots dx_{m_k},$$

where $\partial_{j_a}$ is a derivative with respect to a variable in $x_{m_k}$ for each $m_k \in A$. Integrating by parts in the variables in $A$ for which $R_{m_k} < 1$ then gives the estimate in part (c), and this completes the proof.

We will want to show that sums of dilates of normalized bump functions with weak cancellation satisfy the cancellation properties of the distributions $K \in \mathcal{P}_0(E)$, and we will use the following.

**Lemma 5.12.** Suppose that $\varphi^j$ has weak cancellation with parameter $\epsilon > 0$. Let $L = \{I_1, \ldots, I_a\}$ and $M = \{m_1, \ldots, m_k\}$ be complementary subsets of $\{k_1, \ldots, k_s\}$, and let $R = \{R_{m_1}, \ldots, R_{m_k}\}$ be positive real numbers. Write $x \in \mathbb{R}^N$ as $x = (x', x'')$ where $x' = (x_{I_1}, \ldots, x_{I_a})$ and $x'' = (x_{m_1}, \ldots, x_{m_k})$, and similarly write $I = (I', I'')$ for $I = (I_1, \ldots, I_a)$. Let $\psi \in C_0^\infty(\mathbb{R}^M)$ be a normalized bump function. Then the function

$$\Phi^j_{\psi, R}(x') = \int_{\mathbb{R}^M} \varphi^j(x', x'') \psi((2^{m_1} R_{m_1} \cdot x_{m_1}), \ldots, (2^{m_k} R_{m_k} \cdot x_{m_k})) \, dx_{m_1} \cdots dx_{m_k},$$

can be written as a finite sum of terms, indexed by subsets $A \subset \{k_1, \ldots, k_s\}$, of the form

$$\left[ \prod_{j \in A \cap M} 2^{-\epsilon |I_j-e(j, \tau(j))I_{1+(j)}} \right] \left[ \prod_{j \in M \setminus A} \min \left\{ (2^j R_j)^{+\epsilon}, (2^j R_j)^{-\epsilon} \right\} \right] \varphi^j_A(x').$$

The family $\{\varphi^j_A\} \subset C_0^\infty(\mathbb{R}^L)$ is normalized relative to $\varphi^j$.

**Proof.** To make the exposition and the notation simpler, assume without loss of generality that $x' = (x_{I_1}, \ldots, x_{I_a})$ and $x'' = (x_{m_1}, \ldots, x_{m_k})$ and write $I = (I', I'')$ with $I' = (I_1, \ldots, I_a)$ and $I'' = (m_1, \ldots, m_k)$. According to Definition 5.9, since $\varphi^j$ has weak cancellation,

$$\varphi^j(x', x'') = \sum_{A \subset \{1, \ldots, n\}} \left[ \prod_{j \in A} 2^{-\epsilon |I_j-e(j, \tau(j))I_{1+(j)}} \right] \varphi^j_A(x', x'').$$

Then $\Phi^j_{\psi, R}$ can be written as a finite sum of terms, indexed by $A \subset \{1, \ldots, n\}$, of the form

$$\left[ \prod_{j \in A} 2^{-\epsilon |I_j-e(j, \tau(j))I_{1+(j)}} \right] \int \varphi^j_{A}(x', x'') \psi((2^{m_1} R_{m_1} \cdot x_{m_1}), \ldots, (2^{m_k} R_{m_k} \cdot x_{m_k})) \, dx''.$$

Using Proposition 5.11 and incorporating $\prod_{j \in M \setminus A} 2^{-\epsilon |I_j-e(j, \tau(j))I_{1+(j)}}$ into the bump function, it follows this function can be written

$$\left[ \prod_{j \in A \cap M} 2^{-\epsilon |I_j-e(j, \tau(j))I_{1+(j)}} \right] \left[ \prod_{j \in M \setminus A} \min \left\{ (2^{m_j} R_{m_j})^{+\epsilon}, (2^{m_j} R_{m_j})^{-\epsilon} \right\} \right] \tilde{\varphi}^j_A(x'),$$

which completes the proof. □
5.6 Dyadic sums with weak cancellation

Fix the decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$ and let $E$ be an $n \times n$ matrix satisfying the basic hypothesis given in equation (2.10). Suppose that $\Gamma^o(E) \neq \emptyset$. Let $\Gamma_Z(E)$ be as in equation (3.1).

**Theorem 5.13.** Let $\{\varphi^I : I \in \Gamma_Z(E)\} \subset \mathcal{S}(\mathbb{R}^N)$ be a uniformly bounded family. If each function $\varphi^I$ has weak cancellation with parameter $\epsilon > 0$ relative to $I$, then $K = \sum_{I \in \Gamma_Z(E)}|\varphi^I|_I$ converges in the sense of distributions to a kernel $K \in \mathcal{P}_0(E)$.

The arguments are similar to those in the proofs of Theorem 6.8 and Propositions 6.9, 6.10, and 6.11 of [NRSW12]. The proof consists of two steps:

1. If $F \subset \Gamma_Z(E)$ is a finite set, the distribution $\mathcal{K}_F = \sum_{I \in F}|\varphi^I|_I$ belongs to the class $\mathcal{P}_0(E)$ with constants independent of the set $F$. (Lemma 5.6 shows that $\mathcal{K}_F$ satisfies the appropriate differential inequalities, so we only need to verify that $\mathcal{K}_F$ satisfies the cancellation conditions.)

2. If $\{F_m\}$ is any increasing sequence of finite subsets of $\Gamma_Z(E)$ with $\bigcup F_m = \Gamma_Z(E)$, then $\lim_{m \to \infty} \mathcal{K}_{F_m}$ exists in the sense of distributions.

**Proof of Step 1.**

Let $F \subset \Gamma_Z(E)$ be a finite set and let $\mathcal{K}_F = \sum_{I \in F}|\varphi^I|_I$. To verify the cancellation conditions, let $L = \{l_1, \ldots, l_a\}$ and $M = \{m_1, \ldots, m_b\}$ be complementary subsets of $\{1, \ldots, n\}$. If $x = (x_1, \ldots, x_n) \in \mathbb{R}^N$ write $x = (x', x'')$ where $x' = (x_{l_1}, \ldots, x_{l_a}) \in \mathbb{R}^a$ and $x'' = (x_{m_1}, \ldots, x_{m_b}) \in \mathbb{R}^b$. Let $\psi \in C_0^\infty(\mathbb{R}^L)$ be a normalized bump function with support in the unit ball, and let $R = \{R_{l_1}, \ldots, R_{l_a}\}$ be positive real numbers. We must show that the function

$$K_{F,\psi,R}(x'') = \sum_{I \in F} \int_{\mathbb{R}^L} |\varphi^I|_I(x_1, \ldots, x_n)\psi(R_{l_1} \cdot x_1, \ldots, R_{l_a} \cdot x_a) \, dx_{l_1} \cdots dx_{l_a}$$

satisfies the correct differential inequalities in the $x''$ variables.

To simplify the notation, and without any real loss of generality, we will only consider the case when $L = \{1, \ldots, a\}$ and $M = \{a + 1, \ldots, n\}$, so that $x' = (x_1, \ldots, x_a)$ and $x'' = (x_{a+1}, \ldots, x_n)$. Let $E''$ be the sub-matrix of $E$ consisting of those entries $e(j,k)$ for which $a + 1 \leq j, k \leq n$, and let

$$\Gamma_Z(E'') = \{(i_{a+1}, \ldots, i_n) \in \mathbb{Z}^{n-a} : e(j,k)_{i_k} \leq e(j,k)_{i_j} < 0, a + 1 \leq j, k \leq n\}.$$ 

For each $I'' = (i_{a+1}, \ldots, i_n) \in \Gamma_Z(E'')$ there are only finitely many elements $I \in \Gamma_Z(E)$ which have the same last $n-a$ entries. Let $F'' \subset \Gamma_Z(E'')$ be a finite set and suppose (without loss of generality) that

$$F = \left\{I = (i_1, \ldots, i_n) \in \Gamma_Z(E) : I'' = (i_{a+1}, \ldots, i_n) \in F''\right\}.$$ 

For each $I'' \in \Gamma_Z(E'')$ let

$$\Lambda(I'') = \left\{I' = (i_1, \ldots, i_a) \in \mathbb{Z}^a : (I', I'') \in \Gamma_Z(E)\right\}.$$

Then for each $I \in F$ we can write $I = (I', I'')$ with $I'' \in F''$ and $I' \in \Lambda(I'')$. 

Let $\psi \in C_0^\infty(\mathbb{R}^M)$ be a normalized bump function with support in the unit ball, and let $R = \{R_1, \ldots, R_a\}$ be positive real numbers. To complete step 1 we need to estimate
\[
K_{F, \psi, R}(x'') = \sum_{I'' \in F''} \sum_{I' \in \Lambda(I'')} \int_{\mathbb{R}^M} [\varphi^I_f(x_1, \ldots, x_n)] \psi(R_1 \cdot x_1, \ldots, R_a \cdot x_a) \, dx_1 \cdots dx_n
\]
and its derivatives. Let
\[
\Phi^I_{\psi, R}(x'') = \int_{\mathbb{R}^M} \varphi^I_f(x_1, \ldots, x_n) \psi((2^{i_1} R_1) \cdot x_1, \ldots, (2^{i_n} R_a) \cdot x_a) \, dx_1 \cdots dx_n.
\]
Then
\[
\int_{\mathbb{R}^M} [\varphi^I_f(x_1, \ldots, x_n)] \psi(R_1 \cdot x_1, \ldots, R_a \cdot x_a) \, dx_1 \cdots dx_n = [\Phi^I_{\psi, R}](x'')
\]
and so
\[
K_{F, \psi, R}(x'') = \sum_{I'' \in F''} \left[ \sum_{I' \in \Lambda(I'')} \Phi^I_{\psi, R} \right]_{I''}(x'').
\]
If we can show that for each $I'' \in F''$ the inner sum $\sum_{I' \in \Lambda(I'')} \Phi^I_{\psi, R}$ converges to a function $\tilde{\Phi}^{I''}_{\psi, R} \in C_0^\infty(\mathbb{R}^L)$, and this family is uniformly bounded independent of the choice of $F$, then the required differential inequality estimates for $K_{F, \psi, R}$ will follow from Lemma 5.6. But according to Lemma 5.12, $\Phi^{I''}_{\psi, R}$ is a sum of normalized bump functions multiplied by exponential gains. Thus the proof of step 1 will be complete if we can show that for each fixed $I'' \in F'' \subset \Gamma_2(E)$ and each subset $A \subset \{1, \ldots, n\}$,
\[
\sum_{(i_1, \ldots, i_n) \in \Lambda(I'')} \left[ \prod_{j=1}^{a} 2^{-\epsilon[i_j-e(j, \tau_A(j))]i_j} \right] \left[ \prod_{j \notin A} \min \left\{ (2^{i_j} R_j)^{+\epsilon}, (2^{i_j} R_j)^{-\epsilon} \right\} \right]
\]
converges independently of $I''$ and the finite set $F''$. Without loss of generality, we can assume that $\{1, \ldots, a\} \cap A = \{1, \ldots, b\}$ and $\{1, \ldots, a\} \setminus A = \{b+1, \ldots, a\}$. Thus we need to estimate
\[
\sum_{(i_1, \ldots, i_n) \in \Lambda(I'')} \left[ \prod_{j=1}^{b} 2^{-\epsilon[i_j-e(j, \tau_A(j))]i_j} \right] \left[ \prod_{j=b+1}^{a} \min \left\{ (2^{i_j} R_j)^{+\epsilon}, (2^{i_j} R_j)^{-\epsilon} \right\} \right].
\]
The required estimate follows from Proposition 15.2 in Appendix III.

Proof of Step 2.

We need to check that if $\{F_m \subset \Gamma_2(E)\}$ is a sequence of finite sets with $\bigcup F_m = \Gamma_2(E)$, then the sequence $\{K_{F_m} = \sum_{I \in F_m} [\varphi^I_f]_I\}$ converges in the sense of distributions to an element of $\mathcal{P}_0(E)$. The argument is similar to that on pages 667-668 of [NRSW12]. Since each $\varphi^I_f$ has cancellation in $x_n$, it follows from Proposition 5.11 that we can write $\varphi^I_f = \sum_{k \in C_n} \partial_{x_k} \varphi^I_k$ where each $\varphi^I_k \in C_0^\infty(\mathbb{R}^N)$ is normalized relative to $\varphi^I_f$. It follows that
\[
[\varphi^I_f]_I = \sum_{k \in C_n} [\partial_{x_k} \varphi^I_k]_I = \sum_{k \in C_n} 2^{i_k \cdot d_k} \partial_{x_k} [\varphi^I_k]_I.
\]
Thus if $\psi \in S_0^\infty(\mathbb{R}^N)$ is a test function, we can integrate by parts to get
\[
\langle K_{F_m}, \psi \rangle = \sum_{k \in C_n} \left\langle \sum_{I \in F_m} 2^{i_k \cdot d_k} \partial_{x_k} [\varphi^I_k]_I, \psi \right\rangle = -\sum_{k \in C_n} \left\langle \sum_{I \in F_m} 2^{i_k \cdot d_k} [\varphi^I_k]_I, \partial_{x_k} \psi \right\rangle
\]
\[
= -\sum_{k \in C_n} \int_{\mathbb{R}^N} \left\langle \sum_{I \in F_m} 2^{i_k \cdot d_k} \partial_{x_k} [\varphi^I_k(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n)] \partial_{x_k} \psi(x) \right\rangle \, dx.
\]
Let \( d = \min \{ d_k : 1 \leq k \leq N \} > 0 \). Since \( \{ \varphi_k^l \} \) is a normalized family in \( S(\mathbb{R}^N) \), it follows from Proposition 16.3 that
\[
\left| \sum_{l \in F_m} 2^{i d_k} 2^{\sum_{k=1}^n i_k Q_k} \varphi_k^l(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n) \right|
\leq C_M \sum_{l \in \Gamma(E)} \left[ \prod_{k=1}^n 2^{-i_k Q_k} \right] 2^{i d} \left( 1 + \sum_{j=1}^n 2^{-i_k n_k(x_k)} \right)^{-M}
\leq C_M N_n(x)^d \prod_{k=1}^n N_k(x)^{-Q_k} \leq C_M N_n(x)^d \prod_{j=1}^n N_j(x)^{-Q_j}.
\]

It follows from Corollary 5.7 that \( N_n(x)^d \prod_{j=1}^n N_j(x)^{-Q_j} \) is locally integrable. Thus by the Lebesgue dominated convergence theorem it follows that as \( m \) tends to infinity, \( \langle \mathcal{K}_{F_m}, \psi \rangle \) tends to
\[
- \sum_{k \in \mathcal{C} \cap \mathbb{R}^N} \int \left[ \sum_{l \in F_m} 2^{i d_k} 2^{\sum_{k=1}^n i_k Q_k} \varphi_k^l(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n) \right] \partial_x \psi(x) d x.
\]

This completes the proof. \( \square \)

6 Decomposition of multipliers and kernels

Let \( \mathcal{K} \in \mathcal{P}_0(\mathbb{E}) \). The object of this section is to decompose \( \mathcal{K} \) into a finite sum of distributions, each of which can be written as a dyadic sum of dilates of normalized Schwartz functions (or normalized bump functions) with appropriate cancellation. It is difficult to directly decompose \( \mathcal{K} \) and maintain the cancellation, so we work on the Fourier transform side. The effect of this procedure is that the following steps will be governed by the decomposition of \( \mathbb{B}(1)^c \) in the \( \xi \)-space according to the sets \( \mathcal{E}_S \), while the decomposition of \( \mathbb{B}(1) \) in the \( x \)-space will no longer play any rôle.

6.1 New matrices \( \mathcal{E}_S \)

Let \( \mathcal{S}'(\mathbb{E}) \) denote the set of marked partitions \( S \) such that \( \mathcal{E}_S \cap \mathbb{B}(1)^c \) is non-empty. From Corollary 3.10 we obtain the following equivalent condition.

Corollary 6.1. Let \( S = ((I_1, k_1); \ldots; (I_s, k_s)) \in \mathcal{S}(n) \). Then \( \mathcal{E}_S \cap \mathbb{B}(1)^c \neq \emptyset \) if and only if the cone
\[
\hat{\Gamma}_S = \left\{ (a_1, \ldots, a_s) \in \mathbb{R}^s : \tau_S(k_r, k_p) a_p \leq a_r < 0 \text{ for all } 1 \leq p, r \leq s \right\}, \tag{6.1}
\]
has non-empty interior.

With the decomposition introduced in Section 3.5 and in the notation of Section 5.3, for each \( S \in \mathcal{S}'(\mathbb{E}) \) we want to define new norms on \( \mathbb{R}^N \) which describe the behaviour of multipliers on the set \( \mathcal{E}_S \cap \mathbb{B}(1)^c \) in the same way that the original norms \( \hat{N}_1(t), \ldots, \hat{N}_n(t) \) describe it on the principal region \( \mathcal{E}_{S_0} \cap \mathbb{B}(1)^c \).

Let \( S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in \mathcal{S}'(\mathbb{E}) \). On each \( \mathbb{R}^{l_r} \) we put the norm
\[
\hat{n}_{S,r}(\xi_{l_r}) = \sum_{j \in I_r} n_j(\xi_j)^{c(k_r, j)} = \sum_{j \in I_r} n_j(\xi_j)^{1/\tau_S(j, k_r)},
\]
defined in \((\text{5.3})\) and homogeneous with respect to the dilations \(\tau\).

We now want an \(s \times s\) matrix \(E_S\) satisfying the basic hypotheses and such that \(\Gamma(E_S) = \hat{\Gamma}_S\). We cannot simply use the coefficients \(\tau_S(k_r, k_p)\) because in general they do not satisfy the inequalities \(\tau_S(k_r, k_p) \leq \tau_S(k_r, k_u)\) \(\tau_S(k_u, k_p)\).

Luckily we can replace the coefficients \(\tau_S(k_p, k_r)\) by new ones which do satisfy the basic hypothesis. According to Lemma \((\text{14.2})\) in Appendix I, if the cone is non-empty, the coefficients in the inequalities defining the cone can be replaced by new coefficients which satisfy the basic hypothesis. Thus we have the following result.

**Lemma 6.2.** Let \(S = \{(I_1, k_1); \ldots, (I_s, k_s)\} \in S'(E)\). There is a unique \(s \times s\) matrix \(E_S = \{e_S(r, p)\}\) such that \(e_S(r, p) \leq \tau_S(k_r, k_p)\), and

\[
\Gamma(E_S) = \left\{ a \in \mathbb{R}^s : e_S(r, p)a_p \leq a_r < 0 \right\} = \hat{\Gamma}_S.
\]

According to \((\text{5.4})\), we introduce global norms \(N_{S,s}\) and \(\hat{N}_{S,s}\).

**Definition 6.3.** Let \(S = \{(I_1, k_1); \ldots, (I_s, k_s)\} \in S'(E)\). Set

\[
N_{S,s}(x) = \sum_{p=1}^s \tilde{N}_{S,s}(x_{I_p})^{e_S(r, p)} \approx \sum_{p=1}^s \sum_{k \in I_p} n_k(x_k)^{e(k_r, k) e_S(r, p)},
\]

\[
\hat{N}_{S,s}(\xi) = \sum_{p=1}^s \tilde{N}_{S,s}(\xi_{I_p})^{1/e_S(p, r)} \approx \sum_{p=1}^s \sum_{k \in I_p} n_k(\xi_k)^{e(k_r, k) e_S(p, r)}.
\]

These norms coincide with the norms defined in \((\text{5.4})\), relative to the partition \(I_s = \{I_1, \ldots, I_s\}\) of \(\{1, \ldots, n\}\), to the matrix \(E_S\) and to the vector of exponents \(\alpha_s = (\alpha_1, \ldots, \alpha_n)\) with \(\alpha_j = e(k_r, j)\) if \(j \in I_r\).

We will use the shortened notation \(M_\infty(E_S)\) instead of \(M_\infty(E_S, \mathcal{I}_S, \alpha_S)\).

**Proposition 6.4.** We have the inclusion \(M_\infty(E_S) \subset M_\infty(E)\).

**Proof.** By Corollary \((\text{5.4})\) it is sufficient to check that the entries of the matrix \(E_S^\sharp\) are not greater than the corresponding entries of the matrix \(E\). By \((\text{5.3})\), if \(j \in I_r\) and \(k \in I_p\),

\[
\frac{e_S^\sharp(j, k)}{e_S^\sharp(k_r, j)} e_S(r, p) \leq e_S^\sharp(k_p, k) \leq \frac{e_S^\sharp(k_r, k)}{e_S^\sharp(k_r, j)} e_S(r, p).
\]

\(\square\)

### 6.2 Road map for the dyadic decomposition

Let \(m = \hat{K}\) be the Fourier transform so that \(m \in M_\infty(E)\). We proceed as follows.

1. In Section \((\text{5.3})\) we will construct a partition of unity on \(\mathbb{R}^N\) consisting of functions \(\Psi_0\) and \(\{\Psi_S\}_{S \in S'(E)}\), where \(\Psi_0 \in C_0^\infty(\mathbb{R}^N)\) has support in \(\mathbb{B}(2)\), and where each \(\Psi_S \in M_\infty(E)\) and has support in \(E_3^\sharp \cap \mathbb{B}(1)^c\). Here \(A > 1\) depends only on the matrix \(E\).

We will write

\[
m = \Psi_0 m + \sum_{S \in S'(E)} \Psi_S m = m_0 + \sum_{S \in S'(E)} m_S.
\]

Then \(m_0 \in C_0^\infty(\mathbb{B}(2))\) and each \(m_S \in M_\infty(E)\) is supported in \(E_3^\sharp \cap \mathbb{B}(1)^c\).
(2) For each \( S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S'(E) \), we show that
\[
m_S(\xi_{I_1}, \ldots, \xi_{I_s}) = \sum_{J \in \Gamma(E_S)} m_J(2^{-j_1} \cdot s\xi_{I_1}, \ldots, 2^{-j_s} \cdot s\xi_{I_s})
\]
where \( \{m_J : J \in \Gamma(E_S)\} \subset C_0^\infty(\mathbb{R}^N) \) is a uniformly bounded family with supports in the set where \( 4^{-1} < \hat{\nu}_{S,r}(\xi_{I_s}) < 4 \) for \( 1 \leq r \leq s \).

(3) Writing \( [m_J^S]^J(\xi_{I_1}, \ldots, \xi_{I_s}) = m_J(2^{-j_1} \cdot s\xi_{I_1}, \ldots, 2^{-j_s} \cdot s\xi_{I_s}) \), it then follows that
\[
m(\xi) = m_0(\xi) + \sum_{S \in S'([n])} \sum_{J \in \Gamma(E_S)} [m_J^S]^J(\xi).
\]
This is done in Section 6.4.

(4) Taking inverse Fourier transform, denoted by \( ^\wedge \), we obtain
\[
\mathcal{K} = m_0^\wedge + \sum_{S \in S'([n])} \sum_{J \in \Gamma(E_S)} ([m_J^S]^J)^\wedge.
\]
This gives a decomposition of \( \mathcal{K} \) into sums of dilates of Schwartz functions, which in turn can be written as sums of dilates of normalized bump functions. (See Lemma 6.15 below.)

6.3 Partitions of unity

In this section, we construct a partition of unity on the ‘Fourier transform side’. We begin by slightly modifying our notation. As usual, \( \mathbb{R}^N = \bigoplus_{j=1}^n \mathbb{R}^{C_j} \) and \( E = \{e(j, k)\} \) is an \( n \times n \) matrix satisfying (2.10). Let \( S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S'(E) \) and \( \mathbb{R}^{I_r} = \bigoplus_{j \in I_r} \mathbb{R}^{C_j} \). Instead of taking \( \hat{N}_j(\xi) = \sum_{l=1}^n n_l(\xi)^{1/e(l,j)} \) which might not be differentiable, we choose a smooth version of this norm. Then
\[
\hat{N}_j(\xi) \approx \sum_{l=1}^n n_l(\xi_l)^{1/e(l,j)}, \quad \hat{\nu}_{S,r}(\xi_{I_s}) \approx \sum_{j \in I_r} n_j(\xi_j)^{e(k_r,j)}, \quad \hat{Q}_{S,r} = \sum_{j \in I_r} Q_j e(k_r,j)^{-1},
\]
\[
\tau_S(k_p, k_r) = \min_{j \in I_r} \{e(k_p, j)/e(k_r, j)\}.
\]

Let \( \hat{E}_S^A \) be the set introduced in Definition 6.5 for \( A \geq 1 \). Recall from Lemma 6.9 that there is a constant \( \eta > 1 \) so that
\[
\xi \in \hat{E}_S^A \cap \mathbb{B}(1)^c \implies \begin{cases} n_j(\xi_j)^{e(k_r,j)} < A n_{k_r}(\xi_{k_r}) & \forall j \neq k_p \text{ in } I_r, \\ n_{k_p}(\xi_{k_p}) < A n_{k_r}(\xi_{k_r}) & \forall 1 \leq p \neq r \leq s. \end{cases} \implies \xi \in \hat{E}_S^{\eta A} \cap \mathbb{B}(1)^c.
\]

Now pick \( \psi \in C^\infty(\mathbb{R}) \) and \( \chi \in C^\infty(\mathbb{R}^N) \) such that
\[
\psi(t) = \begin{cases} 1 & \text{if } t \leq 2n, \\ 0 & \text{if } t \geq 4n, \end{cases} \quad \text{and} \quad \chi(\xi) = \begin{cases} 0 & \text{if } |\xi| \leq 1, \\ 1 & \text{if } |\xi| \geq \frac{3}{2}. \end{cases}
\]
For $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in \mathcal{S}'(\mathbb{E})$, set

$$ \Psi_S^\sharp(\xi) = \chi(\xi) \prod_{r=1}^s \prod_{j \in I_r} \psi(\tilde{N}_j(\xi)n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r,j)}). \quad (6.3) $$

Proposition 6.5.

(a) Let $\overline{E}_S$ be the closure of $\hat{E}_S$. Then $\Psi_S^\sharp(\xi) \equiv 1$ in an open neighborhood of the set $\overline{E}_S \setminus \mathbb{B}(2)$.

(b) There is a constant $A > 1$ so that $\Psi_S^\sharp$ is supported in $\hat{E}_S^A \setminus \overline{\mathbb{B}(1)}$.

(c) $\Psi_S^\sharp \in \mathcal{C}\infty(\mathbb{R}^N)$.

Proof. Suppose that $\xi \in \overline{E}_S \setminus \mathbb{B}(2)$. Then $\chi(\eta) = 1$ for $\eta$ in a neighborhood of $\xi$. Moreover, $n_j(\xi)^{1/\epsilon(l,j)} \leq n_r(\xi_{k_r})^{1/\epsilon(k_r,j)}$ for every $j \in I_r$, and so

$$ \tilde{N}_j(\xi)n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r,j)} \approx n_r(\xi_{k_r})^{1/\epsilon(k_r,j)} \sum_{i=1}^n n_i(\xi_i)^{1/\epsilon(l,j)}. $$

It follows that $\psi(\tilde{N}_j(\eta)n_{k_r}(\xi_{k_r})^{-1/\epsilon(k_r,j)}) = 1$ for $\eta$ in an open neighborhood of $\xi$, and so the same is true for $\Psi_S^\sharp(\eta)$.

Next suppose $\Psi_S^\sharp(\xi) \neq 0$. Then $\chi(\xi) \neq 0$, and $\psi(\tilde{N}_j(\xi)n_{k_r}(\xi_{k_r})^{-1/\epsilon(k_r,j)}) \neq 0$ for $1 \leq r \leq s$ for every $j \in I_r$. This shows that $\xi \in \mathbb{B}(1)^c$, and since $n_j(\xi)^{1/\epsilon(l,j)} \leq \tilde{N}_j(\xi)^{1/\epsilon(k_r,j)}$, it follows from the assumption on the support of $\psi$ that

$$ n_j(\xi)^{1/\epsilon(l,j)} \leq n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r,j)} $$

for $j \in I_r$.

It follows that there exists a constant $A > 0$ (depending on $n$ and the matrix $\mathbf{E}$) so that $n_j(\xi)^{1/\epsilon(l,j)} \leq A n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r,j)}$ and $n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r,j)} \leq A n_{k_p}(\xi_{k_p})^{1/\epsilon(k_p,j)}$. But this means that the support of $\Psi_S^\sharp$ is contained in the set $\hat{E}_S^A$ where $\eta$ is the constant from Lemma 6.6.

Finally, if $\xi \notin \mathbb{B}(1)$ and if $\Psi_S^\sharp(\xi) \neq 0$, then $\tilde{N}_j(\xi) \geq 1$ for $1 \leq j \leq n$ and it follows that $n_{k_r}(\xi_{k_r})$ is bounded away from 0. Since the function $\tilde{N}_j(\xi)n_{k_r}(\xi_{k_r})^{-1/\epsilon(k_r,j)}$ is smooth on the set where $\xi_{k_r} \neq 0$, and it follows that $\Psi_S^\sharp$ is smooth.

Lemma 6.6. $\Psi_S^\# \in \mathcal{M}_\infty(\hat{E})$; i.e. for every $\gamma \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n}$ there is a constant $C_\gamma > 0$ so that

$$ |\partial^\gamma \Psi_S^\sharp(\xi)| \leq C_\gamma \prod_{j=1}^n \left[ 1 + \tilde{N}_j(\xi) \right]^{-\|\gamma\|}. $$

Proof. The function $\tilde{N}_j(\xi)$ is homogeneous of degree one relative to the dilations

$$(\xi_1, \ldots, \xi_n) \to (\lambda^{e(1,j)} \cdot \xi_1, \ldots, \lambda^{e(n,j)} \cdot \xi_n).$$

and the function $\rho_{j,k_r}(\xi) = \tilde{N}_j(\xi)n_{k_r}(\xi_{k_r})^{-1/\epsilon(k_r,j)}$ is homogeneous of degree zero. The homogeneous dimension of $\mathbb{R}^{\gamma_1} \times \cdots \times \mathbb{R}^{\gamma_n}$ is $\gamma_1 + \cdots + \gamma_n$. If $\gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n}$, the adapted length of $\gamma$ is $\sum_{l=1}^c e(l,j)\gamma_l$. It follows from Proposition 15.1 in Appendix II that for $\xi \in \mathbb{B}(1)^c$

$$ |\partial^\gamma \rho_{j,k_r}(\xi)| \approx \left[ 1 + \tilde{N}_j(\xi) \right]^{-\sum_{l=1}^c e(l,j)\|\gamma_l\|}. $$
But on the support of $\Psi^\#_S$ which is contained in $\vec{E}_S^A$,
\[
\left[ 1 + \tilde{N}_j(\xi) \right] - \sum_{l=1}^s e(l,j) [\gamma_l] \\
= \prod_{p=1}^s \prod_{l \in I_p} \left[ 1 + \tilde{N}_j(\xi) \right] - [\gamma_l] e(l,j) \leq \prod_{p=1}^s \prod_{l \in I_p} \left[ 1 + n_{k_p}(\xi_{k_p}) \right]^{-[\gamma_l] e(l,j)/e(k_p,j)} \\
\leq \prod_{p=1}^s \prod_{l \in I_p} \left[ 1 + n_{k_p}(\xi_{k_p}) \right]^{-[\gamma_l] e(l,j)} \lesssim \prod_{p=1}^s \prod_{l \in I_p} \left[ 1 + N_l(\xi) \right]^{-[\gamma_l]}
\]
since $e(k_p,j) \leq e(k_p,l)e(l,j)$, $n_{k_p}(\xi_{k_p}) > 1$, and $N_l(\xi) \approx n_{k_p}(\xi_{k_p})^{1/e(k_p,l)}$ on the support of $\Psi^\#_S$ if $l \in I_p$. The estimates of the Lemma now follow from the chain rule and product rule. \hfill\Box

Let $\Psi^\#_0$ be a compactly supported function which is identically equal to 1 on $\mathbb{B}(2)$. We set
\[
\Psi_0 = \Psi^\#_0 [\Psi^\#_0 + \sum_{S \in S^0(\mathbb{E})} \Psi^\#_S]^{-1}, \quad \Psi_S = \Psi^\#_S [\Psi^\#_0 + \sum_{S \in S^0(\mathbb{E})} \Psi^\#_S]^{-1}. \quad (6.4)
\]

Using the fact that, if $m \in \mathcal{M}_\infty(\mathbb{E})$ is bounded away from zero, then also $1/m \in \mathcal{M}_\infty(\mathbb{E})$, we then have

**Corollary 6.7.**

(a) $\Psi_0(\xi) + \sum_{S \in S^0(\mathbb{E})} \Psi_S(\xi) \equiv 1$ for every $\xi \in \mathbb{R}^N$.

(b) $\Psi_S \in \mathcal{M}_\infty(\mathbb{E})$ for $S = 0$ and for every $S \in S^0(\mathbb{E})$.

(c) For $S \in S^0(\mathbb{E})$ the function $\Psi_S$ is supported in $\vec{E}_S^A$.

We now use Corollary 6.4 to obtain a decomposition of a multiplier $m \in \mathcal{M}_\infty(\mathbb{E})$.

**Corollary 6.8.** Let $m \in \mathcal{M}_\infty(\mathbb{E})$. Put $m_0 = \Psi_0 m$, and $m_S = \Psi_S m$ for each $S \in S^0(\mathbb{E})$. Then

(a) $m(\xi) = m_0(\xi) + \sum_{S \in S^0(\mathbb{E})} m_S(\xi)$ for every $\xi \in \mathbb{R}^N$;

(b) $m_S \in \mathcal{M}_\infty(\vec{E})$ for every $S \in S^0(\mathbb{E})$;

(c) $m_S$ is supported in $\vec{E}_S^A$ where $A$ depends only on the matrix $\mathbb{E}$;

(d) $m_0 \in C_0^\infty(\mathbb{R}^N)$ has support in $\mathbb{B}(2)$.

**Remark 6.9.** Since $m_S$ is supported on $\vec{E}_S^A$, we have
\[
|\partial_\xi^\gamma (m_S)(\xi)| \lesssim \prod_{s=1}^s \prod_{j \in I_s} \tilde{N}_j(\xi) - [\gamma_s] \approx \prod_{s=1}^s \prod_{j \in I_s} n_{k_s}(\xi_{k_s})^{-[\gamma_s] e(k_s,j)} \\
\approx \prod_{s=1}^s \tilde{n}_{S,r}(\xi_{I_s}) - \sum_{s=1}^s [\gamma_s] e(k_s,j).
\]

This says that the differential estimates for $m_S$ are equivalent to product multiplier estimates relative to the norms $\{\tilde{n}_{S,r}\}$ on the decomposition $\mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s}$.
Proposition 6.11. Recall that $\theta \in C^\infty_0(\mathbb{R}^r)$. The set $E^A_S$ is not the principal marked partition, one can say more: the function $m_S$ in fact belongs to the class $M_\infty(E_S)$ introduced in Section 6.1.

Proposition 6.10. For $S \in S'(E)$, the function $m_S$ belongs to the class $M_\infty(E_S)$.

Proof. We must show that for any $\gamma = (\gamma_1, \ldots, \gamma_J) \in \mathbb{N}^{I_1} \times \cdots \times \mathbb{N}^{I_L}$ there is a constant $C_\gamma$ so that

$$|\partial^\gamma m_S(\xi)| \leq C_\gamma \prod_{r=1}^{s} (1 + N_{S,r}(\xi))^{-|\gamma_{I_r}|_S},$$

where $|\gamma_{I_r}|_S = \sum_{j \in I_r} |\gamma_j|/c(k_r,j)$ is the length of the multi-index $\gamma_{I_r}$ adapted to the dilations $^*_S$. But this is a simple consequence of the estimate in Remark 6.11 and the fact that on the set $E^A_S$ we have $\hat{n}_{S,r}(\xi_{I_r}) \approx 1 + \hat{N}_{S,r}(\xi)$.

6.4 Dyadic decomposition of a multiplier

We now turn to the task of providing a dyadic decomposition for each multiplier $m_S$. Fix $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in S'(E)$, and write $\mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s}$. On each factor $\mathbb{R}^{I_r}$ choose a function $\theta \in C^\infty_0(\mathbb{R}^{I_r})$ satisfying\(^{12}\)

$$\theta(\xi_{I_r}) = \begin{cases} 1 & \text{if } \hat{n}_{S,r}(\xi_{I_r}) \leq 1, \\ 0 & \text{if } \hat{n}_{S,r}(\xi_{I_r}) \geq 2. \end{cases}$$

Recall that $2^{-j} : S \xi_{I_r} = \{2^{-j/\ell(k_r,j)} : \xi_j\}_{j \in I_r}$. Put $\theta_j(\xi_{I_r}) = \theta(2^{-j} : S \xi_{I_r})$, and

$$\theta_j(\xi_{I_r}) = \theta_j(\xi_{I_r}) - \theta_{j-1}(\xi_{I_r}) = \theta(2^{-j} : S \xi_{I_r}) - \theta(2^{j-1} : S \xi_{I_r}) = \Theta_0(2^{-j} : S \xi_{I_r}).$$

Note that $\Theta_j$ is supported where $\hat{n}_{S,r}(\xi_{I_r}) \approx 2^j$. Precisely:

$$\Theta_j(\xi_{I_r}) \neq 0 \implies 2^{j-1} \leq \hat{n}_{S,r}(\xi_{I_r}) \leq 2^{j+2}.$$

For $0 \neq \xi_{I_r} \in \mathbb{R}^{I_r}$ we have

$$\sum_{j=-\infty}^{\infty} \Theta_j(\xi_{I_r}) = \theta_0(\xi_{I_r}) + \sum_{j=1}^{\infty} \Theta_j(\xi_{I_r}) = 1,$$

and the second equality holds for $\xi_{I_r} = 0$ as well. For $J = (j_1, \ldots, j_s) \in \mathbb{Z}^s$ define

$$\Theta_J(\xi) = \Theta_{J_1}(\xi_{I_1}) \cdots \Theta_{J_s}(\xi_{I_s}).$$

Then $\Theta_J$ is supported where each $\hat{n}_{S,r}(\xi_{I_r}) \approx 2^{j_r}$, and $\sum_{J \in \mathbb{Z}^s} \Theta_J(\xi_{I_1}, \ldots, \xi_{I_s}) \equiv 1$ provided each $\xi_{I_r} \neq 0$. Recall that $m_S$ is supported on $E^A_S \cap E(1)^c$, and $\xi_{I_r} \neq 0$ on this support. Thus we can write

$$m_S(\xi) = \sum_{J \in \mathbb{Z}^s} \Theta_J(\xi)m_S(\xi) = \sum_{J \in \mathbb{Z}^s} \Theta_J(\xi)\Psi_S(\xi)m(\xi).$$

Proposition 6.11. There is a constant $\mu > 0$ depending only on $E$ so that if $J \in \mathbb{Z}^s$ and $\Theta_J(\xi)\Psi_S(\xi)m(\xi) \neq 0$, then $J$ belongs to

$$-\Gamma_{\mathbb{Z}, \mu}(E_S) = \{ J = (j_1, \ldots, j_s) \in \mathbb{Z}^s : 0 < j_p \leq \tau_S(k_p, k_r)j_r + \mu \}.$$

\(^{12}\)To keep notation simpler, we do not indicate the dependence of $\theta$ on the index $r$.  

Proof. Suppose \( \Theta_J(\xi)\Psi_S(\xi)m(\xi) \neq 0 \). Then \( \Theta_J(\xi) \neq 0 \), and it follows that \( 2^{j_r-1} \leq \hat{n}_{S,r}(\xi_{I_r}) \leq 2^{j_r+2} \). Also \( \Psi_S(\xi) \neq 0 \), and it follows that \( \xi \in \mathcal{E}_S^A \) and so
\[
1 \leq \hat{n}_{S,p}(\xi_{I_p})^{1/\gamma} \leq A \hat{n}_{S,r}(\xi_{I_r})
\]
for all \( r, p \in \{1, \ldots, s\} \). It follows that
\[
(2^{j_r-1})^{1/\gamma} \leq \hat{n}_{S,p}(\xi_{I_p})^{1/\gamma} \leq A \hat{n}_{S,r}(\xi_{I_r}) \leq A 2^{j_r+1},
\]
and so
\[
j_p \leq \tau_S(k_p, k_r) j_r + \left[ \tau_S(k_p, k_r)(1 + \log_2(A)) + 1 \right] \leq \tau_S(k_p, k_r) j_r + \mu
\]
for an appropriate constant \( \mu \).

It now follows that
\[
m_S(\xi) = \sum_{J \in -\Gamma_{z,\mu}(E_S)} \Theta_J(\xi)m_S(\xi) = \sum_{J \in -\Gamma_{z,\mu}(E_S)} \Theta_0(2^{-j_1-\gamma_{S} \xi_{I_1}, \ldots, 2^{-j_s-\gamma_{S} \xi_{I_s}}}) m_S(\xi_{I_1}, \ldots, \xi_{I_s}).
\]
Put
\[
m^{J}_S(\xi) = \Theta_0(\xi)m_S(2^{-j_1-\gamma_{S} \xi_{I_1}, \ldots, 2^{-j_s-\gamma_{S} \xi_{I_s}}})
\]
so that we can write
\[
m_S(\xi_{I_1}, \ldots, \xi_{I_s}) = \sum_{J \in -\Gamma_{z,\mu}(E_S)} m^{J}_S(2^{-j_1-\gamma_{S} \xi_{I_1}, \ldots, 2^{-j_s-\gamma_{S} \xi_{I_s}}}).
\]

Proposition 6.12. The set of functions \( \{ m^{J}_S : J \in -\Gamma_{z,\mu}(E_S) \} \) is a uniformly bounded family in \( C^\infty_0(\mathbb{R}^N) \), each supported where \( \frac{\xi}{\gamma} < \hat{n}_{S,r}(\xi_{I_r}) < 4 \) for \( 1 \leq r \leq s \).

Proof. Since \( m_S \) is supported on \( \hat{\mathcal{E}}_S^A \),
\[
|\partial_\xi (m_S(2^{-j_1-\gamma_{S} \xi_{I_1}, \ldots, 2^{-j_s-\gamma_{S} \xi_{I_s}}}))| = 2^{j_1-1/\gamma} \left| \partial_\xi (m_S(2^{-j_1-\gamma_{S} \xi_{I_1}, \ldots, 2^{-j_s-\gamma_{S} \xi_{I_s}}})) \right| \\
\leq 2^{j_1-1/\gamma} \prod_{r=1}^{s} \hat{n}_{S,r}(\xi_{I_r})^{-1/\gamma} \\
= C_\gamma \prod_{r=1}^{s} \hat{n}_{S,r}(\xi_{I_r})^{-1/\gamma}
\]
But on the support of \( \Theta_0 \) the product \( \prod_{r=1}^{s} \hat{n}_{S,r}(\xi_{I_r})^{-1/\gamma} \) is uniformly bounded and bounded away from zero (depending on \( \gamma \)).

We have written \( m_S(\xi) = \sum_{J \in -\Gamma_{z,\mu}(E_S)} m^{J}_S(2^{-J-\gamma_{S} \xi}) \). We want to replace the sum over \( -\Gamma_{z,\mu}(E_S) \) by a sum over \( -\Gamma_{z}(E_S) \).

For each \( J \in -\Gamma_{z,\mu}(E_S) \), choose \( J' = p(J) \in -\Gamma_{z}(E_S) \) at minimal distance from \( J \). It is quite clear that there is a finite upper bound \( M \) for the number of \( J \) having the same \( p(J) \) and that, if \( p(J) = J' \), then \( |j_r - j'_r| \leq c(\mu) \) for each \( r = 1, \ldots, s \). It follows that we can rewrite
\[
m_S(\xi) = \sum_{J \in -\Gamma_{z,\mu}(E_S)} m^{J}_S(2^{-J-\gamma_{S} \xi}) \\
= \sum_{J' \in -\Gamma_{z}(E_S)} \sum_{J : p(J) = J'} m^{J}_S(2^{-J-\gamma_{S} \xi}) \\
= \sum_{J' \in -\Gamma_{z}(E_S)} \tilde{m}^{J'}_S(2^{-J'-\gamma_{S} \xi}).
\]
where the functions

\[ \overline{m}_S^J(\xi) = \sum_{J:p(J) = J'} m_S^J(2^{J'} - J \cdot S \xi) \]

form a a uniformly bounded family in \( C_0^\infty(\mathbb{R}^N) \).

