1. Introduction

The control theory of system is always a hot topic [1–8]. Time delays are of frequent occurrence in many practical systems, which often result in the major source of poor performance and instability. The stability problems of time-delayed systems have been a hot research topic. In this paper, the stability problems of linear systems with time-varying delays will be further analyzed via the LKF method application. The linear systems with time-varying delays are described as:

\[
\begin{aligned}
\dot{x}(t) &= Ax(t) + A_1x(t - h(t)), \\
x(s) &= \psi(s), \quad s \in [-h, 0],
\end{aligned}
\tag{1}
\]

where \(x(t) \in \mathbb{R}^n\) is the state vector of the system. \(A\) and \(A_1\) are real constant matrices with appropriate dimensions. The time-varying delay \(h(t)\) is continuous-time functional and satisfies the following conditions:

\[0 \leq h(t) \leq h, \quad |h(t)| \leq \mu < 1, \quad \forall t \geq 0, \tag{2}\]

where \(h\) and \(\mu\) are positive constants.

To obtain stability criteria of system (1) by using the Lyapunov theorem, the main efforts are concentrated on the following several directions, one is finding an appropriate positive definite functional with a negative definite time derivative along the trajectory of system, e.g., LKF with delay partitioning approach [9,10], LKF with augmented terms [11–16], LKF with triple-integral and quadruple-integral terms [17–19], and so on. The other is reducing the upper bounds of the time derivative of LKF as much as possible by developing various inequality techniques, such as Jensen inequality [20], Wirtinger-based inequality [21], auxiliary function based inequality [22–25], Bessel-Legendre inequality [26], etc. Besides, further increasing the freedom of solving LMI, additional free-weighting-matrix technique is frequently introduced into the derivatives of LKF, for instance, the generalized zero equality [27,28], the one or second-order reciprocally convex combinations [29–31], the free-weighting-matrix approach [32], and so on. Based on those studies in [21,22,26,33], the tighter inequality seems to lead to less conservative results. Recently, Zhang [34] considered the effect of the LKFs and discussed the relationship between the tightness of inequalities and the conservativeness of criteria. The results illustrate the integral inequality that makes the upper bound closer to the true value does not always lead to deduction of a less conservative stability condition if the LKF is not properly constructed. Thus, it is crucial to construct a proper LKF. Recently, to fully utilize the information of delay derivative, a novel LKF with delay-dependent matrix was constructed by Kwon et al. [35] as follows:

\[
V(t) = \xi^T(t)P\xi(t) + \int_0^t \int_{h(t)}^{t}\gamma^T(s)Q_1(t)\gamma(s)\, ds
+ \int_{t-h(t)}^{0} \gamma^T(s)Q_2(t)\gamma(s)\, ds
+ \int_{-h}^{0} \int_{t+\theta}^{t} \gamma^T(s)R\gamma(s)\, ds\, d\theta, \tag{3}\]

where $P > 0, R > 0$ and

$$
Q_1(t) = Q_{01} - h(t)Q_{11} > 0,
\]
$$
Q_2(t) = Q_{20} + (h - h(t))Q_{21} > 0,
\]

$$
\xi^T(t) = \begin{bmatrix}
    x^T(t)x^T(t - h(t))x^T(t - h) \\
    \times \int_{t-h}^{t} x^T(s) ds \int_{t-h}^{t} x^T(s) ds 
\end{bmatrix},
\]
$$
\gamma^T(s) = [x^T(s) \dot{x}^T(s)].
\]

Compared with the general delay-independent LKF, the Lyapunov matrices $Q_1(t), Q_2(t)$ of the above LKF are delay-dependent, which can make further use of the information of time delay and derivative of delay. Kwon et al. have illustrated that the stability conditions based on the LKF (3) with delay-dependent matrices are less conservative than those based on the LKF without delay-dependent matrices. However, to bound the integral items $-\dot{h}(t) \int_{t-h}^{t} \gamma^T(s)Qa\gamma(s) ds$ and $-\dot{h}(t) \int_{t-h}^{t} \gamma^T(s)Qb\gamma(s) ds$ ($\dot{Q}_a > 0, \dot{Q}_b > 0$) via the QGFI technique, two additional positive integral items $\mu \int_{t-h}^{t} \gamma^T(s)Qa\gamma(s) ds$ and $\mu \int_{t-h}^{t} \gamma^T(s)Qb\gamma(s) ds$ are introduced. Indeed, it is difficult to deal with the two integral terms due to their positive definiteness.

