INTRODUCTION

Cysticercosis is an important parasitic infection in the developing countries. It is caused by cestodes, the pork tapeworm, *Taenia solium*. Humans may be either definitive hosts (adult tapeworms residing in the human intestines) or intermediate hosts (the larval stage residing in the tissues) for *T. solium* [1].

Humans can become an intermediate host when they either ingest cysticerci (encysted larvae) or consume eggs. Cysticerci are ingested by eating undercooked pork while eggs are usually ingested by eating contaminated foods, including uncooked or inadequately washed raw vegetables or salads [2]. When eggs reach the stomach, gastric enzymes will break down the egg wall and release larvae. The larvae penetrate the intestinal mucosa into the blood circulation and form cysticerci which can be found in any part of the body, especially central nervous system (neurocysticercosis). There are 2 main forms of neurocysticercosis [3]. One is “isolated cyst” (cysticercus cellulosae), and the other is “racemose cyst (cysticercus racemosus) [4].

We report a case of cerebral cysticercosis in Bangkok, Thailand of which imaging studies showed an atypical convoluted lesion, similar to sparganosis, another kind of cestode infection in the brain.

CASE RECORD

A 30-year-old Thai female presented to the outpatient clinic with generalized tonic-clonic seizure 1 week ago. The duration of the seizure was less than 1 min. The patient passed out for 1 hr, and gained consciousness without memory deficit. There was no history of fever, vomiting, headache, or visual disturbances. No history of previous accident, drug allergy, or cancer was present. Her physical examination was normal. The brain MRI revealed a conglomeration of several small ring enhancing lesions of 1.9 × 1.4 × 1.6 cm in size, at the cortical posterior left middle frontal gyrus. Neither midline shift nor hydrocephalus was seen (Fig. 1). A chest x-ray showed an unremarkable finding. No abnormal calcification was detected by plain radiograph of the femur. Routine blood examinations showed an absence of eosinophilia, and stool examinations showed no parasites.

A left frontal craniotomy was done. A greyish white cyst of about 1 × 2 × 1 cm in size filled with clear fluid and small white nodule was removed. Multiple sections studied revealed necrotic material with neutrophils, mononuclear cells, some eosinophils, surround by granulation tissues (Fig 2A). Nearby the necrotic material, a cyst with cavity larva of *T. solium* was found. There were numerous branching and duct-like imaginations (Fig 2B). Staining with PAS (periodic acid-Schiff) revealed microvilli (Fig. 2C), while Von Kossa staining revealed calcified corpuscles (Fig. 2D).

The patient was treated with albendazole for 3 weeks and was doing well at 1 month follow up. Her family denied any history of cysticercosis.

Parasitic infections of the central nervous system can share similar clinical presentations, depending on the location, size, and number of lesions, and the inflammatory responses evoked by the parasites [2,3]. Regarding cerebral infections in developing countries, the possible diagnosis of the patient with confluent ring enhancing lesion by MRI can be due to cysticercosis, sparganosis, and even tuberculoma [4].

Regarding the imaging studies, Kim et al. [5] described the

**DISCUSSION**

![MRI findings of the patient](image1)

Fig. 1. MRI findings of the patient. (A) Horizontal section of T1 weighted MRI of lesion with ring enhancement. (B) Sagittal section of T1W MRI. (C) T2-weighted MRI with perilesional edema.

![Histopathological findings of the patient](image2)

Fig. 2. Histopathological findings of the patient. (A) Necrotic areas with inflammation. (B) The parasite with branching internal structures. (C) Microvilli at outer membrane of the cyst. (D) Calcified corpuscles inside the parasite.
Table 1. Various stages of neurocysticercosis

| Stage                | MRI findings                                                                 |
|----------------------|-----------------------------------------------------------------------------|
| 1. Non cystic        | Undetectable                                                                |
| 2. Vesicular         | Cyst signal intensity similar to that of CSF on T1- and T2-weighted images; cyst wall is well-defined and thin, with little or no enhancement on gadolinium-enhanced images; scolex can be demonstrated in up to a 50% of the cases |
| 3. Colloidal vesicular | Cyst contents hyperintense on T1- and T2-weighted images (proteinaceous fluid), cyst wall is thick and hypointense, pericystic edema, pericystic enhancement on gadolinium-enhanced images |
| 4. Granular nodular  | Similar to colloidal vesicular stage but with more edema, thicker ring enhancement |
| 5. Calcified nodular | Hypointense nodules, no edema, no enhancement                                |

Dubey et al. [8] claimed that soft tissue cysticercosis can be seen as elongated calcification along the muscle fibers on plain radiographs and CT scan, once the larvae become a final calcified stage, but not the early stage of live cysticerci. A combination of MRI and ultrasonography can be confidently used to diagnose non-invasive cysticercosis in soft tissues [8].

The definite diagnosis of cysticerci can be made only by tissue biopsy. Spargana differ from cysticerci by the absence of bladder walls and armed scolex and the presence of solid non-cavitated body [9]. However, in our case we could not find the scolex by histological studies. Teitelbaum et al. [10] claimed that the scolex in cysticercosis is found in nearly 50% of cases. The reason why we cannot find the scolex is related to “stages of the disease”. According to the stage of the cyst, our case was compatible with “colloidal vesicular stage”, in which larvae begin to degenerate and scoleces disintegrate, with surrounded striking inflammatory responses as shown in Table 1 [11, 12].

Recently, there is a PCR technique which can help molecular genetic confirmation [13]. Unfortunately, we lack molecular facilities in our center. We hope that we will have a chance to investigate more in the future.

**CONFLICT OF INTEREST**

We do not have any conflict of interest related to this work.