Applying this decomposition for each marked partition \( S \in \mathcal{S}'(E) \) we have the following decomposition for multipliers.

**Theorem 6.13.** Let \( m \in \mathcal{M}_\infty(E) \). There is a uniformly bounded collection of functions \( \{m_S^J\} \subset C_0^\infty(\mathbb{R}^N) \) indexed by

\[ S \in \mathcal{S}'(E) = \{T \in \mathcal{S}(n) : \hat{E}_T \cap B(1)^c \neq \emptyset\} \]

and \( J \in \Gamma_S(E_S) \) with the following properties.

(a) If \( S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in \mathcal{S}'(E) \) and \( J \in \Gamma_S(E_S) \), the function \( m_S^J \) is supported where \( c^{-1} < \hat{n}_{S,r}(\xi_{I_r}) < c \) for \( 1 \leq r \leq s \) and an appropriate constant \( c \).

(b) The multiplier \( m \) can be written

\[ m(\xi) = m_0(\xi) + \sum_{S \in \mathcal{S}'(E)} \sum_{J \in \Gamma_S(E_S)} m_S^J(2^{-J_1} \cdot S \xi_{I_1}, \ldots, 2^{-J_s} \cdot S \xi_{I_s}) \] (6.6)

where \( m_0 \in C_0^\infty(\mathbb{R}^N) \) is supported in \( B(2) \).

### 6.5 Dyadic decomposition of a kernel

We can now decompose a distribution \( \mathcal{K} \in \mathcal{P}_0(E) \). We know from Theorem 4.2 that the Fourier transform \( m = \hat{\mathcal{K}} \in \mathcal{M}_\infty(E) \), and by Theorem 6.13 we can write \( m \) as in equation (6.6). Write

\[ [\psi]^J(\xi_{I_1}, \ldots, \xi_{I_s}) = \psi(2^{-J_1} \cdot S \xi_{I_1}, \ldots, 2^{-J_s} \cdot S \xi_{I_s}) \]

so that

\[ \hat{\mathcal{K}} = m_0 + \sum_{S \in \mathcal{S}'(E)} \sum_{J \in \Gamma_S(E_S)} [m_S^J]^J. \]

Then if \( \psi \) denotes the inverse Fourier transform, we have

\[ \mathcal{K} = (m_0)^\psi + \sum_{S \in \mathcal{S}'(E)} \sum_{J \in \Gamma_S(E_S)} ([m_S^J]^J)^\psi. \]

Computing the inverse Fourier transform of \( [m_S^J]^J \) we have

\[ ([m_S^J]^J)^\psi(x_{I_1}, \ldots, x_{I_s}) = 2^{\sum_{r=1}^s J_r} \hat{Q}_r [m_S^J]^\psi(2^{J_1} \cdot S x_{I_1}, \ldots, 2^{J_s} \cdot S x_{I_s}). \]

Since the family \( \{m_S^J\} \) is uniformly bounded in \( C_0^\infty(\mathbb{R}^N) \subset \mathcal{S}(\mathbb{R}^N) \), it follows that the family \( \{([m_S^J]^J)^\psi\} \) is also a uniformly bounded family in \( \mathcal{S}(\mathbb{R}^N) \). Since each \( m_S^J \) is supported where \( c^{-1} < \hat{n}_{S,r}(\xi_{I_r}) < c \) for all \( r \), and since \( \hat{n}_{S,r}(\xi_{I_r}) \approx n_{k_r}(\xi_{k_r}) \), it follows that

\[ \int_{\mathbb{R}^N} (m_S^J)^\psi(x_1, \ldots, x_k, \ldots, x_n) \, dx_k = 0 \] (6.7)

for \( 1 \leq r \leq s \); i.e. the function \( (m_S^J)^\psi \) has cancellation in each of the variables \( \{x_{k_1}, \ldots, x_{k_r}\} \). Let us write

\[ \psi_0 = (m_0)^\psi, \quad \psi_S^J = ([m_S^J]^J)^\psi = ([m_S^{-J}]^J)^J. \] (6.8)
Theorem 6.14. Let \( K \in P_0(E) \). There is a function \( \psi_0 \in S(\mathbb{R}^N) \) and for each \( S \in S'(E) \) there is a uniformly bounded collection of functions \( \{ \psi_S^J \}_{J \in \Gamma_\varepsilon(E_S)} \subset S(\mathbb{R}^N) \) so that:

1. Let \( S = \{(I_1,k_1); \ldots; (I_s,k_s)\} \in S'(E) \).
   
   (a) Each function \( \psi_S^J \) has cancellation in each of the variables \( \{x_{k_1}, \ldots, x_{k_s}\} \), and so has strong cancellation relative to the decomposition \( \mathbb{R}^N = \mathbb{R}^{I_1} \oplus \cdots \oplus \mathbb{R}^{I_s} \).

   (b) The series
   
   \[
   K_S(x) = \sum_{J \in \Gamma_\varepsilon(E_S)} [\psi_S^J]_J(x) = \sum_{J \in \Gamma_\varepsilon(E_S)} 2^{-\sum_{r=1}^s i_r} Q_{i_r} \psi_S^J(2^{-j_r} S x)
   \]

   converges to an element of \( P_0(E_S) \subset P_0(E) \) in the sense of distributions.

2. The distribution \( K \) decomposes as \( K(x) = \psi_0(x) + \sum_{S \in S'(E)} K_S(x) \).

Proof. Let \( m = \widehat{K} \in M_\infty(E) \). Using Theorem 6.13 write

\[
    m = m_0 + \sum_{S \in S'(E)} \sum_{J \in \Gamma_\varepsilon(E_S)} [m_S^J]^J.
\]

Then for each \( S \in S'(E) \) and each \( J \in \Gamma_\varepsilon(E_S) \), let \( \psi_S^J(x) = (m_S^J)^J(x) \). We have already observed in equation (6.7) that \( \psi_S^J \) has cancellation in each variable \( x_{k_r} \), \( 1 \leq r \leq s \), which gives assertion (1a).

Next

\[
    K_S = \sum_{J \in \Gamma_\varepsilon(E_S)} [\psi_S^J]_J = \sum_{J \in \Gamma_\varepsilon(E_S)} [\psi_S^{-J}]_{-J} = \sum_{J \in \Gamma_\varepsilon(E_S)} ([m_S^J]^J)^{\vee} = m_S^\vee.
\]

According to Proposition 6.10, \( m_S \in M_\infty(E_S) \), and using Theorem 4.1 it follows that \( K_S \in P_0(E_S) \). But according to Lemma 5.4, \( M_\infty(E_S) \subset M_\infty(E) \), and every distribution in \( P_0(E_S) \) belongs to \( P_0(E) \). This establishes assertion (1b).

Finally assertion (2) is then a consequence of the identity \( m = m_0 + \sum_{S \in S'(E)} m_S \), and this completes the proof. \( \square \)

Theorem 6.14 shows that each kernel \( K \) can be written as sums of dilates of uniformly bounded families of Schwartz functions. As in [NRSW12], we can improve this result and show that we can replace Schwartz functions by uniformly bounded families of functions compactly supported in the unit ball. We use the following result, which is Lemma 6.5 in [NRSW12].

Lemma 6.15. Let \( \psi \in S(\mathbb{R}^N) \). Then there are functions \( \{ \varphi^k \} \subset C_0^\infty(\mathbb{R}^N) \), \( k \in \mathbb{N} \) such that

\[
    \psi(x) = \sum_{k=0}^{\infty} 2^{-kQ} \varphi^k(2^{-k} \cdot x)
\]

where \( Q \) is the homogeneous dimension of \( \mathbb{R}^N \) relative to the given dilations. The functions \( \{ \varphi^k \} \) have the following properties.

(a) Each \( \varphi^k \) is supported in \( B(1) \).
(b) For any $\delta > 0$ and any $\gamma \in \mathbb{N}^N$ there exists a positive integer $M$ so that

$$\sup_{x \in \mathbb{R}^N} |\partial^\gamma \varphi^k(x)| \leq 2^{-k\delta} \sup_{x \in \mathbb{R}^N} \sum_{|\alpha| \leq M} |\partial^\alpha \psi(x)|.$$  

(c) If $\psi$ has strong cancellation, then each $\varphi^k$ also has strong cancellation.

Now let $K \in \mathcal{P}_0(\mathbf{E})$ and let $K = \psi_0 + \sum_{S \in S'(\mathbf{E})} K_S$ be the decomposition given in Theorem 6.14 where $K_S(x) = \sum_{J \in \Gamma_2(\mathcal{E})} \psi^J_S(x)$, and each $\psi^J_S$ has cancellation in the variables $\{x_{k_1}, \ldots, x_{k_s}\}$. We apply Lemma 6.15 to each function $\psi^J_S$:

$$\psi^J_S(x) = \sum_{k=0}^\infty 2^{-kQ_S} \varphi^{J,k}_S(2^{-k} \cdot x)$$

where each $\{\varphi^{J,k}_S\} \subset C^\infty_0(\mathbb{R}^N)$ is a uniformly bounded family of functions supported in $B(1)$, each having cancellation in the variables $\{x_{k_1}, \ldots, x_{k_s}\}$. Then

$$K_S(x) = \sum_{J \in \Gamma_2(\mathcal{E})} \sum_{k=0}^\infty [\varphi^{J,k}_S](x).$$

The argument on pages 661-663 of [NRSW12] shows that this last sum can be rewritten to yield

$$K_S(x) = \sum_{J \in \Gamma_2(\mathcal{E})} [\varphi^J_S](x)$$

where $\{\varphi^J_S\}$ is a uniformly bounded family in $C^\infty_0(\mathbb{R}^N)$, all supported in $B(1)$, and all having cancellation in the variables $\{x_{k_1}, \ldots, x_{k_s}\}$. Thus we have

**Corollary 6.16.** Let $K \in \mathcal{P}_0(\mathbf{E})$. For each $S \in S'(\mathbf{E})$ there is a uniformly bounded collection of functions $\{\psi^J_S\} \subset C^\infty_0(\mathbb{R}^N)$ and a function $\psi_0 \in S(\mathbb{R}^N)$ so that

(a) Each function $\psi^J_S$ has cancellation in the variables $x_{k_1}, \ldots, x_{k_s}$.

(b) Let

$$[\psi^J_S]_S(x) = 2^{-Jr} [\varphi^J_S](x) 2^{-Jr} x_{l_1}, \ldots, 2^{-Jr} x_{l_s},$$

where

$$2^{-Jr} x_{l_j} = \left\{2^{-Jr} / (r, j) \cdot x_j \right\}_{j \in I_r}.$$  

Then the series $K_S = \sum_{J \in \Gamma_2(\mathcal{E})} [\varphi^J_S](x)$ converges in the sense of distributions to an element $K_S \in \mathcal{P}_0(\mathbf{E}) \subset \mathcal{P}_0(\mathbf{E}).$

(c) $K(x) = \psi_0(x) + \sum_{S \in S'(\mathbf{E})} K_S(x)$.

### 7 The rank of $E$ and integrability at infinity

So far we have analyzed kernel in the restricted class $\mathcal{P}_0(\mathbf{E})$, which are the sum of a kernel in $\mathcal{P}(\mathbf{E})$ with compact support and a Schwartz function.

In this Section we discuss the nature of a distribution $K \in \mathcal{P}(\mathbf{E})$ and show that it depends in the first place on the rank of the matrix $E = \{e(j, k)\}$.

We will see that if the rank equals 1 then the distribution $K$ is a standard (non-isotropic) Calderón-Zygmund kernel. However, if the rank is greater than 1, we will see that the kernel...
$K$ is integrable at infinity, but has worse behavior near the origin than a Calderón-Zygmund kernel.

We will also show that we have integrability at infinity in a more general situation. Suppose that the Fourier transform $m$ of a distribution $K$ satisfies the differential inequalities in Definition 2.3 for pure derivatives; i.e. for every $1 \leq j \leq n$ and for every $\gamma_j \in \mathbb{N}^C$, there is a constant $C_{\gamma_j} > 0$ so that $\left| \partial_{\xi_j}^j m(\xi) \right| \leq C_{\gamma_j} N_j(\xi)^{-[\gamma_j]}$. Then if the rank of $E$ is greater than 1, the function $K$ is integrable at infinity. This result will be used in Section 11 below when we consider distributions which are simultaneously flag kernels for two different flags.

### 7.1 The rank 1 case: Calderón-Zygmund kernels

We begin by recalling the definition of a Calderón-Zygmund kernel $\mathcal{K}$. Start with the usual decomposition

$$\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}, \tag{7.1}$$

and use the standard notation of Section 2. For $a = (a_1, \ldots, a_n)$ an $n$-tuple of positive numbers, define a one-parameter family of dilations by setting

$$\lambda \cdot a \cdot x = (\lambda^{a_1} \cdot x_1, \ldots, \lambda^{a_n} \cdot x_n). \tag{7.2}$$

With this homogeneity, $\mathbb{R}^N$ has homogeneous dimension $Q_a = \sum_{j=1}^n a_j Q_j$, and

$$N_a(x) = n_1(x_1)^{1/a_1} + \cdots + n_n(x_n)^{1/a_n}$$

is a homogeneous norm. We can then define the class of Calderón-Zygmund kernels with this homogeneity.

**Definition 7.1.** $\mathcal{CZ}_a$ is the space of tempered distributions $K$ on $\mathbb{R}^N$ such that

(a) away from the origin, $K$ is given by integration against a smooth function $K$ satisfying the differential inequalities

$$\left| \partial^{\gamma} K(x) \right| \leq C_{\gamma} N_a(x)^{-Q_a - [\gamma]_a},$$

for every multi-index $\gamma$, with $[\gamma]_a = \sum_{j=1}^n a_j [\gamma_j]$;

(b) there is a constant $C > 0$ so that for any normalized bump function $\psi \in C^0_0(\mathbb{R}^N)$ with support in the unit ball and for any $R > 0$, $|\langle K, \psi_R \rangle| \leq C$, where $\psi_R(x) = \psi(R \cdot a \cdot x)$.

It is well known, cf. [NRS01], that, for distributions $K \in \mathcal{CZ}_a$, the corresponding multipliers $m = \hat{K}$ are characterized by the differential inequalities

$$\left| \partial^{\gamma} m(\xi) \right| \leq C_{\gamma} N_a(\xi)^{-[\gamma]_a}.$$

Put

$$N_j(\xi) = n_1(\xi)^{a_1} + \cdots + n_n(\xi)^{a_n} \approx N_a(\xi)^{a_j}.$$

Then these differential inequalities can be written as $\left| \partial^{\gamma} m(\xi) \right| \leq C_{\gamma} \prod_{j=1}^n N_j(\xi)^{-[\gamma_j]}$, and so the multipliers are the elements of the class $\mathcal{M}(E_a)$ where

$$E_a = \left[ \begin{array}{cccc} 1 & a_1 & a_1 & \cdots & a_1 \\ \frac{a_1}{a_1} & 1 & a_1 & \cdots & a_1 \\ \vdots & \vdots & \ddots & \cdots & \vdots \\ \frac{a_1}{a_n} & \frac{a_2}{a_n} & \frac{a_3}{a_n} & \cdots & 1 \end{array} \right]. \tag{7.3}$$

---

13For reasons of compatibility with the framework of this paper, we restrict ourselves to kernels and multipliers which are $C^\infty$ away from the origin and to dilations which are compatible with the decomposition [7.1] and with the dilations in [2.3].
Proposition 7.2. Let $E = \{e(j, k)\}$ satisfy the basic hypotheses $\text{(2.10)}$. The following are equivalent:

(1) $\text{rank}(E) = 1$;

(2) $e(j, k) = e(j, l)e(l, k)$ for all $1 \leq j, k, l \leq n$;

(3) there is a dilation structure on $\mathbb{R}^N$, compatible with the decomposition $\text{(7.1)}$, so that if $m \in M(E)$, then $m$ is a Mihlin-Hörmander multiplier relative to that structure.

(4) there is a dilation structure on $\mathbb{R}^N$, compatible with the decomposition $\text{(7.1)}$, so that if $K \in P(E)$, then $K$ is a Calderón-Zygmund kernel relative to that structure;

Proof. The rank of $E$ equals 1 if and only if all the rows are proportional. Due to the 1’s along the diagonal this means that, for every $j \neq k$ the $j$-th row equals the $k$-th row multiplied by $e(j, k)$. Thus (1) and (2) are equivalent.

If (2) holds, we have in particular that $e(j, k)e(k, j) = 1$ for all $j, k$. Hence $\hat{N}_j = N_j$ for all $j$. Moreover, in analogy with (5.6),

$$N_j(x) \approx N_1(x)^{e(j, 1)}.$$ 

Thus the differential inequalities in Definition $\text{(2.4)}$ can be written

$$|\partial^\gamma m(\xi)| \leq C_\gamma \prod_{j=1}^n \hat{N}_j(\xi)^{-[\gamma_j]}$$

$$\approx \prod_{j=1}^n N_1(\xi)^{-\sum_{j=1}^n e(j, 1)[\gamma_j]} = N_1(\xi)^{-\sum_{j=1}^n e(j, 1)[\gamma_j]}$$

$$= N_1(\xi)^{-[\gamma]},$$

where $[\gamma] = \sum_{j=1}^n e(j, 1)[\gamma_j] = \sum_{j=1}^n e(1, j)^{-1}[\gamma_j]$ is the length of $\gamma$ in the dilation structure that makes $N_1$ a homogeneous norm. Thus the multiplier $m(\xi)$ satisfies the Mihlin-Hörmander differential inequalities relative to the family of dilations, and so (3) holds.

Conversely, assume that (3) holds. Then there are exponents $\beta_1 = 1, \beta_2, \ldots, \beta_n$ such that, setting

$$N(\xi) = \sum_{j=1}^n n_j(\xi)^{\beta_j},$$

every $m \in M(E)$ satisfies the inequalities

$$|\partial^\gamma m(\xi)| \lesssim N(\xi)^{-\sum_{j=1}^n \beta_j^{-1}[\gamma_j]}.$$ 

This is equivalent to saying that $m \in M(E')$ with

$$e'(j, k) = \frac{\beta_k}{\beta_j}.$$ 

Hence in our hypothesis we have the inclusion $M(E) \subseteq M(E')$, which implies that $M_\infty(E) \subseteq M_\infty(E')$. By Proposition $\text{(2.2)}$ this implies that $\Gamma(E) \subseteq \Gamma(E')$. By Lemma $\text{(14.9)}$ the dimension of $\Gamma(E')$ equals the reduced rank of $E'$, which is 1. Hence also $\Gamma(E)$ has dimension 1, so it must coincide with $\Gamma(E')$. This proves that (3) implies (1).

Finally, the equivalence of (3) and (4) is proved in $\text{[NRS01]}$. $\square$
7.2 Higher rank and integrability at infinity

In this section let $E = \{e(j, k)\}$ be an $n \times n$ matrix satisfying the basic hypothesis (2.10), and as usual let $N_j(x) = \sum_{k=1}^{n} n_k(x_k)^{e(j,k)}$ and $\tilde{N}_j(x) = \sum_{k=1}^{n} n_k(x_k)^{1/e(k,j)}$. Let $Q_j$ be the homogeneous dimension of $\mathbb{R}^C$.

Lemma 7.3. Suppose that the rank of $E$ is greater than or equal to 2. If $K$ satisfies the inequality in equation (7.4), then $K$ is integrable over the complement of the unit ball $B(1)$.

Proof. Since the rank of $E$ is strictly larger than 1, it follows from Proposition 7.2 that there are integers $j, k, l \in \{1, \ldots, n\}$ so that $e(j, k) < e(j, l)e(l, k)$. Moreover, for every $k \in \{1, \ldots, n\}$, we have

$$|K(x)| \leq C \prod_{j=1}^{n} N_j(x) \leq C \prod_{j=1}^{n} |x_k|^{-e(j, k)Q_j} = C|x_k|^{-\sum_{j=1}^{n} e(j, k)Q_j} = C|x_k|^{-\tilde{Q}_k}$$

(7.5)

where $\tilde{Q}_k = \sum_{j=1}^{n} e(j, k)Q_j$. Decompose the complement of $B(1)$ as the union of sets $E_\omega$ where $\omega$ ranges over the collection of non-empty subsets of $\{1, \ldots, n\}$, and

$$E_\omega = \{x \in \mathbb{R}^n : |x_k| \geq 1 \text{ for } k \in \omega, |x_k| < 1 \text{ for } k \not\in \omega\}.$$

Fix $\omega$, and let $\{\theta_l\}_{l \in \omega}$ be strictly positive numbers such that $\sum_{l \in \omega} \theta_l = 1$. Then it follows from (7.5) that $|K(x)| \lesssim \prod_{l \in \omega} |x_l|^{-\theta_l Q_l}$, and if we can choose the constants $\{\theta_l\}$ such that $\theta_l Q_l > Q_l$ for every $l$, then

$$\int_{E_\omega} |K(x)| \, dx \lesssim \prod_{l \in \omega} \int_{x_l \in R^C_1, |x_l| \geq 1} |x_l|^{-\theta_l Q_l} \, dx_l < +\infty.$$

We can choose $\{\theta_l\}$ with the required property if $\sum_{l \in \omega} Q_l \tilde{Q}_l^{-1} < 1$, and we can do this for every subset $\omega$ if $\sum_{l=1}^{n} Q_l \tilde{Q}_l^{-1} < 1$. But for any fixed $k \in \{1, \ldots, n\}$, we have $e(j, l) \geq e(j, k)/e(l, k)$ and so

$$\sum_{l=1}^{n} Q_l \tilde{Q}_l^{-1} = \sum_{l=1}^{n} Q_l \left[ \sum_{j=1}^{n} e(j, l)Q_j \right]^{-1} \leq \sum_{l=1}^{n} e(l, k) Q_l \left[ \sum_{j=1}^{n} e(j, k)Q_j \right]^{-1} = 1.$$

(7.6)

Moreover, we can make the inequality in (7.6) strict if there exists a single triple $j, k, l \in \{1, \ldots, n\}$ such that $e(j, k) < e(j, l)e(l, k)$. This completes the proof.

Corollary 7.4. Suppose that rank $(E) \geq 2$. If $K \in \mathcal{P}(E)$ we can write $K = K_0 + K_\infty$ where $K_0, K_\infty \in \mathcal{P}(E)$, $K_0$ is a distribution with compact support in the unit ball, and $K_\infty$ is a distribution given by integration against a function $K_\infty \in C^\infty(\mathbb{R}^n) \cap L^1(\mathbb{R}^n)$ which satisfies the differential inequalities of Definition 2.2. We also will need the following variant of Lemma 7.3.
Lemma 7.5. Suppose that $\mathcal{K}$ is a tempered distribution on $\mathbb{R}^n$ and suppose that its Fourier transform $m = \mathcal{K}$ is a smooth function away from zero which satisfies the following differential inequalities for pure derivatives: for $1 \leq j \leq n$ and for every $\gamma_j \in \mathbb{N}^n$ there exists a constant $C_{\gamma_j} > 0$ so that

$$|\partial_{\xi}^{\gamma_j} m(\xi)| \leq C_{\gamma_j} \hat{N}_j(\xi)^{-|\gamma_j|}.$$  

Then $\mathcal{K}$ is given by integration against a smooth function $K$ away from the origin, and if the rank of the matrix $E$ is greater than 1, then $K$ is integrable at infinity.$^\dag$

Proof. If we can show that $\mathcal{K}$ is given by integration against a function $K$ with $|K(x)| \lesssim n_k(x_k) - \sum_{j=1}^n c(j,k)Q_j$ for $1 \leq k \leq n$, then the argument proceeds as in the proof of Lemma 7.3. Thus fix $k$, and define $\lambda_k x = (\lambda^{(1,k)} \cdot x_1, \ldots, \lambda^{(n,k)} \cdot x_n)$. This is a family of dilations on all of $\mathbb{R}^N$ and $\hat{N}_j(t) = \sum_{k=1}^n n_k(t_k)^{1/\gamma(j,k)}$ is a homogeneous norm. The homogeneous dimension is $\sum_{j=1}^n \gamma(j,k)Q_j$. Choose $\chi \in C^\infty_0(\mathbb{R}^N)$ with $\chi(\xi) \equiv 1$ if $\hat{N}_j(\xi) \leq 1$. Let $m_R(\xi) = \chi(R_j \xi)m(\xi)$. Then for all $\gamma_j \in \mathbb{N}^n$, the product and chain rules show that we have

$$|\partial_{\xi}^{\gamma_j} m_R(\xi)| \leq C_{\gamma_j} \hat{N}_j(\xi)^{-|\gamma_j|}.$$  

Now $m_R \to m$ in the sense of distributions as $R \to 0$, and hence $\mathcal{K}$ is the limit, in the sense of distributions, of the inverse Fourier transform of $m_R$. But it now follows from Proposition 15.4 in Appendix II that $|K(x)| \lesssim n_k(x_k) - \sum_{j=1}^n c(j,k)Q_j$, and this completes the proof. \(\blacksquare\)

7.3 Higher rank and weak-type estimates near zero

If $K$ is the smooth function on $\mathbb{R}^N \setminus \{0\}$ corresponding to a Calderón-Zygmund kernel $\mathcal{K}$, then $K$ satisfies the estimate $\left| \left\{ x \in \mathbb{R}^N : |K(x)| > \lambda \right\} \right| \lesssim \lambda^{-1}$. Moreover, there are Calderón-Zygmund kernels $\mathcal{K}$ such that $\left| \left\{ x \in \mathbb{R}^N : |K(x)| > \lambda \right\} \right| \gtrsim \lambda^{-1}$. In this section we show that the corresponding estimates for kernels $\mathcal{K} \in \mathcal{P}(E)$ associated with the decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_m}$ depend on the reduced rank of $E$. Recall from the discussion in Section 5.3 and Proposition 5.3 that if the reduced rank of $E$ is $m < n$ then there is an $m \times m$ matrix $E^p$ so that $\mathcal{P}_0(E)$ coincides with the space of distributions $\mathcal{P}_0(E^p)$ associated with a coarser decomposition $\mathbb{R}^N = \mathbb{R}^{A_1} \oplus \cdots \oplus \mathbb{R}^{A_m}$.

Lemma 7.6. Suppose that the reduced rank of $E$ is $m$.

(a) If $\mathcal{K} \in \mathcal{P}(E)$, then for $\lambda \geq 1$, $\left| \left\{ x \in \mathbb{R}^N : K(x) > \lambda \right\} \right| \lesssim \lambda^{-1} \log(\lambda)^{m-1}$.

(b) There exists $\mathcal{K} \in \mathcal{P}(E)$ so that $\left| \left\{ x \in \mathbb{R}^N : K(x) > \lambda \right\} \right| \gtrsim \lambda^{-1} \log(\lambda)^{m-1}$ for $\lambda \geq 1$.

If $m = 1$, we are dealing with a Calderón-Zygmund kernel and these facts are well-known, so we may assume $m > 1$.

Proof of Lemma 7.6, part (a). As indicated above, we can assume that $m = n$ by replacing $E$ by its reduced matrix and applying Proposition 5.3. Suppose that $\lambda \geq 1$. For $1 \leq k \leq n$ we have $\prod_{j=1}^n N_j(x)^{Q_j} \geq n_k(x_k) \sum_{l=1}^n c(k,l)Q_l$ and also $\prod_{j=1}^n N_j(x)^{Q_j} \geq \prod_{l=1}^n n_l(x_l)^{Q_l}$. Since $|K(x)| \leq \prod_{j=1}^n N_j(x)^{-Q_j}$, it follows that

$$\left\{ x \in \mathbb{R}^N : |K(x)| > \lambda \right\} \subset \left\{ x \in \mathbb{R}^N : \begin{cases} \prod_{l=1}^n n_l(x_l)^{Q_l} < \lambda^{-1} \quad \text{and} \\ n_k(x_k)^{Q_k} < \lambda^{-Q_k/\sum_{l=1}^n c(k,l)Q_k} \end{cases} \quad 1 \leq l \leq n. \right.$$  

$^\dag$Note that we only make an hypothesis about “pure” derivatives of $m$. We are not assuming that $m \in \mathcal{M}(E)$.  

\(\blacksquare\)
Note that, as in equation (7.6), \( \sum_{i=1}^{n} Q_i \left[ \sum_{k=1}^{n} e(k, t) Q_k \right]^{-1} < 1 \) since the rank of \( E \) is strictly greater than 1. Part (3) of the Lemma then follows from the following calculation. \( \square \)

**Proposition 7.7.** Let \( A_1, \ldots, A_n, \delta \in (0, \infty) \) and put \( A = \prod_{j=1}^{n} A_j \). Put

\[
E(A_1, \ldots, A_n, \delta) = \left\{ x \in \mathbb{R}^N : \sum_{j=1}^{n} a_j(x_j) Q_j < \delta \text{ and } n_j(x_j) Q_j < A_j \text{ for } 1 \leq j \leq n \right\}
\]

There is a constant \( c_n \) depending only on \( n \) so that

\[
\left| E(A_1, \ldots, A_n, \delta) \right| \geq c_n \left\{ \begin{array}{ll}
A & \text{if } A < \delta, \\
\delta \left[ 1 + (\log \left( \frac{A}{\delta} \right) )^{n-1} \right] & \text{if } A \geq \delta
\end{array} \right.
\]

**Proof.** We argue by induction on \( n \), with the case \( n = 1 \) following from Proposition 10.2 in Appendix II. Thus suppose the result is true for \( n - 1 \). We divide the region \( E(A_1, \ldots, A_n, \delta) \) into two parts; the part where \( n_n(x_n) Q_n < \delta[A_1 \cdots A_{n-1}]^{-1} \) is a product of \( n \) balls, and its volume is \( \delta \). For the region where \( n_n(x_n) Q_n \geq \delta[A_1 \cdots A_{n-1}]^{-1} \) we can use the induction hypothesis in the variables \( \{x_1, \ldots, x_{n-1}\} \). \( \square \)

**Proof of Lemma 7.6, part (1).** As before we assume that \( E \) is reduced, i.e., \( m = n \). Recall that \( \lambda \cdot x = (\lambda^{d_1} x_1, \ldots, \lambda^{d_k} x_N) \). Choose a closed interval \( J_k \subset (1, 2^{d_k}) \subset \mathbb{R} \) and let \( \theta_k \in C_0^\infty(\mathbb{R}) \) be an odd function such that \( \theta_k(t) \equiv 0 \) if \( t \geq 0 \), \( \theta_k(t) \equiv 0 \) if \( t \in (1, 2^{d_k}) \), and \( \theta_k(t) \equiv 1 \) if \( t \in J_k \). Then \( \int_{J_k} \theta_k(t) dt = 0 \) and if we put \( \theta_{k,m}(t) = \theta_k(2^{md_k}t) \), the functions \( \theta_{k,m_1} \) and \( \theta_{k,m_2} \) have disjoint supports if \( m_1 \neq m_2 \). Put \( \Theta(t) = \prod_{k=1}^{N} \theta_k(t) \).

The function \( \Theta \) has strong cancellation in the sense of Definition 5.8. It follows from Theorem 5.13 that \( K = \sum_{I \in \mathcal{E}(E)} [\Theta]_I \) converges in the sense of distributions to an element \( K \in \mathcal{E}(E) \). Note that the supports of the functions \( [\Theta]_I \) are disjoint. Let \( \Sigma \) denote the set where \( \Theta = 1 \), so that if \( 2^{-f} \cdot x \in \Sigma \) and \( \Sigma \geq 2^{-\sum_{j=1}^{m} i_j Q_j} > \lambda \) we have \( K(x) > \lambda \). Let \( \Sigma_I = \{ x \in \mathbb{R}^N : 2^{-f} \cdot x \in \Sigma \} \). Then \( |\Sigma_I| = 2^{-\sum_{j=1}^{m} i_j Q_j} |\Sigma| \). We have

\[
\left\{ x \in \mathbb{R}^N : \sum_{I \in \mathcal{E}(E)} \left( 2^{-f} \cdot x \in \Sigma \right) \right\} \subset \{ x \in \mathbb{R}^N : K(x) > \lambda \},
\]

so

\[
\left| \{ x \in \mathbb{R}^N : K(x) > \lambda \} \right| \geq \left| \left\{ x \in \mathbb{R}^N : \sum_{I \in \mathcal{E}(E)} \left( 2^{-f} \cdot x \in \Sigma \right) \right\} \right|
\]

\[
\geq \sum_{I \in \mathcal{E}(E)} |\Sigma_I| \geq \lambda^{-1} # \left( \mathcal{E}(E), \lambda \right)
\]

where \( \Gamma_\mathcal{E}(E, \lambda) \) is the set of \( n \)-tuples \( I = (i_1, \ldots, i_n) \in \mathcal{E}(E) \) such that \( \lambda < 2^{-\sum_{j=1}^{n} i_j Q_j} \leq C \lambda \) with \( C \) a large constant. The cone \( \Gamma(E) = \left\{ t = (t_1, \ldots, t_n) : e(j, k) t_k < t_j < 0 \right\} \) is open since \( E \) has rank \( n \), and the number of lattice points \( (i_1, \ldots, i_n) \) in this cone satisfying

\[
\log(\lambda) < \sum_{j=1}^{n} Q_j i_j < \log(\lambda) + 1
\]

is of the order of \( (\log(\lambda))^{n-1} \). This shows that \( \# \left( \Gamma_\mathcal{E}(E, \lambda) \right) \geq (\log(\lambda))^{n-1} \) which completes the proof of part (1). \( \square \)
8 Convolution operators on homogeneous nilpotent Lie groups

We now turn to the study of convolution operators \( f \rightarrow f \ast K \) with \( K \in \mathcal{P}_0(E) \) and the convolution on a homogeneous nilpotent Lie group \( G \). The underlying manifold of \( G \) is \( \mathbb{R}^N \) for some integer \( N \geq 1 \), and there is a one-parameter group of automorphic dilations, i.e., of automorphisms \( \delta_r : G \rightarrow G \) which, in appropriate coordinates on \( G \), take the form
\[
\delta_r(x_1, \ldots, x_N) = (r^{d_1}x_1, \ldots, r^{d_N}x_N),
\]
with \( d_i > 0 \) for every \( i \). The ordering of the coordinates and the parametrization by \( r \) can be chosen so that
\[
1 \leq d_1 \leq d_2 \leq \cdots \leq d_N.
\]
In these coordinates, the product on \( G \) has the following form. For \( x = (x_1, \ldots, x_N) \), \( y = (y_1, \ldots, y_N) \),
\[
x y = (x_1 + y_1, x_2 + y_2 + M_2(x, y), \ldots, x_N + y_N + M_N(x, y)),
\]
where \( M_2, \ldots, M_N \) are polynomials which vanish for \( x \) or \( y \) equal to 0 and are such that
\[
M_i(\delta_r x, \delta_r y) = \delta_r M_i(x, y).
\]
In particular, each \( M_i \) only depends on the variables \( x_m, y_m \) for which \( d_m < d_i \). Moreover, the Haar measure for \( G \) is Lebesgue measure on \( \mathbb{R}^N \).

If \( f, g \in L^1(G) \), the convolution \( f \ast g \) is defined by
\[
f \ast g(x) = \int_{G \simeq \mathbb{R}^N} f(xy^{-1})g(y) \, dy = \int_{G \simeq \mathbb{R}^N} f(y)g(y^{-1}x) \, dy.
\]

8.1 Convolution of scaled bump functions: compatibility of dilations and convolution

If \( f \in L^1(G) \) and \( \lambda = (\lambda_1, \ldots, \lambda_N) \) with each \( \lambda_j > 0 \), consider the \( N \)-parameter family of dilations of \( f \) by \( \lambda \) given by
\[
f_{\lambda}(x_1, \ldots, x_N) = \left[ \prod_{j=1}^{N} \lambda_j^{-d_j} \right] f(\lambda_1^{-d_1}x_1, \ldots, \lambda_N^{-d_N}x_N),
\]
If \( \varphi, \psi \) are normalized bump functions supported in the unit ball and if \( \lambda = (\lambda_1, \ldots, \lambda_N) \) and \( \mu = (\mu_1, \ldots, \mu_N) \), it is easy to check that for Euclidean convolution \( \varphi \ast \psi = \theta \), where \( \varphi \in C_0^\infty(\mathbb{R}^N) \) is normalized relative to \( \varphi \) and \( \psi \), and \( \nu_j = \max\{\lambda_j, \mu_j\} = \lambda_j \vee \mu_j \). This fact is very useful in studying the convolution of two sums of dilates of bump functions. However, on a more general nilpotent Lie group, this need not be true unless we suitably restrict the \( N \)-tuples \( \lambda = (\lambda_1, \ldots, \lambda_N) \) and \( \mu = (\mu_1, \ldots, \mu_N) \). Let
\[
E_N = \left\{ \lambda = (\lambda_1, \ldots, \lambda_N) \in (0, \infty)^N : \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_N \right\}.
\]
We say that a mapping \( (x_1, \ldots, x_N) \rightarrow (\lambda_1^{-d_1}x_1, \ldots, \lambda_N^{-d_N}x_N) \) is compatible with the group structure of \( G \) if \( \lambda \in E_N \). The significance of this notion comes from the following result, which is Lemma 6.17 in [NRSW12].
Lemma 8.1. Let $\varphi, \psi \in C_0^\infty(G)$ be supported in $\mathbb{B}(1)$. If $\lambda, \mu \in E_N$ there exists $\theta \in C_0^\infty(G)$ so that $\varphi \lambda \ast \psi \mu = \theta$, where $\nu_j = \lambda_j \lor \mu_j = \max\{\lambda_j, \mu_j\}$. Moreover, $\theta$ is normalized relative to $\varphi$ and $\psi$: there are constants $\rho_0 \geq 1$ and $C_m > 0$ independent of $\varphi$ and $\psi$ so that $\theta$ is supported in $\mathbb{B}(\rho_0)$ and $\|\partial^\gamma \theta\|_\infty \leq C_m \sup_{|\gamma| \leq m} \|\partial^\gamma \varphi\|_\infty \sup_{|\gamma| \leq m} \|\partial^\gamma \psi\|_\infty$.

It will be useful for our purposes to have a formulation of Lemma 8.1 for dilations with fewer parameters and with the $N$ variables split into $n$ blocks according to a decomposition $G \cong \mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$. For reasons of compatibility with the group structure, we now require that $C_1, \ldots, C_n \subset \{1, \ldots, N\}$ be sets of consecutive integers, indexed according to the natural ordering:

$$C_1 = \{1, \ldots, i_1\}, \quad C_2 = \{i_1 + 1, \ldots, i_2\}, \quad \ldots \quad C_n = \{i_{n-1} + 1, \ldots, N\}.$$  \hfill (8.7)

This implies that each $G_j \cong \mathbb{R}^{C_j} \oplus \cdots \oplus \mathbb{R}^{C_n}$ is a subgroup of $G$. Formula (8.3) remains true if the individual variables $x_l, y_l \in \mathbb{R}^{C_j}$ are replaced by the blocks of variables $x_j, y_j \in \mathbb{R}^{C_j}$ and the scalar-valued functions $M_j$ by the $\mathbb{R}^{C_j}$-valued functions $M_j = (M_{j_1+1}, \ldots, M_{i_j})$. Notice that the functions $M_j$ still satisfy (8.4). \footnote{In what follows below, after choosing marked partitions, we may have situations where we no longer have sequences of consecutive integers. However this is all right if we can refine to a situation of consecutive integers.}

Let $E = \{e(j, k)\}$ be an $n \times n$ matrix satisfying (2.10). Associated to $E$ is the cone of lattice points

$$\Gamma_Z(E) = \left\{ I = (i_1, \ldots, i_n) \in \mathbb{Z}^n : e(j, k)i_k \leq i_j < 0, \ 1 \leq j, k \leq n \right\}$$

and we consider dilations

$$[f](I) = 2^{-\sum_{j=1}^n i_j} f(2^{-i_1} \cdot x_1, \ldots, 2^{-i_n} \cdot x_n).$$

Note that $(2^{i_1}, \ldots, 2^{i_n})$ is an $n$-tuple while elements of $E_N$ defined in equation (8.4) are $N$-tuples. However $[f](I) = f(\lambda(I))$ where $\lambda(I)$ is obtained from $I$ by setting $\lambda_l = 2^{i_l}$ if $l \in C_k$; that is

$$\lambda(I) = \left(2^{i_1}, \ldots, 2^{i_1}, 2^{i_2}, \ldots, 2^{i_2}, \ldots, 2^{i_n}, \ldots, 2^{i_n}\right).$$ \hfill (8.8)

We want to impose conditions on the matrix $E$, in addition to the basic hypothesis (2.10), which guarantees that if $I \in \Gamma_Z(E)$, then $\lambda(I) \in E_N$.

**Definition 8.2.** An $n \times n$ matrix $E = \{e(j, k)\}$ is doubly monotone if each row is weakly increasing from left to right, and each column is weakly decreasing from top to bottom; i.e.

$$e(j, k) \leq e(j, k + 1) \quad \text{for } 1 \leq j \leq n \text{ and } 1 \leq k < n,$$

$$e(j, k) \geq e(j + 1, k) \quad \text{for } 1 \leq j < n \text{ and } 1 \leq k \leq n.$$ 

**Proposition 8.3.** Let $E = \{e(j, k)\}$ be an $n \times n$ matrix satisfying the basic hypothesis (2.10).

(a) The matrix $E$ is doubly monotone if and only if $e(j + 1, j) \leq 1$ for $1 \leq j \leq n - 1$.

(b) If the matrix $E$ is doubly monotone and if $I \in \Gamma(E)$ then $\lambda(I) \in E_N$. 

Proof. If $E$ is doubly monotone and each row is weakly increasing, then since $e(j+1,j+1) = 1$ we certainly have $e(j+1,j) \leq 1$. Conversely, suppose that $e(k+1,k) \leq 1$ for $1 \leq k \leq n-1$. Then by (2.10) we have
\[
e(j,k) \leq e(j,k+1)e(k+1,k) \leq e(j,k+1),
\]
\[
e(j+1,k) \leq e(j+1,j)e(j,k) \leq e(j,k),
\]
so $E$ is doubly monotone.

Next if $E$ is doubly monotone and $I = (i_1, \ldots, i_n) \in \Gamma(E)$, it follows from the definition of $\lambda(I)$ in equation (8.8) that we only need to show that $i_j \leq i_{j+1}$ for $1 \leq j \leq n-1$. However, since $e(j+1,j) \leq 1$ and $i_j < 0$, we have $i_j \leq e(j+1,j)i_j \leq i_{j+1}$ since $I \in \Gamma(E)$. □

Corollary 8.4. Suppose $E$ is doubly monotone, and let $I = (i_1, \ldots, i_n), J = (j_1, \ldots, j_n) \in \Gamma(E)$. If $\varphi, \psi \in C_{\infty}^\infty(\mathbb{R}^n)$ are supported in the unit ball, then $[\varphi]_I * [\psi]_J = [\theta]_K$ where $\theta \in C_{\infty}^\infty(\mathbb{R}^n)$ is normalized relative to $\varphi$ and $\psi$, and $K = (k_1, \ldots, k_n) \in \Gamma(E)$ with $k_m = \max\{i_m, j_m\}$ for $1 \leq m \leq n$.

Recall that $S \subseteq S'(E)$ means that $\tilde{E}_S \cap B(1)^c \neq \emptyset$. If $S = ((I_1, k_1); \ldots; (I_s, k_s)) \in S'(E)$, the $s \times s$ matrix $E_S = \{e_S(r,p)\}$ was defined in Lemma 6.2. We observe that if we order the sets $\{I_1, \ldots, I_s\}$ so that $k_1 \leq k_2 \leq \cdots \leq k_s$ and if $E$ is doubly monotone, then the same is true of the matrix $E_S$.

Lemma 8.5. Let $S = ((I_1, k_1); \ldots; (I_s, k_s)) \in S'(E)$ with $k_1 < k_2 < \cdots < k_s$, and let $E_S = \{e_S(r,p)\}$ be the $s \times s$ matrix whose existence is established in Lemma 6.2. If the matrix $E$ is doubly monotone, then the matrix $E_S$ is doubly monotone.