Moreover, the main inequalities of [35] were not incorrect due to the following reasons:

the following terms in Theorem 1 of [35]

$$
H_3^T Y_1 G_3 H_2, \quad H_3^T Y_2 G_4 H_3,
\]
$$
H_3^T Y_3 G_3 H_2, \quad H_3^T Y_4 G_4 H_3,
\]

$$
\tilde{d} - d(t)/3 [H_3^T Y_2 Q_0^{-1} Y_2^T H_3 + H_3^T Y_4 \tilde{R}_b^{-1} Y_4^T H_3],
\]

$$
\tilde{d}(t) / 3 [H_3^T Y_1 \tilde{Q}_a^{-1} Y_1^T H_2 + H_3^T Y_3 \tilde{R}_a^{-1} Y_3^T H_2]
\]

appeared in $\Psi_3$ of inequalities (11)–(14) and (26) of [35], respectively, should be

$$
H_3^T W_1 Y_1 G_3 H_2, \quad H_3^T W_2 Y_2 G_4 H_3,
\]
$$
H_3^T W_3 Y_3 G_3 H_2, \quad H_3^T W_4 Y_4 G_4 H_3,
\]

$$
\tilde{d} - d(t)/3 [H_3^T W_2 Q_0^{-1} Y_2^T W_3 + H_3^T W_4 \tilde{R}_b^{-1} Y_4^T W_3],
\]

$$
\tilde{d}(t) / 3 [H_3^T W_1 Y_1 \tilde{Q}_a^{-1} Y_1^T W_2 H_2 + H_3^T W_3 Y_3 \tilde{R}_a^{-1} Y_3^T W_1 H_2]
\]

with $W_1 = \text{diag}(d(t), 1, 1, 1, 1)$ and $W_2 = \text{diag}(\tilde{d} - d(t), 1, 1, 1, 1)$.

Thus, all of the above terms (7)–(9) are non-linear function of $d(t)$ and the inequalities (11)–(14) and (26) in Theorem 1 of [35] are not LMIs, although the Schur complement was used. Indeed, the first element of $W_1, W_2, G_3, G_4$ and $d(t)/3, (\tilde{d} - d(t))/3$ lead to $d^2(t)$ and $\tilde{d}^2(t)$ contained in the terms (7)–(9). Although the terms (8)–(9) are transformed via the Schur complement application, the final forms $\Psi_{1i,j}$ still remain $d^2(t)$. Therefore, Theorem 1 of [35] is incorrect due to the above reasons.

Inspired by the above discussions, this paper constructs the following modified LKF (4) to analyse the stability of the linear time-delayed system (1).

$$
V(t) = \sum_{i=1}^{4} V_i(t)
\]

with

$$
V_1(t) = \xi^T(t) P \xi(t),
\]
$$
V_2(t) = \int_{t-h}^{t} \gamma^T(s)Q_1(t)\gamma(s) ds
\]
$$
+ \int_{t-h}^{t} \gamma^T(s)Q_2(t)\gamma(s) ds,
\]
$$
V_3(t) = \int_{t-h}^{t} \int_{\theta}^{t} \gamma^T(s)\tilde{Q}_a\gamma(s) ds d\theta
\]
$$
+ \int_{t-h}^{t} \int_{\theta}^{t} \gamma^T(s)\tilde{Q}_b\gamma(s) ds d\theta,
\]
$$
V_4(t) = \int_{t-h}^{t} \int_{\theta}^{t} \gamma^T(s) R_1\gamma(s) ds d\theta
\]
$$
+ \int_{t-h}^{t} \int_{\theta}^{t} \gamma^T(s) R_2\gamma(s) ds d\theta,
\]

where, $P, Q_1(t), Q_2(t), \tilde{Q}_a, \tilde{Q}_b, R_1$ and $R_2$ are positive definite matrices.

The main contributions of this paper are summed up as follows:

- To avoid introducing the two additional positive integral items $\mu \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_a\gamma(s) ds$ and $\mu \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_b\gamma(s) ds$, the paper gives the modified LKF with two double integral items $V_3(t)$;
- All of the integral items $V_2(t), V_3(t)$ and $V_4(t)$ are constructed under two subintervals $[0, h(t)]$ and $[h(t), l]$ instead of being considered directly. It further makes full use of the information of time-varying delays $h(t), h - h(t)$ and their derivative. The QGFI technique can be utilized fully in each subinterval, which can further reduces the conservatism of the stability condition;
- To avoid introducing non-linear terms with $h^2(t)$ and $h^3(t)$, this paper introduces some necessary state variables into the LKF, which not only increases the freedom for solving LMIs, but also removes the non-linear terms with $h^2(t)$ and $h^3(t)$ in [35].
Finally, based on the LKF (10) proposed in this paper, a new less conservative stability criterion is obtained than some of the recent existing ones.

