Abstract
We report a patient with autism and cleft lip and palate carrying a de novo heterozygous AUTS2 mutation, c.1464_1467del ACTC (p.Tyr488*). Although the causal relationship between cleft lip and palate and this mutation is unclear, this case report may expand the clinical phenotype of AUTS2 syndrome.

KEYWORDS
autism spectrum disorder, AUTS2, cleft lip and palate, exon 8

1 INTRODUCTION

Autism spectrum disorder (ASD) is characterized by impairments in ordinary social communication, along with restricted and stereotyped behaviors and interests. The morbidity rate remains under 1% of the population with onset before the age of 3 years. In recent years, advances in genomic techniques have provided novel insight into the genetic causes of ASD, including mutations in the autism susceptibility candidate 2 (AUTS2) gene.

AUTS2 is a well-conserved gene in vertebrates, comprising 19 exons located on chromosome 7q11.22. The frequency of AUTS2 mutation is 1/2000.2 Its 19 exons are divided into two parts: the first six exons at the 5′ end, which are separated by large introns, and the remaining 13 exons at the 3′ end, which are compact with smaller clustered introns.2 In addition to ASD, variants in AUTS2 have been demonstrated to be associated with other neurodevelopmental disorders such as schizophrenia and developmental delay, along with physical malformations such as dysmorphic features, short stature, and microcephaly.2

We encountered a patient with ASD and a heterozygous AUTS2 mutation that was defined as likely pathogenic in ClinVar (GenomeDx, RCV000657843.1). However, the phenotype of this mutation has never been reported.

Here, we report the clinical details of a patient with this mutation. To our knowledge, this is the first case of an AUTS2 variant associated with cleft lip and palate.
2 | CASE REPORT

The 8-year-old patient was the first child born to nonconsanguineous, healthy Japanese parents. The family history was unremarkable. The boy was born at 36 weeks of gestation by vaginal delivery and did not suffer asphyxia. His birth weight was 2005 g (−2.5 SD), with a height of 44.2 cm (−2.3 SD), and head circumference of 26.5 cm (−4.8 SD). He exhibited dysmorphic features, including highly arched eyebrows, micrognathia (Figure 1A), cleft lip and palate, microcephaly, left cryptorchidism, right inguinal hernia, and a ventricular septal defect that was closed at 10 months of age. The cleft lip and palate were treated surgically at 10 and 19 months of age, respectively. His motor and intellectual developments were delayed from early childhood; he walked alone at 23 months old and spoke a single word at 35 months old. He required tube feeding from the age of 4 months owing to feeding difficulties. Brain magnetic resonance imaging and electroencephalogram revealed no abnormalities. Various blood tests, including amino acid analysis, lactate, and pyruvate, were normal. Chromosomal analysis and array comparative genomic hybridization showed no abnormalities.

At 3 years of age, the patient exhibited marked hyperactivity, impulsivity, and acoustic hyperesthesia. His face was always expressionless, and he could not make eye contact. He showed developmental language delay, and the diagnosis of ASD was finally made. Medications were needed to control his remarkable hyperactivity, such as risperidone, atomoxetine, and aripiprazole. Oral food intake gradually increased, and nasogastric tube feeding was not required by the age of 3 years and 9 months; however, his feeding difficulties continued until almost 5 years of age. He was still small in terms of physical status at 5 years and 10 months: weight 10.9 kg (−2.9 SD), height 94.6 cm (−3.7 SD), and head circumference 43.0 cm (−4.4 SD). He is currently enrolled in special support education classes.