Proof. From the construction of $E_S$ we have
\[
e_S(r+1, r) \leq \tau_S(r+1, r) = \min_{j \in I_r} \frac{e(k_{r+1}, j)}{e(k_r, j)} \leq e(k_{r+1}, k_r).
\]
If $\{e(j,k)\}$ is doubly monotone, $e(k_{r+1}, k_r) \leq 1$ because of our ordering of the sets $\{I_1, \ldots, I_s\}$, and it follows that $e_S(r+1, r) \leq 1$. Since $E_S$ satisfies the basic hypothesis (2.10), it then follows from part (3) of Proposition 3.3 that it is also doubly monotone. □

Continue to fix $S = ((I_1, k_1); \ldots; (I_s, k_s)) \in S'(E)$ with $k_1 < k_2 < \cdots < k_s$. In Definition 8.3.12 we introduced the family of dilations
\[
2^{-j_r}t = (2^{-j_r}t_{I_1}, \ldots, 2^{-j_r}t_{I_s}, \ldots, 2^{-j_r}t_{I_s}),
\]
where
\[
2^{-j_r}t_{I_r} = \left\{2^{-j_r}e(k_r,j) \cdot t_j : j \in I_r\right\} = \left\{2^{-j_r}\tau_S(j,k_r) \cdot t_j : j \in I_r\right\}.
\]
Recall that $\Gamma(E_S) = \{(j_1, \ldots, j_s) \in \mathbb{Z}^s : e_S(p,r)j_r \leq j_p < 0\}$.

Lemma 8.6. Suppose that $E$ is doubly monotone. If $J = (j_1, \ldots, j_s) \in \Gamma(E_S)$ then the mapping $t \rightarrow 2^{-j_r}t$ is compatible with the group structure.

Proof. Let $l, m \in \{1, \ldots, n\}$ with $l \leq m$ and $l \in I_r$, $m \in I_p$. According to Proposition 8.3.3 it suffices to show that $j_re(k_r,l)^{-1} \leq j_pe(k_p,m)^{-1}$. If $J = (j_1, \ldots, j_s) \in \Gamma(E_S)$ then $e_S(p,r)j_r \leq j_p$. But then since $j_r < 0$,
\[
\frac{j_p}{j_r} \leq e_S(p,r) \leq \tau_S(k_p, k_r) = \min_{j \in I_r} \frac{e(k_p, j)}{e(k_r, j)} \leq \frac{e(k_p, l)}{e(k_r, l)} \leq \frac{e(k_p, m)e(m, l)}{e(k_r, l)} \leq \frac{e(k_p, m)}{e(k_r, l)}
\]
where the last inequality follows since $l \leq m$ and the matrix $E$ is (weakly) increasing across each row. This means that $j_re(k_r,l)^{-1} \leq j_pe(k_p,m)^{-1}$, completing the proof. □
8.2 Automorphic flag kernels and $L^p$-boundedness of convolution operators

In this section we discuss $L^p$-boundedness of operators

$$T_K f = f * K,$$

given by convolution (relative to some homogeneous group structure on $\mathbb{R}^N$) with a kernel $K \in P(E)$. The matrix $E$ is assumed to satisfy the basic hypotheses (2.10).

The reader should be aware that there are two possible interpretations of the symbol $f * K$, depending on whether the underlying group is the standard abelian $\mathbb{R}^n$ or some non-abelian group $G$. Whenever clarification is required, we will write $T_K^E$ to specify the group. For ordinary convolution on $\mathbb{R}^N$, it can be easily verified that a kernel in $P(E)$ is a product kernel, as defined in Section 2 of NRS01. In fact, the differential inequalities of a product kernel follow from the inequalities $N_j(x) \geq n_j(x_j)$, $j = 1, \ldots, n$, and the cancellation conditions are the same as in Definition 2.2 (b). By NRS01, we have the following theorem.

**Theorem 8.7.** Let $\delta_\lambda$ be any family of dilations on $\mathbb{R}^N$ and $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$ be any decomposition of $\mathbb{R}^N$ into homogeneous subspace. Suppose that the matrix $E$ satisfies the basic hypotheses. Then, for every $K \in P(E)$, the operator $T_K$ is bounded on $L^p$ for $1 < p < \infty$.

Considering now a general homogeneous group law as in (8.3), we must be more specific on all the ingredients needed to define a class $P(E)$.

We fix a decomposition $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$ where the $C_j$ are as in (8.7). In the notation of NRS01, the subgroups $G_j = \mathbb{R}^{C_j} \oplus \cdots \oplus \mathbb{R}^{C_n}$ form the standard flag

$$\mathcal{F} : \quad (0) \subset G_n \subset G_{n-1} \subset \cdots \subset G_2 \subset G_1 = G.$$

On each $\mathbb{R}^{C_j}$ we also fix a homogeneous norm $n_j$ for the automorphic dilations $\delta_\lambda$ in (8.1). A distribution $K$ is an automorphic flag kernel on the standard flag if it satisfies the differential inequalities

$$|\partial^\gamma K(x)| \leq C_\gamma \prod_{j=1}^n [n_1(x_1) + \cdots + n_j(x_j)]^{-Q_j - |\gamma|},$$

and the cancellation conditions in Definition 2.2 (b).

The differential inequalities for the automorphic flag multiplier $m = \tilde{K}$ are

$$|\partial^\gamma m(\xi)| \leq C_\gamma \prod_{j=1}^n [n_j(\xi_j) + \cdots + n_n(\xi_n)]^{-|\gamma|}.$$

(See Definition 2.3.2 in NRS01 for details.)

We show that, if $E$ is doubly monotone, a distribution $K \in P_0(E)$ is always an automorphic flag kernel for a standard flag.

**Proposition 8.8.** If $K \in P_0(E)$ where the class of distributions is defined by a doubly monotone matrix, then $K$ is an automorphic flag kernel on the standard flag.

**Proof.** Let $K \in P_0(E)$ where the class of distributions is defined by a doubly monotone matrix $E = \{e(j, k)\}$ and let $m = \tilde{K}$. Note that for $\xi \in \mathbb{B}(1)^c$ we have

$$\tilde{N}_j(\xi) = \sum_{k=1}^n n_k(\xi_k)^{1/e(k,j)} \geq \sum_{k=j}^n n_k(\xi_k)^{1/e(k,j)} \geq \sum_{k=j}^n n_k(\xi_k).$$
since for \( k \geq j \) we have \( e(k,j) \leq 1 \). Thus if \( \gamma \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \) we have

\[
|\partial^\gamma m(\xi)| \leq C_\gamma \prod_{j=1}^n (1 + \hat{N}_j(\xi))^{-|\gamma_j|} \leq C_\gamma \prod_{j=1}^n [n_j(\xi_j) + \cdots + n_n(\xi_n)]^{-|\gamma_j|}.
\]

\[\square\]

**Theorem 8.9.** Let \( G \) be a homogeneous nilpotent Lie group, endowed with automorphic dilations \( \delta_\lambda, G \cong \mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}, \) the \( C_j \) being as in (8.7). If \( \mathbf{E} \) is a doubly monotone matrix satisfying the basic hypothesis, and if \( \mathcal{K} \in \mathcal{P}_0(\mathbf{E}) \), then the operator \( T_K[\varphi] = \varphi * \mathcal{K} \), defined initially for \( \varphi \in \mathcal{S}(\mathbb{R}^N) \), extends uniquely to a bounded operator on \( L^p(G) \) for \( 1 < p < \infty \). If the rank of \( \mathbf{E} \) is greater than one, the same holds for \( \mathcal{K} \in \mathcal{P}(\mathbf{E}) \).

**Proof.** If \( \mathcal{K} \in \mathcal{P}_0(\mathbf{E}) \), it follows from Proposition 8.8 that \( \mathcal{K} \) is an automorphic flag kernel on the standard flag. The result now follows from Theorem 8.14 in [NRSW12]. Assume now that the rank of \( \mathbf{E} \) is greater than 1 and \( \mathcal{K} \in \mathcal{P}(\mathbf{E}) \). By Corollary 7.4, we can write \( \mathcal{K} = \mathcal{K}_0 + \mathcal{K}_\infty \) where \( \mathcal{K}_0 \in \mathcal{P}_0(\mathbf{E}) \) and \( \mathcal{K}_\infty \in L^1(\mathbb{R}^N) \). The operator \( f \to f * \mathcal{K}_\infty \) is bounded on \( L^p(G) \) for \( 1 \leq p \leq \infty \). \[\square\]

## 9 Composition of operators

If \( \mathcal{K} \in \mathcal{P}_0(\mathbf{E}) \) let \( T_K[f] = f * \mathcal{K} \) be the corresponding left-invariant convolution operator on the homogeneous nilpotent Lie group \( G \). \( T_K \) is initially defined on the Schwartz space \( \mathcal{S}(\mathbb{R}^N) \). We are interested in the composition of two operators \( T_K, T_L \) with \( \mathcal{K}, L \in \mathcal{P}_0(\mathbf{E}) \). Formally \( T_L \circ T_K[f] = T_K[f] * L = (f * \mathcal{K}) * L = f * (\mathcal{K} * L) = T_{K * L} \).

To give a concrete meaning to these equalities is easy if convolution is relative to the (abelian) additive structure of \( \mathbb{R}^N \), because we can refer to the Fourier multipliers \( m = \hat{\mathcal{K}}, m' = \hat{L} \). For \( f \in \mathcal{S}(\mathbb{R}^N), T_L \circ T_K[f] = \mathcal{F}^{-1}(m m' \hat{f}), \) where \( \mathcal{F} \) denotes the Fourier transform, and the convolution kernel of \( T_L \circ T_K \) is \( \mathcal{F}^{-1}(m m') = \mathcal{K} * L \). In fact, since \( \mathcal{M}_\infty(\mathbf{E}) \) is closed under pointwise product, we can conclude as follows.

**Theorem 9.1.** Let \( \mathbf{E} \) be a matrix satisfying the basic hypotheses and let \( \mathcal{K}, L \in \mathcal{P}_0(\mathbf{E}) \). With respect to ordinary convolution on \( \mathbb{R}^N \), then \( \mathcal{K} * L \in \mathcal{P}_0(\mathbf{E}) \).

Suppose now that \( \mathbb{R}^N \cong G \) is a noncommutative homogeneous group. It is still easy to verify that \( \mathcal{K} * L \) is a well-defined distribution. In fact,

\[
\mathcal{K} = \mathcal{K}_0 + \varphi_0, \quad L = L_0 + \psi_0,
\]

where \( \mathcal{K}_0, L_0 \) have compact support and \( \varphi_0, \psi_0 \) are Schwartz functions. Hence

\[
\mathcal{K} * L = \mathcal{K}_0 * L_0 + \mathcal{K}_0 * \psi_0 + \varphi_0 * L_0 + \varphi_0 * \psi_0,
\]

where each summand is well defined. However, it is not guaranteed that the convolution \( \mathcal{K} * L \) is in the same class.

The main result of this section is that, under the assumptions introduced in Section 8, \( \mathcal{K} * L \in \mathcal{P}_0(\mathbf{E}) \), and so \( \mathcal{P}_0(\mathbf{E}) \) is an algebra under convolution on the group \( G \). We recall the assumptions:

(i) the underlying dilations on \( \mathbb{R}^N \) are automorphisms of \( G \);

(ii) the subspaces \( \mathbb{R}^{C_j} \) are as in (8.7);

(iii) the matrix \( \mathbf{E} \) is doubly monotone.
Theorem 9.2. Suppose that conditions (i)-(iii) above are satisfied. If \( K, L \in \mathcal{P}_0(E) \) then \( K \ast L \in \mathcal{P}_0(E) \).

The following outline provides an informal road map for the long proof which begins in Section 9.1. Let \( K, L \in \mathcal{P}_0(E) \).

(A) According to Theorem 6.14,

\[ K = \varphi_0 + \sum_{S \in S'(E)} K_S \quad \text{and} \quad L = \psi_0 + \sum_{T \in S'(E)} L_T \]

where \( \varphi_0, \psi_0 \in S(\mathbb{R}^N) \) and

\[ K_S = \sum_{I \in \Gamma_z(E_S)} [\varphi_S^I]_I \quad \text{and} \quad L_T = \sum_{J \in \Gamma_z(E_T)} [\psi_T^J]_J. \]

Here \( \{\varphi_S^I\} \) and \( \{\psi_T^J\} \) are uniformly bounded families of functions in \( C_0^\infty(\mathbb{R}^N) \), and

\[
\begin{align*}
\Gamma_z(E_S) &= \left\{ i = (i_1, \ldots, i_s) \in \mathbb{Z}^s : \tau_S(k_p, k_r)i_r \leq i_p < 0, \quad 1 \leq r, p \leq s \right\}, \\
\Gamma_z(E_T) &= \left\{ j = (j_1, \ldots, j_q) \in \mathbb{Z}^q : \tau_T(\ell_b, \ell_a)j_a \leq j_b < 0, \quad 1 \leq a, b \leq q \right\}.
\end{align*}
\]

Then the problem of studying the composition \( T_L \circ T_K \) reduces essentially to the study of the finite number of compositions \( \{T_{L_T} \circ T_{K_S}\} \) for \( S, T \in S'(E) \). This reduction is discussed in Section 9.1.

(B) We fix marked partitions \( S = ((I_1, k_1); \ldots; (I_s, k_s)) \) and \( T = ((J_1, \ell_1); \ldots; (J_q, \ell_q)) \) in \( S'(E) \), and we simplify notation by writing \( \varphi_S^I = \varphi^I \) and \( \psi_T^J = \psi^J \). Thus we need to study \( T_{L_T} \circ T_{K_S} \) where

\[
K_S = \sum_{I \in \Gamma_z(E_S)} [\varphi^I]_I = \lim_{F_1 \nearrow \Gamma_z(E_S)} \sum_{I \in F_1} [\varphi^I]_I = \lim_{F \nearrow \Gamma_z(E_S)} K_{F_1, S},
\]

\[
L_T = \sum_{J \in \Gamma_z(E_T)} [\psi^J]_J = \lim_{F_2 \nearrow \Gamma_z(E_T)} \sum_{J \in F_2} [\psi^J]_J = \lim_{F_2 \nearrow \Gamma_z(E_T)} L_{F_2, T}.
\]

Here \( F_1, F_2 \) are finite sets of indices, and the limits exist in the sense of distributions.

(C) Recall from Corollary 6.1 that, since \( S, T \in S'(E) \), \( \Gamma_z(E_S) \) and \( \Gamma_z(E_T) \) have nonempty interiors. By Lemma 6.2 in Section 6.1 there are new matrices \( E_S = \{e_S(p, r)\} \) and \( E_T = \{e_T(b, a)\} \) which satisfy the basic hypothesis such that \( e_S(p, r) \leq \tau_S(k_p, k_r), e_T(b, a) \leq \tau_T(\ell_b, \ell_a) \).

If \( F_1 \subset \Gamma_z(E_S) \) and \( F_2 \subset \Gamma_z(E_T) \) are any two finite sets of indices then \( T_{L_{F_2, T}} \circ T_{K_{F_1, S}} = T_{H_{F_1, F_2, S, T}} \) where

\[
H_{F_1, F_2, S, T} = K_{F_1, S} \ast L_{F_2, T} = \sum_{I \in F_1} \sum_{J \in F_2} [\varphi^I]_I \ast [\psi^J]_J.
\]

In Section 9.2 we see that it suffices to show that \( \lim_{F_1 \nearrow \Gamma_z(E_S)} \lim_{F_2 \nearrow \Gamma_z(E_T)} H_{F_1, F_2, S, T} \) exists in the sense of distributions and belongs to \( \mathcal{P}_0(E) \). More generally, for arbitrary finite subsets \( F \subset \Gamma_z(E_S) \times \Gamma_z(E_T) \), we show that

\[
H_{F, S, T} = \sum_{(I, J) \in F} [\varphi^I]_I \ast [\psi^J]_J \in \mathcal{P}_0(E) \quad \text{with estimates independent of the set } F;
\]
(b) In the sense of distributions, \( \lim_{F \not \in \Gamma_2(E_S) \times \Gamma_2(E_T)} H_{F,S,T} \) exists and belongs to \( P_0(E) \).

(D) In Section 9.3 we summarize the support, decay, and cancellation properties of the convolutions \([\varphi^I]_I \ast [\psi^J]_J\) that are needed in our analysis.

(E) In order to study \( H_{F,S,T} \) we write

\[
\Gamma_2(E_S) \times \Gamma_2(E_T) = \bigcup_{W \in W(S,T)} \Gamma_W(S,T)
\]

where the index set \( W(S,T) \) is finite, and the sets \( \{ \Gamma_W(S,T) \subset \Gamma_2(E_S) \times \Gamma_2(E_T) \} \) are disjoint. This partition of \( \Gamma_2(E_S) \times \Gamma_2(E_T) \) is somewhat complicated, but it has the property that if \((I, J) = ((i_1, \ldots, i_s), (j_1, \ldots, j_q)) \in \Gamma_W(S,T)\), then for \( 1 \leq r \leq s \) and \( 1 \leq a \leq q \), if \( I_r \cap J_a \neq \emptyset \) the ratio \( i_r/j_a \) is suitably restricted. Having made the partition, it then suffices to show that for every \( W \in W(S,T) \), \( \lim_{F \not \in \Gamma_W(S,T)} H_{F,S,T} \) converges in the sense of distributions and belongs to \( P_0(E) \). This partition is described in Section 9.4.

(F) Now fix \( W \in W(S,T) \), and let \( F \subset \Gamma_W(S,T) \) be a finite set. We study of \( H_{F,S,T} = \sum_{(I, J) \in F} [\varphi^I]_I \ast [\psi^J]_J \).

(a) For each convolution \([\varphi^I]_I \ast [\psi^J]_J\) there is a normalized bump function \( \theta^I,J \) and a set of dilations \( M(I, J) \) so that \([\varphi^I]_I \ast [\psi^J]_J = [\theta^I,J]_M(I,J) \).

(b) There are \( s \) parameters \((i_1, \ldots, i_s)\) in \( I \) and \( q \) parameters \((j_1, \ldots, j_q)\) in \( J \), and the function \([\theta^I,J]_M(I,J)\) is dilated by some collection of these dilations. However not all of these need appear in \( M(I, J) \). We will say that a parameter \( i_r \) or \( j_a \) from \( I \cup J \) is ‘fixed’ if it appears among the parameters in \( M(I, J) \), and ‘free’ if it does not appear. These notions are defined precisely in Section 9.5.

(c) Let \( I^*_a \) be the indices in \( I_r \) which are fixed, and let \( J^*_a \) be the indices in \( J_a \) which are fixed. Some of these sets may be empty (if \( I_r \) or \( J_a \) consists entirely of free indices), and we suppose there are \( \alpha \leq s \) non-empty sets \( I^*_1, \ldots, I^*_\alpha \) and \( \beta \leq q \) non-empty set \( J^*_{a_1}, \ldots, J^*_{a_\beta} \).

(d) The sets \( I^*_1, \ldots, I^*_\alpha, J^*_{a_1}, \ldots, J^*_{a_\beta} \) are disjoint and their union is \( \{1, \ldots, \beta\} \). This leads to a new decomposition

\[
\mathbb{R}^N = \bigoplus_{j=1}^{\alpha} \mathbb{R}^{I^*_j} \oplus \bigoplus_{k=1}^{\beta} \mathbb{R}^{J^*_{a_k}}.
\]

This decomposition is discussed in Section 9.6.

(G) Associated to this last decomposition, we show in Section 9.7 that there is an \((\alpha + \beta) \times (\alpha + \beta)\) matrix \( E(S,T,W) \) with associated family of norms \( N^# \), \( N^#_\alpha \), \( N^#_{\alpha+\beta} \) on \( \mathbb{R}^N \). In Section 9.8 we show that the corresponding family of distributions \( P_0(E(S,T,W)) \) is contained in the original family \( \mathcal{P}(E) \). Theorem 9.2 then follows if we can show that

\[
\sum_{(I, J) \in \Gamma_W(S,T)} [\varphi^I]_I \ast [\psi^J]_J \in P_0(E(S,T,W)).
\]

This is the heart of the matter, and we argue as follows.
a) Each convolution \([\varphi^I]_I \ast [\psi^J]_J = [\theta^{I,J}]_{M(I,J)}\) where \(\theta^{I,J} \in C_0^\infty(\mathbb{R}^N)\) is normalized relative to \(\varphi^I\) and \(\psi^J\), and where \(M(I,J)\) is an \(\alpha + \beta\)-tuple of integers coming from \(\alpha + \beta\) of the integers in \(I = (i_1, \ldots, i_q)\) and \(J = (j_1, \ldots, j_q)\). Since each function \(\varphi^I\) and \(\psi^J\) has strong cancellation, the function \(\theta^{I,J}\) will have appropriate decay in the free variables and weak cancellation in the fixed variables. (See Lemma \[\text{9.3}\] below.)

b) We let \(\mathcal{R}(S, T, W)\) denote the (infinite) set of \(\alpha + \beta\)-tuples \(M = M(I, J)\) that arise in this way as the dilation for some convolution \([\varphi^I]_I \ast [\psi^J]_J\). For each \(M \in \mathcal{R}(S, T, W)\), we let \(F(M)\) be the set of pairs \((I, J) \in \Gamma_W(S, T)\) such that \(M(I, J) = M\). It follows that

\[
\sum_{(I,J) \in \Gamma_W(S,T)} [\varphi^I]_I \ast [\psi^J]_J = \sum_{M \in \mathcal{R}(S, T, W)} \left( \sum_{(I,J) \in F(M)} \theta^{I,J} \right)_M.
\]

c) Because of the decay properties of \(\theta^{I,J}\), for each \(M \in \mathcal{R}(S, T, W)\), the inner infinite sum \(\sum_{(I,J) \in F(M)} \theta^{I,J}\) converges to a function \(\Theta^M \in C_0^\infty\), and the family of functions \(\{\Theta^M\}\) is uniformly bounded and has weak cancellation relative to \(M\). Thus

\[
\sum_{(I,J) \in \Gamma_W(S,T)} [\varphi^I]_I \ast [\psi^J]_J = \sum_{M \in \mathcal{R}(S, T, W)} [\Theta^M]_M.
\]

Theorem \[\text{5.13}\] then shows that \(\sum_{(I,J) \in \Gamma_W(S,T)}[\varphi^I]_I \ast [\psi^J]_J \in \mathcal{P}_0(\mathbb{E}(S, T, W))\). The details are provided in Sections \[9.9\] and \[9.10\].

9.1 A preliminary decomposition

Let \(K, L \in \mathcal{P}_0(\mathbb{E})\). According to Corollary \[6.10\], we can write

\[
K = \varphi_0 + \sum_{S \in S'(\mathbb{E})} K_S = \varphi_0 + \sum_{S \in S'(\mathbb{E})} \sum_{I \in \Gamma_2(\mathbb{E}_S)} [\varphi^I_S]_I,
\]

\[
L = \psi_0 + \sum_{T \in S'(\mathbb{E})} L_T = \psi_0 + \sum_{T \in S'(\mathbb{E})} \sum_{J \in \Gamma_2(\mathbb{E}_T)} [\psi^J_T]_J,
\]

where \(\varphi_0, \psi_0 \in S(\mathbb{R}^N)\) and \(\{\varphi^I_S\}\) and \(\{\psi^J_T\}\) are uniformly bounded families of functions in \(C_0^\infty(\mathbb{R}^N)\) supported in \(B(1)\). Each \(\varphi^I_S\) has cancellation in the variables \(\{x_{k_1}, \ldots, x_{k_q}\}\) and each \(\psi^J_T\) has cancellation in the variables \(\{x_{l_1}, \ldots, x_{l_q}\}\). We have

\[
T_K \circ T_L = \varphi_0 \ast L + K \ast \psi_0 + \sum_{S,T \in S'(\mathbb{E})} T_{K_S} \circ T_{L_T}.
\]

Since the first two terms on the right-hand side are Schwartz functions, to prove Theorem \[9.2\] it suffices to show that each composition \(T_{K_S} \circ T_{L_T}\) is a convolution operator \(T_{\mathcal{H}_S, T}\) where \(\mathcal{H}_S, T \in \mathcal{P}_0(\mathbb{E})\).

9.2 Reduction to the case of finite sets

It follows from Corollary \[6.10\] that

\[
K_S(x) = \lim_{F \supset \Gamma_2(\mathbb{E}_S)} \sum_{I \in F} [\varphi^I_S]_I(x), \quad L_T(x) = \lim_{G \supset \Gamma_2(\mathbb{E}_T)} \sum_{J \in G} [\psi^J_T]_J(x)
\]

where the limits are taken in the sense of distributions, \(F\) ranges over finite subsets of \(\Gamma_2(\mathbb{E}_S)\), and \(G\) ranges over finite subsets of \(\Gamma_2(\mathbb{E}_T)\). It follows that

\[
T_{K_S} \circ T_{L_T}[f] = \lim_{F \supset \Gamma_2(\mathbb{E}_S)} \lim_{G \supset \Gamma_2(\mathbb{E}_T)} \left[ f \ast \sum_{I \in F} \sum_{J \in G} [\varphi^I_S]_I \ast [\psi^J_T]_J \right].
\]
Thus it will suffice to show that \( \lim_{F \to F_0, T \to T_0} \mathcal{H}_{F_1, F_2} = \sum_{I \in F_1, J \in F_2} [\varphi^l_S]_I \ast [\psi^l_T]_J \in \mathcal{P}_0(E) \) where the limits are taken in the sense of distributions. To do this, we will show that for any finite sets \( F_1 \subset \Gamma_Z(E_S) \) and \( F_2 \subset \Gamma_Z(E_T) \),

\[
\mathcal{H}_{F_1, F_2} = \sum_{I \in F_1} \sum_{J \in F_2} [\varphi^l_S]_I \ast [\psi^l_T]_J \in \mathcal{P}_0(E)
\]

with estimates that are independent of the choice of the finite subsets \( F \) and \( G \), and

\[
\mathcal{H}_{S, T} = \lim_{F_1 \to \Gamma_Z(E_S), F_2 \to \Gamma_Z(E_T)} \mathcal{H}_{F_1, F_2} \in \mathcal{P}_0(E)
\]

Thus to prove Theorem 9.2, it will suffice establish the following result.

**Lemma 9.3.** For each \( S, T \in S'(E) \) there exists \( \mathcal{H}_{S, T} \in \mathcal{P}_0(E) \) so that

\[
K_S \ast L_T = \sum_{(I, J) \in \Gamma_Z(E_S) \times \Gamma_Z(E_T)} [\varphi^l_S]_I \ast [\psi^l_T]_J = \mathcal{H}_{S, T}
\]

where the series converges in the sense of distributions as the limit of sums over finite subsets of \( \Gamma_Z(E_S) \times \Gamma_Z(E_T) \).

### 9.3 Properties of the convolution \([\varphi^l_S]_I \ast [\psi^l_T]_J\)

In order to proceed further, we will need information about the support, decay, and cancellation properties of each of the convolutions \([\varphi^l_S]_I \ast [\psi^l_T]_J\) that appear in equation (9.1). The required estimates are given in Lemma 9.4 below. The statement essentially incorporates the results of Lemmas 6.17 and 6.18 and Corollary 6.19 in [NRSW12]. Since the setting now is somewhat more complicated, we include a sketch of the proof.

Suppose that \( G \) is a homogeneous nilpotent Lie group with underlying manifold \( \mathbb{R}^N \), and that the one-parameter family of automorphic dilations on \( G \) is given by

\[
\delta_t(x) = (t^{d_1}x_1, \ldots, t^{d_N}x_N).
\]

Let \( \ast \) denote the convolution on \( G \).

**Lemma 9.4.** Let \( \varphi, \psi \in C_0^\infty(\mathbb{R}^N) \) have support in the unit ball and put

\[
[\varphi]_{\lambda}(x) = \prod_{m=1}^N \lambda_m^{-d_m} [\varphi(\lambda_1^{-d_1}x_1, \ldots, \lambda_N^{-d_N}x_N)],
\]

\[
[\psi]_{\mu}(x) = \prod_{m=1}^N \mu_m^{-d_m} [\psi(\mu_1^{-d_1}x_1, \ldots, \mu_N^{-d_N}x_N)].
\]

Assume that \( 0 < \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_N \) and \( 0 < \mu_1 \leq \mu_2 \leq \cdots \leq \mu_N \).

(a) [Support properties] There exists \( \theta \in C_0^\infty(\mathbb{R}^N) \), normalized with respect to \( \varphi \) and \( \psi \), so that,

\[
[\varphi]_{\lambda} \ast [\psi]_{\mu}(x) = \prod_{m=1}^n \nu_m^{-d_m} \theta(\nu_1^{-d_1}x_1, \ldots, \nu_N^{-d_N}x_N) = [\theta]_{\nu}(x)
\]

where \( \nu_j = \lambda_j \vee \mu_j = \max\{\lambda_j, \mu_j\} \).

(b) [Cancellation and decay properties] The estimates come in three parts, depending on whether there is cancellation in any of the first \( N - 1 \) variables \( \{x_1, \ldots, x_{N-1}\} \), or in the last variable \( x_N \).
(i) Let \( C,D \subset \{1,\ldots,N-1\} \), and suppose that \( \varphi \) has cancellation in the variables \( x_j \) for \( j \in C \), and that \( \psi \) has cancellation in the variables \( x_k \) for \( k \in D \). Put

\[
C_1 = \left\{ j \in \{1,\ldots,N-1\} : \varphi \text{ has cancellation in } x_j \text{ and } \lambda_j < \mu_j \right\},
\]

\[
C_2 = \left\{ j \in \{1,\ldots,N-1\} : \varphi \text{ has cancellation in } x_j \text{ and } \lambda_j \geq \mu_j \right\},
\]

\[
D_1 = \left\{ j \in \{1,\ldots,N-1\} : \psi \text{ has cancellation in } x_j \text{ and } \mu_j \leq \lambda_j \right\},
\]

\[
D_2 = \left\{ j \in \{1,\ldots,N-1\} : \psi \text{ has cancellation in } x_j \text{ and } \mu_j > \lambda_j \right\},
\]

so that

\[
C_1 \cup C_2 = C, \quad C_1 \cap C_2 = \emptyset,
\]

\[
D_1 \cup D_2 = D, \quad D_1 \cap D_2 = \emptyset,
\]

\[
\text{then the } \Theta-\text{function}
\]

There exists \( \epsilon > 0 \) depending only on the group structure so that \( \varphi|_\lambda \ast \psi|_\mu \) can be written as a finite sum of terms of the form

\[
\prod_{j \in C_1} \left( \frac{\lambda_j}{\mu_j} \right)^\epsilon + \left( \frac{\lambda_j}{\lambda_{j+1}} \right)^\epsilon \right) \times \prod_{k \in D_1} \left( \frac{\mu_k}{\lambda_k} \right)^\epsilon + \left( \frac{\mu_k}{\mu_{k+1}} \right)^\epsilon \right) \times
\]

\[
\times \prod_{j \in C_2} \left( \frac{\lambda_j}{\mu_j+1} \right)^\epsilon \times \prod_{k \in D_2} \left( \frac{\lambda_j}{\mu_j} \right)^\epsilon \times \left[ \Theta_{C_2',D_2'} \right]_{\nu}
\]

(9.2)

where

\[
C_2 = C_2' \cup C_2'', \quad C_2' \cap C_2'' = \emptyset,
\]

\[
D_2 = D_2' \cup D_2'', \quad D_2' \cap D_2'' = \emptyset.
\]

The functions \( \{ \Theta_{C_2',D_2'} \} \subset C_0^\infty(\mathbb{R}^N) \) are normalized relative to \( \varphi \) and \( \psi \) and have cancellation in the variables \( x_j \) for \( j \in C_2'' \cup D_2'' \).

(ii) Suppose that \( \varphi \) also has cancellation in the variable \( x_N \). If \( \lambda_N < \mu_N \), there is an additional factor \( \left( \frac{\lambda_N}{\mu_N} \right)^\epsilon \) in equation (9.2). If \( \lambda_N \geq \mu_N \) then the function \( \Theta_{C_2',D_2'} \) in equation (9.2) also has cancellation in the variable \( x_N \).

(iii) Suppose that \( \psi \) also has cancellation in the variable \( x_N \). If \( \lambda_N < \mu_N \), then the function \( \Theta_{C_2',D_2'} \) in equation (9.2) also has cancellation in the variable \( x_N \). If \( \lambda_N \geq \mu_N \) there is an additional factor \( \left( \frac{\lambda_N}{\mu_N} \right)^\epsilon \) in equation (9.2).

Sketch of the proof.

Because of the monotonicity of the \( \lambda \)'s and the \( \mu \)'s, assertion (a) follows immediately from Lemma 8.1, so the real content of the lemma is assertion (b). Let us first consider the case of Abelian convolution. Then there is no need to distinguish between the first \( N-1 \) variable and the last variable. If (say) \( \varphi \) has cancellation in the variable \( x_j \) then we can write \( \varphi = \partial_{x_j} \phi \) where \( \phi \) is normalized in terms of \( \varphi \). Suppose that \( \lambda_j < \mu_j \). Then moving the derivative \( \partial_{x_j} \) across the convolution, we have

\[
[\varphi]\lambda \ast [\psi]_\mu = [\partial_{x_j} \phi] \lambda \ast [\psi]_\mu = \lambda_j^d_j \partial_{x_j} (\varphi) \lambda \ast [\psi]_\mu
\]

\[
= \lambda_j^d_j \varphi \lambda \ast \partial_{x_j} (\psi) \mu = \left( \frac{\lambda_j}{\mu_j} \right)^{d_j} \varphi \lambda \ast [\partial_{x_j} \psi]_\mu = \left( \frac{\lambda_j}{\mu_j} \right)^{d_j} \theta \mu
\]
where we have use part (3) to write \([\phi]_\lambda \ast [\partial_x \psi]_\mu = [\theta]_\nu\) where \(\theta\) is normalized. On the other hand, if \(\lambda_j \geq \mu_j\), we can put the derivative in front of the whole convolution, and we have

\[
[\varphi]_\lambda \ast [\psi]_\mu = [\partial_x \varphi]_\lambda \ast [\psi]_\mu = \lambda_j^{d_j} \partial_x \big((\varphi)_\lambda \ast [\psi]_\mu\big) = \lambda_j^{d_j} \partial_x \big((\theta')_\nu\big) = [\partial_x \theta']_\nu
\]

where \([\varphi]_\lambda \ast [\psi]_\mu = [\theta']_\nu\) by part (3), and now \(\partial_x \theta'\) has cancellation in the variable \(x_j\). Thus the lemma follows in the case of Abelian convolution on \(\mathbb{R}^n\).

For convolution \(\ast\) on a homogeneous nilpotent Lie group, in general it is not the case that \(\partial_x f \ast g = f \ast \partial_x g\). However, we have the following facts.\(^{16}\)

(a) If \(X\) is a left-invariant vector field and \(Y\) is a right-invariant vector field then \(X[f \ast g] = f \ast X[g]\) and \(Y[f \ast g] = Y[f] \ast g\);

(b) If \(X\) is a left-invariant vector field and \(Y = \tilde{X}\) is the unique right-invariant vector field agreeing with \(X\) at the origin, then \(X[f] \ast g = f \ast Y[g]\);

(c) For any \(1 \leq j \leq N - 1\) we can write

\[
\frac{\partial f}{\partial x_j}(x) = Z_j[f](x) + \sum_{k=j+1}^N P_{j,k}(x) \frac{\partial f}{\partial x_k}(x) = Z_j[f](x) + \sum_{k=j+1}^N \frac{\partial}{\partial x_k}[P_{j,k}(x)f(x)]
\]

where \(Z_j\) is either a left- or a right-invariant vector field, and \(P_{j,k}\) is a polynomial of the form

\[
P_{j,k}(x_1, \ldots, x_{k-1}) = \sum_{\alpha \in \mathfrak{A}(j,k)} c_{j,k}(\alpha) x_1^{\alpha_1} \cdots x_{k-1}^{\alpha_{k-1}}
\]

where \(\mathfrak{A}(j,k) = \{(\alpha_1, \ldots, \alpha_{k-1}) \in \mathbb{Z}^{k-1} : \alpha_1 d_1 + \cdots + \alpha_{k-1} d_{k-1} = d_k - d_j\}\).

We can establish part (d) of the lemma by repeating the Abelian argument, but replacing the derivative \(\partial_x\) by the appropriate invariant vector field \(Z_j\). When \(j < N\) this introduces an error which is a sum of terms with cancellation in variables \(x_k\) with \(k > j\). Explicitly,

\[
[\partial_x \varphi]_\lambda = \lambda_j^{d_j} \partial_x \big((\varphi)_\lambda\big) = \lambda_j^{d_j} Z_j((\varphi)_\lambda) + \lambda_j^{d_j} \sum_{k=j+1}^N \partial_{x_k} \big(P_{j,k}(x)[\varphi]_\lambda(x)\big)
\]

Now it follows as in Proposition 4.5 of [NRSW12] that

\[
[\partial_x \varphi]_\lambda = \lambda_j^{d_j} Z_j((\varphi)_\lambda) + \sum_{k=j+1}^N \left(\frac{\lambda_j}{\lambda_k}\right)^{d_j} \lambda_k^{d_k} \partial_{x_k} \big((\Theta_{j,k})_\lambda\big)
\]

where the functions \(\Theta_{j,k}\) are normalized relative to \(\phi\). The term \(\lambda_j^{d_j} Z_j((\varphi)_\lambda)\) is handled as in the Abelian case, since now the vector field \(Z_j\) can either be moved across a convolution or put in front of the convolution. This gives a gain of \(\left(\frac{\lambda_j}{\lambda_k}\right)^{d_j}\). The remaining terms now have cancellation in variables \(x_k\) with \(k > j\), and there is a gain \(\left(\frac{\lambda_j}{\lambda_k}\right)^{d_j} \leq \left(\frac{\lambda_j}{\lambda_{j+1}}\right)^{d_j}\). Of course when \(j = N\), there is no correction term. This completes the sketch. Complete details can be found in Section 6 of [NRSW12].

\(^{16}\)See Proposition 6.16 in [NRSW12] or page 22 in [PSS2].
9.4 A further decomposition of $\Gamma_Z(\mathbf{E}_S) \times \Gamma_Z(\mathbf{E}_T)$

Fix two marked partitions $S = \{(I_1, k_1); \ldots; (I_s, k_s)\}$, $T = \{(J_1, \ell_1); \ldots; (J_q, \ell_q)\} \in S'(\mathbf{E})$. We return to the study of the infinite sum $\sum_{(I,J)\in \Gamma_Z(\mathbf{E}_S)\times \Gamma_Z(\mathbf{E}_T)} [\varphi^I] \ast [\psi^J]$. To analyze this, we need a further decomposition of the index set $\Gamma_Z(\mathbf{E}_S) \times \Gamma_Z(\mathbf{E}_T)$. Recall from equation (1.15) that

$$[\varphi^I](x) = 2^{-\sum_{r=1}^s i_r \bar{Q}_{S,r}} \varphi^I(2^{-i_1} \xi_{I_1}, \ldots, 2^{-i_s} \xi_{I_s}),$$

$$[\psi^J](x) = 2^{-\sum_{a=1}^q j_a \bar{Q}_{T,a}} \psi^J(2^{-j_1} \tau T_{J_1}, \ldots, 2^{-j_q} \tau T_{J_q}),$$

where, using the identities $e(k_r, j) = \tau_S(j, k_r)^{-1}$ and $e(\ell_a, l) = \tau_T(l, \ell_a)^{-1}$ from Proposition 3.8 together with (3.6) and Definition 3.12(b), we have

$$\bar{Q}_{S,r} = \sum_{j \in I_r} Q_j e(k_r, j) = \sum_{j \in I_r} Q_j \tau_S(j, k_r),$$

$$2^{-i_r} \xi_{I_r} = \left\{2^{-i_r/\tau_S(j, k_r)} \cdot \xi_j : j \in I_r\right\} = \left\{2^{-i_r/\tau_S(j, k_r)} \cdot \xi_j : j \in I_r\right\};$$

$$\bar{Q}_{T,a} = \sum_{\ell \in \ell_a} Q_a e(\ell_a, l) = \sum_{\ell \in \ell_a} Q_a \tau_T(l, \ell_a),$$

$$2^{-j_a} \tau T_{J_a} = \left\{2^{-j_a/\tau_T(v, \ell_a)} \cdot \xi_v : v \in J_a\right\} = \left\{2^{-j_a/\tau_T(v, \ell_a)} \cdot \xi_v : v \in J_a\right\}.$$  

According to Lemma 9.3 for each index $j$, $1 \leq j \leq n$, the scale of the support of the convolution $[\varphi^I] \ast [\psi^J]$ in the direction of each coordinate $\xi_j$ is the maximum of the scales of the supports of each factor. We let $1 \leq r \leq s$ and $1 \leq a \leq q$ and focus on indices $j \in I_r \cap J_a$ provided that the intersection is non-empty. The size of the support of $[\varphi^I]$ in the direction of $\xi_j$ is on the order of $2^{\tau_S(j, k_r)}$, while the size of the support of $[\psi^J]$ is on the order of $2^{\tau_T(v, \ell_a)}$. Since the indices $i_r$ and $j_a$ are negative, we have

$$2^{i_r} \tau_S(j, k_r) \geq 2^{j_a} \tau_T(v, \ell_a) \iff i_r \tau_S(j, k_r) \geq j_a \tau_T(v, \ell_a) \iff \frac{i_r}{j_a} \geq \frac{\tau_T(v, \ell_a)}{\tau_S(j, k_r)} = \frac{e(k_r, j)}{e(\ell_a, l)}.$$  

Write $\bar{I}_r \cap J_a = \{v_1, \ldots, v_m\}$, and order these indices so that

$$0 < \frac{\tau_T(v_1, \ell_a)}{\tau_S(j, k_r)} \leq \frac{\tau_T(v_2, \ell_a)}{\tau_S(j, k_r)} \leq \cdots \leq \frac{\tau_T(v_m, \ell_a)}{\tau_S(j, k_r)} < \infty.$$  

The ratios in equation (9.5) divide the positive real axis into at most $m+1$ subintervals. For any $I = (i_1, \ldots, i_s) \in \Gamma_Z(\mathbf{E}_S)$ and $J = (j_1, \ldots, j_q) \in \Gamma_Z(\mathbf{E}_T)$, the ratio $i_r/j_a$ must lie in one of these intervals. We partition $\Gamma_Z(\mathbf{E}_S) \times \Gamma_Z(\mathbf{E}_T)$ into disjoint sets so that for $(I, J)$ in each set, the ratios $i_r/j_a$ always lie in the same interval.

To describe and index this decomposition, we proceed as follows. Let

$$\Sigma_{ST} = \{(I_r, J_a) : 1 \leq r \leq s, 1 \leq a \leq q, I_r \cap J_a \neq \emptyset\},$$

For each $(I_r, J_a) \in \Sigma_{ST}$ consider the set of $m_{r,a} + 1$ intervals

$$\left\{\frac{\tau_T(v_1, \ell_a)}{\tau_S(j, k_r)}, \frac{\tau_T(v_2, \ell_a)}{\tau_S(j, k_r)}, \ldots, \frac{\tau_T(v_{m_{r,a}+1}, \ell_a)}{\tau_S(j, k_r)}\right\} = E^r_{m_{r,a}},$$

$$\left\{\frac{\tau_T(v_1, \ell_a)}{\tau_S(j, k_r)}, \frac{\tau_T(v_2, \ell_a)}{\tau_S(j, k_r)}, \ldots, \frac{\tau_T(v_{m_{r,a}+1}, \ell_a)}{\tau_S(j, k_r)}\right\} = E^r_{m_{r,a}}.$$  

\[17\] Since $S$ and $T$ are fixed, we now write $\varphi^I$ and $\psi^J$ instead of $\varphi^I$ and $\psi^J$.

\[18\] We should write $I_r \cap J_a = \{v_1, v_2, \ldots, v_{m_{r,a}}\}$, but as long as the context is clear we omit the dependence on $(r, a)$ for simplicity of notation.
and let
\[ \tilde{W}(S,T) = \prod_{(I_r, J_a) \in \Sigma_{S,T}} \{ E_r^{a,1}, E_r^{a,2}, \ldots, E_r^{a,m_r} \}; \]
i.e., the set of functions which assign to each \((I_r, J_a) \in \Sigma_{S,T}\) one of the intervals in \([7][7]\).
Hence, if \(W \in \tilde{W}(S,T)\) and \((I_r, J_a) \in \Sigma_{S,T}\), \(W(I_r, J_a)\) is one of these intervals, and we write
\[ W(I_r, J_a) = E_r^{a,w(I_r, J_a)} \]
so that \(w(I_r, J_a) \in \{0, 1, \ldots, m_r,a\}\). (Thus \(W(I_r, J_a)\) is one of the \(m_r,a + 1\) intervals, while \(w(I_r, J_a)\) is the number of that interval.) Setting \(j = w(I_r, J_a)\), let
\[ \Lambda_W(J_a, I_r) = \begin{cases} \infty & \text{if } j = 0, \\ \frac{\tau_r(v_j, k_r)}{\tau_r(v_j, k_r)} & \text{if } j > 0, \end{cases} \quad \Lambda_W(I_r, J_a) = \begin{cases} \frac{\tau_r(v_j, k_r)}{\tau_r(v_j, k_r)} & \text{if } j < m_r,a, \\ \infty & \text{if } j = m_r,a, \end{cases} \]
so that \(\Lambda_W(J_a, I_r)^{-1}\) and \(\Lambda_W(I_r, J_a)\) are the left and right endpoints of \(E_{w(I_r, J_a)}\).
We now construct the desired partition. For \(W \in \tilde{W}(S,T)\), put
\[ \Gamma_W(S,T) = \left\{ ((i_1, \ldots, i_s), (j_1, \ldots, j_q)) \in \Gamma_{\mathbf{E}_S}(\mathbf{E}_S) \times \Gamma_{\mathbf{E}_T}(\mathbf{E}_T) : \right. \]
\[ \left. (I_r, J_a) \in \Sigma_{S,T} \implies \frac{1}{\Lambda_W(J_a, I_r)} \leq \frac{i_r}{j_a} < \Lambda_W(I_r, J_a) \right\}. \quad (9.7) \]
It may happen that for some \(W \in \tilde{W}(S,T)\) the set \(\Gamma_W(S,T)\) is empty\(^{19}\) and so we put
\[ \mathcal{W}(S,T) = \left\{ W \in \tilde{W}(S,T) : \Gamma_W(S,T) \neq \emptyset \right\}. \]
The following Proposition is an immediate consequence of the definition of \(\Gamma_W(S,T)\) and the ordering in equation \([9.7]\).