This paper is organized as follows. Section 2 gives the problem statement and provides some lemmas. Section 3 presents a new stability criterion for the linear time-varying delay system. Numerical examples and conclusions are drawn in Sections 4 and 5, respectively.

Notation: The notation \( P > 0 \) (\( P < 0 \)) mean that matrix \( P \) is positive (negative) definite. \( I \) represents an identity matrix with the corresponding dimension. \( \ast \) denotes the symmetric terms in a block matrix and diag\{\} denotes a block-diagonal matrix. \( e_i \) \( (i = 1, \ldots, m) \) is block entry matrices. For example, \( e_2 = [0 \ 1 \ 0 \ \ldots \ 0] \).

\[ F^{[h(t)]} \] denotes \( F \) is the function of \( h(t) \). Sym\{\} \( B = B + B^T \).

2. Problem formulation

The main purpose of this paper is to derive the stability criterion for the system (1) satisfying the condition (2) by using a modified LKF. To further explain the topic of this paper, the following research flow chart is given in Figure 1. To achieve this purpose, the following lemma is important.

Lemma 2.1 (QGFMI [35]): For given any matrices \( X, Y \), a positive matrix \( R \) and a continuous differentiable function \( \omega(s) | s \in [a, b] \), the following inequality holds

\[
- \int_a^b \omega^T(s)R\omega(s) \, ds \\
\leq \begin{bmatrix} \eta_0 \\ \eta_1 \end{bmatrix}^T \begin{bmatrix} (b - a)X^{1/2}X^{-1}X^{1/2} & \frac{1}{3}YX^{-1}Y \\ \ast & \end{bmatrix} \begin{bmatrix} \eta_0 \\ \eta_1 \end{bmatrix},
\]

where \( \eta_0 \) is an any vector, and

\[
\eta_1^T = \left[ \int_a^b \omega^T(s) \, ds \right] \frac{1}{b - a} \int_a^b \int_a^b \omega^T(s) \, ds \, d\theta \].

3. Main results

The main objective of this section is to describe the effect of the proposed LKF on reducing the conservatism of the stability criterion. A novel theorem is derived by employing the LKF proposed in previous section and a corollary for comparison is also given. For the sake of simplicity on matrix representation, the notations of several symbols and matrices are defined as:

\[
h_d = 1 - \frac{1}{h(t)}, \quad \bar{\mu} = \mu + \frac{1}{h(t)},
\]

\[
\gamma^T(s) = [x^T(s) \dot{x}^T(s)],
\]

\[
v_1(t) = \int_{t-h(t)}^t x^T(s) h(t) \, ds,
\]

\[
v_2(t) = \int_{t-h(t)}^{t-h(t)} x^T(s) \, ds,
\]

\[
\xi^T(t) = [x^T(t) x^T(t-h(t)) h(t-v_1(t)) v_2(t)],
\]

\[
\xi^T(\theta) = \begin{bmatrix} x^T(t) x^T(t-h(t)) x^T(t-h) \\
\dot{x}^T(t-h(t)) \dot{x}^T(t-h(t)) \end{bmatrix} \begin{bmatrix} v_1(t) \\ v_2(t) \end{bmatrix}
\]

\[
\times \left[ \int_{t-h(t)}^t x^T(s) \, ds \int_{t-h(t)}^{t-h(t)} x^T(s) \, ds \right] \frac{1}{h(t)}
\]

\[
\times \left[ \int_{t-h(t)}^t x^T(s) \, ds \int_{t-h(t)}^{t-h(t)} x^T(s) \, ds \right] \frac{1}{h(t)}
\]

\[
\times h(t) v_1(t) (h(t) - h(t)) v_2(t).
\]

Theorem 3.1: The system (1) satisfying the conditions (2) is stable for given values of \( h \geq 0, \mu < 1 \), if there exist real positive definite matrices \( P \in \mathbb{R}^{m \times m}, (R_1, R_2, Q_1, Q_2, Q_0, \tilde{Q}_0, R_0, R_\in \mathbb{R}^{n \times 2n}) \), symmetric matrices \( Q_0, \tilde{Q}_0, R_0, R_\in \mathbb{R}^{n \times 2n} \) and any matrices \( (\bar{U} \in \mathbb{R}^{2n \times n}), N \in \mathbb{R}^{4n \times 2n}, X_i \in \mathbb{R}^{7n \times 2n}, Y_i \in \mathbb{R}^{4n \times 2n} \),
(i = 1, 2, 3, 4) such that $\hat{R}_a > 0$, $\hat{R}_b > 0$ and the following LMIs hold

$$
\begin{bmatrix}
\Pi_{[0,h(t)]} & \Omega_{[a1,4]} & h_d\Omega_{[b3,4]} & \Omega_{[b1,3]} \\
* & -h\hat{R}_b & 0 & 0 \\
* & * & -\hat{\mu}h\hat{Q}_b & 0 \\
* & * & * & -3h\hat{\mu}h\hat{R}_b \\
* & * & * & -3h\hat{\mu}h\hat{Q}_b \\
\end{bmatrix} < 0,
$$

where the definitions of some symbols are shown in Appendix 1.