A trio exome analysis was performed as described previously.5 The research protocol was approved by the local institutional ethical review board of the University of Tsukuba and Keio University School of Medicine following the Ethical Guidelines for Human Genome/Gene Analysis Research of the Ministry of Health, Labor and Welfare of Japan and the Declaration of Helsinki Principles. Informed consent was obtained from the parents. Genomic DNA was extracted from peripheral blood leukocytes of the patient and both parents, and whole-exome sequencing was performed using the SureSelect XT Human All Exon V6 (Agilent Technologies) and HiSeq 2500 (Illumina) platforms. Whole-exome sequencing revealed a mutation in autism susceptibility candidate 2 (AUTS2), NM_015570.3:c.1464_1467del ACTC (p.Tyr488*), which was determined to be a de novo mutation in the patient (Figure 1B). These sequence data have been reported to ClinVar by GenomeDx under accession number RCV000657843.1. This variant is located in exon 8, at the C-terminus of AUTS2 and is predicted to disrupt mRNA translation.

3 | DISCUSSION

The main functions of AUTS2 involve neuronal migration, extension, and branching of the neurites and construction of the correct neuronal network.4 Previous studies have indicated that mutations in AUTS2 are associated with not only neurodevelopmental disorders such as ASDs, attention deficit hyperactivity disorder, and intellectual disability but also short stature, microcephaly, feeding difficulties, dysmorphic features, and other malformations.7-9 Beunders et al2 coined the term "AUTS2 syndrome" to describe these various symptoms and established a scoring system composed of four grades: 0-7, 8-12, 13-18, and 19-31. Patients with deletions at the N-terminus typically show only neurodevelopment disorders, whereas those with deletions at the C-terminus exhibit neurodevelopment disorders as well as other physical features and feeding difficulties.1,2 Mutations in the C-terminus of AUTS2 appear to cause more severe phenotypes. Our
TABLE 1  Features of the AUTS2 syndrome depending on region of the deletion²

(Continues)
patient has a deletion in exon 8 of AUTS2, which is located in the C-terminus, and he presents a severe phenotype consistent with these previous descriptions. Indeed, the patient’s AUTS2 syndrome score was 16/31, which is classified as the second most severe grade2 (Table 1).

Considering the biological function of AUTS2 in the brain, researchers found that nuclear AUTS2 combines with the promoter/enhancers of various genes related to brain development.4,10 Gao et al.11 showed that the most important amino acids to recruit P300, which is a well-known histone acetyltransferase known to play a role in craniofacial development, may be located at positions 404-717.11 These positions correspond to the region between exon 7 and exon 16.2 The de novo mutation identified in our patient creates a stop codon at amino acid 488 in exon 8. This mutation may cause nonsense-mediated decay and loss of the entire cDNA or result in loss of the region needed for recruiting P300. Many distant-acting enhancers for craniofacial development are also associated with P300.

The main unique features of our AUTS2 syndrome patient are the cleft lip and palate. The prevalence of cleft lip and palate is approximately 1.7 per 1000 live births in Asia, which also has the highest average occurrence rate of cleft lip and palate worldwide. In Japanese populations, the prevalence of cleft lip and palate is 2.06 per 1000 live births and shows a significant male bias.6 The definite cause of cleft lip and palate remains largely unknown.6 There are many known risk factors, including maternal smoking, alcohol consumption, medications, nutrition, and genetic factors. Our patient did not have any of these risk factors for cleft lip and palate except for ethnic group and sex.

Since this is the only reported case of cleft palate associated with AUTS2 mutation, a causal relationship warrants further investigation. Moreover, further studies should focus on the broader functions of AUTS2 beyond its role in the nervous system to explain why a variant of this gene would cause physical malformations, including cleft lip and palate.

ACKNOWLEDGMENTS

We would like to express our gratitude to the patient and his family. This study was supported by the Initiative on Rare and Undiagnosed Diseases from the Japan Agency for Medical Research and the Development and Research on Rare and Intractable Diseases from the Ministry of Health, Labor and Welfare, Japan. We would like to thank Editage (www.editage.jp) for English language editing.

CONFLICT OF INTEREST

The authors have no conflict of interest to declare.

AUTHOR CONTRIBUTIONS

SS, TE, MT, and TO examined the patient. HS, TU, TT, and KK performed exome analysis. KI, HF, DK, AS, MT, HS, TU, TT, and KK analyzed data. SS, TE, KI, and HT wrote the paper. All authors have read and approved the final manuscript.