**Proposition 9.5.** Let \(S = \{(I_1, k_1); \ldots; (I_s, k_s)\}\), \(T = \{(J_1, \ell_1); \ldots; (J_q, \ell_q)\} \in S'(\mathbf{E})\).

(a) The sets \(\{\Gamma_W(S,T) : W \in \mathcal{W}(S,T)\}\) partition the set \(\Gamma_{\mathbf{E}_S}(\mathbf{E}_S) \times \Gamma_{\mathbf{E}_T}(\mathbf{E}_T)\):
\[ \Gamma_{\mathbf{E}_S}(\mathbf{E}_S) \times \Gamma_{\mathbf{E}_T}(\mathbf{E}_T) = \bigcup_{W \in \mathcal{W}(S,T)} \Gamma_W(S,T), \]
\[ W_1, W_2 \in \mathcal{W}(S,T), \quad W_1 \neq W_2 \implies \Gamma_{W_1}(S,T) \cap \Gamma_{W_2}(S,T) = \emptyset. \]

(b) Let \(W \in \mathcal{W}(S,T)\) and suppose \(I_r \cap J_a = \{v_1, \ldots, v_m\} \neq \emptyset\), ordered as in equation \([9.7]\).
Suppose that \(W(I_r, J_a) = E_{w(I_r, J_a)}\). Let \(((i_1, \ldots, i_s), (j_1, \ldots, j_q)) \in \Gamma_W(S,T)\). Then for \(1 \leq k \leq m\),
\[ k \leq w(I_r, J_a) \iff j_a \tau_t(v_k, \ell_a) \geq i_r \tau_S(v_k, k_r) \]
\[ k > w(I_r, J_a) \iff j_a \tau_t(v_k, \ell_a) < i_r \tau_S(v_k, k_r) \]
In particular,
\[ (1) \text{ if } w(I_r, J_a) = 0, \text{ then } i_r \tau_S(v_k, k_r) > j_a \tau_t(v_k, \ell_a) \text{ for all } 1 \leq k \leq m; \]
\[ (2) \text{ if } w(I_r, J_a) = m \text{ then } i_r \tau_S(v_k, k_r) \leq j_a \tau_t(v_k, \ell_a) \text{ for all } 1 \leq k \leq m; \]

---

\(^{19}\)For instance, if there are equalities among the weak inequalities in \([9.5]\), some of the intervals are empty.
Definition 9.6. Let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\}, T = \{(J_1, \ell_1); \ldots; (J_q, \ell_q)\} \in \mathcal{S}'(E)$ and $W \in \mathcal{W}(S, T)$. Recall that if $I_r \cap J_a \neq \emptyset$ then $W(I_r, J_a) = E_{w(I_r, J_a)}$ where $\{E_0, \ldots, E_m\}$ are the intervals listed in equation (9.6).

(3) if $k_r \in I_r \cap J_a$ then

\begin{align*}
k_r &\leq w(I_r, J_a) \implies i_r \leq \tau_T(k_r, \ell_a) j_a < 0, \\
k_r &> w(I_r, J_a) \implies \tau_T(k_r, \ell_a) j_a < i_r < 0;
\end{align*}

(4) if $\ell_a \in I_r \cap J_a$ then

\begin{align*}
\ell_a &> w(I_r, J_a) \implies j_a < \tau_S(\ell_a, k_r) i_r < 0, \\
\ell_a &\leq w(I_r, J_a) \implies \tau_S(\ell_a, k_r) i_r \leq j_a < 0.
\end{align*}

To summarize, we have partitioned $\Gamma_Z(E_S) \times \Gamma_Z(E_T)$ into a disjoint union of sets $\Gamma_W(S, T)$. Let $I = (i_1, \ldots, i_s)$ and $J = (j_1, \ldots, j_q)$. Then $(I, J) \in \Gamma_W(S, T)$ if and only if

\begin{align}
&e_S(p, r) i_r \leq i_p < 0 & &\text{for } r, p \in \{1, \ldots, s\}, \\
&\ell_T(b, a) j_a \leq j_b < 0 & &\text{for } a, b \in \{1, \ldots, q\}, \\
&\Lambda_W(I_r, J_a) j_a < i_r & &\text{if } I_r \cap J_a \neq \emptyset, \\
&\Lambda_W(J_a, I_r) i_r \leq j_a & &\text{if } I_r \cap J_a \neq \emptyset.
\end{align}

(9.8)

It can happen that $\Lambda_W(I_r, J_a)$ or $\Lambda_W(J_a, I_r)$ is $+\infty$, in which case there is simply no corresponding inequality between $i_r$ and $j_a$. However, if there is no bound of an index $i_r$ by any $j_a$, then $\Lambda_W(I_r, J_a) = +\infty$ for every $a$ such that $I_r \cap J_a \neq \emptyset$, and this means that the scale of the dilation by $i_r$ is always smaller than the scale of the dilation by the corresponding $j_a$. Similarly, if there is no bound of $j_a$ by any $i_r$, then the scale of the dilation by $j_a$ is always less than or equal to the scale of the dilation by the corresponding $i_r$.

### 9.5 Fixed and free indices

Continue to fix $S = \{(I_1, k_1); \ldots; (I_s, k_s)\}, T = \{(J_1, \ell_1); \ldots; (J_q, \ell_q)\} \in \mathcal{S}'(E)$. The index set $\mathcal{W}(S, T)$ is finite, so formally, using the partition from Proposition [9.5], we have

\[
\mathcal{K}_S \star \mathcal{L}_T(x) = \sum_{W \in \mathcal{W}(S, T)} \left[ \sum_{(I, J) \in \mathcal{W}(S, T)} [\varphi_I']_I * [\psi_J']_J(x) \right] = \sum_{W \in \mathcal{W}(S, T)} \mathcal{R}_{S, T, W}(x).
\]

Thus to prove Lemma 9.3 (and hence prove Theorem 9.2) it suffices to show that for each $W \in \mathcal{W}(S, T)$ the inner infinite sum

\[
\mathcal{R}_{S, T, W} = \sum_{(I, J) \in \mathcal{W}(S, T)} [\varphi_I']_I * [\psi_J']_J
\]

converges in the sense of distributions, and that the sum belongs to the class $\mathcal{P}_0(E)$. We will do this by showing that there is a matrix $E(S, T, W)$ so that $\mathcal{R}_{S, T, W} \in \mathcal{P}_0(E(S, T, W)) \subset \mathcal{P}_0(E)$.

**Definition 9.6.** Let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\}, T = \{(J_1, \ell_1); \ldots; (J_q, \ell_q)\} \in \mathcal{S}'(E)$ and $W \in \mathcal{W}(S, T)$. Recall that if $I_r \cap J_a \neq \emptyset$ then $W(I_r, J_a) = E_{w(I_r, J_a)}$ where $\{E_0, \ldots, E_m\}$ are the intervals listed in equation (9.6).

\[\text{In the notation of the next section, this means that in the first case, } i_r \text{ is a free index, and in the second case } j_a \text{ is a free index. See Definition 9.6}\]
(a) Set

\[ I_r^* = \bigcup_{I_r \cap J_a \neq \emptyset} \left\{ j \in I_r \cap J_a : i_r \tau_S(j, k_r) > j_a \tau_T(j, \ell_a) \forall ((i_1, \ldots, i_s), (j_1, \ldots, j_q)) \in \Gamma_W(S, T) \right\} \]

\[ = \bigcup_{I_r \cap J_a \neq \emptyset} \left\{ v_k \in I_r \cap J_a : k > w(I_r, J_a) \right\}; \]

\[ J_a^* = \bigcup_{I_r \cap J_a \neq \emptyset} \left\{ j \in I_r \cap J_a : i_r \tau_S(j, k_r) \leq j_a \tau_T(j, \ell_a) \forall ((i_1, \ldots, i_s), (j_1, \ldots, j_q)) \in \Gamma_W(S, T) \right\} \]

\[ = \bigcup_{I_r \cap J_a \neq \emptyset} \left\{ v_k \in I_r \cap J_a : k \leq w(I_r, J_a) \right\} \quad (9.9) \]

(b) An index \( r, 1 \leq r \leq s \) is **fixed** if \( I_r^* \neq \emptyset \), and is **free** if \( I_r^* = \emptyset \).

(c) An index \( a, 1 \leq a \leq q \) is **fixed** if \( J_a^* \neq \emptyset \), and is **free** if \( J_a^* = \emptyset \).

**Remark 9.7.** The notions of fixed and free indices and the definitions of the sets \( I_r^* \) and \( J_a^* \) depend on the choice of \( S, T \in \mathcal{S}(E) \) and on the choice of \( W \in \mathcal{W}(S, T) \). In particular, they are the same for all choices of \( (I, J) \in \Gamma_W(S, T) \).

Clearly \( I_r^* \subset I_r, J_a^* \subset J_a \) and \( I_r^* \cap J_a^* = \emptyset \). Also, for every \( j \in \{1, \ldots, n\} \) there is a unique pair \( (I_r, J_a) \in \Sigma_{S,T} \) so that \( j \in I_r \cap J_a \), and then either \( j \in I_r^* \) or \( j \in J_a^* \). Thus we have a disjoint decomposition

\[ \{1, \ldots, n\} = \bigcup_{r=1}^{s} I_r^* \cup \bigcup_{a=1}^{q} J_a^*. \quad (9.10) \]

The following Proposition provides an explanation of the significance of fixed and free indices. The proof just involves unwinding the definitions.

**Proposition 9.8.**

(a) An index \( r \in \{1, \ldots, s\} \) is free if and only if for every \( j \in I_r \) and every \( (I, J) \in \Gamma_W(S, T) \), the scale of the support of \( |\varphi^j|_I \) is smaller in the direction of \( x_j \) than the scale of the support of \( |\psi^j|_J \).

(b) An index \( r \in \{1, \ldots, s\} \) is fixed if and only if there exists at least one \( j \in I_r \) so that for every \( (I, J) \in \Gamma_W(S, T) \), the scale of the support of \( |\varphi^j|_I \) in the direction of \( x_j \) is larger than the scale of the support of \( |\psi^j|_J \).

(c) The indices \( j \in \{1, \ldots, n\} \) for which the scale of the support of \( |\varphi^j|_I \) is larger than the scale of the support of \( |\psi^j|_J \) in the direction of \( x_j \) is precisely \( \bigcup_{r=1}^{s} I_r^* \).

(d) An index \( a \in \{1, \ldots, q\} \) is free if and only if for every \( j \in J_a \) and for every \( (I, J) \in \Gamma_W(S, T) \), the scale of the support of \( |\psi^j|_J \) in the direction of \( x_j \) is smaller than the scale of the support of \( |\varphi^j|_I \).
(e) An index \(a \in \{1, \ldots, q\}\) is fixed if and only if there exists at least one \(j \in J_a\) so that for every \((I,J) \in \Gamma_W(S,T)\) the scale of the support of \([\psi^I]_J\) is larger than the scale of the support of \([\varphi^I]_J\) in the direction of \(x_j\).

(f) The indices \(j \in \{1, \ldots, n\}\) for which the scale of the support of \([\psi^I]_J\) is larger than the scale of the support of \([\varphi^I]_J\) in the direction of \(x_j\) is precisely \(\bigcup_{a=1}^{\beta} J_a^*\).

Let \(S^* = \{r_1, \ldots, r_\alpha\}\) denote the subset of \(\{1, \ldots, s\}\) consisting of fixed indices, and let \(T^* = \{a_1, \ldots, a_\beta\}\) denote the subset of \(\{1, \ldots, q\}\) consisting of fixed indices. It may happen that \(\alpha = 0\) or that \(\beta = 0\), but we always have \(\alpha + \beta \geq 1\). Then we can write

\[
\{1, \ldots, n\} = \bigcup_{r \in S^*} I_r^* \cup \bigcup_{a \in T^*} J_a^* = \bigcup_{j=1}^{\alpha} I_{r_j}^* \cup \bigcup_{k=1}^{\beta} J_{a_k}^*. \tag{9.11}
\]

### 9.6 A finer decomposition of \(\mathbb{R}^N\)

Using the decomposition in equation (9.11) we study the new decomposition of \(\mathbb{R}^N\) indexed by the fixed indices in \(\{1, \ldots, s\}\) and \(\{1, \ldots, q\}\):

\[
\mathbb{R}^N = \bigoplus_{r \in S^*} \mathbb{R}^{I_r^*} \oplus \bigoplus_{a \in T^*} \mathbb{R}^{J_a^*} = \bigoplus_{j=1}^{\alpha} \mathbb{R}^{I_{r_j}^*} \oplus \bigoplus_{j=1}^{\beta} \mathbb{R}^{J_{a_j}^*}
\]

where

\[
\mathbb{R}^{I_r^*} = \{x = (x_1, \ldots, x_n) \in \mathbb{R}^N : x_j \neq 0 \Rightarrow j \in I_r^*\},
\]

\[
\mathbb{R}^{J_a^*} = \{x = (x_1, \ldots, x_n) \in \mathbb{R}^N : x_j \neq 0 \Rightarrow j \in J_a^*\}.
\]

Write elements of \(\mathbb{R}^{I_r^*}\) and \(\mathbb{R}^{J_a^*}\) as \(x_{I_r^*} = \{x_j : j \in I_r^*\}\) and \(x_{J_a^*} = \{x_j : j \in J_a^*\}\). This gives us a set of coordinates on \(\mathbb{R}^N\).

Order these coordinates so that the corresponding set of indices \(\{k_{r_1}, \ldots, k_{r_\alpha}, \ell_{a_1}, \ldots, \ell_{a_\beta}\}\) together are increasing. With this ordering, rename the subspaces as \(\mathbb{R}^{V_1}, \ldots, \mathbb{R}^{V_{n+\beta}}\). Then every element \(x \in \mathbb{R}^N\) is an \((\alpha + \beta)\)-tuple \(x = (x_{v_1}, \ldots, x_{v_\alpha}, x_{v_{\alpha+\beta}})\) where \(x_{v_m} \in \mathbb{R}^{V_m}\) and \(V_k\) is either \(I_{r_k}\) for some \(r \in S^*\) or \(J_{a_k}\) for some \(a \in T^*\). By the choice of the ordering, if \(m_1 < m_2\) then

\[
V_{m_1} = I_{r_k}, \quad V_{m_2} = I_{r_p} \quad \Rightarrow \quad k_p < k_r,
\]

\[
V_{m_1} = I_{r_k}, \quad V_{m_2} = J_{a} \quad \Rightarrow \quad \ell_a < k_k,
\]

\[
V_{m_1} = J_{a_k}, \quad V_{m_2} = I_{r} \quad \Rightarrow \quad \ell_k < k_t,
\]

\[
V_{m_1} = J_{a_k}, \quad V_{m_2} = J_{b} \quad \Rightarrow \quad \ell_b < k_k.
\]

On each component \(\mathbb{R}^{V_m}\) we use the dilation structure inherited from either \(I_{r_k}\) or \(J_{a_k}\). Thus from (9.4) we define a dilation which we write \(\circ\) by setting

\[
\lambda \circ x_{v_m} = \begin{cases} 
\{\lambda^{\tau(j,k_r)} \cdot x_{j} : j \in I_{r_k}^*\} & \text{if } x_{v_m} = x_{I_{r_k}^*} \\
\{\lambda^{\tau(j,k_a)} \cdot x_{j} : j \in J_{a_k}^*\} & \text{if } x_{v_m} = x_{J_{a_k}^*} 
\end{cases} \tag{9.12}
\]

(To keep notation simple we write \(\circ\) instead of \(\circ_{S,T,W}\).) The corresponding homogeneous norms are given by

\[
n_{S,r}(x_{I_{r_k}^*}) = \sum_{j \in I_{r_k}} n_j(x_j)^{1/\tau(j,k_r)}, \quad n_{T,a}(x_{J_{a_k}^*}) = \sum_{j \in J_{a_k}} n_j(x_j)^{1/\tau(j,k_a)},
\]
and the homogeneous dimension of $\mathbb{R}^{V_{\alpha}}$ is then
\[
Q_m = \begin{cases} Q_{I_r} = \sum_{j \in I_r} Q_j \tau_S(j, k_r) & \text{if } \bar{x}_m = x_{I_r}; \\ Q_{J_s} = \sum_{j \in J_s} Q_j \tau_T(j, \ell_s) & \text{if } \bar{x}_m = x_{J_s}. \end{cases}
\]

### 9.7 The matrix $E_{S,T,W}$

If \((i_1, \ldots, i_s, j_1, \ldots, j_q) \in \Gamma(W, S) \subset \Gamma_2(E_S) \times \Gamma_2(E_T)\), we obtain an \((\alpha + \beta)\)-tuple \(\{i_r, i_{r_a}, j_{a1}, \ldots, j_{a\beta}\}\) by keeping only the \(i_r\) and \(j_s\) corresponding to fixed indices \(S^*\) and \(T^*\). Let \(\pi : \mathbb{Z}^{s+q} \to \mathbb{Z}^{\alpha+\beta}\) be the mapping which takes \((i_1, \ldots, i_s, j_1, \ldots, j_q) \in \mathbb{Z}^{s+q}\) to \((i_r, i_{r_a}, j_{a1}, \ldots, j_{a\beta}) \in \mathbb{Z}^{\alpha+\beta}\). Our next objective is to describe the inequalities satisfied by the entries of these \((\alpha + \beta)\)-tuples.

It follows from equation (9.8) that
\[
e_S(r_j, r_k)i_{r_a} \leq i_{r_j} < 0 \quad \text{for } j, k \in \{1, \ldots, \alpha\},
\]
\[
e_T(a, a_m)j_{a_m} \leq j_{a_1} < 0 \quad \text{for } l, m \in \{1, \ldots, \beta\},
\]
\[
\Lambda_W(I_{r_j}, J_{a_m})j_{a_m} \leq i_{r_j} \quad \text{if } I_{r_j} \cap J_{a_m} \neq \emptyset,
\]
\[
\Lambda_W(J_{a_m}, I_{r_j})i_{r_j} \leq j_{a_m} \quad \text{if } I_{r_j} \cap J_{a_m} \neq \emptyset.
\]

Let
\[
\Gamma(S, T, W) = \{ (i_r, i_{r_a}, j_{a1}, \ldots, j_{a\beta}) \in \mathbb{Z}^{\alpha+\beta} \text{ which satisfy (9.13)} \}.
\]

Thus \(\pi : \Gamma_W(S, T) \to \Gamma(S, T, W)\).

**Proposition 9.9.** The mapping \(\pi : \Gamma_W(S, T) \to \Gamma(S, T, W)\) is onto.

**Proof.** Thus suppose that the \((\alpha + \beta)\)-tuple \((i_r, i_{r_a}, j_{a1}, \ldots, j_{a\beta})\) satisfies the inequalities in equation (9.13). First observe that the first two lines of inequalities describe the projections of $\Gamma(E_S)$ and $\Gamma(E_T)$ onto the smaller sets of coordinates. Since $E_S$ and $E_T$ satisfy the basic hypotheses (2.10), it follows from Lemma (14.1) that there exists \((i_1, \ldots, i_s) \in \Gamma(E_S)\) and \((t_1, \ldots, t_q) \in \Gamma(E_T)\) such that
\[
\pi(i_1, \ldots, i_s, j_1, \ldots, j_q) = (i_r, i_{r_a}, j_{a1}, \ldots, j_{a\beta}).
\]

We claim that \((i_1, \ldots, i_s, j_1, \ldots, j_q) \in \Gamma_W(S, T)\), so we need to check all the inequalities in equation (9.8). The first two lines are clearly satisfied, since they only depend on the fact that \((i_1, \ldots, i_s) \in \Gamma(E_S)\) and \((j_1, \ldots, j_q) \in \Gamma(E_T)\). Also the second two lines are satisfied provided that \(r = r_j\) and \(a = a_m\) for some \(j \in \{1, \ldots, \alpha\}\) and \(m \in \{1, \ldots, \beta\}\). It remains to check what happens if \(i_r\) is a free index or \(j_a\) is a free index. But as we observed in the summary on page 66 if \(i_r\) is a free index and \(I_r \cap J_a \neq \emptyset\) then \(\Lambda_W(I_r, J_a) = \infty\) so there is no third line in the inequalities. Also if \(i_r\) is a free index, then the scale of the dilation \(\tau_S(j, k_r)\) must be smaller than the scale of the dilation \(\tau_T(j, \ell_s)\) for every \(j \in I_r \cap J_a\). This says that the ratio \(i_r/j_a\) must lie in the largest (i.e. the unbounded) interval, and this is the statement of the fourth inequality. A similar argument works if \(j_a\) is a free index. \(\square\)

The cone $\Gamma(S, T, W) \subset \mathbb{R}^{\alpha+\beta}$ is defined by the inequalities in (9.13), which, using the notation in Section 14.2, is defined by a partial matrix $B_W$, with indices varying in the disjoint union $S^* \cup T^*$ and given by
\[
b(\mu, \nu) = \begin{cases} e_S(\mu, \nu) & \text{if } \mu, \nu \in S^* \\ e_T(\mu, \nu) & \text{if } \mu, \nu \in T^* \\ \Lambda_W(I_\mu, J_\nu) & \text{if } \mu \in S^*, \nu \in T^* \\ \Lambda_W(J_\mu, I_\nu) & \text{if } \mu \in T^*, \nu \in S^*.
\end{cases}
\]
Lemma 9.10. The matrix $B_W$ is connected.

Proof. We must prove that, given $\mu \neq \nu \in S^* \sqcup T^*$, there are $\lambda_1, \ldots, \lambda_n \in S^* \sqcup T^*$ such that

$$b_W(\mu, \lambda_1)b_W(\lambda_1, \lambda_2) \cdots b_W(\lambda_n, \nu) < \infty.$$ 

There is no doubt that this holds if both $\mu$ and $\nu$ belong either to $S^*$ or to $T^*$ because all the $\epsilon_S$ and $\epsilon_T$ are finite. For the other two cases it is necessary and sufficient to prove that there exist $r \in S^*$, $a \in T^*$ with $\Lambda_W(I_r, J_a) = 0$ and $r' \in S^*$, $a' \in T^*$ with $\Lambda_W(J_a, I_{r'}) = 0$ (equivalently with $w(I_r, J_a) \neq 0$ and $w(I_{r'}, J_a') \neq 0$).

Assume that one of these conditions is violated, e.g., that $w(I_r, J_a) = 0$ for all $r \in S^*, a \in T^*$. By (9.9), this implies that $I_r \cap J_a \subseteq I_r^*$ for every $r, a$. Hence $T^* = \emptyset$ and the proof is completed. □

By Lemma 9.3 there is matrix $E_{S,T,W}$ which satisfies the basic hypotheses (2.10) so that we have $\Gamma(S, T, W) = \Gamma(E_{S,T,W})$.

Proposition 9.11. If $(m_1, \ldots, m_{a+\beta}) \in \Gamma_1(E_{S,T,W})$, the corresponding dilation of $\mathbb{R}^N$ given by

$$(\mathbf{x}_1, \ldots, \mathbf{x}_{a+\beta}) \rightarrow (2^{-m_1} \circ \mathbf{x}_1, \ldots, 2^{-m_{a+\beta}} \circ \mathbf{x}_{a+\beta})$$

is still compatible (in the sense of Section 8.7) with the nilpotent Lie group structure.

Proof. Let $1 \leq r_1 < r_2 \leq n$. Then $\mathbf{x}_{r_1}$ and $\mathbf{x}_{r_2}$ are coordinates that belong to one of the sets $\{I_{r_1}^*, 1 \leq j \leq \alpha\}$ or $\{J_{a+k}, 1 \leq k \leq \beta\}$. Write the $(a+\beta)$-tuple $(m_1, \ldots, m_{a+\beta}) = (i_{r_1}, \ldots, i_{r_2}, k_{a_1}, \ldots, k_{a_{a_2}})$. There are thus four cases to consider.

If $\mathbf{x}_{r_1} \in I_{r_1}^*$ and $\mathbf{x}_{r_2} \in I_{r_2}^*$, we proceed as in Lemma 8.6. After taking logarithm to base 2 the scales of the corresponding dilations are $i_{r_1} \tau_S(l, i_{r_1})$ and $i_{r_2} \tau_S(l, i_{r_2})$. Now $e_S(r_{r_2, r_1}) < i_{r_1} < i_{r_2} < 0$ so

$$\frac{i_{r_2}}{i_{r_1}} \leq e_S(r_{r_2, r_1}) \leq \tau_S(k_{r_2, k_{r_1}}) = \frac{\min_{j \in l_{r_1}} \epsilon(k_{r_2, j})}{\epsilon(k_{r_1, j})} \leq \frac{e(k_{r_2, l_1})}{e(k_{r_1, l_1})} \leq \frac{e(k_{r_2, l_2})}{e(k_{r_1, l_1})}$$

since $e(l_2, l_1) = 1$. Thus

$$i_{r_1} \tau_S(l, i_{r_1}) = \frac{i_{r_1}}{e(k_{r_1, l_1})} \leq \frac{i_{r_2}}{e(k_{r_2, l_1})} = i_{r_2} \tau_S(l, i_{r_2}),$$

which is the desired inequality. A similar argument works if $\mathbf{x}_{r_1} \in J_{a_{i_1}}$ and $\mathbf{x}_{r_2} \in J_{a_{i_2}}$.

Now suppose $\mathbf{x}_{r_1} \in I_{r_1}^* \cap J_{a_{i_1}}$ and $\mathbf{x}_{r_2} \in I_{r_2}^* \cap J_{a_{i_2}}$. This time, after taking logarithm to base 2 the scales of the corresponding dilations are $i_{r_1} \tau_S(l, i_{r_1})$ and $j_{a_{i_1}} \tau_T(l, j_{a_{i_2}})$. Just as before, it follows that

$$i_{r_1} \tau_S(l, i_{r_1}) \leq i_{r_2} \tau_S(l, i_{r_2}).$$

But now since $l_2 \in J_{a_{i_2}}^*$, we know that the $i$-scale at this variable is less than or equal to the $j$-scale at this variable. Thus

$$i_{r_2} \tau_S(l, i_{r_2}) \leq j_{a_{i_2}} \tau_T(l, j_{a_{i_2}}).$$

Putting the last two inequalities together gives the required estimate. A similar argument works if $\mathbf{x}_{r_1} \in I_{r_1}^* \cap J_{a_{i_1}}$ and $\mathbf{x}_{r_2} \in I_{r_2}^* \cap J_{a_{i_2}}$, and this completes the proof. □
9.8 The class $\mathcal{P}_0(E_{S,T,W})$

Given the decomposition $\mathbb{R}^N = \bigoplus_{j=1}^\alpha \mathbb{R}^{J_j'} \oplus \bigoplus_{j=1}^\beta \mathbb{R}^{J_j}$ and the matrix $E_{S,T,W}$, we have the space of distributions $\mathcal{P}_0(E_{S,T,W})$ and the corresponding space of multipliers $\mathcal{M}_\infty(E_{S,T,W})$. For notational convenience we use the symbol $e_W$ to denote the entries of $E_{S,T,W}$. Recall that their indices vary in the disjoint union $S^* \cup T^*$ of the sets $S^* \subset \{1, \ldots, s\}$ and $T^* \subset \{1, \ldots, q\}$ of fixed indices relative to $W$.

Lemma 9.12. $\mathcal{M}_\infty(E_{S,T,W}) \subset \mathcal{M}_\infty(E)$ and consequently $\mathcal{P}_0(E_{S,T,W}) \subset \mathcal{P}_0(E)$.

Proof. The dual norms for the space $\mathcal{M}_\infty(E_{S,T,W})$ are given by

$$\hat{N}_{r,W}(\xi) = \sum_{p \in S^*} \hat{n}_{S,p}(\xi_{T,p})^{1/\epsilon_W(p,r)} + \sum_{b \in T^*} \hat{n}_{T,b}(\xi_{J,b})^{1/\epsilon_W(b,r)}, \quad r \in S^*;$$

$$\hat{N}_{a,W}(\xi) = \sum_{p \in S^*} \hat{n}_{S,p}(\xi_{T,p})^{1/\epsilon_W(I_p,a)} + \sum_{b \in T^*} \hat{n}_{T,b}(\xi_{J,b})^{1/\epsilon_W(b,a)}, \quad a \in T^*.$$ 

By Corollary 5.4 it suffices to show, for each $(j,k)$, the entries $e_W^*(j,k)$ of the $n \times n$ matrix $E_{S,T,W}$ satisfy the inequality

$$e_W^*(j,k) \leq e(j,k).$$

By (5.4), $e_W^*(j,k) = \frac{\alpha_k}{\alpha_j} e_W(\mu,\nu)$, where

(i) $\mu, \nu \in S^* \cup T^*$ are such that $j \in I^*_\mu$ (if $\mu \in S^*$) or $j \in J^*_\mu$ (if $\mu \in T^*$) and $k \in I^*_\nu$ or $J^*_\nu$ accordingly;

(ii) $\alpha_k$ is the exponent of the norm of $\xi_k$ in

$$\hat{n}_{S,p}(\xi_{T,p}) = \sum_{k \in I^*_p} n_k(\xi_k)^{e(k_p,k)} \quad (k \in I^*_p), \quad \hat{n}_{T,b}(\xi_{J,b}) = \sum_{k \in J^*_b} n_k(\xi_k)^{e(l_b,k)} \quad (k \in J^*_b).$$

We then have the inequalities

$$e_W^*(j,k) = \begin{cases} 
\frac{e(k_p,k)}{e(k_p,j)} e_W(\mu,\nu) & \text{if } \mu, \nu \in S^*, \ j \in I^*_\mu, \ k \in I^*_\nu \\
\frac{e(k_p,j)}{e(l_b,k)} e_W(\mu,\nu) & \text{if } \mu, \nu \in T^*, \ j \in J^*_\mu, \ k \in J^*_\nu \\
\frac{e(k_p,j)}{e(k_p,j)} e_W(\mu,\nu) & \text{if } \mu \in S^*, \ \nu \in T^*, \ j \in I^*_\mu, \ k \in J^*_\nu \\
\frac{e(k_p,j)}{e(k_p,j)} e_W(\mu,\nu) & \text{if } \mu \in T^*, \ \nu \in S^*, \ j \in J^*_\mu, \ k \in I^*_\nu.
\end{cases}$$

If $\mu, \nu \in S^*$ and $j \in I^*_\mu, k \in I^*_\nu$, using the inequality $e_W(\mu,\nu) \leq b_W(\mu,\nu)$, we have

$$e_W^*(j,k) \leq \frac{e(k_p,k)}{e(k_p,j)} b_W(\mu,\nu) = \frac{e(k_p,k)}{e(k_p,j)} \min_{l \in I^*_\nu} \frac{e(k_p,l)}{e(k_p,j)} \leq \frac{e(k_p,k)}{e(k_p,j)} \leq e(j,k),$$

and similarly if $\mu, \nu \in T^*$.

Assume now that $\mu \in S^*, \ \nu \in T^*, \ j \in I^*_\mu, \ k \in J^*_\nu$. In this case the inequality $e_W(\mu,\nu) \leq b_W(\mu,\nu)$ may not be sufficient (e.g., we may have $b_W(\mu,\nu) = \infty$). However, we can use the basic inequality

$$e_W(\mu,\nu) \leq e_W(\mu,\nu)e_W(\nu',\nu) \leq b_W(\mu,\nu)b_W(\nu',\nu) \leq \Lambda_W(I^*_\mu, J^*_\nu) \tau_T(\ell_\nu, \ell_\nu),$$

where
which holds for all \( \nu' \in T^* \). Choosing \( \nu' \) so that \( j \in J_{\nu'} \), we have, with \( m = w(\mu, \nu') \),

\[
e^*_W(j, k) \leq \frac{e(\ell_{\nu'}, k)}{e(k_\mu, j)} \Lambda_W(I_\mu, J_{\nu'}) \tau_T(\ell_{\nu'}, \ell_{\nu'})\]

\[
= \frac{e(\ell_{\nu'}, k) e(k_\mu, v_m)}{e(k_\mu, j)} \min_{i \in J_{\nu'}} \frac{e(\ell_{\nu'}, i)}{e(\ell_{\nu'}, i)} e(\ell_{\nu'}, 1) \leq \frac{e(k_\mu, v_m) e(\ell_{\nu'}, k)}{e(k_\mu, j)} e(\ell_{\nu'}, j).
\]

(9.16)

Since \( j \in I^*_\mu \cap J_{\nu'} \), it follows from (9.9) that \( k = v_{m'} \) with \( m' > m \) in the ordering \( 9.5 \) on \( I_\mu \cap J_{\nu'} \), i.e.,

\[
e(k_\mu, v_m) = \tau_T(v_m, \ell_{\nu'}) \leq \tau_S(v_m, k_\mu) = e(k_\mu, j).
\]

Hence

\[
e^*_W(j, k) \leq \frac{e(\ell_{\nu'}/, k)}{e(\ell_{\nu'}, j)} \leq e(j, k).
\]

The last case, with \( \mu \in T^* \), \( \nu \in S^* \), \( j \in J^*_\mu \), \( k \in I^*_\nu \), is treated similarly. \( \square \)

### 9.9 Estimates for \([\varphi]_I \ast [\psi]_J\)

Fix marked partitions \( S = ((I_1, k_1); \ldots; (I_s, k_s)) \) and \( T = ((J_1, \ell_1); \ldots; (J_q, \ell_q)) \), and let \( W \in \mathcal{W}(S, T) \). Recall that

\[
I^*_r = \bigcup_{I_r \cap J_a \neq \emptyset} \{ j \in I_r \cap J_a : \frac{i_r}{e(k_r, j)} > \frac{j_a}{e(\ell_a, j)} \forall \{(i_1, \ldots, i_s), (j_1, \ldots, j_q)\} \in \Gamma_{E,S,T,W} \}.
\]

\[
J^*_a = \bigcup_{I_r \cap J_a \neq \emptyset} \{ j \in I_r \cap J_a : \frac{i_r}{e(k_r, j)} \leq \frac{j_a}{e(\ell_a, j)} \forall \{(i_1, \ldots, i_s), (j_1, \ldots, j_q)\} \in \Gamma_{E,S,T,W} \}.
\]

Then

\[
S^* = \{ r \in \{1, \ldots, s\} : I^*_r \neq \emptyset \} = \{ r_1, \ldots, r_\alpha \}
\]

\[
T^* = \{ a \in \{1, \ldots, q\} : J^*_a \neq \emptyset \} = \{ a_1, \ldots, a_\beta \}
\]

are the fixed indices. Write \( \mathbb{R}^N = \bigoplus_{j=1}^{\alpha+\beta} V_j \) as in subsection 9.6. Thus if \( \mathbf{x} \in \mathbb{R}^N \), \( \mathbf{x} = (\mathbf{x}_1, \ldots, \mathbf{x}_{\alpha+\beta}) \) where each \( \mathbf{x}_m \) is either equal to \( \mathbf{x}_{r} = \{ x_j : j \in I^*_r \} \) for some \( r \in S^* \) or is equal to \( \mathbf{x}_{a} = \{ x_j : j \in I^*_a \} \) for some \( a \in T^* \). In equation (9.12) we introduced a family of dilations on the space \( V_m \) by setting

\[
\lambda \circ \mathbf{x}_m = \begin{cases}
\left\{ \lambda^{1/\ell(k_r, j)} \cdot x_j : j \in I^*_r \right\} & \text{if } \mathbf{x}_m = \mathbf{x}_{I^*_r}, \\
\left\{ \lambda^{1/\ell(\ell_a, j)} \cdot x_j : j \in J^*_a \right\} & \text{if } \mathbf{x}_m = \mathbf{x}_{J^*_a}.
\end{cases}
\]

Let \( I = (i_1, \ldots, i_s) \) and \( J = (j_1, \ldots, j_q) \) with \( (I, J) \in \Gamma_{W}(S, T) \). If \( \varphi, \psi \in C_0^\infty(\mathbb{R}^N) \) have support in the unit ball, it follows from from part (9) of Lemma 9.3 that there is a function \( \theta \in C_0^\infty(\mathbb{R}^N) \), normalized with respect to the functions \( \varphi \) and \( \psi \), so that

\[
[\varphi]_I \ast [\psi]_J(\mathbf{x}) = 2^{-\sum_{j=1}^{\alpha+\beta} m_j} \theta(2^{-m_1} : \mathbf{x}_1, \ldots, 2^{-m_{\alpha+\beta}} : \mathbf{x}_{\alpha+\beta}),
\]
where $Q^*_j$ is the homogeneous dimension of $V_j$, and

\[
m_j = i_r \quad \text{if } \mathfrak{m}_r = x_{r*},
\]

\[
m_j = j_\alpha \quad \text{if } \mathfrak{m}_r = x_{j_\alpha*}.
\]

Thus the indices $\{m_1, \ldots, m_{n+\beta}\}$ are some permutation of the indices $\{r_1, \ldots, r_{n+\beta}\}$. Note that if $S^{**} = \{r_{n_1+1}, \ldots, r_s\} \subset \{1, \ldots, s\}$ and $T^{**} = \{a_{\beta+1}, \ldots, a_q\} \subset \{1, \ldots, q\}$ are the free indices, they do not appear among the indices $\{m_1, \ldots, m_{n+\beta}\}$.

Now suppose that $\varphi$ has cancellation in the variables $\{x_{k_1}, \ldots, x_{k_\gamma}\}$ and that $\psi$ has cancellation in the variables $\{x_{k_1}, \ldots, x_{k_\gamma}\}$. In order to obtain additional estimates of the function $\theta$, we will use part (b) of Lemma 9.4. Using the notation of Lemma 9.4, we have

\[
C = \{k_1, \ldots, k_s\} \subset \{1, \ldots, n\},
\]

\[
D = \{\ell_1, \ldots, \ell_q\} \subset \{1, \ldots, n\}.
\]

The dilations are given by

\[
\lambda_j = 2^{i_r/\varepsilon(k_j, j)} \quad \text{if } j \in I_r,
\]

\[
\mu_k = 2^{j_\alpha/\varepsilon(\ell_\alpha, k)} \quad \text{if } j \in J_\alpha.
\]

The set $C_1 = \{k_r : \lambda k_r < \mu \ell_a\}$ is now the union of two disjoint subsets:

\[
C'_1 = \{k_r : I^*_r = \emptyset\} = \{k_r : r \text{ is free}\},
\]

\[
C''_1 = \{k_r : I^*_r \neq \emptyset \text{ and } k_r \notin I^*_r\} = \{k_r : r \text{ is fixed and } k_r \notin I^*_r\}.
\]

The same is true of the set $D_1 = \{\ell_a : \mu \ell_a \leq \lambda \ell_a\}$:

\[
D'_1 = \{\ell_a : J^*_a = \emptyset\} = \{\ell_a : a \text{ is free}\},
\]

\[
D''_1 = \{\ell_a : J^*_a \neq \emptyset \text{ and } \ell_a \notin J^*_a\} = \{\ell_a : a \text{ is fixed and } \ell_a \notin J^*_a\}.
\]

The sets $C_2$ and $D_2$ are given by

\[
C_2 = \{k_r : r \text{ is fixed and } k_r \in I^*_r\},
\]

\[
D_2 = \{\ell_a : a \text{ is fixed and } \ell_a \in J^*_a\}.
\]

Define maps

\[
\sigma_1 : \{1, \ldots, s\} \to \{1, \ldots, q\} \text{ such that } k_r \in J_{\sigma_1(r)},
\]

\[
\sigma_2 : \{1, \ldots, q\} \to \{1, \ldots, s\} \text{ such that } \ell_a \in I_{\sigma_2(a)},
\]

and note that

\[
1 \leq r \leq s \text{ and } r \text{ is free } \implies \sigma_1(r) \text{ is fixed},
\]

\[
1 \leq a \leq q \text{ and } a \text{ is free } \implies \sigma_2(a) \text{ is fixed}.
\]

Applying part (d) of Lemma 9.3 we have the following result.

**Lemma 9.13.** Let $(I, J) \in \Gamma(E_{S,T,W})$, let $\varphi, \psi$ be normalized bump functions, and suppose that $\varphi$ has cancellation in the variables $\{x_{k_1}, \ldots, x_{k_\gamma}\}$ and that $\psi$ has cancellation in the variables $\{x_{\ell_1}, \ldots, x_{\ell_\gamma}\}$. Write $[\varphi]_{1} \ast [\psi]_{2} = [\theta]_M$ as in Lemma 9.3. There exists $\epsilon > 0$ depending only on the group structure so that $\theta$ can be written as a finite sum of terms of the form

\[
\prod_{k_r \in C'_1} 2^{-cG_1(k_r)} \prod_{k_r \in C''_1} 2^{-cG_2(k_r)} \prod_{\ell_a \in D'_1} 2^{-cH_1(\ell_a)} \prod_{\ell_a \in D''_1} 2^{-cH_2(\ell_a)} \theta_{C''_2 \ast D''_2}
\]

where the factors are defined as follows.
a) $C_2$ and $D_2$ are each partitioned into two disjoint subsets:

$$C_2 = C_2' \cup C_2'', \quad C_2' \cap C_2'' = \emptyset,$$

$$D_2 = D_2' \cup D_2'', \quad D_2' \cap D_2'' = \emptyset.$$

b) The functions $\{ \theta_{C_2', D_2'} \} \subset C_0^\infty(\mathbb{R}^n)$ are normalized relative to $\varphi$ and $\psi$.

c) The function $\theta_{C_2', D_2'}$ has cancellation in each variable $x_m = x_{I_r'}$ if $r \in C_2''$.

d) The function $\theta_{C_2', D_2'}$ has cancellation in each variable $x_m = x_{I'_a}$ if $a \in D_2''$.

e) The expressions $G_j(r)$ and $H_j(a)$ are given by:

$$G_1(i_r) = \min \left\{ \frac{j_{\sigma_1(r)}}{e(\ell_{\sigma_1(r)}, k_r)} - i_r, \ i_{r+1} - i_r \right\};$$

$$H_1(j_a) = \min \left\{ \frac{k_{\sigma_2(a)}}{e(k_{\sigma_2(a)}, \ell_a)} - j_a, \ j_{a+1} - j_a \right\};$$

$$G_2(i_r) = i_{r+1} - i_r;$$

$$H_2(j_a) = j_{a+1} - j_a.$$ 

The meaning of this result is as follows. The original functions $\varphi^I$ or $\psi^J$ have cancellation in variables whose indices belong to $C_0 \cup C_1 \cup C_2$ and to $D_0 \cup D_1 \cup D_2$. Then with $\varphi^I \ast \psi^J = [\theta^I,J]_{M'}$, the function $\theta^I,J$ can be written as a sum of terms in which a normalized bump function $\Theta^I \ast_{C_1', D_1'}$ are multiplied by certain small factors.

A) If $r \in \{1, \ldots, s\}$ or $a \in \{1, \ldots, q\}$ is a free variable then $r \in C_1'$ or $a \in D_1'$. If $r$ is free, the scale of $[\varphi^I]_I$ in the coordinate $x_{k_r}$ must be smaller than the scale of $[\psi^J]_J$ in $x_{k_r}$, which is $j_{\sigma_1(r)}/e(\ell_{\sigma_1(r)}, k_r)$. Thus there is a gain, either of order $-\epsilon[j_{\sigma_1(r)}/e(\ell_{\sigma_1(r)}, k_r) - i_r]$ or of order $-\epsilon[i_{r+1} - i_r]$, due either to integration by parts or to replacing the derivative $\partial_{x_{k_r}}$ with the corresponding invariant differential operator. This leads to the term $2^{-\epsilon G_1(r)}$, and there is a similar explanation for the term $2^{-\epsilon H_1(a)}$. In particular, there is an gain associated with all free indices.

B) If $r \in \{1, \ldots, s\}$ or $a \in \{1, \ldots, q\}$ is a fixed variable, then $r \in C_2' \cup C_2$ or $a \in D_2' \cup D_2$.

a) For indices $r \in C_2'$, $k_r \notin I'_s$ and so the scale of $[\varphi^I]_I$ in the coordinate $x_{k_r}$ must be smaller than the scale of $[\psi^J]_J$ in $x_{k_r}$, which is $j_{\sigma_1(r)}/e(\ell_{\sigma_1(r)}, k_r)$. Thus there is a gain, either of order $-\epsilon[j_{\sigma_1(r)}/e(\ell_{\sigma_1(r)}, k_r) - i_r]$ or of order $-\epsilon[i_{r+1} - i_r]$, due either to integration by parts or to replacing the derivative $\partial_{x_{k_r}}$ with the corresponding invariant differential operator. This leads to the term $2^{-\epsilon G_1(r)}$ and there is a similar explanation for the term $2^{-\epsilon H_1(a)}$.

b) For an index $r \in C_2$, it may happen that the cancelation of $[\varphi^I]_I$ in the variable $x_{k_r}$ leads to cancellation in this variable of the convolution $[\varphi^I]_I \ast [\psi^J]_J$. We let $C_2''$ be the elements of $C_2$ where this happens and $C_2'$ be the complementary set. Then $\theta_{C_2', D_2''}$ does have cancellation in the variables $x_{I_r'}$ for $r \in C_2''$. In the same way $\theta_{C_2'', D_2'}$ does have cancellation in the variables $x_{I'_a}$ for $a \in D_2''$.

c) For indices $r \in C_2' = C_2 \setminus C_2''$ or $a \in D_2'' = D_2 \setminus D_2'$, since cancellation does not persist in the convolution, there is an exponential gain of order $-\epsilon[i_{r+1} - i_r]$ or $-\epsilon[j_{a+1} - j_a]$ due replacing an ordinary derivative by a left- or right-invariant operator. This leads to the terms $2^{-\epsilon G_2(r)}$ and $2^{-\epsilon H_2(a)}$. 

Remarks 9.14. Let \((I, J) \in \Gamma(E_{S,T,W})\).

1) If \(k_r \in C'_1\) then \(i_r \leq j_{\sigma_1(r)} e(\ell_{\sigma_1(r)}, k_r)^{-1}\) and \(\sigma_1(r)\) is a fixed index. Similarly, if \(\ell_a \in D'_1\) then \(j_a \leq k_{\sigma_2(a)} e(k_{\sigma_2(a)}, \ell_a)^{-1}\) and \(\sigma_2(a)\) is a fixed index.

2) If \(k_r \in C''_1\) then \(\sigma_1(r)\) is also fixed, and

\[
\frac{i_r}{j_{\sigma_1(r)}} \geq \tau_W(J_{\sigma_1(r), I_r})^{-1} \geq A_W(J_{\sigma_1(r), I_r})^{-1} = \frac{e(k_r, v_{m_r, \sigma_1(r)})}{e(\ell_{\sigma_1(r)}, v_{m_r, \sigma_1(r)})} \geq e(\ell_{\sigma_1(r)}, k_r)^{-1}
\]

where the second inequality follows from the definition of \(\tau_W\) since \(J^*_{\sigma_1(r)} \cap I_r \neq \emptyset\), and the last inequality follows from the basic hypothesis. Thus \(i_r - e(\ell_{\sigma_1(r)}, k_r)^{-1}j_{\sigma_1(r)} \leq 0\).

Similarly, if \(j_a \in D''_1\), it follows that \(j_a - e(k_{\sigma_2(a)}, \ell_a)^{-1}i_{\sigma_2(a)} \leq 0\).

9.10 Proof of Theorem 9.2

We have seen on page 61 that Theorem 9.2 follows from Lemma 9.3 which deals with sums of convolutions \([\varphi^I]_J \ast [\psi^J]_J\) where \((I, J) \in \Gamma(E_S) \times \Gamma(E_T)\). In section 9.3 we partitioned \(\Gamma(E_S) \times \Gamma(E_T)\) into disjoint sets \(\Gamma_W(S, T)\) for \(W \in \mathcal{W}(S, T)\). Thus the proof of Lemma 9.15 and hence Theorem 9.2 follows from the following result.

Lemma 9.15. If \(F \subset \Gamma_W(S, T)\) is any finite set, then

\[
\mathcal{H}_F = \sum_{(S,T) \in F} [\varphi^I]_J \ast [\psi^J]_J \in \mathcal{P}_0(E_{S,T,W})
\]

with constants independent of the finite set \(F\). Moreover, \(\lim_{F \to \Gamma_W(S, T)} \mathcal{H}_F = \mathcal{H}_{S,T,W} \in \mathcal{P}_0(E_{S,T,W})\) with convergence in the sense of distributions. In particular, it follows from Lemma 9.13 that \(\mathcal{H}_{S,T,W} \in \mathcal{P}_0(E)\).

Proof. Recall from page 65 that

\[
\sum_{(I,J) \in \Gamma_W(S,T)} [\varphi^I]_J \ast [\psi^J]_J = \sum_{M \in \mathfrak{M}(S,T,W)} \left[ \sum_{(I,J) \in F(M)} g^I_J \right]_M = \sum_{M \in \mathfrak{M}(S,T,W)} [\Theta^M]_M.
\]

We first show that for each \(M \in \mathfrak{M}(S,T,W)\), the sum \(\sum_{(I,J) \in F(M)} g^I_J\) converges to a normalized bump function. Given \(M = (m_1, \ldots, m_{\alpha+\beta})\), this determines the indices \(i_r\) and \(j_a\) for which \(r\) and \(a\) are fixed, i.e. \(r \in \{r_1, \ldots, r_a\}\) and \(a \in \{a_1, \ldots, a_\delta\}\). Thus \(i_r\) and \(j_a\) belong to the sets \(C''_1, D'_1, C_2, D_2\). We must sum over the remaining indices corresponding to free variables \(r\) and \(a\) for which \(k_r \in C'_1\) and \(\ell_a \in D'_1\). We write the free variables as \(\{r_{\alpha+1}, \ldots, r_s\}\) and \(\{a_{\beta+1}, \ldots, a_q\}\). Using Lemma 9.13 it follows that \(\sum_{(I,J) \in F(M)} g^I_J\) is a finite sum of terms (indexed by subsets \(C''_2 \subset C_2\) and \(D''_2 \subset D_2\)) of the form

\[
\prod_{k_r \in C''_1} 2^{-eG_1(r)} \prod_{\ell_a \in D''_2} 2^{-eH_2(a)} \prod_{k_r \in C''_1} 2^{-eG_2(r)} \prod_{\ell_a \in D''_2} 2^{-eH_2(a)} \sum_{(r_{\alpha+1}, \ldots, r_s) \in C''_1} \prod_{v=\alpha+1}^s 2^{-eG_1(r_v)} \sum_{(a_{\beta+1}, \ldots, a_q) \in D''_2} \prod_{v=\beta+1}^q 2^{-eH_2(a_v)} \theta_{C''_2, D''_2}
\]

where each function \(\theta_{C''_2, D''_2}\) has cancellation in the variables \(x_m = x_I\) if \(r \in C''_2\) and \(x_m = x_J\) if \(a \in D''_2\).
We have
\[
\sum_{(s_\alpha, \ldots, s_{\beta+1}) \in C_0^s} \prod_{v=0}^{\alpha+1} 2^{-sG_1(r_e)} \prod_{v=\beta+1}^{s} 2^{-sH_1(a_v)} \theta_{C_0^s, D_0^s} \leq \prod_{v=\alpha+1}^{\beta+1} \left[ \sum_{j_{x_0}, k_{x_0} \in C_0^s} 2^{-s[j_{x_0}(r_e) - e_{x_0}]} \right] \prod_{v=\beta+1}^{s} \left[ \sum_{j_{x_0}, k_{x_0} \in C_0^s} 2^{-s[k_{x_0}(a_v) - e_{x_0}]} \right] < \infty.
\]

It follows that \( \sum_{(I,J) \in F(M)} \theta^{I,J} \) is a finite sum of terms of the form
\[
\prod_{k_r \in C_0^s} 2^{-sG_1(r)} \prod_{\ell_a \in D_0^s} 2^{-sH_1(a)} \prod_{k_r \in C_0^s} 2^{-sG_2(r)} \prod_{\ell_a \in D_0^s} 2^{-sH_2(a)} \theta_{M,C_0^s, D_0^s}^{I,J}
\]
where \( \theta_{M,C_0^s, D_0^s}^{I,J} \) is a normalized bump function. It remains to show that
\[
\sum_{M \in \mathbb{B}(S,T,W) \cap C_0^s} \prod_{k_r \in C_0^s} 2^{-sG_1(r)} \prod_{\ell_a \in D_0^s} 2^{-sH_1(a)} \prod_{k_r \in C_0^s} 2^{-sG_2(r)} \prod_{\ell_a \in D_0^s} 2^{-sH_2(a)} \theta_{M,C_0^s, D_0^s}^{I,J}
\]
converges in the sense of distributions to an element of \( P_0(E_{S,T,W}) \). However, this follows from Theorem 5.1 once we observe that each term in the sum is a function with weak cancellation with parameter \( \epsilon > 0 \) relative to the multi-index \( M \). This completes the proof. \( \square \)

10 Convolution of Calderón-Zygmund kernels

In this section we study the convolution of two or more compactly supported Calderón-Zygmund kernels with different homogeneities, and show that the result belongs to an appropriate class \( P_0(E_0) \).

10.1 Calderón-Zygmund kernels

Recalling the notion of Calderón-Zygmund kernel given in Definition 7.1 we define the corresponding class of kernels with rapid decay at infinity.

**Definition 10.1.** \( CZ_{a,0} \) is the space of tempered distributions \( \mathcal{K} \) on \( \mathbb{R}^N \) such that

(a) away from the origin, \( \mathcal{K} \) is given by integration against a smooth function \( K \) satisfying the differential inequalities
\[
|\partial^\gamma K(x)| \leq C_{\gamma,M} N_{a}(x)^{-Q_{a} - |\gamma|_{a}} (1 + N_{a}(x))^{-M},
\]

for every \( \gamma \) and \( M \);

(b) there is a constant \( C \) \( > 0 \) so that for any normalized bump function \( \psi \in C_0^\infty(\mathbb{R}^N) \) with support in the unit ball and for any \( R > 0 \), \( \langle K, \psi_R \rangle \leq C \), where \( \psi_R(x) = \psi(R^{-a} x) \).

It follows from the results of Section 4 that, for distributions \( \mathcal{K} \in CZ_{a,0} \), the corresponding multipliers \( m = \tilde{K} \) are characterized by the differential inequalities
\[
|\partial^\gamma m(\xi)| \leq C_{\gamma} [1 + N_{a}(\xi)]^{-|\gamma|_{a}}.
\]
These differential inequalities characterize the multipliers belonging to the class $\mathcal{M}_\infty(E_a)$ where $E_a$ is the matrix in (7.3). It follows that, if $K \in CZ_{a,0}$, then $K \in P_0(E_a)$. Moreover, the matrix $E_a$ is doubly monotone if and only if $a_1 \geq a_2 \geq \cdots \geq a_n$. Hence this is the compatibility condition with an underlying nilpotent Lie group structure in the sense of Section 8.1.

Finally, it follows from our decomposition result that if $K \in P_0(E_a)$, there exists $\Phi \in \mathcal{S}(\mathbb{R}^N)$ and a uniformly bounded family $\{\varphi^j\} \subset C^\infty_0(\mathbb{R}^N)$ such that $\int_{\mathbb{R}^N} \varphi^j(x) \, dx = 0$ for all $j$, and, in the sense of distributions,

$$\mathcal{K}(x) = \sum_{j=-\infty}^{0} [\varphi^j]_j(x) + \Phi(x) = \sum_{j=-\infty}^{0} 2^{-jQ_a} \varphi^j(2^{-j\alpha_1} \cdot x_1, \ldots, 2^{-j\alpha_n} \cdot x_n) + \Phi(x). \quad (10.1)$$

### 10.2 A general convolution theorem

Let $K_1, \ldots, K_p$ be Calderón-Zygmund kernels on a homogeneous nilpotent Lie group $G \cong \mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$. Suppose that the kernel $K_\ell$ is in the class $CZ_{a_\ell,0}$ associated with the dilations $\lambda^{a_\ell} : x = (\lambda^{a_\ell^1} x_1, \ldots, \lambda^{a_\ell^n} x_n)$. If $G$ is not abelian, we assume that (8.7) holds, as well as the compatibility condition $a_\ell^j \geq a_{\ell+1}^j$ for all $j, \ell$.

**Theorem 10.2.**

(a) The convolution $K_1 \ast \cdots \ast K_p$ belongs to the class $P_0(E)$ where $e(j,k) = \max_{1 \leq \ell \leq p} a_\ell^j / a_\ell^k$.

(b) Conversely, every $E$ arises in this way. Precisely, let $E = \{e(j,k)\}$ be any $n \times n$ matrix satisfying (2.10). There are $n$ sequences $a_k$ such that $e(j,k) = \max_{1 \leq \ell \leq n} a_\ell^j / a_\ell^k$. If $E$ is doubly monotone, each $a_k$ can be taken non-increasing.

**Proof.** We have the identity $CZ_{a_\ell,0} = P_0(E_\ell)$, where $e_\ell(j,k) = (a_\ell^j / a_\ell^k)^{-1}$. By Proposition 5.2, each $K_\ell \in P_0(E)$. Moreover, if $a_\ell^j \geq a_{\ell+1}^j$ for all $j, \ell$, $E$ is doubly monotone. Then part (a) follows from Theorems 9.1 and 9.2.

To establish (b), put $a_\ell^j = e(j, \ell)$. Since $E$ is doubly monotone, $a_\ell^j = e(j, \ell) \geq e(j+1, \ell) = a_\ell^j+1$, so $a_1^j \geq a_2^j \geq \cdots \geq a_n^j$. For any $1 \leq j, \ell \leq n$ we have

$$a_\ell^j / a_\ell^k = e(j, \ell) e(k, \ell) / e(k, \ell) = e(j, k)$$

so $\max_{1 \leq j \leq m} (a_\ell^j / a_\ell^k) \leq e(j, k)$. On the other hand

$$e(j, k) = e(j, k) / e(k, k) \leq \max_{1 \leq \ell \leq n} e(j, \ell) / e(k, \ell) = \max_{1 \leq \ell \leq n} a_\ell^j / a_\ell^k$$

This completes the proof. \qed

### 10.3 Convolution of two Calderón-Zygmund kernels

Part (a) of Theorem 10.2 determines the minimal class $P_0(E)$ containing a finite family of Calderón-Zygmund classes $CZ_{a_\ell,0}$ and part (b) shows that every class $P_0(E)$ arises in this way. It is possible, however, that a convolution

$$K_1 \ast K_2 \ast \cdots \ast K_p,$$

with $K_j \in CZ_{a_j,0}$, is contained in a proper subalgebra of the class $P_0(E)$ which appears in Theorem 10.2 (a).
We show that such a situation occurs with two Calderón-Zygmund classes having different homogeneities. Let $\mathbf{a} = (a_1, \ldots, a_n)$ and $\mathbf{b} = (b_1, \ldots, b_n)$ with $a_j \geq a_{j+1}$ and $b_j \geq b_{j+1}$ for all $j$, and set

$$
\lambda \cdot \mathbf{a} \mathbf{x} = (\lambda^{a_1} x_1, \ldots, \lambda^{a_n} x_n),
\lambda \cdot \mathbf{b} \mathbf{x} = (\lambda^{b_1} x_1, \ldots, \lambda^{b_n} x_n).
$$

Let $\mathcal{K} \in \mathcal{P}_0(\mathbf{E}_a)$ and $\mathcal{L} \in \mathcal{P}_0(\mathbf{E}_b)$. If we apply part (a) of Theorem 10.2, we obtain that $\mathcal{K} \ast \mathcal{L} \in \mathcal{P}_0(\mathbf{E})$, where the entries of $\mathbf{E}$ are

$$
e(j, k) = \max \left\{ \frac{a_j}{a_k}, \frac{b_j}{b_k} \right\}.
$$

(10.2)

Notice that

$$
e(j, k) e(k, j) = \max \left\{ \frac{b_j/a_j}{b_k/a_k}, \frac{b_k/a_k}{b_j/a_j} \right\},
$$

so that the reduced rank of $\mathbf{E}$ can be as large as $n$. We will show that $\mathcal{K} \ast \mathcal{L}$ belongs to the sum of $n - 1$ classes $\mathcal{P}_0(\mathbf{E}_m)$ where each $\mathbf{E}_m$ has reduced rank equal to 2.

As in (10.1), write

$$
\mathcal{K}(\mathbf{x}) = \sum_{j=-\infty}^{0} [\varphi^j]_j(\mathbf{x}) + \Phi(\mathbf{x}) = \sum_{j=-\infty}^{0} 2^{-jQ_a} \varphi^j(2^{-j a_1} \cdot x_1, \ldots, 2^{-j a_n} \cdot x_n) + \Phi(\mathbf{x}),
\mathcal{L}(\mathbf{x}) = \sum_{k=-\infty}^{0} [\psi^k]_k(\mathbf{x}) + \Psi(\mathbf{x}) = \sum_{k=-\infty}^{0} 2^{-kQ_b} \psi^k(2^{-k b_1} \cdot x_1, \ldots, 2^{-k b_n} \cdot x_n) + \Psi(\mathbf{x}).
$$

Since $\mathcal{K} \ast \mathcal{L}$, $\Phi \ast \Psi \in \mathcal{S}(\mathbb{R}^N)$, we only need to analyze the double sum

$$
\sum_{j=-\infty}^{0} \sum_{k=-\infty}^{0} [\varphi^j]_j \ast [\psi^k]_k.
$$

(10.3)

Let $\sigma$ be the permutation of $\{1, \ldots, n\}$ so that $\frac{b_{\sigma(1)}}{a_{\sigma(1)}} \leq \frac{b_{\sigma(2)}}{a_{\sigma(2)}} \leq \ldots \leq \frac{b_{\sigma(n)}}{a_{\sigma(n)}}$. For simplicity, we will suppose that all the inequalities are strict\(^{21}\).

We split the double sum in (10.3) into $n + 1$ two-parameter sums. Set

$$
\mathcal{N}_m = \sum_{(j, k) \in \Gamma_m} [\varphi^j]_j \ast [\psi^k]_k, \quad 0 \leq m \leq n,
$$

(10.4)

where

$$
\Gamma_0 = \left\{ (j, k) \in \mathbb{Z} \times \mathbb{Z} : j < 0, \quad k < 0, \quad \frac{j}{k} \leq \frac{b_{\sigma(1)}}{a_{\sigma(1)}}, \right\},
\Gamma_m = \left\{ (j, k) \in \mathbb{Z} \times \mathbb{Z} : j < 0, \quad k < 0, \quad \frac{b_{\sigma(m)}}{a_{\sigma(m)}} \leq \frac{j}{k} \leq \frac{b_{\sigma(m+1)}}{a_{\sigma(m+1)}}, \quad 1 \leq m \leq n - 1, \right\},
\Gamma_n = \left\{ (j, k) \in \mathbb{Z} \times \mathbb{Z} : j < 0, \quad k < 0, \quad \frac{b_{\sigma(n)}}{a_{\sigma(n)}} \leq \frac{j}{k} \right\}.
$$

(10.5)

Then clearly $\sum_{j=-\infty}^{0} \sum_{k=-\infty}^{0} [\varphi^j]_j \ast [\psi^k]_k = \sum_{m=0}^{n} \mathcal{N}_m$.

\(^{21}\) The proof below shows that this restriction does not affect the validity of the final result.
Lemma 10.3. For \(0 \leq m \leq n\) let \(A_m = \{\sigma(1), \ldots, \sigma(m)\}\) and \(B_m = \{\sigma(m+1), \ldots, \sigma(n)\}\). Then the distribution \(N_m \in \mathcal{P}_0(E_m)\) where \(E_m = \{e_m(j,k)\}\) is the \(n \times n\) matrix whose entries are given by

\[
e_m(j,k) = \frac{b_j}{b_k} \quad \text{if } j \in A_m \text{ and } k \in A_m,
\]

\[
e_m(j,k) = \frac{b_j a_{\sigma(m+1)}}{a_k b_{\sigma(m+1)}} \quad \text{if } j \in A_m \text{ and } k \in B_m.
\]

\[
e_m(j,k) = \frac{a_j b_{\sigma(m)}}{b_k a_{\sigma(m)}} \quad \text{if } j \in B_m \text{ and } k \in A_m,
\]

\[
e_m(j,k) = \frac{a_j}{b_k} \quad \text{if } j \in B_m \text{ and } k \in B_m.
\]

Proof. We use the fact that \([\varphi^j]_k * [\psi^k]_k(x) = 2^{-\sum_{p=1}^n l_p} \varphi^{j,k}(2^{-l_1} \cdot x_1, \ldots, 2^{-l_n} \cdot x_n)\) where \(l_p = j a_p \lor k b_p\). Now if \((j,k) \in \Gamma_m\) then

\[
l_p = \begin{cases} 
    kb_p & \text{if } p \in \{\sigma(1), \ldots, \sigma(m)\} = A_m, \\
    ja_p & \text{if } p \in \{\sigma(m+1), \ldots, \sigma(n)\} = B_m.
\end{cases}
\]

(10.6)

If \(L(j,k)\) is the multiindex with components \(l_p\) as above, one easily verifies that

\((j,k) \in \Gamma_m \implies L(j,k) \in \Gamma(E_m)\).

Consider first the case \(1 \leq m \leq n - 1\), where \(A_m\) and \(B_m\) are both nonempty. Then the map \((j,k) \in \Gamma_m \mapsto L(j,k)\) is injective. Since each term \([\varphi^j]_k * [\psi^k]_k\) has weak cancellation, it follows from Lemma 5.13 that the series (10.4) converges to a kernel in the class \(\mathcal{P}_0(E_m)\).

Suppose now that \(m = 0\) (the case \(m = n\) can be treated in the same way). In this case the matrix \(E_0\) has rank 1 and the statement is that \(N_0 \in CZ_{\mathbb{N},0}\). Notice that \(L(j,k) = ja\) only depends on \(j\). Hence for each \(j\) we must verify that

\[
\sum_{k=\gamma_{\sigma(1)}(j)}^{\gamma_{\sigma(1)}(j)} [\varphi^j]_k * [\psi^k]_k = [\tilde{\varphi}^j]_j
\]

with uniformly bounded functions \(\tilde{\varphi}^j\) with mean value zero (the scaling by \(j\) being as in (10.1)). It follows from Lemma 9.4 that each term in the sum is a normalized bump function times a factor that decreases exponentially with \(k\). The mean value zero property is obvious. \(\square\)

Remarks 10.4.

1. Recall that \(\frac{b_{\sigma(1)}}{a_{\sigma(1)}} < \frac{b_{\sigma(2)}}{a_{\sigma(2)}} < \cdots < \frac{b_{\sigma(m)}}{a_{\sigma(m)}} < \frac{b_{\sigma(m+1)}}{a_{\sigma(m+1)}} < \cdots < \frac{b_{\sigma(n-1)}}{a_{\sigma(n-1)}} < \frac{b_{\sigma(n)}}{a_{\sigma(n)}}\), and that \(a_1 \geq a_2 \geq \cdots \geq a_n\), \(b_1 \geq b_2 \geq \cdots \geq b_n\). We claim that \(e(j+1,j) \leq 1\) for \(1 \leq j \leq n - 1\).

- If \(j, j+1 \in A_m\), then since \(b_{j+1} \leq b_j\),

\[
e(j+1,j) = \frac{b_{j+1}}{b_j} \leq \frac{b_j}{b_j} = 1;
\]

- If \(j \in A_m\) and \(j+1 \in B_m\) then \(a_{j+1} b_{\sigma(m+1)} \leq a_{\sigma(m+1)} b_{j+1} \leq \frac{a_{\sigma(m)}}{b_{\sigma(m)}}\) and so

\[
e(j+1,j) = \frac{a_{j+1} b_{\sigma(m)}}{b_j a_{\sigma(m)}} \leq \frac{a_{j+1} b_{\sigma(m)}}{b_{j+1} a_{\sigma(m)}} \leq 1.
\]

\(^{22}\) The fact that the components \(l_p\) are not integers is irrelevant as long as they belong to a fixed lattice.
• If \( j \in B_m \) and \( j + 1 \in A_m \) then \( \frac{b_{j+1}}{a_{j+1}} \leq \frac{b_{\sigma(m)}}{a_{\sigma(m)}} \) and so
\[
e(j + 1, j) = \frac{b_{j+1}a_{\sigma(m)+1}}{a_{j}b_{\sigma(m)+1}} \leq \frac{b_{\sigma(m)}a_{\sigma(m)+1}}{a_{\sigma(m)}b_{\sigma(m)+1}} \leq 1.
\]

• If \( j, j+1 \in B_m \), then since \( a_{j+1} \leq a_j \),
\[
e(j + 1, j) = \frac{a_{j+1}}{a_j} \leq 1.
\]

It now follows from Proposition 3.3 that the matrix \( E_m \) is doubly monotone.

2. For \( m = 0, n \), \( E_m \) has rank one and \( N_0 \in CZ_{a,0}, N_n \in CZ_{b,0} \). For \( 1 \leq m \leq n - 1 \), we can also think of the distribution \( N_m \) on the coarser decomposition
\[
\mathbb{R}^N = \left( \bigoplus_{j \in A_m} \mathbb{R}^{C_j} \right) + \left( \bigoplus_{j \in B_m} \mathbb{R}^{C_j} \right).
\]
with exponents, in the notation of Section 5.3 \( \alpha_m = (\alpha_{m,1}, \ldots, \alpha_{m,n}) \) given by
\[
\alpha_{m,j} = \begin{cases} 1/b_j & \text{if } j \in A_m \\ 1/a_j & \text{if } j \in B_m. \end{cases}
\]
\[
E_m^\alpha = \left[ \begin{array}{c} 1 \\ \frac{b_{\sigma(m)}}{a_{\sigma(m)}} \end{array} \right].
\]
(Note that the product of the off-diagonal elements is at least 1.)

3. The proof of Lemma 10.3 shows that, if \( G \) is the additive group \( \mathbb{R}^N \), the inclusion (10.7) holds without any monotonicity assumption on the \( a_j \) and the \( b_j \) and with the same definition of \( \sigma(m) \).\(^{23}\)

Proposition 10.5. We have the inclusion
\[
CZ_{a,0} \ast CZ_{b,0} \subseteq \sum_{m=1}^{n-1} P_0(E_m), \tag{10.7}
\]
Moreover, the class \( \sum_{m=1}^{n-1} P_0(E_m) \) is contained in \( P_0(E) \), where \( E \) is the matrix with entries from \( P_0(E) \), and is closed under convolution.

Proof. The inclusion follows since \( N_0 \in P_0(E_1), N_n \in P_0(E_{n-1}) \). By Proposition 5.2, the first part of the statement follows from the inequalities
\[
e_m(j, k) \leq \max \left\{ \frac{a_j}{a_k}, \frac{b_j}{b_k} \right\},
\]
which can be easily verified. To prove the second part of the statement, observe that each \( K \in \sum_{m=1}^{n-1} P_0(E_m) \) decomposes as
\[
K = \sum_{m=1}^{n-1} N_m + \sum_{l=1}^{n} M_l,
\]
\(^{23}\) This can also be proved more directly by decomposing the multiplier \( \mu = \hat{K} \hat{L} \). Assuming, as we may, that the variables have been ordered so that \( \sigma(m) = m \) for every \( m \), \( \mu \) can be decomposed as a sum \( \mu = \sum_{m=1}^{n-1} \mu_m \), where \( \mu_m \in M_\infty(E_m) \) and \( E^m \cap \text{supp} \mu_m \) is contained in the set where
\[
N_b(\xi_1, \ldots, \xi_m)^{b_m} \leq AN_b(\xi_m, \ldots, \xi_n)^{a_m}, \quad N_a(\xi_{m+1}, \ldots, \xi_n)^{a_{m+1}} \leq AN_b(\xi_1, \ldots, \xi_{m+1})^{b_{m+1}}.
\]
where \( N_m \in \mathcal{P}_0(E_m) \) has the form

\[
N_m = \sum_{(j,k) \in \Gamma_m} [\varphi^{j,k}]_{L(j,k)},
\]

where the \( \varphi^{j,k} \) are uniformly bounded and have cancellation in the variables \( x_{A(m)} \) and \( x_{B(m)} \), and \( M_l \in CZ_{\gamma_l,a} \), where \( \gamma_l = (\gamma_l^1, \ldots, \gamma_l^n) \) and

\[
\gamma_l^m = \begin{cases} a_{r(i)}b^m_m & \text{if } \frac{b_m}{a_m} \leq \frac{b_{r(i)}}{a_{r(i)}} \\ b_{r(i)}a^m_m & \text{if } \frac{b_m}{a_m} \geq \frac{b_{r(i)}}{a_{r(i)}} \end{cases}
\]

Given a second kernel \( K' = \sum_{m=1}^{n-1} N'_m + \sum_{l=1}^{n} M'_l \), we consider the convolutions

\[
N_m * N'_m, \quad M'_m * M'_m, \quad M_l * N'_m, \quad M_l * M'_m.
\]

We prove that, assuming \( m \leq m' \), \( N_m * N'_m \in \sum_{p=m}^{m'} \mathcal{P}_0(E_p) \). The proofs of the following statements are left to the reader:

\[
N_m * M'_l \in \begin{cases} \sum_{p=m}^{l-1} \mathcal{P}_0(E_p) & \text{if } m < l' \\ \sum_{p=m}^{l} \mathcal{P}_0(E_p) & \text{if } m \geq l' \end{cases} \quad (\text{similarly for } M_l * N'_m);
\]

\[
M_l * M'_l \in \sum_{p=l}^{l'} \mathcal{P}_0(E_p) \quad (l < l').
\]

Let

\[
N_m = \sum_{(j,k) \in \Gamma_m} [\varphi^{j,k}]_{L(j,k)}, \quad N'_m = \sum_{(j',k') \in \Gamma_m} [\psi^{j',k'}]_{L'(j',k')}.
\]

where the components of \( L'(j',k') \) are defined by \[10.6\] with \( m' \) in place of \( m \). We isolate a single term \([\varphi^{j,k}]_{L(j,k)} \ast [\psi^{j',k'}]_{L'(j',k')} \) in the convolution, which is scaled by the multi-index \( L(j,k) \vee L'(j',k') = (l_p)_{1 \leq p \leq n} \), where

\[
L(j,k)_p = \begin{cases} kbp & \text{if } p \in A_m \\ jap & \text{if } p \in B_m \\ k'bp & \text{if } p \in A_{m'} \\ j'ap & \text{if } p \in B_{m'}.
\end{cases}
\]

Consider first the case \( k \leq k' \).

If \( p \in A_m \subset A_{m'} \), then \( l_p = k'bp \).

Assume now that \( r, s \in \{m+1, \ldots, m'\}, r < s \). Then \( p = \sigma(r), q = \sigma(s) \in B_m \cap A_{m'} \). If \( ja_p \geq k'bp \), then

\[
j \geq k' \frac{b_p}{a_p} \geq k' \frac{b_p}{a_q}.
\]

If

\[
m'' = \max \{ r : k'bp_{\sigma(r)} > ja_{\sigma(r)} \},
\]

\[
l_p = \begin{cases} k'bp & \text{if } p = \sigma(r) \text{ with } r \leq m'' \\ jap & \text{if } p = \sigma(r) \text{ with } m'' < r \leq m'.
\end{cases}
\]

Assume that \( R' \) is nonempty, i.e., that, for \( q = \sigma(m'), k'bp_q \leq ja_q \). Since \( (j',k') \in \Gamma_{m'} \), we have

\[
j' < k' \frac{b_q}{a_q} \leq j.
\]
Therefore \( l_p = ja_p \) for all \( p \in B_{m'} \). To conclude,
\[
l_p = \begin{cases} 
  k'b_p & \text{if } p \in A_{m''}, \\
  ja_p & \text{if } p \in B_{m''}.
\end{cases}
\]

Notice that \((j, k') \in \Gamma_{m''}\) by \(\text{(10.9)}\). We then have
\[
\sum_{\substack{(j, k) \in \Gamma_m \\
(j', k') \in \Gamma_{m'} \\
k \leq k'}} \sum_{m''} \sum_{(j, k) \in \Gamma_{m''}} \sum_{(j', k') \in \Gamma_{m'}} \sum_{k \leq k', j \leq j'} [\varphi^{j,k}]_{L(j, k)} \ast [\psi^{j',k'}]_{L'(j', k')} = \tag{10.10}
\]

By Lemma \(\text{[9.3]}\), the terms in the innermost sum are uniformly bounded up to a factor which decays exponentially in \(j'\) and \(k\) and have weak cancellation in the variables \(x_{A_{m''}}, x_{B_{m''}}\). So the sum in \(\text{(10.10)}\) belongs to \(\sum_{m''} P_0(E_{m''})\).

Consider now \(k > k'\). Then \(l_p = ka_p\) for \(p \in A_m\). Since \((j, k) \in \Gamma_m\), for \(p = \sigma(m + 1)\) we have \(ja_p \geq kb_p > k'b_p\). Hence \(l_p = ja_p\). By \(\text{(10.8)}\), we obtain that \(l_p = ja_p\) for all \(p \in B_m \cap A_{m'}\).

In particular, since \((j', k') \in \Gamma_{m'}\), for \(p = \sigma(m')\) we have \(ja_p \geq kb_p > j'a_p\) so that \(j > j'\). Then \(l_p = ja_p\) for all \(p \in B_{m'}\). To conclude, \(L(j, k) \lor L'(j', k') = L(j, k) \in \Gamma_m\) and
\[
\sum_{\substack{(j, k) \in \Gamma_m \\
(j', k') \in \Gamma_{m'} \\
k > k'}} \sum_{m''} \sum_{(j, k) \in \Gamma_{m''}} \sum_{(j', k') \in \Gamma_{m'}} \sum_{k < k', j < j'} [\varphi^{j,k}]_{L(j, k)} \ast [\psi^{j',k'}]_{L'(j', k')} = \tag{10.11}
\]

Repeating the same arguments used in the other case, we conclude that the sum in \(\text{(10.11)}\) belongs to \(P_0(E_m)\).

\section{11 Two-flag kernels and multipliers}

In this Section we show the surprising fact, already mentioned in Section \(\text{11.2}\) that distributions which are simultaneously flag kernels for two opposite flags are in fact the elements of an appropriate class \(P(E)\). We will recall the definition of flag-kernel in Section \(\text{11.1}\) and define two-flag kernels in Section \(\text{11.2}\). We consider the special case of step-two flags (which is considerably simpler than the general case) in Section \(\text{11.3}\) and the general situation in Section \(\text{11.4}\). The key point is that if \(m\) is the Fourier transform of a compactly supported distribution satisfying the differential inequalities of flag kernels, then \(m\) actually satisfies improved estimates. This is established in Section \(\text{11.5}\).

\subsection{11.1 Flag kernels and multipliers}

We recall the definition of flag kernel introduced in \([NRS01]\). Let \(\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}\), and use the notation of Section \(\text{2}\) so that \(n_j\) is a homogeneous norm on \(\mathbb{R}^{C_j}\), which has homogeneous dimension \(Q_j\). An \(n\)-step flag is a strictly increasing sequence of \(n\) subspaces
of $\mathbb{R}^N$, each of which is a direct sum of the subspaces $\{\mathbb{R}^{C_1}, \ldots, \mathbb{R}^{C_n}\}$. In particular, denote by $\mathcal{F}$ the flag
\begin{equation}
\mathcal{F}: \quad (0) \subset \mathbb{R}^{C_n} \subset \mathbb{R}^{C_{n-1}} \oplus \mathbb{R}^{C_n} \subset \cdots \subset \mathbb{R}^{C_2} \oplus \cdots \oplus \mathbb{R}^{C_n} \subset \mathbb{R}^N.
\end{equation}
Given an $n$-tuple $a = (a_1, \ldots, a_n)$ of positive real numbers, we consider the dilations
\begin{equation}
\lambda \cdot a \cdot x = (\lambda^{a_1} \cdot x_1, \ldots, \lambda^{a_n} \cdot x_n)
\end{equation}
developed in (7.2) and introduce on $\mathbb{R}^N$ the partial norms
\begin{equation}
N_j'(x) = n_1(x_1)^{1/a_1} + \cdots + n_j(x_j)^{1/a_j},
\end{equation}
so that $N_j'$ does not involve the variables $x_{j+1}, \ldots, x_n$. Recall that if $L = \{l_1, \ldots, l_r\} \subset \{1, \ldots, n\}$ with $l_1 < \cdots < l_r$, we denote by $\mathbb{R}^L$ the space $\mathbb{R}^{C_{l_1}} \oplus \cdots \oplus \mathbb{R}^{C_{l_r}}$. The “quotient flag” of $\mathcal{F}$ on $\mathbb{R}^L$, denoted by $\mathcal{F}_L$, is then
\begin{equation}
(0) \subset \mathbb{R}^{C_{l_r}} \subset \mathbb{R}^{C_{l_{r-1}}} \oplus \mathbb{R}^{C_{l_r}} \subset \cdots \subset \mathbb{R}^{C_{l_2}} \oplus \cdots \oplus \mathbb{R}^{C_{l_r}} \subset \mathbb{R}^L
\end{equation}
and the corresponding partial norms are given for $1 \leq j \leq r$ by
\begin{equation}
N_{L,j}(x_1, \ldots, x_j) = n_{l_1}(x_1)^{1/a_1} + \cdots + n_i(x_i)^{1/a_i}.
\end{equation}

Notice that intrinsic to the flag structure is an ordering of the subspaces $\mathbb{R}^{C_j}$, which must be taken into account in the labeling of variables, norms etc.

**Definition 11.1.** A flag kernel associated to the flag $\mathcal{F}$ and the dilations $\lambda \cdot a \cdot x$ is a distribution $\mathcal{K}$ on $\mathbb{R}^N$ with the following size estimates and cancellation conditions:

(A) [Differential Inequalities] Away from the subspace where $x_1 = 0$ the distribution $\mathcal{K}$ is given by integration against a smooth function $K$ which satisfies
\begin{equation}
|\partial_{x_{l_1}} \cdots \partial_{x_{l_r}} K(x_1, \ldots, x_n)| \leq C_\gamma \prod_{j=1}^n N_j'(x_1, \ldots, x_j)^{-\alpha_j(Q_j + \|\gamma_j\|)}.
\end{equation}

(B) [Cancellation Conditions] Let $L = \{l_1, \ldots, l_r\}$ and $M = \{m_1, \ldots, m_s\}$ be complementary subsets of $\{1, \ldots, n\}$, let $R = \{R_1, \ldots, R_s\}$ be positive real numbers, and let $\psi \in C_0^\infty(\mathbb{R}^M)$ be a normalized bump function with support in the unit ball. Define a distribution $\mathcal{K}_\psi, R$ on $\mathbb{R}^{C_{l_1}} \oplus \cdots \oplus \mathbb{R}^{C_{l_r}}$ by setting $\langle \mathcal{K}_\psi, R, \varphi \rangle = \langle \mathcal{K}_\psi \ast \psi, R, \varphi \rangle$ for every $\varphi \in C_0^\infty(\mathbb{R}^L)$. Then $\mathcal{K}_\psi, R$ uniformly satisfies the analogue of the estimates in (3) on the space $\mathbb{R}^L$: i.e. away from the subspace of $\mathbb{R}^L$ where $x_1 = 0$, the distribution $\mathcal{K}_\psi, R$ is given by integration against a smooth function $K_\psi, R$ and for every $\gamma = (\gamma_1, \ldots, \gamma_r) \in \mathbb{N}^{C_{l_1}} \times \cdots \times \mathbb{N}^{C_{l_r}}$, there is a constant $C_\gamma$ depending only on the constants in (3) and in particular independent of $\psi$ and $R$ so that
\begin{equation}
|\partial_{l_1} \cdots \partial_{l_r} K_\psi, R(x_1, \ldots, x_r)| \leq C_\gamma \prod_{j=1}^r N_{L,j}(x_1, \ldots, x_j)^{-\alpha_j(Q_j + \|\gamma_j\|)}.
\end{equation}

As usual, if $s = n$, we require that $|\langle \mathcal{K}, \psi, R \rangle|$ is bounded independently of $R$.

The following is Theorem 2.3.9 in [NRS01].

**Theorem 11.2.** If $\mathcal{K}$ is a flag kernel adapted to the flag (11.1) and the family of dilations (11.2), the Fourier transform $m = \hat{\mathcal{K}}$ is function smooth away from the subspace where $\xi_n = 0$ which satisfies the differential inequalities
\begin{equation}
|\partial_{\xi_1} \cdots \partial_{\xi_n} m(\xi_1, \ldots, \xi_n)| \leq C_\gamma \prod_{j=1}^n \left(n_j(\xi_j)^{1/a_j} + \cdots + n_n(\xi_n)^{1/a_n}\right)^{-\alpha_j(\|\gamma_j\|)}.
\end{equation}

Conversely, any function satisfying (11.6) is the Fourier transform of a flag kernel adapted to the flag (11.1) and dilations (11.2).
11.2 Pairs of opposite flags

In Section 11.1 we chose a particular ordering of the subspaces \( \{ \mathbb{R}^C_1, \ldots, \mathbb{R}^C_n \} \) to define the flag \( \mathcal{F} \) in (11.1) and a particular family of dilations on \( \mathbb{R}^N \) in (11.2). We can consider the opposite flag obtained by reversing the indices \( \{1, \ldots, n\} \) and choosing a different one-parameter family of dilations. Our objective is then to study two-flag distributions which are simultaneously flag kernels for the two different flags and two different homogeneities. Thus set
\[
\mathcal{F} : \quad (0) \subset \mathbb{R}^C_1 \subset \mathbb{R}^C_n \supseteq \mathbb{R} \supseteq \mathbb{R}^N, \\
\mathcal{F}^\perp : \quad (0) \subset \mathbb{R}^C_1 \subset \mathbb{R}^C_n \supseteq \mathbb{R} \supseteq \mathbb{R}^{C-1} \subset \mathbb{R}^N.
\]
(11.7)

Let \( \mathbf{a} = (a_1, \ldots, a_n) \) and \( \mathbf{b} = (b_1, \ldots, b_n) \) be two \( n \)-tuples of positive real numbers. Define two one-parameter families of dilations
\[
\lambda_{\mathbf{a}} \mathbf{x} = (\lambda^{a_1} \cdot \mathbf{x}_1, \ldots, \lambda^{a_n} \cdot \mathbf{x}_n), \\
\lambda_{\mathbf{b}} \mathbf{x} = (\lambda^{b_1} \cdot \mathbf{x}_1, \ldots, \lambda^{b_n} \cdot \mathbf{x}_n),
\]
(11.8)
and associate the first dilation with the flag \( \mathcal{F} \) and the second with the flag \( \mathcal{F}^\perp \). Along with satisfying the appropriate cancellation conditions, a two-flag distribution \( K \) then satisfies the following differential inequalities. Away from the set where \( \mathbf{x}_1 = 0 \) or where \( \mathbf{x}_n = 0 \), \( K \) is given by integration against a smooth function \( \hat{K} \) and
\[
|\partial^\gamma K(\mathbf{x})| \leq C_\gamma \left\{ \prod_{j=1}^n \left( n_1(\mathbf{x}_1)^{a_j/a_1} + \cdots + n_{j-1}(\mathbf{x}_{j-1})^{a_j/a_{j-1}} + n_j(\mathbf{x}_j) \right)^{-(Q_j + [\gamma_j])} \\
\prod_{j=1}^n \left( n_j(\mathbf{x}_j) + n_{j+1}(\mathbf{x}_{j+1})^{b_j/b_{j+1}} + \cdots + n_n(\mathbf{x}_n)^{b_n/n} \right)^{-(Q_j + [\gamma_j])} \right. 
\]
(11.9)

The corresponding Fourier transform \( m = \hat{K} \) satisfies
\[
|\partial^\gamma m(\xi)| \leq C_\gamma \left\{ \prod_{j=1}^n \left( n_j(\xi_j) + n_{j+1}(\xi_{j+1})^{a_j/a_{j+1}} + \cdots + n_n(\xi_n)^{a_n/a_n} \right)^{-[\gamma_j]} \\
\prod_{j=1}^n \left( n_1(\xi_1)^{b_j/b_1} + \cdots + n_{j-1}(\xi_{j-1})^{b_{j-1}/b_j} + n_j(\xi_j) \right)^{-[\gamma_j]} \right. 
\]

11.3 Two-step flags

We first consider the case of two-step flags, where \( \mathbb{R}^N = \mathbb{R}^n \oplus \mathbb{R}^m \). As we will see, this situation is much simpler than the general case considered later in Section 11.3. Write elements of \( \mathbb{R}^N \) as \( (\mathbf{x}, \mathbf{y}) \) with \( \mathbf{x} \in \mathbb{R}^n \) and \( \mathbf{y} \in \mathbb{R}^m \). For notational convenience we assume isotropic dilations on each component. There are two flags \( \mathcal{F} \) and \( \mathcal{F}^\perp \) adapted to this decomposition:
\[
\mathcal{F} : \quad (0) \subset \mathbb{R}^n \subset \mathbb{R}^n \oplus \mathbb{R}^m = \mathbb{R}^N \quad \text{and} \quad \mathcal{F}^\perp : \quad (0) \subset \mathbb{R}^m \subset \mathbb{R}^n \oplus \mathbb{R}^m = \mathbb{R}^N.
\]

Let \( \mathbf{a} = (a_1, a_2) \) and \( \mathbf{b} = (b_1, b_2) \) be two pairs of positive real numbers and put
\[
\lambda_{\mathbf{a}}(\mathbf{x}, \mathbf{y}) = (\lambda^{a_1} \mathbf{x}, \lambda^{a_2} \mathbf{y}), \\
\lambda_{\mathbf{b}}(\mathbf{x}, \mathbf{y}) = (\lambda^{b_1} \mathbf{x}, \lambda^{b_2} \mathbf{y}).
\]
(11.9)
Associate the family of dilations $\lambda \cdot (x, y)$ with the flag $\mathcal{F}$ and the family $\lambda \cdot b (x, y)$ with the flag $\mathcal{F}^ \perp$. A distribution $K$ on $\mathbb{R}^n \times \mathbb{R}^m$ is then a two-flag kernel relative to this data if it satisfies appropriate cancellation conditions and is given by integration against a smooth function $K$ which satisfies the differential inequalities

$$
|\partial^a_\xi \partial^b_\eta K(x, y)| \leq C_{\alpha, \beta} \begin{cases} 
|x|^{-n-|\alpha|} (|x|^{a_2/a_1} + |y|)^{-m-|\beta|} & \text{for } x \neq 0 \text{ (flag } \mathcal{F}) \\
(|x| + |y|)^{-n-|\alpha|} |y|^{-m-|\beta|} & \text{for } y \neq 0 \text{ (flag } \mathcal{F}^ \perp) 
\end{cases} \quad (11.10)
$$

If $m(\xi, \eta) = \widehat{K}(\xi, \eta)$ is the Fourier transform, then

$$
|\partial^a_\xi \partial^b_\eta m(\xi, \eta)| \leq C_{\alpha, \beta} \begin{cases} 
(\xi | + |\eta|^{a_1/a_2})^{-|\alpha|} |\eta|^{-|\beta|} & \text{for } \eta \neq 0 \text{ (flag } \mathcal{F}) \\
|\xi|^{-|\alpha|} (|\xi|^{b_2/b_1} + |\eta|)^{-|\beta|} & \text{for } \xi \neq 0 \text{ (flag } \mathcal{F}^ \perp)
\end{cases} \quad (11.11)
$$

It follows that both $K$ and $m$ are smooth away from the origin.

**Proposition 11.3.** Suppose that $\frac{a_2}{b_1} < \frac{a_1}{b_2}$, and let

$$
N_1(x, y) = |x| + |y|^{b_1/b_2} \quad \widehat{N}_1(\xi, \eta) = |\xi| + |\eta|^{a_1/a_2}
$$

$$
N_2(x, y) = |x|^{a_2/a_1} + |y| \quad \widehat{N}_2(\xi, \eta) = |\xi|^{b_2/b_1} + |\eta|
$$

be the norms associated with the matrix

$$
E = \begin{bmatrix} 1 & \frac{b_2}{b_1} \\ \frac{a_2}{a_1} & 1 \end{bmatrix} \quad (11.12)
$$

satisfying the basic hypotheses.

If $K$ is a two-flag kernel on $\mathbb{R}^n \times \mathbb{R}^m$ adapted to the dilations given in (11.9), then

(a) the corresponding function $K$ is integrable at infinity;

(b) $K \in \mathcal{P}(E)$ and $\widehat{K} = m \in \mathcal{M}(E)$;

(c) we can write $K = K_0 + K_\infty$ where $K_\infty \in L^1(\mathbb{R}^N) \cap C^\infty(\mathbb{R}^N)$, and $K_0$ is a two-flag kernel supported in $B(1)$.

Conversely, if $K$ is in $\mathcal{P}(E)$, then $K$ is a two-flag kernel (and $\widehat{K} = m$ a two-flag multiplier) on $\mathbb{R}^n \times \mathbb{R}^m$ adapted to the dilations given in (11.9).

**Proof.** We have already observed that $m$ is smooth away from the origin, and it follows from equation (11.11) that we have the following estimates for pure derivatives of $m$:

$$
|\partial^a_\xi m(\xi, \eta)| \lesssim (|\xi| + |\eta|^{a_1/a_2})^{-|\alpha|},
$$

$$
|\partial^b_\eta m(\xi, \eta)| \lesssim (|\xi|^{b_2/b_1} + |\eta|)^{-|\beta|}
$$

Since the rank of $E$ is greater than 1, it follows from Lemma 7.5 that $K$ is smooth away from the origin and is integrable at infinity. This establishes (a).

Next let $\chi \in C^\infty_0(\mathbb{R}^n \times \mathbb{R}^n)$ have support in the unit ball, with $\chi(x, y) \equiv 1$ if $|x| + |y| \leq \frac{1}{2}$. Obviously $K_0 = \chi K$ satisfies the differential inequalities (11.10) and it easy to verify that it also satisfies the cancellations in Definition (11.1). By (9), $K_\infty = (1 - \chi) \mathcal{K} \in L^1(\mathbb{R}^n) \cap C^\infty(\mathbb{R}^n)$. This establishes (c).

Being a two-flag kernel we know that $K_0$ satisfies (11.10). A case by case analysis shows that these estimates can be combined and improved.
(1) Suppose \(|x| \geq |y|^{b_1/b_2}\). Then \(|x|^{-1} \lesssim (|x| + |y|^{b_1/b_2})^{-1}\) and hence the first inequality shows that
\[
|\partial_x^a \partial_y^\beta K_0(x,y)| \lesssim (|x| + |y|^{b_1/b_2})^{-n-|\alpha|}(|x|^{a_2/a_1} + |y|)^{-m-|\beta|} .
\] (11.13)

(2) Suppose \(|y| \geq |x|^{a_2/a_1}\). Then \(|y|^{-1} \lesssim (|x|^{a_2/a_1} + |y|)^{-1}\), and the second inequality again gives the estimate in (11.13).

(3) Finally suppose \(|x| < |y|^{b_1/b_2}\) and \(|y| < |x|^{a_2/a_1}\). Here we must have
\[
|x| < |x|^{a_2/b_2} \quad \text{and} \quad |y| < |y|^{a_2/b_2} .
\]
Since \(a_2b_1 > a_1b_2\), this means that \(|x| > 1\) and \(|y| > 1\), and this is outside the support of \(K_0\). It follows that for all \((x, y) \in \mathbb{R}^n \oplus \mathbb{R}^m\) we have the improved estimates
\[
|\partial_x^a \partial_y^\beta K(x,y)| \lesssim (|x| + |y|^{b_1/b_2})^{-n-|\alpha|}(|x|^{a_2/a_1} + |y|)^{-m-|\beta|} .
\]

This shows that \(K_0 \in \mathcal{P}_0(E)\) since the cancellations conditions for the flag kernels are the same as the cancellation conditions for \(P_0(E)\). This establishes (d) and completes the proof. □

Remarks 11.4.

(1) For a matrix \(E\) of the form (11.12), the condition \(\frac{a_1}{b_1} \leq \frac{a_2}{b_2}\) is equivalent to the basic hypotheses. If the inequality is an equality, \(E\) is reducible and the class \(P(E)\) consists of Calderón-Zygmund kernels.

The arguments used in the proof of Proposition 11.3 can adapted to prove that, if the opposite inequality \(\frac{a_1}{b_1} > \frac{a_2}{b_2}\) holds, then a kernel \(K \in \mathcal{P}(E)\) (defined by the same differential inequalities and cancellations as in Definition 2.2) is integrable near 0 instead than at infinity. This suggests that the essentially local nature of the kernels strongly depends on the basic hypotheses.

(2) One may observe that a \(2 \times 2\) matrix satisfying the basic hypotheses can always be put in the form (11.12) for appropriate \(a_j, b_j\) with \(\frac{a_1}{b_1} \leq \frac{a_2}{b_2}\). This means that, for every two-fold decomposition \(\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \mathbb{R}^{C_2}\) and every \(E\) satisfying the basic hypotheses, the class \(P(E)\) coincides either with a class of two-flag kernels or with a class of Calderón-Zygmund kernels, depending on its rank.

As we will see next, this is specific of two-fold decomposition. However, it follows from Lemma 5.3 that the same also holds for general decompositions, as long as the reduced rank of \(E\) is not greater than 2.

11.4 General two-flag kernels

In the case of the two-step flags, the improved estimates for the kernel followed easily from the two-flag estimates simply by considering possible cases. However, if the number of norms is greater than two, this argument no longer works. Observe that the differential inequalities for the kernel \(K\) give no information when \(x_1 = x_n = 0\) while other \(x_j \neq 0\). In particular, it does not follow from the inequalities alone that the kernel is non-singular away from the origin. Nevertheless, we have the following result.

Theorem 11.5. Suppose that \(\frac{a_1}{b_1} \leq \frac{a_2}{b_2} \leq \cdots \leq \frac{a_m}{b_m}\) with at least one strict inequality, and let \(K\) be a two-flag kernel for the flags \(\mathcal{F}\) and \(\mathcal{F}^\perp\) with homogeneities \(a\) and \(b\) respectively.
(a) The function $K$ is integrable at infinity, and we can write $K = K_0 + K_\infty$ where $K_\infty \in L^1(\mathbb{R}^N) \cap C^\infty(\mathbb{R}^N)$, and $K_0$ is a two-flag kernel supported in $B(1)$.

(b) The kernel $K_0$ belongs to the class $\mathcal{P}_0(\mathcal{E})$ associated to the matrix

$$
\mathbf{E} = \begin{bmatrix}
1 & b_1/b_2 & b_1/b_3 & \cdots & b_1/b_{n-1} & b_1/b_n \\
1/a_1 & b_2/b_3 & b_2/b_4 & \cdots & b_2/b_{n-1} & b_2/b_n \\
a_3/a_1 & a_3/a_2 & 1 & \cdots & b_3/b_{n-1} & b_3/b_n \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
a_{n-1}/a_1 & a_{n-1}/a_2 & a_{n-1}/a_3 & \cdots & 1 & b_{n-1}/b_n \\
a_{n}/a_1 & a_n/a_2 & a_n/a_3 & \cdots & a_n/a_{n-1} & 1 \\
\end{bmatrix}.
$$

(11.14)

(c) Conversely, every kernel in $\mathcal{P}_0(\mathcal{E})$ is a two-flag kernel for the flags $\mathcal{F}$ and $\mathcal{F}^*$ with homogeneities $a$ and $b$ respectively.

Proof. If two ratios $a_j/b_j, a_k/b_k$ are equal, the product $e(j,k)e(k,j)$ is 1. By Proposition [11.5], the matrix $\mathbf{E}$ can be reduced to $\mathbf{E}^*$ of the same type. We may then assume that all inequalities are strict.

The first part of the proof proceeds as the proof of Proposition [11.3]. Combining the two kinds of estimates for pure derivatives of the Fourier transform $m$, we see that $m$ satisfies

$$
|\partial^j_\xi m(\xi)| \lesssim \hat{N}_j(\xi)^{-1} \tau_j
$$

where

$$
\hat{N}_j(\xi) = n_1(\xi_1)^{b_j/b_k} + \cdots + n_{j-1}(\xi_{j-1})^{b_j/b_{j-1}} + n_j(\xi_j)^{b_j/b_{j-1}} \cdots + n_n(\xi_n)^{a_j/a_n}.
$$

We want to apply Lemma 7.5 and so we need to check that the matrix $\mathbf{E}$ satisfies the basic hypothesis of (2.10) and has rank greater than 1. We proceed to check this.

We want to show that $e(j,k) \leq e(j,l)e(l,k)$ where $e(j,k) = \begin{cases} 
\frac{b_j}{b_k} & \text{if } j \leq k, \\
\frac{a_j}{a_k} & \text{if } j \geq k. 
\end{cases}$ Thus we need to show

$$
e(j,k) = \frac{b_j}{b_k} \leq \begin{cases} 
\frac{a_j}{a_k} & \text{if } j \leq k, \\
\frac{b_j}{b_k} & \text{if } j \leq l, \text{ if } j \leq k, \\
\frac{b_j}{b_k} & \text{if } j \leq l, \text{ if } j \leq k, \\
\frac{b_j}{b_k} & \text{if } j \leq l, \text{ if } j \leq k, \\
\frac{b_j}{b_k} & \text{if } j \leq k, \end{cases}
$$

$$
e(j,k) = \frac{a_j}{a_k} \leq \begin{cases} 
\frac{b_j}{b_k} & \text{if } j \leq k, \\
\frac{a_j}{a_k} & \text{if } j \leq l, \text{ if } j \geq k, \\
\frac{a_j}{a_k} & \text{if } j \leq l, \text{ if } j \geq k, \\
\frac{a_j}{a_k} & \text{if } j \leq k, \end{cases}
$$

However it is easy to check that all of these inequalities follow from the assumption in the Theorem. Thus $\mathbf{E}$ satisfies the basic hypotheses. Also one can check that

$$
\det(\mathbf{E}) = \prod_{j=2}^{n} \left( 1 - \frac{a_j}{b_j} \right) \neq 0
$$

so in fact the matrix $\mathbf{E}$ has rank $n$. Thus it follows from Lemma 7.5 that $K$ is integrable at infinity.

The proof of part (b) will use the following result, which shows that estimates for pure derivatives leads to estimates for mixed derivatives. In order to keep our focus on the proof of Theorem 11.5 we defer the proof to Section 11.5.
Lemma 11.6. Let \( m \in C^\infty(\mathbb{R}^N \setminus \{0\}) \). Suppose that for every \( \gamma_j \in \mathbb{N}^C \) there is a constant \( C_{\gamma_j} > 0 \) so that
\[
|\partial_{\xi_j}^{\gamma_j} m(\xi)| \leq C_{\gamma_j} \hat{N}_j(\xi)^{-[\gamma_j]}.
\]
Then for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^C_1 \times \cdots \times \mathbb{N}^C_n \) there is a constant \( C_{\gamma} > 0 \) so that if \( \xi \in \mathbb{B}(1)^C \),
\[
|\partial_{\xi_1}^{\gamma_1} \cdots \partial_{\xi_n}^{\gamma_n} m(\xi)| \leq C_{\gamma} \prod_{j=1}^{n} \hat{N}_j(\xi)^{-[\gamma_j]}.
\]

We now turn to the proof of Theorem 11.5 part (b), which is more involved than in the situation considered in Section 11.3. We start by decomposing the Fourier transform \( m_0 \) of the kernel \( K_0 \) by means of a smooth cutoff function supported in \( B(2) \) and equal to 1 on \( B(1) \). We obtain \( m_0 = m' + m'' \), where \( m' \) is in \( C_0(\mathbb{R}^N) \), while \( m'' \) is supported in \( B(1)^c \) and satisfies the inequalities (11.11). Denoting by \( K', K'' \) the inverse Fourier transforms of \( m', m'' \) respectively, we then have \( K_0 = K' + K'' \).

We consider \( m'' \) first. Since it satisfies the inequalities (11.11), the two types of estimates can be combined together to give
\[
|\partial_{\xi_1}^{\gamma_1} m''(\xi)| \lesssim \hat{N}_j(\xi)^{-[\gamma_j]},
\]
whenever we differentiate only in the \( \xi_j \)-variables (pure derivatives). Applying Lemma 11.6 and recalling that \( m'' \) is supported in \( B(1)^c \), we obtain inequalities for all derivatives of \( m'' \), namely
\[
|\partial_{\xi_1}^{\gamma_1} \cdots \partial_{\xi_n}^{\gamma_n} m''(\xi)| \lesssim \prod_{j=1}^{n} (1 + \hat{N}_j(\xi))^{-[\gamma_j]},
\]
which tells us that \( m'' \in \mathcal{M}_\infty(E) \).

By Theorem 1.1 it follows that \( K'' \in \mathcal{P}_0(E) \). Using a cutoff function in the \( x \)-variables, we could then split \( K'' \) as \( K_0 + K'' \), with \( K_0 \in \mathcal{P}_0(E) \) and \( K'' \in \mathcal{S}(\mathbb{R}^N) \).

We next observe that \( K' \in C^\infty(\mathbb{R}^n) \) because \( m' \) has compact support. It follows that \( K \) coincides with a smooth function away from the origin. We can then apply Theorem 7.5 and conclude that \( K \) is integrable at infinity.

Hence \( K' \in C^\infty(\mathbb{R}^N) \cap L^1(\mathbb{R}^N) \) and the same holds for \( K' + K'' = K_\infty \).

Finally, part (c) is an obvious consequence of (b).

Remark 11.7.
As mentioned in Remark 11.4, for a general matrix \( E \) with reduced rank larger than 2, it is not true that the class \( \mathcal{P}(E) \) coincides with a class of two-flag kernels. In fact, such a coincidence occurs if and only if the equality \( e(j, \ell) = e(j, k) e(k, \ell) \) holds whenever the triple \( j, k, \ell \) is ordered \( (j < k < \ell \text{ or vice-versa}) \).

The following statement is a direct consequence of Theorem 11.2.

Corollary 11.8. Let \( K, L \) be two compactly supported two-flag kernels as in Theorem 11.5 for the same pair of flags and the same homogeneities. Then the convolution \( K \ast L \) is also a two-flag kernel of the same type.

11.5 Proof of Lemma 11.6

In this section we complete the proof of Theorem 11.5 by proving Lemma 11.6 i.e. we show that if \( m \in C^\infty(\mathbb{R}^N) \) satisfies the estimates for the class of multipliers \( \mathcal{M}(E) \) for pure derivatives, then the estimates for mixed derivatives follow automatically. We will use the following result, which is easily proved by estimating the decay of the Fourier transform of \( f \).
Proposition 11.9. Let $f \in C^\infty_0(\mathbb{R}^N)$ be supported in the unit ball. Suppose that
\[ |\partial^\gamma f(\eta)| \leq C_\gamma \]
for each $j$ and each $\gamma_j \in \mathbb{N}^{C_i}$. Then for every $\gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n}$ we have
\[ |\partial^\gamma f(\eta)| \leq C_\gamma \]
where the constants $\{C_\gamma\}$ depend only on the constants $\{C_\gamma\}$.

Next let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in \mathcal{S}(n)$. For $\xi \in \mathbb{B}(1)^c \cap \hat{E}_S^A$, we give a quantitative estimate of the size of a ball about $\xi$ that we want contained in some larger region $\hat{E}_S^A$. Recall from Definition 3.12 and equation (3.5) that we defined a dilatation structure $\lambda^\gamma \xi, \xi \in \mathbb{B}(1)^c \cap \hat{E}_S^A$ and a corresponding smooth homogeneous norm $\hat{\nu}_{S, r}(\xi_{I_r}) \approx \sum_{j \in I_r} n_j(\xi_j)^{\epsilon(k_r, j)}$ on $\mathbb{R}^r$. Let $C \geq 1$ be a constant such that, for all $1 \leq r \leq s$, we have
\[ \hat{\nu}_{S, r}(\xi_{I_r} + \eta_{I_r}) \leq C \left[ \hat{\nu}_{S, r}(\xi_{I_r}) + \hat{\nu}_{S, r}(\eta_{I_r}) \right]. \tag{11.17} \]

Proposition 11.10. Let $S = \{(I_1, k_1); \ldots; (I_s, k_s)\} \in \mathcal{S}(n)$ and let $C$ be the constant from equation (11.17). Let $\xi = (\xi_1, \ldots, \xi_n) \in \mathbb{B}(1)^c \cap \hat{E}_S^A$. If $\epsilon < (2C)^{-1}$, then
\[ \left\{ \eta \in \mathbb{R}^N : \hat{\nu}_{S, r}(\xi_{I_r} - \eta_{I_r}) = \sum_{j \in I_r} n_j(\eta_j - \xi_j)^{\epsilon(k_r, j)} < \epsilon n_{k_r}(\xi_{k_r}), \ 1 \leq r \leq s \right\} \subset \hat{E}_S^{A'} \]
where $A'$ is a constant that depends only on $A$ and $C$.

Proof. Let $\xi \in \hat{E}_S^A$. Recall from part 11 of Lemma 3.9 that
\[ n_{k_r}(\xi_{k_r}) > A^{-1} n_j(\xi_j)^{\epsilon(k_r, j)} \quad \forall j \in I_r, j \neq k_r, \quad \text{and} \]
\[ n_{k_r}(\xi_{k_r}) > A^{-1} n_{k_r}(\xi_{k_r})^{1/\tau_{S(k_r, k_t)}} \quad \forall t \in \{1, \ldots, s\}, \ t \neq r. \]
Conversely, if $\eta \in \mathbb{B}(1)^c$ satisfies
\[ n_{k_r}(\eta_{k_r}) > A^{-1} n_j(\eta_j)^{\epsilon(k_r, j)} \quad \forall j \in I_r, j \neq k_r, \quad \text{and} \]
\[ n_{k_r}(\eta_{k_r}) > A^{-1} n_{k_r}(\eta_{k_r})^{1/\tau_{S(k_r, k_t)}} \quad \forall t \in \{1, \ldots, s\}, \ t \neq r. \]
then $\eta \in \hat{E}_S^{A'}$ where $\tau$ is a constant that depends only on the coefficients $\{\epsilon(j, k)\}$.

If $n_j(\eta_j - \xi_j)^{\epsilon(k_r, j)} < \epsilon n_{k_r}(\xi_{k_r})$ for $1 \leq r \leq s$ and all $j \in I_r$, and if $C \epsilon < \frac{1}{2}$, then
\[ n_{k_r}(\xi_{k_r}) \leq C \left[ n_{k_r}(\xi_{k_r}) + n_{k_r}(\eta_{k_r}) \right] \leq C \left[ \epsilon n_{k_r}(\xi_{k_r}) + n_{k_r}(\eta_{k_r}) \right] < \frac{1}{2} n_{k_r}(\xi_{k_r}) + C n_{k_r}(\eta_{k_r}) \]
so that for $1 \leq r \leq s$,
\[ n_{k_r}(\xi_{k_r}) < 2 C n_{k_r}(\eta_{k_r}). \tag{11.18} \]
Next, if $j \in I_r$,
\[ n_j(\eta_j) \leq C \left[ n_j(\xi_j - \eta_j) + n_j(\xi_j) \right] < C \left[ (\epsilon n_{k_r}(\xi_{k_r}))^{1/\epsilon(k_r, j)} + (An_{k_r}(\xi_{k_r}))^{1/\epsilon(k_r, j)} \right], \]
and it follows from (11.18) that
\[ n_j(\eta_j) \leq C' n_{k_r}(\eta_{k_r})^{1/\epsilon(k_r, j)} \tag{11.19} \]
where $C'$ depends on $C$, $\epsilon$, and $A$. Finally, if $1 \leq t \leq s$ with $t \neq r$, it follows from (11.19) that $n_{k_t}(\eta_{k_t}) \leq C' n_{k_r}(\xi_{k_r})^{1/\epsilon(k_r, k_t)}$, and so
\[ n_{k_t}(\eta_{k_t}) \leq C' \left( An_{k_r}(\xi_{k_r}) \right)^{\tau_{S(k_r, k_t)}} \leq C'' n_{k_r}(\eta_{k_r})^{\tau_{S(k_r, k_t)}} \tag{11.20} \]
where $C''$ depends on $C$, $\epsilon$, and $A$. It now follows from the inequalities in (11.19) and (11.20) that $\eta \in \hat{E}_S^{A'}$, and this completes the proof. \qed
We now prove Lemma III.10.

Let \( \xi \in \mathcal{B}(1)^r \). Then if \( A > 1 \) there exists \( S = ((I_1, k_1); \ldots; (I_s, k_s)) \in \mathcal{S}(n) \), so that \( \xi \in \hat{E}^A_S \). We have \( \hat{n}_r(\xi) \approx n_{k_r}(\xi_{k_r})^{1/e(k_r-j)} \) for every \( r \in \{1, \ldots, s\} \) and every \( j \in I_r \). (Here the implied constants depend on \( A \).) Thus to establish the Lemma we need to show that for every \( \gamma = (\gamma_1, \ldots, \gamma_n) \in \mathbb{N}^{C_1} \times \cdots \times \mathbb{N}^{C_n} \) there is a constant \( C_\gamma > 0 \) so that

\[
|\partial^\gamma_{\xi} m(\xi)| \leq C_\gamma \prod_{r=1}^s n_{k_r}(\xi_{k_r})^{-\sum_{j \in I_r} |\gamma_j|/e(k_r-j)}.
\]

According to Proposition III.10 there exists \( \epsilon > 0 \) and a constant \( A' \) depending only on \( A \) so that

\[
\{ \eta \in \mathbb{R}^n : n_j(\eta_j - \xi_j)^{1/e(k_r-j)} < \epsilon n_{k_r}(\xi_{k_r}) \text{ for } 1 \leq r \leq s \text{ and } j \in I_r \} \subset \hat{E}^A_S'.
\]

For \( 1 \leq r \leq s \) let \( \varphi_r \in C^\infty(\mathbb{R}^r) \) be supported where \( n_j(\eta_j) \leq 1 \) for all \( j \in I_r \), with \( \hat{n}_{S_r}(\eta_{I_r}) \equiv 1 \) if \( n_j(\eta_j) \leq \frac{1}{2} \) for all \( j \in I_r \). Put

\[
f(\eta) = \left( \prod_{r=1}^s \varphi_r(\eta_{I_r}) \right) m\left( \xi_{I_1} + [\epsilon n_{k_1}(\xi_{k_1})]^{\gamma_{S_1}} \eta_{I_1}, \ldots, \xi_{I_s} + [\epsilon n_{k_s}(\xi_{k_s})]^{\gamma_{S_s}} \eta_{I_s} \right).
\]

Here, the function \( m \) is evaluated at the point whose \( j^{th} \)-coordinate is

\[
v_j = \xi_j + [\epsilon n_{k_j}(\xi_{k_j})]^{1/e(k_r-j)} \cdot \eta_j
\]
when \( j \in I_r \). Clearly \( f \in C^\infty(\mathbb{R}^n) \) and is supported where \( n_j(\eta_j) \leq 1 \) for all \( 1 \leq j \leq n \). Moreover

\[
f(\eta) = m\left( \xi_{I_1} + [\epsilon n_{k_1}(\xi_{k_1})]^{\gamma_{S_1}} \eta_{I_1}, \ldots, \xi_{I_s} + [\epsilon n_{k_s}(\xi_{k_s})]^{\gamma_{S_s}} \eta_{I_s} \right)
\]
if \( n_j(\eta_j) \leq \frac{1}{2} \) for all \( j \). If \( f(\eta) \neq 0 \), so that \( n_j(\eta_j) \leq 1 \), then

\[
n_j(v_j - \xi_j) = n_j\left(n_{k_j}(\xi_{k_j})^{1/e(k_r-j)} \cdot \eta_j\right) = [\epsilon n_{k_j}(\xi_{k_j})]^{1/e(k_r-j)} n_j(\eta_j) \leq [\epsilon n_{k_j}(\xi_{k_j})]^{1/e(k_r-j)},
\]
and it follows that \( m \) is evaluated at a point of \( \hat{E}^A_S' \).

Consider ‘pure’ derivatives \( \partial^\gamma_{\eta_j} f \). Some of the derivatives will fall on \( (\prod_{r=1}^s \varphi_r(\eta_{I_r})) \) and the rest fall on the term involving \( m \). Derivatives of \( (\prod_{r=1}^s \varphi_r(\eta_{I_r})) \) are bounded by constants independent of \( m \). On the other hand, if \( \gamma_j \in \mathbb{N}^{|I_r|} \), using the chain rule, the hypothesis about pure derivatives of \( m \), and the fact that we are evaluating \( m \) at points in \( \hat{E}^A_S' \), we get

\[
\partial^\gamma_{\eta_j}\left[m\left( \xi_{I_1} + [\epsilon n_{k_1}(\xi_{k_1})]^{\gamma_{S_1}} \eta_{I_1}, \ldots, \xi_{I_s} + [\epsilon n_{k_s}(\xi_{k_s})]^{\gamma_{S_s}} \eta_{I_s} \right)\right]
\]

\[
= \left[\partial^\gamma_{\eta_j} m\right]\left( \xi_{I_1} + [\epsilon n_{k_1}(\xi_{k_1})]^{\gamma_{S_1}} \eta_{I_1}, \ldots, \xi_{I_s} + [\epsilon n_{k_s}(\xi_{k_s})]^{\gamma_{S_s}} \eta_{I_s} \right) \prod_{j \in I_r} [\epsilon n_{k_j}(\xi_{k_j})]^{1/|\gamma_j|/e(k_r-j)}
\]

\[
\leq C\gamma_j \prod_{j \in I_r} n_{k_j}(\xi_{k_j})^{-|\gamma_j|/e(k_r-j)} \prod_{j \in I_r} [\epsilon n_{k_j}(\xi_{k_j})]^{1/|\gamma_j|/e(k_r-j)} \leq C\gamma_j.
\]
Thus \( f \in C^\infty(\mathbb{R}^N) \) is supported in the unit ball, and pure derivatives are bounded. It follows from Proposition \([11.9]\) that all derivatives are bounded by constants depending only on the \( \{C_{\gamma_j}\} \). But for \( n_j(\eta_j) \leq \frac{1}{r} \), we have
\[
\partial_{\eta_{i_1}}^{\gamma_{i_1}} \cdots \partial_{\eta_{i_s}}^{\gamma_{i_s}} f(\eta) = \left[ \partial_{\eta_{i_1}}^{\gamma_{i_1}} \cdots \partial_{\eta_{i_s}}^{\gamma_{i_s}} \right] (v_1, \ldots, v_n) \prod_{r=1}^{s} n_{k_r}(\eta_{k_r})^{\sum_{j=1}^{r} \gamma_j} |\gamma_{j}|^{\varepsilon(k_r,j)}.
\]
where \( v_j = \xi_j + |e_{k_r}(\eta_{k_r})|^{1/\varepsilon(k_r,j)} \cdot \eta_j \). When \( \eta = 0 \), the uniform bounds on \( f \) give the desired estimates for the derivatives of \( m \), and this completes the proof. \( \square \)

12 Extended kernels and operators

Operators of the form \( T_Kf = f \ast K \) with \( K \in \mathcal{P}_0(\mathcal{E}) \) are “constant coefficient” operators. In this section we consider a more general class of operators which have “variable coefficients”. Identify the space \( \mathbb{R}^N \) with a nilpotent Lie group \( G \cong \mathbb{R}^N \) as in Section \( 9 \) and consider kernels of the form \( K(x,z) \), with \( (x,z) \in G \times G \), so that for each \( x \in G \), \( K(x,\cdot) \in \mathcal{P}(\mathcal{E}) \), with smooth dependence on \( x \). More precisely, assume that for each norm \( | \cdot |_M \) defined in \([2.13]\) and each \( \beta \),
\[
\sup_x |X^\beta K(x,\cdot)|_M < \infty,
\]
where \( X^\beta \) is a monomial in the left-invariant vector fields of \( G \) acting on the \( x \)-variable. We also assume (unless \( G = \mathbb{R}^N \) as an additive group) the hypotheses of Theorems \([8.3]\) and \([9.2]\) to guarantee that proper kernels define bounded convolution on \( L^p \), \( 1 < p < \infty \) and form a class closed under convolution.

Kernels of this kind will be said to belong to the “extended class”, to distinguish them from the “proper” kernels in \( \mathcal{P}_0(\mathcal{E}) \) which are independent of \( x \). Operators corresponding to these extended kernels are given formally by
\[
Tf(x) = \int_G K(x,y^{-1}x)f(y)dy;
\]
that is, if \( f \in \mathcal{S}(\mathbb{R}^N) \), \( Tf(x) = \langle K(x,\cdot), f_x \rangle \), with \( f_x(y) = f(xy^{-1}) \).

Note that the extended class of operators is left-invariant in the following sense. If \( a \in G \) set \( L_af(x) = f(ax^{-1}x) \). Then \( L_a^{-1}TL_a \) is an operator again of the form \([12.2]\), with \( K(x,z) \) replaced by \( K(ax,z) \). Observe that the semi-norms \([12.1]\) of \( K(x,z) \) and \( K(ax,z) \) are the same.

Our main results concerning this extended class of kernels and operators are as follows.

**Theorem 12.1.** Each operator \( T \) given by \([12.2]\) is bounded on \( L^p(\mathbb{R}^N) \), \( 1 < p < \infty \).

**Theorem 12.2.** The class of these operators form an algebra under addition and composition of operators.

12.1 The \( L^p \) boundedness of the operators

Recall that if \( \delta_r : G \to G \) is the one-parameter group of automorphic dilations of the group \( G \), the coordinates on \( \mathbb{R}^N \) are chosen so that \( \delta_r(x_1, \ldots, x_N) = (r^{d_1}x_1, \ldots, r^{d_N}x_N) \) with \( d_1 \leq d_2 \leq \cdots \leq d_N \). Let \( | \cdot |_G \) be a smooth homogeneous norm, so that \( |\delta_r x|_G = r |x|_G \). The homogeneous dimension of \( G \) is \( Q = \sum_{j=1}^{N} d_j \), and \( d(x,y) = |y^{-1}x|_G \) is a left-invariant quasidistance. Let \( B_r(x) = \{ y \in G : d(x,y) < r \} \). Then \( |B_r(x)| = |B_r(0)| = r^Q |B_1(0)| \). We will write \( B_r(0) = B_r \).
In proving Theorem 12.1 we make a preliminary reduction to kernels $K(x, z)$ that are supported when $z \in B_1$. In fact let $\eta$ be a $C^\infty$ function supported in $B_1$ which equals 1 when $z \in B_{1/2}$. Then writing $K(x, z) = K_0(x, z) + K_\infty(x, z) = K(x, z)\eta(z) + K(x, z)(1 - \eta(z))$, we see that $K_\infty(x, z)$ is bounded and rapidly decreasing as $|z| \to \infty$. Now the operator $T_\infty$, that is $\int K_\infty(x, y)f(xy^{-1})dy$, and hence, by Minkowski’s inequality, is bounded on $L^p$, for all $1 \leq p \leq \infty$.

Thus suppose $K(x, z)$ is supported when $z \in B_1$. We make a further assumption that $K(x, z)$ is supported when $x \in B_\lambda$, where $\lambda$ is so small that $B_{2\lambda}$ is strictly contained in the torus $T = \{x : |x_j| < \frac{1}{2}, \ j = 1, \ldots, N\}$. (Later we will lift this hypothesis.) In this case we can extend $K$ outside of $T$ by periodicity, and expand $K(x, z)$ as Fourier series in the $x$-variable,

$$K(x, z) = \sum_{k \in \mathbb{Z}^N} e^{2\pi ik \cdot x} \mathcal{H}_k(z),$$

with

$$\mathcal{H}_k(z) = \frac{1}{(2\pi)^N} \int_T e^{-2\pi ik \cdot x} K(x, z)dx.$$  \hfill (12.3)

Each kernel $\mathcal{H}_k(z)$ can be written as $\alpha_k K_k(z)$ in such a way that the $\alpha_k$ are rapidly decreasing coefficients and the $K_k$ are proper kernels, supported for $z \in B_1$, whose semi-norms $|K_k|_M$ are uniformly bounded in $k$ for every $M$. This can be done via the following diagonal argument. Integrating by parts in (12.3), we obtain that, for every integer $q$,

$$|\mathcal{H}_k|_M \leq \frac{C_q}{|k|^q} |K_k|_{q,M},$$

where $|K|_{q,M}$ denotes the supremum of the semi-norms implied by (12.1) over $|\beta| \leq q$. Then, given $q$, we inductively choose increasing integers $m_q$ such that

$$\frac{C_q}{m_q} |K|_{q,q} < \frac{1}{m_q^{q/2}}.$$

For $m_q \leq |k| < m_{q+1}$, we set

$$\alpha_k = \frac{C_q}{|k|^q} |K|_{q,q}.$$

Then $\alpha_k < |k|^{-q/2}$, showing that the $\alpha_k$ are rapidly decreasing, and the kernels $K_k = \alpha_k^{-1} \mathcal{H}_k$ are uniformly bounded in every $M$-norm (we remark that the $M$-norms are increasing in $M$). Upon relabeling the series and with a slight abuse of notation, this gives

$$K(x, z) = \sum_{n=1}^{\infty} a_n(x) K_n(z).$$  \hfill (12.4)

Here $a_n(x) = \eta(x) \alpha_k e^{2\pi ik \cdot x}$, $K_n(z) = K_k(z)$ (for a $k$ that depends on $n$); also $\eta$ is a suitable $C^\infty$ cut-off function supported in $x \in B_\lambda$. With this choice, the $a_n(x)$ are a rapidly decreasing sequence of $C^\infty$ functions, each supported in $B_\lambda$. Clearly now the operator $T$ whose kernel is given by (12.2) is bounded on $L^p$, in view of Theorem 8.9.

Now, with the above $\lambda$ fixed, we will drop the restriction that $K(x, z)$ is supported for $x \in B_\lambda$, by a further decomposition which writes $\mathbb{R}^N$ as an union of balls $B_\lambda(x_m) = x_m \cdot B_\lambda$, with these balls chosen so they are “almost” disjoint. For this we need the following lemma.

**Lemma 12.3.** Given $\lambda > 0$, there is a collection $\{B_\lambda(x_m)\}$ so that

(1) $\{B_{\lambda/2}(x_m)\}$ covers $\mathbb{R}^N$. 

(2) for every \( \mu > 0 \), the collection \( \{B_\mu(x_m)\} \) has the bounded intersection property: there exists an integer \( M = M_\mu \) so that no point \( x \in \mathbb{R}^M \) is contained in more than \( M \) of the \( \{B_\mu(x_m)\} \).

**Proof.** Fix a constant \( c_1 \) (which is small with \( \lambda \), and which will be chosen momentarily) and choose the centers \( x_m \) so that the balls \( \{B_1(x_m)\} \) are disjoint, and so that this is a maximal family with respect to that property. Now if \( \bigcup B_{3/2}(x_m) \) does not cover \( \mathbb{R}^N \), there exists an \( x_0 \), so that \( d(x_0, x_m) \geq \lambda/2 \) for all \( m \). We then claim that \( B_{c_1}(x_0) \) must be disjoint from all the \( B_{c_1}(x_m) \), violating the maximality. In fact if this disjointness fails, then there is an \( x' \in B_{c_1}(x_0) \cap B_{c_1}(x_m) \) for some \( m \). This means \( d(x', x_0) < c_1 \) and \( d(x', x_m) < c_1 \), which by the quasi-triangle inequality \( d(x_0, x_m) \leq c(d(x', x_0) + d(x', x_m)) \) gives a contradiction with \( d(x_0, x_m) \geq \lambda/2, \) when \( \lambda/2 \geq 2c_1 \). Thus if we choose \( c_1 = \lambda/4c \) we get conclusion (1).

To prove the second conclusion we may choose \( \mu \geq c_1 \). Suppose \( x' \) and \( x'' \) belong to \( B_\mu(x_m) \). Then \( d(x', x'') \leq 2c\mu \), so \( x'' \in B_{2c\mu}(x') \), and hence \( B_\mu(x_m) \subset B_{2c\mu}(x') \). If \( x' \) belongs to \( M \) of the \( B_\mu(x_m) \), then \( B_\mu(x_m) \subset B_{2c\mu}(x') \) for each of these \( m \). Since then \( B_{c_1}(x_m) \subset B_{2c\mu}(x') \) and the \( B_{c_1}(x_m) \) are disjoint, we have

\[
\sum m(B_{c_1}(x_m)) \leq m(B_{2c\mu}(x')),
\]

where the sum is taken over those \( m \). By homogeneity we get \( Mc_1 \leq (2c\mu)^Q \), and conclusion (2) is established with \( M = (2c/c_1)^Q \). \( \square \)

We now return to the proof of Theorem 12.1. Let us fix a positive \( C^\infty \) function \( \varphi \) that equals 1 in \( B_{3/2} \) and vanishes outside \( B_{3} \). Let \( \varphi_m(x) = \varphi(x_m^{-1} \cdot x) \), with the \( x_m \) as given in Lemma 12.3. Then because of conclusions (1) and (2) of the lemma, \( 1 \leq \sum \varphi_m(x) \leq M \). Set \( \psi_m(x) = \varphi_m(x)/\sum \varphi_m(x) \). Since \( \{X^\alpha \varphi_m\} \) are bounded uniformly in \( m \), the same is true of \( \{\psi_m\} \). Notice that the \( \{\psi_m\} \) give a partition of unity, with \( \psi_m \) supported in \( B_1(x_m) \).

We let \( K_m(x, z) = \psi_m(x)K(x, z) \) and \( T_m(f)(x) = \int K_m(x, y^{-1}x)f(y)dy \). Then \( T = \sum T_m \). Observe that \( T_m \) is of the form \( L_{x_m}T'L_{x_m}^{-1} \), where \( L_x \) is left-translation by \( x \) and \( T' \) is an operator for which we already know its \( L^p \) boundedness by Theorem 8.9. Hence

\[
||T_m(f)||_{L^p} \leq A_p||f||_{L^p}, \tag{12.5}
\]

uniformly in \( m \), for \( 1 < p < \infty \). Now because \( T = \sum T_m \), the lemma (with \( \mu = \lambda \)) gives us

\[
\int |T|^pd\mathbf{x} \leq M_\lambda \sum m \int |T_m(f)|^pd\mathbf{x}
\]

However by (12.5),

\[
\int |T_m(f)|^pd\mathbf{x} \leq A_p^p \int |f|^pd\mathbf{x}.
\]

This is because \( x \in B_\lambda(x_m) \) and \( y^{-1}x \in B_1 \) imply \( y \in B_\mu(x_m) \) here with \( \mu = c(\lambda + 1) \), in view of the fact that \( d(y, x_m) \leq c(d(x(x_m) + d(y, x)) \), and the support properties of \( K_m(x, z) \). Again by conclusion (2) of Lemma 12.3

\[
\sum m \int_{B_\mu(x_m)} |f|^pd\mathbf{x} \leq M_\mu \int |f|^pd\mathbf{x},
\]

giving the conclusion \( ||T(f)||_{L^p} \leq A'_p||f||_{L^p} \) and so proving Theorem 12.1.
12.2 The algebra of operators

Proceeding to the proof of Theorem 12.2, we first summarize and slightly rephrase the essential idea of the previous subsection. Whenever \( \mathcal{K}(x, z) \) is a kernel of the extended class that is supported for \( |z| \leq 1 \), then we can write it as

\[
\mathcal{K}(x, z) = \sum_{n,m} a_{n,m}(x) \mathcal{K}_{n,m}(z),
\]

where

(a) the \( \mathcal{K}_{n,m} \) are proper kernels, each supported for \( z \) in the unit ball, with \( M \)-norms that are uniform in \( n \) and \( m \);

(b) the \( a_{n,m}(x) \) are \( C^\infty \) functions, each supported in \( x \in B_3(x_m) \);

(c) for every \( \alpha \), \( \sup_x |X^\alpha a_{n,m}(x)| \) is rapidly decreasing as \( n \to \infty \), uniformly in \( m \).

To prove Theorem 12.2 we study the composition of two operators \( T \) and \( S \) given by

\[
T(f)(x) = \int \mathcal{K}(x, y^{-1}x)f(y)dy, \quad S(f)(x) = \int \mathcal{L}(x, y^{-1}x)f(y)dy
\]

where \( \mathcal{K} \) and \( \mathcal{L} \) are both kernels of the extended class. We consider first their essential parts, that is, we restrict ourselves to \( \mathcal{K}(x, z) \) and \( \mathcal{L}(x, z) \) that are supported when \( z \) is in the unit ball \( B_1 \). Now by (12.6), \( T = \sum_{n,m} T_{n,m} \) and \( S = \sum_{n',m'} S_{n',m'} \) where

\[
T_{n,m}(f)(x) = a_{n,m}(x)(f \ast \mathcal{K}_{n,m})(x), \quad S_{n',m'}(f)(x) = b_{n',m'}(x)(f \ast \mathcal{L}_{n',m'})(x).
\]

and where \( \{ \mathcal{K}_{n,m} \} \) and \( \{ \mathcal{L}_{n',m'} \} \) are uniform families of proper kernels, each supported in \( |z| \leq 1 \).

We next observe that, for each \( m \), \( T_{n,m} \circ S_{n',m'} = 0 \) unless \( m' \) belongs to a subset of boundedly many \( m' \) (depending on \( m \)). In fact, by the support properties of \( a_{n,m} \) and \( b_{n',m'} \), and the kernels \( \mathcal{K}_{n,m} \) and \( \mathcal{L}_{n',m'} \), the product \( T_{n,m} \circ S_{n',m'} \) is non-vanishing only if the quasi-distance between \( B_3(x_m) \) and \( B_3(x_{m'}) \) does not exceed 1. Thus by conclusion (2) of Lemma 12.3, this only happens for at most \( M_\mu \) of the \( m' \), where \( \mu = c^2(2\lambda + 1) \).

From this, and the rapid decrease of \( a_{n,m} \) and \( b_{n',m'} \) as \( n \to \infty \) and \( n' \to \infty \), we see that the analysis of the composition can be reduced to the case when both \( T \) and \( S \) are each one summand. So we write \( T = a \circ U \), \( S = b \circ V \), where \( U(f) = f \ast \mathcal{K} \) and \( V(f) = f \ast \mathcal{L} \), with both \( \mathcal{K} \) and \( \mathcal{L} \) proper kernels supported for \( |z| \leq 1 \). Now

\[
T \circ S = a \circ U \circ b \circ V = a \circ b \circ U \circ V + a \circ [b, U] \circ V.
\]

The term \( a \circ b \circ U \circ V \) is of the right form because it corresponds to the kernel \( a(x)b(x)(L \ast K)(z) \), and \( \mathcal{L} \ast K \) is a proper kernel by Theorem 9.2. On the other hand,

\[
[b, U](f)(x) = \int (b(x) - b(y))\mathcal{K}(y^{-1}x)f(y)\,dy.
\]

Write \( b(x) - b(y) = c(x, z) \), with \( z = y^{-1}x \); thus \( c(x, z) = b(x) - b(xz) \). Recall that \( c(x, z) \) can be restricted to \( z \in B_1 \), (the support of \( K \)), and so can be taken to have compact \( z \)-support. Also, \( c(x, z) \) is jointly \( C^\infty \), and \( \sup_x |X^\alpha c(x, z)| < \infty \), uniformly in \( z \).

At this stage we invoke the following lemma.

Lemma 12.4. Let \( \mathcal{K} \in \mathcal{P}_0(\mathcal{E}) \) and \( c \in C^\infty_0(\mathbb{R}^N) \). Then \( c\mathcal{K} \in \mathcal{P}_0(\mathcal{E}) \).
Proof. We use the Fourier transform characterization of Theorems 12.1 and 12.2 if \( m = \hat{K} \), then \( m \in \mathcal{M}_\infty(E) \) and

\[
\hat{cK}(\xi) = m * \hat{c}(\xi) = \int_{\mathbb{R}^N} m(\xi - \eta)\hat{c}(\eta)d\eta.
\]

We have \( \hat{N}_j(\xi + \eta) \leq C[\hat{N}_j(\xi) + \hat{N}_j(\eta)] \), and if \( |\xi| \) is the Euclidean norm of \( \xi \), there are positive real numbers \( a \) and \( b \) so that \( |\xi|^a \leq \hat{N}_j(\xi) \leq |\xi|^b \) for \( 1 \leq j \leq n \) and all \( |\xi| \geq 1 \). Let \( 0 < \delta < ab^{-1} \) and write

\[
\partial^\gamma (m * \hat{c}) = \int_{|\eta| \leq |\xi|^{\delta}} \partial^\gamma_x m(\xi - \eta) \hat{c}(\eta)d\eta + \int_{|\eta| \geq |\xi|^{\delta}} \partial^\gamma_x m(\xi - \eta)\hat{c}(\eta)d\eta = I + II.
\]

If \( |\eta| \leq |\xi|^{\delta} \) then \( \hat{N}_j(\xi - \eta) \approx \hat{N}_j(\xi) \) for all \( 1 \leq j \leq n \) and all sufficiently large \( |\xi| \), and hence

\[
|I| \leq \int_{|\eta| < |\xi|^{\delta}} \prod_{j=1}^n (1 + \hat{N}_j(\xi - \eta))^{-1}[\xi_j] |\hat{c}(\eta)| d\eta \lesssim \prod_{j=1}^n (1 + \hat{N}_j(\xi))^{-1}[\xi_j].
\]

On the other hand, because of the rapid decrease of \( \hat{c} \),

\[
|II| \leq c_M |\xi|^{-M} \leq c_M \prod_{j=1}^n (1 + \hat{N}_j(\xi))^{-[\alpha_j]}
\]

if \( M \geq \sum_{j=1}^n [\alpha_j] \). As a result, \( cK \in \mathcal{D}_0(E) \). \( \square \)

We now apply Lemma 12.4 to the kernel \( c(x, z)K(z) \) for each fixed \( x \). This shows that \( c(x, z)K(z) \) is an extended kernel. An examination of the argument guarantees that every semi-norm \( (12.1) \) of this kernel is controlled by only finitely many of the semi-norms \( \sup_{x, z} |\partial^\gamma_x \partial^\gamma_z c(x, z)| \) of \( c \) and the \( M \)-norms of \( K \).

Coming to the operator \( [b, U] \circ V \), we see that

\[
([b, U] \circ V)(f)(x) = \int \mathcal{M}(x, y^{-1}x)f(y)dy,
\]

where \( \mathcal{M}(x, \cdot) = L * \tilde{K}(x, \cdot) \), where \( V(f) = f * L \), and where \( \tilde{K}(x, z) = c(x, z)K(z) \).

Then \( \mathcal{M}(x, z) \) is an extended kernel, in view of Theorem 12.2 moreover any semi-norm \( (12.1) \) of \( \mathcal{M} \) is controlled by finitely many semi-norms of \( b, K \) and \( L \). Finally, the rapid decrease of the \( a_{n,m} \), as \( n \to \infty \) (and the corresponding decrease of the \( b_{n',m'} \), as \( n' \to \infty \)) then assures that \( T \circ S \) is an operator of the extended class under the assumption to both \( K(x, z) \) and \( L(x, z) \) are supported when \( |z| \leq 1 \).

The case when either one or both \( K(x, z) \) and \( L(x, z) \) are supported for \( z \) away from the origin is a simpler version of the above argument. In effect, when \( K \) is supported when \( |z| \leq 1 \), and \( L \) is supported when \( |z| \geq c > 0 \), then we need only use the facts that a convolution of a Schwartz function with a distribution of compact support is a Schwartz function, or that the convolution of two Schwartz functions is again a Schwartz function. This allows us to finish the proof of Theorem 12.2.

13 The role of pseudo-differential operators

In this section we study the interplay of pseudo-differential operators with the operators of the extended class treated in Section 12. While more general cases can also be treated, for simplicity we restrict ourselves to the situation where the homogeneous group underlying our
Euclidean space $\mathbb{R}^N$ is a stratified group, and where the matrix $E$ arises from the two-flag example in Theorem 11.5 where $a_1 = \cdots = a_n = 1$ and $b_j = \frac{1}{j}$. Thus we take

$$E = \begin{bmatrix} 1 & 2 & 3 & \cdots & n-1 & n \\ 1 & 1 & 3/2 & \cdots & (n-1)/2 & n/2 \\ 1 & 1 & 1 & \cdots & (n-1)/3 & n/3 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & 1 & \cdots & 1 & n/(n-1) \\ 1 & 1 & 1 & \cdots & 1 & 1 \end{bmatrix}.$$  

In this case of a stratified group we have the double identification of $\mathbb{R}^N = \mathbb{R}^{C_1} \oplus \cdots \oplus \mathbb{R}^{C_n}$ with the underlying group and also (via exponential coordinates) with its Lie algebra $\mathfrak{g}$. We also assume that the subspace $\mathbb{R}^{C_k} = \mathfrak{h}_k$ is the subspace homogeneous of degree $k$ under the automorphic dilations $\delta_r$. The fact that $\mathfrak{g}$ is stratified guarantees that $\mathfrak{h}_{k+1} = [\mathfrak{h}_k, \mathfrak{h}_1]$. Suppose the cardinality of $C_k$ is $c_k$. If $x = (x_1, \ldots, x_n) \in \mathbb{R}^N$ with $x_k \in \mathbb{R}^{C_k}$, write $x_k = (x_{k,1}, \ldots, x_{k,c_k})$. The automorphic dilations on $\mathfrak{h}_k$ are given by $\delta_\lambda x_k = (\lambda^k x_{k,1}, \ldots, \lambda^k x_{k,c_k})$, the homogeneous dimension of $\mathfrak{h}_k$ is $k c_k$, and for $\alpha_k \in \mathbb{N}^{c_k}$, we have $[\alpha_k] = k [\alpha_k]$, where $[\alpha_k]$ is the standard length of the multi-index.

We take the homogeneous norm on $\mathfrak{h}_k$ to be $n_k(t_k) = |t_k|_\times = \left( \sum_{j=1}^{C_k} |t_{k,j}|^2 \right)^{1/2k}$, where $| \cdot |$ denotes the Euclidean norm. Then

$$N_j(x) = |x_1| + |x_2| \frac{1}{\beta} + \cdots + |x_{j-1}| \frac{1}{\beta \cdots \frac{1}{\beta}} + |x_j| \frac{1}{\beta} + |x_{j+1}| \frac{1}{\beta} + \cdots + |x_n| \frac{1}{\beta}$$

$$\hat{N}_j(\xi) = |\xi_1| + |\xi_2| \frac{1}{\beta} + \cdots + |\xi_{j-1}| \frac{1}{\beta} + |\xi_j| \frac{1}{\beta} + |\xi_{j+1}| \frac{1}{\beta} + \cdots + |\xi_n| \frac{1}{\beta} \quad (13.1)$$

Notice that $N_n = \hat{N}_0$ is a homogeneous norm for the automorphic dilations $\delta_\lambda$, and $N_1$ is equal to the Euclidean norm.

We will consider standard pseudo-differential operators of order 0. By this we mean operators of the form

$$f \mapsto P(f)(x) = \int_{\mathbb{R}^N} a(x, \xi) \hat{f}(\xi) e^{2\pi i x \cdot \xi} d\xi; \quad (13.2)$$

defined for Schwartz functions $f$, where the symbol $a(x, \xi)$ is assumed to be of compact support in $x$ and satisfy the differential inequalities

$$|\partial_x^\alpha \partial_\xi^\beta a(x, \xi)| \leq A_{\alpha, \beta} (1 + |\xi|)^{-|\alpha|}. \quad (13.3)$$

In what follows the errors introduced by commutators will be smoothing operators in the following sense. For $1 < p < \infty$, the space $L^p_1$ consists of all $f$ in $L^p$ so that $X f$ (taken in the weak sense) belongs to $L^p(G)$, for each left-invariant vector field $X$ of the generating sub-space $\mathfrak{h}_1$ of $\mathfrak{g}$. We define a norm on $L^p_1$ by setting

$$||f||_{L^p_1} = ||f||_{L^p} + \sum_{j=1}^g ||X_j(f)||_{L^p}, \quad (13.4)$$

where $\{X_1, \ldots, X_g\}$ a basis for the subspace $\mathfrak{h}_1$. We shall also see below that an $f \in L^p$ belongs to $L^p_1$ if and only if

$$||f(xh) - f(x)||_{L^p} = O(N_n(h)), \quad \text{as } h \to 0. \quad (13.5)$$

An operator will be said to be smoothing if it maps $L^p$ to $L^p_1$, for all $1 < p < \infty$.

The following theorem will be proved in the next sections.
Theorem 13.1. Suppose $P$ is a standard pseudo-differential operator of order 0. Then $P$ belongs to the extended class treated in Section 12. Moreover if $T$ is any operator of this class, then the commutator $[T, P]$ is a smoothing operator.

13.1 The isotropic extended kernels

For the proof of Theorem 13.1 it is necessary to consider a special sub-class $CZ_0 \subset \mathcal{P}_0(E)$, (the isotropic Calderón-Zygmund kernels on $\mathbb{R}^N$ which agree with a Schwartz function at infinity) and a corresponding sub-class of the “extended” kernels. A distribution $K \in CZ_0$ is assumed to satisfy the stronger inequalities

$$|\partial^\gamma K(z)| \leq A_\alpha |z|^{-N-|\gamma|}(1 + |z|)^{-M}, \quad (13.6)$$

for every $\gamma$ and $M$. Moreover these kernels are required to satisfy only the one type of cancellation property which arises when $n = 1$. It follows from Theorems 4.1 and 4.2 (for the case $n = 1$) that this is equivalent to the condition that the Fourier transform $m = \hat{K}$ satisfies $|\partial^\gamma m(\xi)| \leq A'_\alpha (1 + |\xi|)^{-|\gamma|}$. But then it follows from equation (13.1) that $m \in M_\infty(E)$, and hence $CZ_0 \subset \mathcal{P}_0(E)$. We call elements of $CZ_0$ isotropic proper kernels.

Together with $CZ_0$ we consider the extended kernels $K(x, z)$ such that for $x$ fixed, $K(x, \cdot) \in CZ_0$. More precisely, we shall assume that these have compact support in $x$ and all $x$-derivatives $\partial^\alpha_x K(x, \cdot)$ are isotropic proper kernels uniformly in $x$. Notice that, having assumed compact support in $x$, this condition can be equivalently formulated with the $x$-derivatives replaced by left-invariant, or right-invariant, vector fields. We will refer to these kernels as isotropic extended kernels.

The key fact we need is the following.

Proposition 13.2. Suppose $P$ is a pseudo-differential operator of order 0, with symbol $a(x, \xi)$ having compact support in $x$. Then $P$ can be represented in the following three alternative forms: for any Schwartz function $f$:

(a) $P(f)(x) = \int_{\mathbb{R}^N} K(x, x - y)f(y) dy$;

(b) $P(f)(x) = \int_{\mathbb{R}^N} K^L(x, y^{-1}x)f(y) dy$;

(c) $P(f)(x) = \int_{\mathbb{R}^N} K^R(x, xy^{-1})f(y) dy$.

Here $K$, $K^L$, and $K^R$ are each isotropic extended kernels.

The realization is well-known; see for instance Sections 4 and 7.4 of Chapter 6. In this case $\hat{K}(x, \cdot) = a(x, \cdot)$ (where the Fourier transform acts on the second variable), and reduces to the fact that a multiplier $m(\xi)$ that satisfies the differential inequalities $|\partial^\alpha_x m(\xi)| \leq A_\alpha (1 + |\xi|)^{-|\alpha|}$ arises as the Fourier transform of an isotropic proper kernel, and so this is covered by Theorems 4.1 and 4.2. The other two representations need further analysis.

First we assert that

$$y^{-1}x = L_{x, y}(x - y), \quad (13.7)$$

where for each $(x, y) \in G \times G$, $L_{x, y}$ is a linear transformation that depends polynomially on $x$ and $y$. In fact, by the homogeneity of our group and using the Campbell-Hausdorff formula we can write for each $1 \leq k \leq n$ and each $1 \leq j \leq c_k$,

$$(y^{-1}x)_{k,j} = x_{k,j} - y_{k,j} + \sum_{\ell < k} \sum_{j=1}^{c_k} y_{k,j}^{(x,y)}(x, y) \cdot (x_{\ell,j} - y_{\ell,j})$$
with $p_{i,j}$ polynomials in $x$ and $y$ jointly homogeneous at degree $k - \ell$ (see for example Section 6.6 in [NRSW12], or Chapter 1 of [FSS2]). This gives (13.7) with $L_{x,y}$ represented by a block-triangular matrix which in particular implies that $\det(L_{x,y}) = 1$, for all $x$ and $y$. Now let $M_{x,y}$ denote the inverse of $L_{x,y}$. Then $x - y = M_{x,y}(y^{-1}x)$ and $M_{x,y}$ is again polynomially dependent on $x$ and $y$.

Thus both $\Phi$, $K$ of Lemma 13.3 is complete.

Define a (non-linear) mapping $\Phi = \Phi_\mathbf{x} : \mathbb{R}^N \to \mathbb{R}^N$ by setting $\Phi_\mathbf{x}(\mathbf{z}) = M_{x,x^{-1}}(\mathbf{z})$. Given $\mathbf{x}$ and $\mathbf{w}$,

$$\Phi_\mathbf{x}((x - w)^{-1}x) = M_{x,x^{-1}}(x - w)((x - w)^{-1}x) = x - (x - w) = w$$

so $\Phi_\mathbf{x}$ maps $\mathbb{R}^N$ onto $\mathbb{R}^N$ and the inverse of $\Phi_\mathbf{x}$ is given by $\Phi_\mathbf{x}^{-1}(w) = (x-w)^{-1}x = L_\mathbf{x,x^{-1}}(w)$.

Thus both $\Phi_\mathbf{x}$ and $\Phi_\mathbf{x}^{-1}$ are polynomial mappings of $\mathbb{R}^N$ to itself (and hence diffeomorphisms) that each depend polynomially on $x$. In our applications of these mappings below, the range of $x$ is restricted to a compact set, in view of the support hypothesis on the symbol $a(\mathbf{x}, \xi)$ and the resulting fact that $K(x, z)$ has compact-support in $x$.

We set down the following two simple properties of the mappings $\Phi_\mathbf{x}$:

1) $|\Phi_\mathbf{x}(\mathbf{z})| \equiv |\mathbf{z}|$, for $|\mathbf{z}| \leq 1$;

2) $|\mathbf{z}|^{1/2} \lesssim |\Phi_\mathbf{x}(\mathbf{z})| \lesssim |\mathbf{z}|^\delta$, for $|\mathbf{z}| \geq 1$.

The first assertion is a consequence of the fact that $\Phi$ is a diffeomorphism that fixes the origin. For the second, we see first that $|\Phi_\mathbf{x}(\mathbf{z})| \leq c|\mathbf{z}|^\delta$, $|\mathbf{z}| \geq 1$ because of the polynomial dependence (of degree $n$) of the linear mappings $M_{x,y}$. Since the same inequality holds for the inverse $\Phi_\mathbf{x}^{-1}$ we get the reverse inequality $|\mathbf{z}|^{1/2} \lesssim c|\Phi_\mathbf{x}(\mathbf{z})|$, again for large $|\mathbf{z}|$.

Our proof of the second representation [9] in Proposition [13.2] starts with knowing the first representation and defining $K^L(x, z) = K(x, \Phi_\mathbf{x}(z))$. Then, at least formally, we have

$$\int K^L(x, y^{-1}x)f(y)dy = \int K(x, x-y)f(y)dy = P(f)(x).$$

In order to justify this it will suffice to see that $K^L(x, z)$ is, for each $x$, an isotropic proper kernel, and (in both variables) an isotropic extended kernel. For this we make the following observation.

**Lemma 13.3.** Let $K(\mathbf{z}) \in C \mathbb{Z}_0$. Suppose $\Phi$ is a $C^\infty$ diffeomorphism of $\mathbb{R}^N$ fixing the origin, and assume that $|\Phi(\mathbf{z})| \gtrsim |\mathbf{z}|^\delta$, for some $\delta > 0$ and all $|\mathbf{z}| \geq 1$. Then $K \circ \Phi \in C \mathbb{Z}_0$ where the distribution $K \circ \Phi$ is defined by $\langle K \circ \Phi, \varphi \rangle = \langle K, \varphi(\Phi^{-1})J_{\Phi^{-1}} \rangle$ for every test function $\varphi$, where $J_\Phi$ is the Jacobian determinant of $\Phi$.

**Proof.** Away from the origin $K \circ \Phi$ is the $C^\infty$ function $K(\Phi(\mathbf{z}))$. Since $\Phi(0) = 0$ it follows that $|\Phi(\mathbf{z})| \gtrsim c|\mathbf{z}|$ for small $|\mathbf{z}|$, and hence $K \circ \Phi$ satisfies (13.10) on the unit ball because $\Phi$ does. Moreover the assumption $|\Phi(\mathbf{z})| \gtrsim c|\mathbf{z}|^\delta$ for $|\mathbf{z}| \geq 1$, implies the rapid decrease at infinity of $K(\Phi(\mathbf{z}))$, since the same holds for $K(\mathbf{z})$. It remains to verify the cancellation conditions for $K \circ \Phi$, i.e. $|\langle K \circ \Phi, \varphi(R) \rangle| \leq C$ for all $R \geq 1$ where $\varphi$ is a normalized $C^\infty$ function supported in the unit ball. However $|\langle K \circ \Phi, \varphi(R) \rangle| = |\langle K, \varphi(\Phi^{-1})J_{\Phi^{-1}} \rangle|$, where it is easy to verify that for each $R$, $\Psi_R(\mathbf{x})$ is supported in the ball $|\mathbf{x}| \leq cR^{-1}$, and satisfies $|\partial_\mathbf{x}^\mathbf{a} \Psi_R(\mathbf{x})| \leq c_\mathbf{a} R^{|\mathbf{a}|}$, with bounds $c$ and $c_\mathbf{a}$ independent of $R$. Thus we may think of $\Psi_R(\mathbf{x})$ as of the form $c_1\Psi(c_2R\mathbf{x})$, for some $c_1$ and $c_2$ independent of $R$, verifying that $K \circ \Phi$ satisfies the requisite cancellation condition. Thus the proof of Lemma 13.3 is complete.

Hence we have proved the representation [10] of Proposition 13.2. The representation [11] is proved in the same way.
13.2 Proof of Theorem [13.1]

Turning to the proof of Theorem [13.1] we see by the identity (3) in Proposition [13.2] that the pseudo-differential operator $P$ belongs to the extended class of operators, establishing the first assertion of Theorem [13.1]. Now let $T$ be any operator in the extended class,

$$ T(f)(x) = \int L(x, y^{-1}x) f(y) dy, $$

with $L(x, z)$ a kernel of the extended class. We examine the commutator $[T, P]$. Let $B$ be a ball containing the $x$–support of the symbol $a(x, \xi)$ of $P$, and hence containing the $x$-supports of $K(x, z)$, $K^L(x, z)$ and $K^R(x, z)$. We now first decompose $T$ as $T_0 + T_\infty$ via $L(x, z) = L_0(x, z) + L_\infty(x, z)$ where $L_0(x, z) = \eta(x)L(x, z)$, $L_\infty(x, z) = (1 - \eta(x))L_\infty(x, z)$ with $\eta \in C^\infty$ of compact support which $= 1$ on the double $B^*$ at the ball $B$. Thus $K_0(x, z)$ has compact $x$–support, while $K_\infty(x, z)$ is supported on the complement of $B^*$. (Note that this is different from the decomposition $T = T_0 + T_\infty$ in Section [12.1].

Now by reasoning as in Section [12.1] we can write

$$ T_0(f)(x) = \sum_n T_n(f)(x) = \sum_n a_n(x)(f * H_n)(x) \quad \text{(13.9)} $$

where $a_n(x)$ are $C^\infty$ functions, supported in a common compact set, for which $\sup_x |\partial^\alpha_x a_n(x)|$ is rapidly decreasing in $n$, for each fixed $\alpha$. The kernels $H_n$ are proper kernels and their semi-norms are each uniformly bounded in $n$.

For the pseudo-differential operator $P$ we shall use the “right–invariant” representation (3) in Proposition [13.2]. This gives by the reasoning establishing (13.9), that

$$ P(f)(x) = \sum_{n'} P_{n'}(f)(x) = \sum_{n'} b_{n'}(x)(K_{n'} * f)(x). \quad \text{(13.10)} $$

Here the $b_{n'}(x)$ are $C^\infty$ functions, supported in a compact set (in view of the support property of $K^R(x, z)$), for which $\sup_x |\partial^\alpha_x b_{n'}(x)|$ is rapidly decreasing in $n'$ for each fixed $\alpha$, and the $K_{n'}$ are isotropic proper kernels and their semi-norms are each uniformly bounded in $n'$. The rapid decrease in $n$ and $n'$ pointed out above reduces the study of the commutator $[T_0, P]$ to that where only a single term of each of the sums, (13.9) and (13.10), appears.

Thus we look at the commutator $[a \circ U, b \circ V]$, where $U(f) = f * H$ and $V(f) = K * f$. This commutator is handled by the following

**Lemma 13.4.**

1. $U$ and $V$ commute,
2. $[b, U]$ is a smoothing operator,
3. $[a, V]$ is a smoothing operator,

and the bounds of the mappings $[b, U]$ and $[a, V]$ depend only on finitely many of the semi-norms controlling $a, b, H$, and $K$.

Suppose first that the lemma is proved. There $aU \circ bV = abU \circ V + [a, U]V$. However $U \circ V = V \circ U$, by conclusion (1). Thus

$$ [a \circ U, b \circ V] = a \circ [U, b \circ V] + [a, b \circ V] \circ U $$
$$ = a \circ [U, b] \circ V + ab \circ [U, V] + b \circ [a, V] \circ U + [a, b] \circ V \circ U $$
$$ = a \circ [U, b] \circ V + b \circ [a, V] \circ U. $$

As well as multiplication by $a$ and $b$, both $U$ and $V$ map $L^p$ to itself, since they are convolution operators with proper kernels. Thus by conclusions (2) and (3) of the lemma, $[a \circ U, b \circ V]$ maps $L^p$ to $L^p$, and we have achieved our desired result for $[T_0, P]$. 
Proof of Lemma 13.4. The first conclusion (which is key) follows immediately because $U$ is left-invariant and $V$ is right-invariant. Let us now consider $[b, U]$, and begin with the representation given for $[b, U]$ in (12.7) (here $\mathcal{H}$ plays the role of $K$). We have that $[b, U]$ is an operator of the extended class, represented by the kernel $\tilde{H}(x, z) = c(x, z)H(x, z)$, where $c(x, z)$ is the $C^\infty$ function given by $b(x) - b(xz^{-1})$. Notice however that $c(x, 0) = 0$, and thus

$$c(x, z) = \sum_{k=1}^{n} \sum_{j=1}^{c_k} z_{k,j} \cdot c_{k,j}(x, z),$$

where $c_{k,j}$ are again $C^\infty$ functions. Hence

$$\tilde{H}(x, z) = \sum_{k,j} z_{k,j} \cdot \tilde{H}_{k,j}(x, z)$$

where by Lemma 12.3 we know that each $\tilde{H}_{k,j}(x, z)$ is an extended kernel. Now if $X$ is a left-invariant vector field, then

$$X[b, U](f)(x) = X \left( \int \tilde{H}(x, y^{-1}x)f(y)dy \right) = \int H'(x, y^{-1}x)f(y)dy,$$

where by (13.11) we have that

$$H'(x, z) = \sum_{j=1}^{n} \left( X_z(z_j \cdot \tilde{H}_{j}(x, z)) + X_{z_j}(z_j \cdot \tilde{H}_{j}(x, z)) \right).$$

At this stage we need the following observation.

Lemma 13.5. Suppose $\mathcal{H}$ is a proper kernel and $X$ is a left-invariant vector field of degree 1 (that is, in the subspace $\mathfrak{h}_1$ of the Lie algebra). Then for each $(k, j)$, $1 \leq k \leq n$, $1 \leq j \leq c_k$, $X(z_{k,j}H(z))$ is a proper kernel.

This can be proved by using the Fourier transform characterization of proper kernels. First write $X$ as

$$X = \frac{\partial}{\partial x_1} + \sum_{\ell=2}^{n} \sum_{s=1}^{c_\ell} q_{\ell,s}(z) \frac{\partial}{\partial z_{\ell,s}} = \frac{\partial}{\partial x_1} + \sum_{\ell=2}^{n} Q_{\ell}(z) \cdot \nabla_{z_{\ell}},$$

where $Q_{\ell}(z) = Q_{\ell}(z_1, \ldots, z_{\ell-1})$ are homogeneous polynomials of degree $\ell - 1$ (in the homogeneity of the automorphic dilations). Consider first the case $k = 1$. The Fourier transform of $X(z_{1,j}H(z))$ is then a linear combination of $m = \mathcal{H}$ and $\xi_{\ell}Q_{\ell}(2\pi i \delta_{\xi}) \partial_{\xi_{1,j}} m(\xi)$. However, it is clear from (13.1) that $\tilde{N}_j(\xi)^k \geq |\xi_k|$ if $j \leq k$. The effect of the factor $\xi_{\ell}$, which has size $|\xi_{\ell}|$, is counterbalanced by the effect of $Q_{\ell}(2\pi i \delta_{\xi}) \partial_{\xi_{1,j}}$ on $m(\xi)$, in view of the estimates for $m$. The situation when $k > 1$ (and hence $\partial_{\xi_{1,j}}$ is replaced by $\partial_{\xi_{k,j}}$) leads to an even better estimate, which then establishes Lemma 13.5.

Using the lemma we see therefore that $X_x[b, U]$ is an operator with an extended kernel, and hence by Theorem 12.1 we have that $[b, U]$ maps $L^p$ to $L^p_1$, establishing conclusion (2) of Lemma 13.3.

Finally, for conclusion (3) we may appeal to the standard theory of pseudo-differential operators that guarantees that the commutator $[a, V]$ is an operator of “order 1”, and in particular maps $L^p$ to $L^p_1$; or we may argue in the same spirit as in the case of conclusion (2), but here the details are simpler. In any case, Lemma 7.4 is now established and this proves that $[T_0, P]$ is bounded from $L^p$ to $L^p_1$. \qed
To complete the proof of Theorem 13.3 it remains to deal with $[T_\infty, P] = T_\infty P - PT_\infty$. We will see that the terms $T_\infty P$ and $PT_\infty$ are separately smoothing operators (in fact, infinitely smoothing) because of disjointness of relevant supports. Consider first $T_\infty P$. Then $T_\infty(Pf) = T_\infty(F)$, where $F$ is supported in the ball $B$ (where the symbol $a(x, \xi)$ is supported). However

$$T_\infty(F)(x) = \int K_\infty(x, y^{-1}x)F(y)dy$$

and $K_\infty(x, z)$ is supported for $x$ outside $B^*$. Hence in the integral above we have that $|y^{-1}x| \geq c > 0$, for an appropriate $c$. Moreover if $X$ is any left-invariant operator then $X(T_\infty F)(x)$ is given by $\int K'_\infty(x, y^{-1}x)F(y)dy$ with $K'_\infty(x, z) = X_\xi K_\infty(x, z) + X_\xi K_\infty(x, z)$. Since now $K'_\infty(x, z)$ is bounded and has rapid decay in $z$, we can restrict ourselves here to $|z| \geq c > 0$, this ensures that $T_\infty P$ maps $L^p$ to $L^p$. In fact the same argument shows that $X^\alpha(T_\infty P)$ maps $L^p$ to itself for any monomial $X^\alpha$ of left-invariant differential operators.

Essentially the same argument works for $PT_\infty$. Here $(PT_\infty)(f) = \int K^L(x, y^{-1}x)f(y)dy$ by Proposition 13.2 with $F$ supported in the complement of $B^*$ and $K(x, z)$ supported where $x \in B$. Then again $|y^{-1}x| \geq c > 0$, and we may proceed as before. Altogether then, the proof of Theorem 13.3 is completed.

### 13.3 The space $L^p_1$

We conclude by proving the equivalence of the condition that $f \in L^p_1$ with the Lipschitz-type condition (13.5).

**Proposition 13.6.** Let $1 < p < \infty$. Then

$$f \in L^p_1 \iff \|f(xh) - f(x)\|_{L^p} = O(N_n(h)), \text{ as } h \to 0.$$

**Proof.** Let $X$ be a left-invariant vector field in the subspace $\mathfrak{h}_1$ of the Lie algebra, and set $h_t = \exp(tX)$. Then $|h_t| = |h| \approx |t|$, $t \in \mathbb{R}$. So

$$\|f(xh) - f(x)\|_{L^p} = O(N_n(h)), \text{ as } h \to 0 \implies \|\frac{1}{t}(f(xh_t) - f(x))\|_{L^p} = O(1) \text{ as } t \to 0.$$  

Thus by the weak compactness of $L^p$, there is a sequence $\{h_n\}$, $n \to 0$ so that $\frac{1}{t}(f(xh_{t_n}) - f(x))$ converges weakly in $L^p$ and hence in the sense of distributions. Thus in that sense, $X(f) \in L^p$. Since this holds for all $X \in \mathfrak{h}_1$, we have that $f \in L^p_1$.

Conversely, suppose $f \in L^p_1$, and $h = \exp(sX)$ where $X \in \mathfrak{h}_1$. Then $N_n(h) = |h| \lesssim |s|$ and

$$f(xh) - f(x) = \int_0^s \frac{d}{dt}f(x \exp(tX)) dt = \int_0^s Xf(x \exp(tX)) dt.$$  

Hence, $\|f(xh) - f(x)\|_{L^p} \lesssim |s| \|X(f)\|_{L^p}$. To extend this to any element $h$ we use the following assertion.

**Lemma 13.7.** Suppose $G$ is a stratified group. Then there is an integer $M$, so that every $h \in G$, can be written as $h = h_1h_2 \cdots h_M$, where each $h_j \in \exp \mathfrak{h}_1$ and $|h_j| \leq cN_n(h)$ for all $1 \leq j \leq M$.

Assuming for a moment this to be true, the desired estimate for $f(xh) - f(x)$ then follows for the special case when $h \in \exp \mathfrak{h}_1$ by writing

$$f(xh) - f(x) = \sum_{j=1}^M f(xh_1 \cdots h_j) - f(xh_1 \cdots h_{j-1}). \quad \square$$
Proof of Lemma 13.7 Let \( V = \exp(B_1) \), where \( B_1 \) is the unit ball in \( h \). Then \( V \) is an analytic submanifold of \( E \) which generates \( G \). By Proposition 1.1 of \(RSSS\), there exists an integer \( m \) such that \( V^m \) contains an open set \( A \). Since \( V = V^{-1} \), \( V^{2m} \) contains a neighborhood of the identity. This proves the statement for \( |h| < \delta \) for some \( \delta > 0 \) with \( M = 2m \). By homogeneity, the same holds for every \( h \in G \). \( \square \)

14 Appendix I: Properties of cones \( \Gamma(A) \)

In this appendix we study properties of the cone \( \Gamma(E) \) defined in (5.1). Our results provide motivation for the basic hypothesis (2.10) imposed on the matrix \( E \).

14.1 Optimal inequalities and the basic hypothesis

Definition 14.1. Let \( A = \{a(j,k) : 1 \leq j, k \leq n\} \) be an \( n \times n \) matrix of strictly positive real numbers. Then

\[
\Gamma^0(A) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : a(j,k)t_k < t_j < 0 \right\}
\]

\[
\Gamma(A) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : a(j,k)t_k \leq t_j < 0 \right\}
\]

are (possibly empty) convex polyhedral cones contained in the negative orthant of \( \mathbb{R}^n \). The dimension of either cone is the maximal number of linearly independent vectors it contains. Equivalently, this is the dimension of the smallest subspace of \( \mathbb{R}^n \) containing the cone.

\( \Gamma(A) \) is defined by a collection of linear inequalities involving pairs of coordinates. It may happen that different matrices (i.e., different sets of such inequalities) give rise to the same cone. The following Lemma shows that there is a unique optimal set of inequalities, and that the corresponding matrix satisfies the basic hypothesis (2.10).

Lemma 14.2. Let \( A = \{a(j,k)\} \) be an \( n \times n \) matrix of strictly positive real numbers, and suppose that the corresponding cone \( \Gamma(A) \) is not empty. Then there exists a unique \( n \times n \) matrix \( \tilde{A} = \{\tilde{a}(j,k)\} \) with the following properties:

(a) The coefficients of \( \tilde{A} \) satisfy the inequalities (2.10) of the basic hypothesis:

\[
1 = \tilde{a}(j,j) \quad \text{for } 1 \leq j \leq n,
\]

\[
0 < \tilde{a}(j,k) \leq \tilde{a}(j,l)\tilde{a}(l,k) \quad \text{for } 1 \leq j, k, l \leq n.
\]

(b) \( \Gamma(A) = \Gamma(\tilde{A}) \).

Moreover, if \( \tilde{A} \) satisfies (a) and (b), then \( \tilde{a}(j,k) \leq a(j,k) \) for \( 1 \leq j, k \leq n \).

Proof. For any \( t = (t_1, \ldots, t_n) \in \Gamma(A) \), \( t_j < 0 \) and \( 0 < t_jt_k^{-1} \leq a(j,k) \) for \( 1 \leq j, k \leq n \). If \( \Gamma(A) \neq \emptyset \) define

\[
0 < \tilde{a}(j,k) = \sup_{t \in \Gamma(A)} \frac{t_j}{t_k} \leq a(j,k). \quad (14.1)
\]

Then \( \tilde{a}(j,j) = 1 \) and for any \( j, k, l \in \{1, \ldots, n\} \)

\[
\tilde{a}(j,k) = \sup_{t \in \Gamma(A)} \frac{t_j}{t_k} = \sup_{t \in \Gamma(A)} \left[ \frac{t_j}{t_l} \frac{t_j}{t_k} \right] \leq \sup_{t \in \Gamma(A)} \frac{t_j}{t_l} \sup_{t \in \Gamma(A)} \frac{t_l}{t_k} = \tilde{a}(j,l)\tilde{a}(l,k).
\]

This establishes (a).

Let \( v = (v_1, \ldots, v_n) \in \Gamma(\tilde{A}) \). Since \( v_k < 0 \) and \( \tilde{a}(j,k) \leq a(j,k) \), it follows that \( a(j,k)v_k \leq \tilde{a}(j,k)v_k \leq v_j \), and so \( v_jv_k^{-1} \leq a(j,k) \). Thus \( v \in \Gamma(A) \) and it follows that \( \Gamma(\tilde{A}) \subset \Gamma(A) \).
Conversely, if \( \mathbf{v} = (v_1, \ldots, v_n) \in \Gamma(\mathbf{A}) \), then \( v_j v_k^{-1} \leq \sup_{t \in \Gamma(\mathbf{A})} t_j t_k^{-1} = \tilde{a}(j, k) \) and so \( \tilde{a}(j, k) v_k \leq v_j \). It follows that \( \Gamma(\mathbf{A}) \subseteq \Gamma(\tilde{\mathbf{A}}) \), and this establishes (ii).

Next we show that the matrix \( \tilde{\mathbf{A}} \) is unique. Let \( \mathbf{C} = \{ c(j, k) : 1 \leq j, k \leq n \} \) be any matrix satisfying (i) and (iii). Since \( \Gamma(\mathbf{C}) = \Gamma(\mathbf{A}) \), if \( \mathbf{t} \in \Gamma(\mathbf{C}) \) then \( c(j, k) t_k \leq t_j \), and so

\[
\tilde{a}(j, k) = \sup_{t \in \Gamma(\mathbf{A})} t_j t_k^{-1} = \sup_{t \in \Gamma(\mathbf{C})} t_j t_k^{-1} \leq c(j, k).
\]

To establish the reverse inequality, consider the vectors \( \mathbf{w}_l = (-c(1, l), \ldots, -c(n, l)) \). Since \( \mathbf{C} \) satisfies (i), we have \( c(j, l) \leq c(j, k) c(k, l) \), or equivalently \( c(j, k)(-c(k, l)) \leq (-c(j, l)) \). This shows that \( \mathbf{w}_l \in \Gamma(\mathbf{C}) = \Gamma(\tilde{\mathbf{A}}) \) for \( 1 \leq l \leq n \). It follows that \( \tilde{a}(j, k)(-c(k, l)) \leq -c(j, l) \) for all \( 1 \leq j, k, l \leq n \). Letting \( l = k \), we have \( \tilde{a}(j, k)(-c(k, k)) \leq -c(j, k) \), and since \( c(k, k) = 1 \) we have \( c(j, k) \leq \tilde{a}(j, k) \). Thus \( \tilde{a}(j, k) = \tilde{a}(j, k) \), which shows that \( \mathbf{A} \) is unique. We have already observed that \( \tilde{a}(j, k) \leq a(j, k) \), and since the matrix \( \tilde{\mathbf{A}} \) is unique, this completes the proof.

It can be shown that, in the hypotheses of Lemma 14.2,

\[
\tilde{a}(j, k) = \begin{cases} 
\min \{ a(j, i_1)a(i_1, i_2) \cdots a(i_r, k) : r \geq 0, \{ i_1, \ldots, i_r \} \subset \{1, \ldots, n\} \} & \text{if } j \neq k \\
1 & \text{if } j = k \end{cases}
\]

### 14.2 Partial matrices

In Lemma 14.2 it is assumed that the cone \( \Gamma(\mathbf{A}) \) is defined by the full number \( n(n-1) \) inequalities \( a(j, k)t_k \leq t_j \) where \( 1 \leq j \neq k \leq n \). We also need to consider cases in which we begin with fewer inequalities. We formulate this as follows. Let \( \mathbf{B} = \{ b(j, k) \} \) be an \( n \times n \) matrix, where this time each \( b(j, k) \) is either a positive real number or the symbol \( \infty \). As before we put

\[
\Gamma(\mathbf{B}) = \{ \mathbf{t} = (t_1, \ldots, t_n) \in \mathbb{R}^n : b(j, k)t_k \leq t_j < 0 \}.
\]

but now if \( b(j, k) = \infty \), the inequality \( b(j, k)t_k \leq t_j < 0 \) puts no constraint on the relation between the two negative real numbers \( t_k \) and \( t_j \). It is still the case that \( \Gamma(\mathbf{B}) \) is a polyhedral cone in the negative orthant of \( \mathbb{R}^n \). We call \( \mathbf{B} \) a **partial matrix**. We say that a partial matrix \( \mathbf{B} = \{ b(j, k) \} \) is **connected** if for any two indices \( j, k \in \{1, \ldots, n\} \) there are indices \( i_1, \ldots, i_a \in \{1, \ldots, n\} \) (with a possibly dependent on \( j \) and \( k \)) so that

\[
b(j, i_1)b(i_1, i_2) \cdots b(i_{a-1}, i_a)b(i_a, k) < +\infty.
\]

It then follows that

\[
b(j, i_1)b(i_1, i_2) \cdots b(i_j, i_{j+1}) \cdots b(i_{a-1}, i_a)b(i_a, k) t_k \leq t_j < 0
\]

so if \( \mathbf{B} \) is connected and \( \mathbf{t} \in \Gamma(\mathbf{B}) \) it follows that

\[
\sup_{\mathbf{t} \in \Gamma(\mathbf{B})} \frac{t_j}{t_k} \leq b(j, i_1)b(i_1, i_2) \cdots b(i_j, i_{j+1}) \cdots b(i_{a-1}, i_a)b(i_a, k) < +\infty.
\]

We then have the following analogue of Lemma 14.2

**Lemma 14.3.** Let \( \mathbf{B} = \{ b(j, k) \} \) be an \( n \times n \) connected, partial matrix, and suppose that the corresponding cone \( \Gamma(\mathbf{B}) \) is not empty. Then there exists a unique \( n \times n \) matrix \( \tilde{\mathbf{B}} = \{ \tilde{b}(j, k) \} \) with the following properties:

...
(a) The coefficients of $\tilde{B}$ are all finite positive real numbers, and
\[
1 = \tilde{b}(j, j) \quad \text{for } 1 \leq j \leq n, \\
0 < \tilde{b}(j, k) \leq \tilde{b}(j, l)\tilde{b}(l, k) \quad \text{for } 1 \leq j, k, l \leq n.
\]

(b) $\Gamma(B) = \Gamma(\tilde{B})$.

Moreover, if $\tilde{B}$ satisfies (a) and (b), then $\tilde{b}(j, k) \leq b(j, k)$ for $1 \leq j, k \leq n$.

Proof. There is only a minor change from the proof of Lemma 14.2. Since $b(j, k)$ might equal $\infty$ we cannot directly conclude that $\sup_{t \in \Gamma(B)} t_j t_k^{-1}$ is finite by observing that it is bounded by $b(j, k)$ as in equation (14.1). However, since $B$ is connected, it is still the case that $\sup_{t \in \Gamma(B)} t_j t_k^{-1} < \infty$, and we can define $\tilde{b}(j, k)$ to this supremum. The proof of (a) then proceeds as before, and we set $\Gamma(\tilde{B}) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : \tilde{b}(j, k) t_k \leq t_j < 0 \right\}$.

Note that if $b(j, k) < \infty$ then $\tilde{b}(j, k) = \sup_{t \in \Gamma(B)} \frac{t_j}{t_k} \leq b(j, k)$ as before. The proofs that $\Gamma(\tilde{B}) = \Gamma(B)$ and the uniqueness of $B$ also follow as before.

14.3 Projections

Let $1 < p < n$ and let $\pi_{n,p} : \mathbb{R}^n \to \mathbb{R}^p$ be the projection onto the first $p$ coordinates: $\pi_{n,p}(x_1, \ldots, x_n) = (x_1, \ldots, x_p)$. Let $A_n = \{ a(j, k) : 1 \leq j, k \leq n \}$ be an $n \times n$ matrix with strictly positive entries which satisfies the basic hypotheses
\[
a(j, j) = 1 \quad 1 \leq j \leq n, \\
a(j, l) \leq a(j, k)a(k, l) \quad 1 \leq j, k, l \leq n.
\]

Let $A_p = \{ a(j, k) : 1 \leq j, k \leq p \}$ be the corresponding $p \times p$ matrix (which of course also satisfies the basic hypotheses). We then have two cones:
\[
\Gamma(A_n) = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : a(j, k) t_k \leq t_j < 0, 1 \leq j, k \leq n \right\},
\]
\[
\Gamma(A_p) = \left\{ u = (u_1, \ldots, u_p) \in \mathbb{R}^p : a(j, k) u_k \leq u_j < 0, \leq j, k \leq p \right\}.
\]

Lemma 14.4. The projection $\pi_{n,p}$ maps the cone $\Gamma(A_n)$ onto the cone $\Gamma(A_p)$.

Proof. If $a(j, k) t_k \leq t_j < 0$ for $1 \leq j, k \leq n$, then $a(j, k) t_k \leq t_j < 0$ for $1 \leq j, k \leq p$, and so it is clear that $\pi$ maps $\Gamma(A_n)$ into $\Gamma(A_p)$. The main point of the Lemma is that the mapping is onto. But since
\[
\pi_{n,p} = \pi_{p+1,p} \circ \pi_{p+2,p+1} \circ \cdots \circ \pi_{n,n-1}
\]
it clearly suffices to show that the mapping $\pi_{n,n-1} : \Gamma(A_n) \to \Gamma(A_{n-1})$ is onto.

Let $(u_1, \ldots, u_{n-1}) \in \Gamma(A_{n-1})$. We must show that there exists $u_n < 0$ so that
\[
1 \leq j \leq n - 1 \quad \Rightarrow \quad a(j, n) u_n \leq u_j \quad \text{and} \quad a(n, j) u_j \leq u_n
\]

If we let $E_j$ be the closed interval $\left[ a(n, j) u_j, \frac{u_j}{a(n, j)} \right]$, then we must show that $\bigcap_{j=1}^{n-1} E_j \neq \emptyset$.

For any $j, k \in \{1, \ldots, n-1\}$ we have
\[
a(n, j) u_j \leq \frac{a(k, j)}{a(k, n)} u_j \quad \text{since } a(k, j) \leq a(k, n)a(n, j) \text{ and } u_j < 0,
\]
\[
\leq \frac{u_k}{a(k, n)} \quad \text{since } (u_1, \ldots, u_{n-1}) \in \Gamma(A_{n-1}) \text{ and hence } a(k, j) u_j \leq u_k.
\]
It follows that for any index $1 \leq \ell \leq n - 1$ we have
\[
a(n, \ell)u_\ell \leq \sup \{a(n, j)u_j : 1 \leq j \leq n - 1\} \leq \inf \left\{ \frac{u_k}{a(k, n)} : 1 \leq k \leq n - 1\right\} \leq \frac{u_\ell}{a(\ell, n)}\]
and hence we have produced a closed, non-empty interval in $\bigcap_{j=1}^{n-1} E_j$:
\[
\left[ \sup \{a(n, j)u_j : 1 \leq j \leq n - 1\}, \inf \left\{ \frac{u_k}{a(k, n)} : 1 \leq k \leq n - 1\right\}\right] \subset \bigcap_{j=1}^{n-1} E_j.
\]
\[\square\]

14.4 The dimension of $\Gamma(E)$

**Proposition 14.5.** Let $E$ be an $n \times n$ matrix satisfying the basic hypothesis (2.10). Then the cone $\Gamma(E)$ is not empty. In particular, the 2n vectors

\[
\begin{align*}
v_l &= (-e(1, l), \ldots, -e(n, l)), & 1 \leq l \leq n \\
w_l &= (-e(l, 1)^{-1}, \ldots, -e(l, n)^{-1}), & 1 \leq l \leq n
\end{align*}
\]

all belong to $\Gamma(E)$.

**Proof.** Fix $l \in \{1, \ldots, n\}$ and let $v_j = -e(j, l)$. Then it follows from (2.10) that $e(j, l) \leq e(j, k)e(k, l)$ and so $e(j, k)v_k = -e(j, k)e(k, l) \leq -e(j, l) = v_j$. This shows that $v_l \in \Gamma(E)$. Similarly, let $w_j = -e(l, j)^{-1}$. Then since $e(l, k) \leq e(l, j)e(j, k)$, $e(j, k)w_k = -\frac{e(j, k)}{e(l, j)} \leq -\frac{1}{e(l, j)}$, and so $w_l \in \Gamma(E)$. This completes the proof. \[\square\]

Since the vectors $v_l$ in Proposition 14.5 are the negatives of the columns of $E$, we have the following corollary.

**Corollary 14.6.** Let $E$ be an $n \times n$ matrix satisfying the basic hypotheses (2.10). Then the dimension of $\Gamma(E)$ is greater than or equal to the rank of $E$.

**Lemma 14.7.** Let $E$ be an $n \times n$ matrix satisfying the basic hypotheses (2.10). The following are equivalent:

(i) the interior of $\Gamma(E)$ is non-empty;

(ii) the dimension of $\Gamma(E)$ is $n$;

(iii) $1 < e(j, k)e(k, j)$ for every pair $1 \leq j \neq k \leq n$.

**Proof.** Obviously (i) implies (ii). Conversely, since $\Gamma(E)$ is convex, if it contains a basis of $\mathbb{R}^n$ it also contains the convex hull of this basis together with 0, which is open.

In order to prove that (iii) implies (i), we argue by induction on $n$. For $n = 1$, $\Gamma(E) = (-\infty, 0)$ which has dimension 1. For $n = 2$, det$(E) = 1 - e(1, 2)e(2, 1) < 0$, so the rank of $E$ is 2, and hence by Corollary 14.6 the dimension of $\Gamma(E)$ is 2 and its interior is a nontrivial angle.

Thus assume that the Lemma is true for all $(n-1) \times (n-1)$ matrices $E'$ satisfying equation (2.10). Let $E$ be an $n \times n$ matrix satisfying equation (2.10) such that $1 < e(j, k)e(k, j)$ for every pair $1 \leq j \neq k \leq n$. Let $E'$ be the sub-matrix consisting of the first $n - 1$ rows and columns. Then clearly $E'$ also satisfies equation (2.10) and the hypothesis of the Lemma, so by the induction hypothesis, the dimension of $\Gamma(E')$ is $n - 1$, and $\Gamma(E')$ contains a non-empty open set $U \subset \mathbb{R}^{n-1}$. 
Let \( t' = (t_1, \ldots, t_{n-1}) \in U \). Then the components of \( t' \) satisfy the strict inequalities \( e(k,j)t_j < t_k \) for all \( j \neq k \). Since \( t_j < 0 \) and \( e(k,j) \leq e(k,n)e(n,j) \), it follows that \( e(k,n)e(n,j)t_j \leq e(k,j)t_j < t_k \) and so \( e(n,j)t_j < e(k,n)^{-1}t_k \) for all \( j, k \). Therefore

\[
\max \left\{ e(n,j)t_j : 1 \leq j \leq n-1 \right\} < \min \left\{ e(k,n)^{-1}t_k : 1 \leq k \leq n-1 \right\}.
\] (14.2)

But if \( t' \in \Gamma(E') \) then \( t = (t', t_n) = (t_1, \ldots, t_{n-1}, t_n) \) in \( \Gamma(E) \) if and only if for all \( 1 \leq j, k \leq n-1 \),

\[
\max \left\{ e(n,j)t_j : 1 \leq j \leq n-1 \right\} \leq t_n \leq \min \left\{ e(k,n)^{-1}t_k : 1 \leq k \leq n-1 \right\}.
\]

It follows from (14.2) that the set of \( t_n \) for which this is true is non empty and contains the open interval \( (m(t'), M(t')) \) where

\[
m(t') = \max \left\{ e(n,j)t_j : 1 \leq j \leq n-1 \right\},
\]

\[
M(t') = \min \left\{ e(k,n)^{-1}t_k : 1 \leq k \leq n-1 \right\}.
\]

Then

\[
\{(t', t_n) : t' \in U \text{ and } m(t') < t_n < M(t')\}
\]

is an open subset of \( \Gamma(E) \).

Conversely, if \( 1 < e(j,k)e(k,j) \) for every pair \( 1 \leq j \neq k \leq n \), it follows from Lemma 14.7 in Appendix I that \( \Gamma(E) \) has dimension \( n \) and in particular has non-empty interior. On the other hand, if \( \Gamma^o(E) \) is non-empty, then the projection of \( \Gamma(E) \) onto the two dimensional subspace spanned by \( x_j \) and \( x_k \) is open and non-empty. Since this projection is contained in \( \{(x_j, x_k) \in \mathbb{R}^2 : e(j,k)x_k < x_j < e(k,j)^{-1}x_k\} \), it follows that \( 1 < e(j,k)e(k,j) \). \( \square \)

**Proposition 14.8.** Let \( E \) be an \( n \times n \) matrix satisfying the basic hypothesis (2.10), and suppose that \( 1 < e(j,k)e(k,j) \) for all \( j \neq k \). Then for any indices \( k_1, \ldots, k_s \) it follows that

\[
1 < e(k_1, k_2)e(k_2, k_3) \cdots e(k_{s-1}, k_s)e(k_s, k_1)
\]

provided that the indices \( \{k_1, \ldots, k_s\} \) are not all the same.

**Proof.** The basic hypothesis implies that we always have

\[
1 \leq e(k_1, k_2)e(k_2, k_3) \cdots e(k_{s-1}, k_s)e(k_s, k_1).
\]

We argue by induction on \( s \). If \( s = 2 \), the hypothesis of the Proposition implies that we cannot have \( 1 = e(k_1, k_2)e(k_2, k_1) \) unless \( k_1 = k_2 \). Now suppose the statement is true for any set of indices of length \( s-1 \), and let \( k_1, \ldots, k_s \) be indices which are not all equal. Consider the product \( e(k_1, k_2)e(k_2, k_3) \cdots e(k_{s-1}, k_s)e(k_s, k_1) \). Without loss of generality we can assume \( k_1 \neq k_2 \) for otherwise \( e(k_1, k_2) = 1 \) and the result follows by induction. But then

\[
1 < e(k_1, k_2)e(k_2, k_1) \leq e(k_1, k_2)e(k_2, k_3)e(k_3, k_1) \leq \cdots \leq e(k_1, k_2)e(k_2, k_3) \cdots e(k_{s-1}, k_s)e(k_s, k_1)
\]

which completes the proof. \( \square \)
14.5 The reduced matrix \( E^r \)

In this section we show that if the dimension of \( \Gamma(E) \) is \( s < n \), there is an \( s \times s \) sub-matrix \( E^r \) of \( E \) satisfying the hypothesis of Lemma [14.7] so that \( \Gamma(E^r) \subset \mathbb{R}^s \) has dimension \( s \), and that \( \Gamma(E) \) is the graph of a linear mapping from \( \mathbb{R}^s \) to \( \mathbb{R}^n \).

Let \( E = \{e(j,k)\} \) be an \( n \times n \) matrix satisfying the basic hypothesis (2.10). If \( j, k \in \{1, \ldots, n\} \) write \( j \sim k \) if and only if \( e(j,k)e(k,j) = 1 \). It is immediate that \( j \sim j \) and \( j \sim k \iff k \sim j \). Suppose that \( j \sim k \) and \( k \sim l \). Then since \( e(j,k)e(k,j) = 1 \) and \( e(k,l)e(l,k) = 1 \),

\[
1 \leq e(j,l)e(l,j) \leq (e(j,k)e(k,l))(e(l,k)e(k,j)) = (e(j,k)e(k,j))(e(k,l)e(l,k)) = 1
\]

so that \( j \sim l \). Thus ‘\( \sim \)’ is an equivalence relation.

There are other equivalent formulations of this relation, based on the following remarks.

(i) If \( e(j,k)e(k,j) = 1 \), the basic hypotheses imply that, for every \( \ell \),

\[
\frac{1}{e(k,j)} \leq \frac{e(j,\ell)}{e(k,\ell)} \leq \frac{1}{e(j,k)} \leq \frac{e(\ell,j)}{e(\ell,k)} \leq \frac{e(\ell,k)}{e(\ell,j)} \leq e(k,j).
\]

Hence the above inequalities are all equalities, i.e., the \( j \)-th and \( k \)-th row of \( E \) are proportional. Conversely, if the \( j \)-th and the \( k \)-th rows \( E_j, E_k \) are proportional, then \( E_j = e(j,k)E_k \) and \( E_k = e(k,j)E_j \), hence \( e(j,k)e(k,j) = 1 \).

In the same way, one proves that \( j \sim k \) if and only if the \( j \)-th and \( k \)-th column are proportional.

(ii) If \( t = (t_1, \ldots, t_n) \in \Gamma(E) \) and if \( j \sim k \), then \( e(j,k)t_k \leq t_j = e(j,k)e(k,j)t_j \leq e(j,k)t_k \) so for all \( t \in \Gamma(E) \),

\[
t = (t_1, \ldots, t_n) \in \Gamma(E), \quad j \sim k \quad \implies \quad t_j = e(j,k)t_k. \tag{14.3}
\]

Conversely, if \( \Gamma(E) \) is contained in the hyperplane \( t_j = \lambda t_k \), this condition is satisfied in particular by the vectors \( v_k, w_k \) in (14.3). Hence \( e(j,k) = \lambda = e(k,j)^{-1} \) and therefore \( j \sim k \).

Let \( \{k_1, \ldots, k_s\} \) be representatives of the distinct equivalence classes in \( \{1, \ldots, n\} \) and let \( E^r \) be the \( s \times s \) matrix whose entries are \( \{e(k_a,k_b) : 1 \leq a, b \leq s\} \). Then \( E^r \) satisfies the same basic hypothesis, and if \( a \neq b \) we have \( e(k_a,k_b)e(k_b,k_a) > 1 \). The matrix \( E^r \) is called a reduced matrix for \( E \). It is not uniquely determined by \( E \) since it depends on the choice of representatives of the \( s \) distinct equivalence classes. The number \( s \) is called the reduced rank of \( E \).

Let \( \Pi : \mathbb{R}^n \to \mathbb{R}^s \) be the projection given by \( \Pi(t) = \Pi(t_1, \ldots, t_n) = (t_{k_1}, \ldots, t_{k_s}) \). If \( t \in \Gamma(E) \) then clearly \( \Pi(t) \in \Gamma(E^r) \), so \( \Pi : \Gamma(E) \to \Gamma(E^r) \). On the other hand, if \( t^v = (t_{k_1}, \ldots, t_{k_s}) \in \Gamma(E^r) \), set \( \sigma(t^v) = (t_1, \ldots, t_n) \) where \( t_j = e(j,k_a)t_{k_a} \) if \( j \sim k_a \). We claim \( \sigma(t^v) \in \Gamma(E) \). To see this, let \( 1 \leq j, k \leq n \) and suppose \( j \sim k \) and \( k \sim k_b \). Then since \( e(k_a,k_b)t_{k_b} \leq t_{k_a} \),

\[
e(j,k)t_k = e(j,k)e(k,k_b)t_{k_b} = e(j,k)e(k,k_b)e(k_a,k_b)^{-1}e(k_a,k_b)t_{k_b} \leq e(j,k)e(k,k_b)e(k_a,k_b)^{-1}t_{k_a} = e(j,k)e(k,k_b)e(k_a,k_b)^{-1}e(j,k_a)^{-1}e(j,k_a)t_{k_a} = e(j,k)e(k,k_b)e(k_a,k_b)^{-1}e(j,k_a)^{-1}t_j \leq t_j
\]

since \( e(j,k_a)e(k_a,k_b) = \frac{e(k_a,k_b)}{e(k_a,k_b)} \leq e(j,k_a)e(k,b) \). It follows that \( e(j,k)t_k \leq t_j \) as required, so \( \sigma(t^v) \in \Gamma(E) \). Thus if \( t = (t_1, \ldots, t_n) \in \Gamma(E) \), the coordinates \( t_j \) for \( j \notin \{k_1, \ldots, k_s\} \) are uniquely determined by \( \Pi(t) \). It follows that the mapping \( \Pi : \Gamma(E) \to \Gamma(E^r) \) is one-to-one and onto, with the inverse mapping given by \( \sigma \). We have established the following.
Lemma 14.9. Let $E$ be an $n \times n$ matrix satisfying the basic hypothesis (2.10). Let $j \sim k$ if and only if $1 = e(j,k)e(k,j)$. This is an equivalence relation, and suppose there are $s$ distinct equivalence classes. Let $\{k_1, \ldots, k_s\}$ be representatives of the distinct equivalence classes, and let $E^\flat$ be the $s \times s$ reduced matrix whose entries are $\{e(k_a,k_b) : 1 \leq a, b \leq s\}$.

a) The reduced matrix $E^\flat$ satisfies the basic hypothesis (2.10).

b) $1 < e(k_a,k_b)e(k_b,k_a)$ for all $1 \leq a \neq b \leq s$.

c) The dimension of $\Gamma(E)$ is $s$.

d) $\Gamma(E^\flat) \subset \mathbb{R}^s$ has dimension $s$, and thus has non-empty interior.

e) Let $\Pi : \mathbb{R}^n \to \mathbb{R}^s$ be given by $\Pi(t) = \Pi(t_1, \ldots, t_n) = (t_{k_1}, \ldots, t_{k_s})$. Then $\Pi : \Gamma(E) \to \Gamma(E^\flat)$ is one-to-one and onto.

f) Let $V = \left\{ t = (t_1, \ldots, t_n) \in \mathbb{R}^n : t_j = e(j,k_a)t_{k_a} \text{ if } j \sim k_a \right\}$. Then $V$ is an $s$-dimensional subspace of $\mathbb{R}^n$, and $\Gamma(E) \subset V$.

15 Appendix II: Estimates for homogeneous norms

Consider a family of dilations on $\mathbb{R}^m$ given by $\lambda \cdot x = (\lambda^{d_1}x_1, \ldots, \lambda^{d_m}x_m)$ with homogeneous dimension $Q = d_1 + \cdots + d_m$. Let $N : \mathbb{R}^m \to [0, \infty)$ be a smooth homogeneous norm relative to this family so that $N(x) \approx |x_1|^{1/d_1} + \cdots + |x_m|^{1/d_m}$. For any $\gamma = (\gamma_1, \ldots, \gamma_m) \in \mathbb{N}^m$, let $[\gamma] = d_1\gamma_1 + \cdots + d_m\gamma_m$.

Proposition 15.1. Let $\rho(x)$ be homogeneous of degree $p$. For $\gamma \in \mathbb{N}^m$ there is a constant $C_\gamma > 0$ so that $|\partial_\gamma^p \rho(x)| \leq C_\gamma N(x)^{p-\Vert \gamma \Vert}$.

Proof. Let $\gamma = (\gamma_1, \ldots, \gamma_m) \in \mathbb{N}^m$. Differentiating the equation $\lambda^\rho \rho(x) = \rho(\lambda \cdot x)$ we obtain

$$\lambda^\rho \partial_\gamma^p \rho(x) = \lambda^{\sum_{j=1}^m d_j\gamma_j} \partial_\gamma^p \rho(\lambda \cdot x) = \lambda^{\Vert \gamma \Vert} \partial_\gamma^p \rho(\lambda \cdot x).$$

It follows that $|\partial_\gamma^p \rho(x)|^{1/(p-\Vert \gamma \Vert)}$ is homogeneous of degree 1. Since $N$ is continuous and strictly positive on the compact set $\{x : N(x) = 1\}$, it follows that $|\partial_\gamma^p \rho(x)| \leq C_\gamma N(x)^{p-\Vert \gamma \Vert}$. \(\square\)

Proposition 15.2. There is a constant $c$ so that $|\{x \in \mathbb{R}^m : N(x) \leq 1\}| = c A^Q$.

Proof. Let $\mathbb{B}_N(1) = \{x \in \mathbb{R}^m : N(x) < 1\}$. Then $N(x) \leq A$ if and only if $N(A^{-1} \cdot x) = A^{-1}N(x) \leq 1$, and this is true if and only if $A^{-1} \cdot x \in \mathbb{B}_N(1)$. If $T_A(x) = A \cdot x$, this means that $x \in T_A(\mathbb{B}(1))$. Since $\det(T_A) = A^Q$, the Proposition follows. \(\square\)

Proposition 15.3. If $a = (a_1, \ldots, a_m) \in \mathbb{N}^m$, write $x^a = \prod_{j=1}^m x_j^{a_j}$.

(a) For $a \in \mathbb{N}^m$ and $M < [a] + Q$ there exists $C > 0$ so that

$$\int_{N(x) \leq A} |x^a| N(x)^{-M} \, dx \leq C A^{[a] + Q - M}.$$
(b) For \( a \in \mathbb{N}^m, M > [a] + Q \) there exists \( C > 0 \) so that
\[
\int_{N(x) \geq A} |x^a| N(x)^{-M} \, dx \leq C \, A^{[a]+Q-M}.
\]

(c) For \( a \in \mathbb{N}^m, M = [a] + Q, \) and \( B > 4A, \) there exists \( C > 0 \) so that
\[
\int_{A < N(x) < B} |x^a| N(x)^{-M} \, dx \leq C \log \left( \frac{B}{A} \right).
\]

Proof. We have \( |x^a| = \prod_{j=1}^m |x_j|^{a_j} \lesssim \prod_{j=1}^m N(x)^{a_j} = N(x)^{[a]} \). Thus if \( [a] + Q - M > 0, \)
\[
\int_{N(x) \leq A} |x^a| N(x)^{-M} \, dx \lesssim \sum_{j=1}^\infty \int_{2^{-j+1} A < N(x) \leq 2^{-j} A} N(x)^{[a]-M} \, dx
\]
\[
\approx \sum_{j=1}^\infty (2^{-j} A)^{[a]-M} \left| \left\{ x : N(x) \leq 2^{-j+1} A \right\} \right|
\]
\[
\approx \sum_{j=1}^\infty (2^{-j} A)^{[a]-M} (2^{-j+1} A)^Q \lesssim A^{[a]+Q-M}.
\]
Similarly, if \( [a] + Q - M < 0, \)
\[
\int_{N(x) \geq A} |x^a| N(x)^{-M} \, dx \lesssim \sum_{j=1}^\infty \int_{2^j A \leq N(x) < 2^{j+1} A} N(x)^{[a]-M} \, dx
\]
\[
\approx \sum_{j=0}^\infty (2^j A)^{[a]-M} \left| \left\{ x : N(x) \leq 2^{-j+1} A \right\} \right|
\]
\[
\approx \sum_{j=0}^\infty (2^j A)^{[a]-M} (2^{-j} A)^Q
\]
\[
\lesssim A^{[a]+Q-M}.
\]
Finally, if \( [a] + Q - M = 0, \)
\[
\int_{A \leq N(x) \leq B} |x^a| N(x)^{-M} \, dx \lesssim \int_{A \leq N(x) \leq B} N(x)^{[a]-M} \, dx.
\]
If \( B > 4A, \) choose \( j < k \) so that \( 2^{j-1} < A \leq 2^j \leq 2^k \leq B < 2^{k+1}. \) Then
\[
\int_{A \leq N(x) \leq B} N(x)^{[a]-M} \, dx \leq \sum_{l=j}^{k+1} \int_{2^{l-1} \leq N(x) < 2^l} N(x)^{[a]-M} \, dx
\]
\[
\leq \sum_{l=j}^{k+1} 2^l ([a]-M) \left| \left\{ x : N(x) \leq 2^{l+1} \right\} \right|
\]
\[
\leq \sum_{l=j}^{k+1} 2^l ([a]-M+Q) = k - j + 2 \approx \log \left( \frac{B}{A} \right).
\]
This completes the proof. \( \square \)
Proposition 15.4. Let $m \in C^\infty(\mathbb{R}^m \setminus \{0\})$ have compact support, and let $L = \{l_1, \ldots, l_r\} \subset \{1, \ldots, m\}$. Suppose for every $\gamma \in \mathbb{N}$ there is a constant $C > 0$ so that if $j \in L$ then

$$|\partial_{\xi_j}^\gamma m(\xi_1, \ldots, \xi_m)| \leq CN(\xi)^{-d_j \gamma}.$$ 

Put $K(x) = \int_{\mathbb{R}^m} e^{2\pi i (x, \xi)} m(\xi) d\xi$. There is a constant $C > 0$ independent of the support of $m$ so that

$$|K(x)| \leq C \left( \sum_{j \in L} |x_j|^{1/d_j} \right)^{-Q}.$$ 

Proof. Let $\varphi \in C_0^\infty(\mathbb{R})$ with $\varphi(t) \equiv 1$ if $|t| \leq 1$, $\varphi(t) \equiv 0$ if $|t| \geq 2$ and $0 \leq \varphi(t) \leq 1$ for all $t$. We have

$$K(x) = \int_{\mathbb{R}^m} e^{2\pi i (x, \xi)} \varphi(\lambda N(\xi)) m(\xi) d\xi + \int_{\mathbb{R}^m} e^{2\pi i (x, \xi)} [1 - \varphi(\lambda N(\xi))] m(\xi) d\xi = I + II.$$ 

Since $m$ is bounded, we have

$$|I| \leq ||m||_{\infty} \left( |\xi_1| : N(\xi) \leq 2\lambda^{-1} \right) \lesssim \lambda^{-Q}.$$ 

On the other hand, the chain, the product rule, and Proposition 15.1 show that

$$|\partial_{\xi_j}^\gamma [1 - \varphi(\lambda N(\xi))] m(\xi)| \leq CN(\xi)^{-d_j \gamma}$$

since any derivative of $\varphi(\lambda N(\xi))$ is supported where $\lambda N(\xi) \leq 2$. For $j \in L$ we can integrate by parts $M$ times in the variable $\xi_j$ and obtain

$$|II| \lesssim |x_j|^{-M} \int_{N(\xi) \geq \lambda^{-1}} |\partial_{\xi_j}^M [1 - \varphi(\lambda N(\xi))] m(\xi)| d\xi$$

$$\lesssim |x_j|^{-M} \int_{N(\xi) \geq \lambda^{-1}} N(\xi)^{-Md_j} d\xi$$

$$\lesssim |x_j|^{-M} \lambda^{-Q + d_j M}.$$ 

Setting $\lambda = |x_j|^{1/d_j}$, it follows that $|K(x)| \lesssim |x_j|^{-Q/d_j}$ for every $j \in L$, and hence that

$$|K(x)| \lesssim \min_{j \in L} |x_j|^{-Q/d_j} \approx \left( \sum_{j \in L} |x_j|^{1/d_j} \right)^{-Q}.$$ 

This completes the proof. \qed

Remark 15.5. Note that in this Proposition, we only assume estimates on “pure” $\xi_j$ derivatives of $m$ for $j \in L$. The conclusion is that the inverse Fourier transform $K = \hat{m}$ has the expected decay relative to the partial norm $N_L(x) = \sum_{j \in L} |x_j|^{1/d_j}$. If $L = \{1, \ldots, n\}$, the conclusion is that $K(x) \lesssim N(x)^{-Q}$.

16 Appendix III: Estimates for geometric sums

Proposition 16.1. Let $\epsilon > 0$, $a_1, \ldots, a_m > 0$ with $m \geq 2$ and $\prod_{j=1}^m a_j \neq 1$. Set

$$\Gamma = \left\{ I = (i_1, \ldots, i_m) \in \mathbb{Z}^m : a_{j_1} i_j \leq a_{j+1} i_{j+1} < 0 \text{ for } 1 \leq j \leq m-1, a_m i_m \leq i_1 < 0 \right\}.$$ 

For $I = (i_1, \ldots, i_m) \in \Gamma$ set $\Lambda(I) = [i_2 - a_1 i_1] + \cdots + [i_m - a_m i_{m-1}] + [i_1 - a_m i_m]$. Then there is a constant $C > 0$ depending on $\{\epsilon, a_1, \ldots, a_m\}$ so that $\sum_{I \in \Gamma} 2^{-\epsilon \Lambda(I)} \leq C$. 

Proof. \( \Gamma \) is a convex cone and \( \{ t \in \Gamma : \sum_{j=1}^{m} |t_j| = 1 \} \) is compact. Then \( \Lambda(t) \geq 0 \) on \( \Gamma \), and if \( \Lambda(t) = 0 \) with \( t \in \Gamma \), then \( t_1 = a_m \ell_m \) and \( t_{j+1} = a_j t_j \) for \( 1 \leq j \leq m - 1 \), so that \( t_1 = (\prod_{j=1}^{m} a_j) t_1 \). Since \( \prod_{j=1}^{m} a_j \neq 1 \), it follows that \( \Lambda(t) > 0 \) for \( t \in \Gamma \). In particular, by compactness there exists \( \eta > 0 \) so that if \( t \in \Gamma \) and \( |t| = 1 \) then \( \Lambda(t) > \eta \). Since \( \Lambda \) is continuous, there is an open neighborhood of \( \{ t \in \Gamma : \sum_{j=1}^{m} |t_j| = 1 \} \) on which \( \Lambda(t) > \eta \). By homogeneity it follows that \( \Lambda(t) \geq \eta \sum_{j=1}^{m} |t_j| \) for all \( t \in \Gamma \).

If \( I \in \Gamma \), then \( \Lambda(I) \geq \eta \sum_{j=1}^{n} |i_j| \). Thus we have

\[
\sum_{I \in \Gamma} 2^{-\epsilon \Lambda(I)} \leq \sum_{I \in \Gamma} 2^{-\epsilon \eta \sum_{j=1}^{m} |i_j|} \leq \left( \sum_{i=0}^{\infty} 2^{-\epsilon \eta} \right)^{m}
\]

which is a constant depending only on \( \epsilon \) and \( a_1, \ldots, a_m \). This completes the proof. \( \square \)

Now let \( E = \{ e(j, k) \} \) be an \( n \times n \) matrix satisfying (2.10) such that \( 1 < e(j, k) e(k, j) \) for all \( 1 \leq j, k \leq n \). Let \( \epsilon > 0 \). Let \( \tau : \{ 1, \ldots, n \} \to \{ 1, \ldots, n \} \) with \( \tau(j) \neq j \) for all \( j \). Let \( 0 < b < a \leq n \). Put

\[
\Gamma(Z)(E) = \{ I = (i_1, \ldots, i_n) \in \mathbb{Z}^n : e(j, k) i_k \leq i_j, \quad 1 \leq j, k \leq n \},
\]

\[
\Gamma(Z')(E') = \{ I' = (i_1, \ldots, i_a) \in \mathbb{Z}^a : e(j, k) i_k \leq i_j, \quad 1 \leq j, k \leq a \},
\]

\[
\Gamma(Z'')(E'') = \{ I'' = (i_a+1, \ldots, i_n) \in \mathbb{Z}^{n-a} : e(j, k) i_k \leq i_j, \quad a+1 \leq j, k \leq n \}.
\]

Note that \( \Gamma(Z)(E) \subset \Gamma(Z')(E') \times \Gamma(Z'')(E'') \). Also, if \( I'' \in \Gamma(Z'')(E'') \) then

\[
\Lambda(I'') = \left\{ I' = (i_1, \ldots, i_a) \in \mathbb{Z}^a : (I', I'') \in \Gamma(Z)(E) \right\} \subset \Gamma(Z')(E').
\]

Proposition 16.2. Let \( R_{b+1}, \ldots, R_a \) be positive real numbers. Then

\[
F = \sum_{I' \in \Gamma(Z')(E')} \left[ \prod_{j=1}^{b} 2^{-[e(j, \tau(j)) i_j]} \right] \left[ \prod_{j=b+1}^{a} \min \left\{ (2^{i_j} R_j)^{\epsilon}, (2^{i_j} R_j)^{-\epsilon} \right\} \right]
\]

converges and is bounded by a constant \( C \), depending on \( \epsilon, E \) but independent of \( R_{b+1}, \ldots, R_a \). Here it is understood that if \( b = 0 \) the first product is empty, and if \( 0 < b = a \) the second product is empty.

Proof. We argue by induction on \( n \geq 1 \). When \( n = 1 \) we have

\[
F = \sum_{j \in \mathbb{Z}} \min \left\{ (2^j R)^{\epsilon}, (2^j R)^{-\epsilon} \right\}.
\]

which converges and is independent of \( R \). Thus assume that the result is true for some \( n-1 \geq 1 \). There are two possibilities. First suppose that \( b = 0 \). Then

\[
F = \sum_{I' \in \Gamma(Z')(E')} \prod_{j=1}^{a} \min \left\{ (2^{i_j} R_j)^{\epsilon}, (2^{i_j} R_j)^{-\epsilon} \right\}
\]

\[
\leq \sum_{(i_1, \ldots, i_a) \in \mathbb{Z}^a} \prod_{k=1}^{a} \min \left\{ (2^{i_k} R_k)^{\epsilon}, (2^{i_k} R_k)^{-\epsilon} \right\}
\]

\[
= \prod_{j=1}^{a} \left[ \sum_{i_j \in \mathbb{Z}} \min \left\{ (2^{i_j} R_j)^{\epsilon}, (2^{i_j} R_j)^{-\epsilon} \right\} \right]
\]
which is independent of \(R_1, \ldots, R_a\).

Next suppose that \(b \geq 1\) so that the product \(\prod_{j=1}^{b} 2^{-\epsilon[i_j-e(\sigma(j))]_{i_{\tau(j)}}}\) is non-empty. There are now two possibilities.

**Case 1:**

Suppose there exists \(j_0 \in \{1, \ldots, b\}\) such that \(j_0 \neq \tau(k)\) for any \(k \in \{1, \ldots, b\}\). Without loss of generality, assume \(j_0 = 1\). Set

\[
\Gamma_2(E') = \{ \vec{\tau} = (i_2, \ldots, i_a) \in \mathbb{Z}^{a-1} : e(j, k)i_k \leq i_j, \quad 2 \leq j, k \leq a \}.
\]

Then \(\Gamma_2(E') \subset \{ (i_1, \vec{\tau}) : e(1, \tau(1))i_{\tau(1)} \leq i_1 \text{ and } \vec{\tau} \in \Gamma_2(E') \}\). Since the index \(i_1\) does not appear in the product \(\prod_{j=2}^{b} 2^{-\epsilon[i_j-e(\sigma(j))]_{i_{\tau(j)}}}\), the sum \(F\) is dominated by

\[
\sum_{\vec{\tau} \in \Gamma_2(E')} \left[ \prod_{j=2}^{b} 2^{-\epsilon[i_j-e(\sigma(j))]_{i_{\tau(j)}}} \right] \left[ \prod_{j=b+1}^{a} \min \left\{ (2^{i_j}R_j)^{+\epsilon}, (2^{i_j}R_j)^{-\epsilon} \right\} \right] \times \sum_{i_{\tau(1)} \in i_1} 2^{-\epsilon[i_1-e(1, \tau(1))]_{i_{\tau(1)}}}
\]

But

\[
\sum_{i_{\tau(1)} \in i_1} 2^{-\epsilon[i_1-e(1, \tau(1))]_{i_{\tau(1)}}} \leq \left[ 1 - 2^{-\epsilon e(1, \tau(1))} \right]^{-1},
\]

and so

\[
F \leq \frac{1}{1 - 2^{-\epsilon e(1, \tau(1))}} \sum_{\vec{\tau} \in \Gamma_2(E')} \left[ \prod_{j=2}^{b} 2^{-\epsilon[i_j-e(\sigma(j))]_{i_{\tau(j)}}} \right] \left[ \prod_{j=b+1}^{a} \min \left\{ (2^{i_j}R_j)^{+\epsilon}, (2^{i_j}R_j)^{-\epsilon} \right\} \right] \times \sum_{i_{\tau(1)} \in i_1} 2^{-\epsilon[i_1-e(1, \tau(1))]_{i_{\tau(1)}}}.
\]

The result now follows by induction since in the remaining sum we have replaced \(\{1, \ldots, n\}\) with \(\{2, \ldots, n\}\).

**Case 2:**

Now assume that each \(j \in \{1, \ldots, b\}\) is equal to \(\tau(k)\) for at least one \(k \in \{1, \ldots, b\}\). Let \(\sigma(j) \in \{1, \ldots, b\}\) be a choice of some pre-image of \(j\). Then \(\sigma : \{1, \ldots, b\} \to \{1, \ldots, b\}\), and since \(\tau(\sigma(j)) = j\), it follows that \(\sigma\) is one-to-one. Thus \(\sigma\) (and hence also \(\tau\)) is a permutation of \(\{1, \ldots, b\}\). It follows that we can decompose \(\{1, \ldots, b\}\) into a disjoint union of non-empty subsets \(C_1, \ldots, C_p\) which are the minimal closed orbits of the mapping \(\tau\). We can write \(C_l = \{j_l, 1, \ldots, j_l, m_l\}\) with \(\tau(j_l, k) = j_l, k+1\) for \(1 \leq k < m_l - 1\) and \(\tau(j_l, m_l) = j_l, 1\). Then for \(1 \leq l \leq p\) let

\[
\Gamma'_l = \{ (i_l, 1, \ldots, i_l, m_l) \in \mathbb{Z}^{m_l+1} : e(j_l, k, \tau(j_l, k))i_{\tau(j_l, k)} \leq i_{j_l, k}, \quad 1 \leq k \leq m_l \}.
\]

Then \(\Gamma_2(E') \subset \Gamma'_1 \times \cdots \times \Gamma'_p\), and so

\[
F \leq \prod_{l=1}^{p} \left[ \sum_{i_l \in \Gamma'_l} \prod_{k=1}^{m_l} 2^{-\epsilon[i_{j_l, k}-e(j_l, k, \sigma(j_l))]_{i_{\tau(j_l, k)}}} \right] \left[ \prod_{k=a+1}^{b} \min \left\{ (2^{i_{j_l, k}}R_k)^{+\epsilon}, (2^{i_{j_l, k}}R_k)^{-\epsilon} \right\} \right]
\]

However \(\sum_{i_l \in \Gamma'_l} \prod_{k=1}^{m_l} 2^{-\epsilon[i_{j_l, k}-e(j_l, k, \sigma(j_l))]_{i_{\tau(j_l, k)}}}\) is uniformly bounded by Proposition 14.8 and Proposition 16.1. Also, \(\sum_{i_l \in \mathbb{Z}} \min \left\{ (2^{i_{j_l, k}}R_k)^{+\epsilon}, (2^{i_{j_l, k}}R_k)^{-\epsilon} \right\}\) is bounded independently of \(R_k\). Thus \(F\) is bounded independently of \(i_{a+1}, R_{a+1}, \ldots, R_b\). This completes the proof. \(\square\)
Proposition 16.3. Let $E = \{e(j,k)\}$ be an $n \times n$ matrix satisfying $2.10$, and suppose that $1 < e(j,k)e(k,j)$ for all $j \neq k$. Let $e = \max \{e(j,k) : 1 \leq j, k \leq n\}$. Let $\alpha_j > 0$, $M_j \geq 0$ for $1 \leq j \leq n$. If $M \geq \sum_{j=1}^{n}(e(\alpha_j + 1) + M_j)$ there is a constant $C = C(M_1, \ldots, M_n, n, e)$ so that for all $(A_1, \ldots, A_n)$ with $A_j > 0$,

$$
\sum_{I \in \Gamma_\varepsilon(E)} \left[ \prod_{j=1}^{n} 2^{-i_j \alpha_j} \right] \left[ 1 + \sum_{k=1}^{n} 2^{-i_k A_k} \right]^{-M} \leq C \prod_{j=1}^{n} \left[ A_j^{e(j,1)} + \cdots + A_n^{e(j,n)} \right]^{-\alpha_j} \prod_{j=1}^{n} (1 + A_j)^{-M_j}.
$$

Proof. Let $N_j(A) = \sum_{k=1}^{n} A_k^{e(j,k)}$. If $I = (i_1, \ldots, i_n) \in \Gamma_\varepsilon(E)$ then for any $1 \leq j \leq n$ we have $-i_j < -e(j,k)i_k$ and so

$$
1 + 2^{-i_j} N_j(A) \leq 1 + \sum_{k=1}^{n} 2^{-i_k e(j,k)} A_k^{e(j,k)} \leq 1 + \sum_{k=1}^{n} [2^{-i_k} A_k]^{e(j,k)} \leq \left[ 1 + \sum_{k=1}^{n} 2^{-i_k A_k} \right]^e.
$$

Therefore

$$
\left[ 1 + \sum_{k=1}^{n} 2^{-i_k A_k} \right]^{-M} \leq \prod_{j=1}^{n} \left[ 1 + \sum_{k=1}^{n} 2^{-i_k A_k} \right]^{-e(\alpha_j + 1)} \prod_{j=1}^{n} \left[ 1 + A_j \right]^{-M_j} \leq \prod_{j=1}^{n} \left[ 1 + 2^{-i_j} N_j(A) \right]^{-\alpha_j} \prod_{j=1}^{n} \left[ 1 + A_j \right]^{-M_j},
$$

and so

$$
\sum_{I \in \Gamma_\varepsilon(E)} \left[ \prod_{j=1}^{n} 2^{-i_j \alpha_j} \right] \left[ 1 + \sum_{k=1}^{n} 2^{-i_k A_k} \right]^{-M} \leq \sum_{I \in \Gamma_\varepsilon(E)} \prod_{j=1}^{n} 2^{-i_j \alpha_j} \left[ 1 + 2^{-i_j} N_j(A) \right]^{-\alpha_j} \prod_{j=1}^{n} \left[ 1 + A_j \right]^{-M_j} \leq C \prod_{j=1}^{n} \left[ \sum_{i_1 \leq 0} \left[ 1 + 2^{-i_j} N_j(A) \right]^{-\alpha_j} \right] \prod_{j=1}^{n} \left[ 1 + A_j \right]^{-M_j} \leq \prod_{j=1}^{n} \left[ N_j(A)^{-\alpha_j} \right] \prod_{j=1}^{n} \left[ 1 + A_j \right]^{-M_j}.
$$

This completes the proof. \qed