**Proof:** Construct an LKF (10).

The time derivative of $V(t)$ with respect to time along the trajectory of the system (1) is as follows:

$$
\dot{V}_1(t) = 2\zeta^T(t)P \begin{bmatrix}
\dot{x}(t) \\
h_d\dot{x}(t-h(t)) \\
x(t) - h\dot{d}\dot{x}(t-h(t)) \\
h_d\dot{x}(t-h(t)) - \dot{x}(t-h(t)) \\
\end{bmatrix},
$$

$$
\dot{V}_2(t) = \gamma^T(t)Q_1(t)\gamma(t) + h_d\gamma^T(t-h(t)) \\
\times [Q_2(t) - Q_1(t)]\gamma(t-h(t)) \\
- \gamma^T(t-h)Q_2(t)\gamma(t) \\
- h(t)\int_{t-h(t)}^{t} \gamma^T(s)Q_{11}\gamma(s) \, ds \\
- h(t)\int_{t-h(t)}^{t} \gamma^T(s)Q_{12}\gamma(s) \, ds,
$$

$$
\dot{V}_3(t) = h(t)\gamma^T(t)\hat{Q}_a\gamma(t) + \hat{\mu}h_d(h-h(t))\gamma^T(t-h(t)) \\
\times (t-h(t))\hat{Q}_b\gamma(t-h(t)) \\
- h_d\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_a\gamma(s) \, ds \\
- \hat{\mu}\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_b\gamma(s) \, ds,
$$

$$
\dot{V}_4(t) = h(t)\gamma^T(t)R_1\gamma(t) + h_d(h-h(t))\gamma^T(t-h(t)) \\
\times (t-h(t))R_2\gamma(t-h(t)) \\
- h_d\int_{t-h(t)}^{t} \gamma^T(s)R_1\gamma(s) \, ds \\
- \int_{t-h}^{t-h(t)} \gamma^T(s)R_2\gamma(s) \, ds.
$$

For additional symmetric matrices $Q_a$, $Q_b$, $R_a$ and $R_b$, the following zero equations are satisfied

$$
0 = \hat{h}(t) \begin{bmatrix}
\dot{x}^T(t)Q_a\dot{x}(t) - \dot{x}^T(t-h(t))Q_a\dot{x}(t-h(t)) \\
- 2 \int_{t-h(t)}^{t} x^T(s)Q_a\dot{x}(s) \, ds + x^T(t-h(t)) \\
\times Q_b\dot{x}(t-h(t)) - x^T(t-h(t))Q_b\dot{x}(t-h(t)) \\
- 2 \int_{t-h(t)}^{t} x^T(s)Q_b\dot{x}(s) \, ds
\end{bmatrix}
$$

Taking the zero inequalities in $V_2$ and $V_4$, we have the following integral terms from $V_2$ to $V_4$

$$
\varphi = -\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_a\gamma(s) \, ds \\
- \hat{\mu}\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_b\gamma(s) \, ds \\
- h_d\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_a\gamma(s) \, ds \\
- \int_{t-h}^{t-h(t)} \gamma^T(s)\hat{Q}_b\gamma(s) \, ds.
$$

It follows from Lemma 1 with an augmented vector $\gamma(s)$ that

$$
- \int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_a\gamma(s) \, ds \\
\leq \xi^T(t) \begin{bmatrix} H_1 \\ H_2 \end{bmatrix}^T \begin{bmatrix}
H(t)X_1\hat{Q}_a^{-1}X_1^T \\
* \\
\frac{d(t)}{3}Y_1\hat{Q}_a^{-1}Y_1^T
\end{bmatrix} + \text{Sym}[Y_1G_1]
$$

$$
- \mu\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_b\gamma(s) \, ds
$$

$$
\leq \hat{\mu}\xi^T(t) \begin{bmatrix} H_1 \\ H_3 \end{bmatrix}^T \begin{bmatrix}
(h-h(t))X_2\hat{Q}_b^{-1}X_2^T \\
* \\
\frac{h-h(t)}{3}Y_2\hat{Q}_b^{-1}Y_2^T
\end{bmatrix} + \text{Sym}[Y_2G_2]
$$

$$
- h_d\int_{t-h(t)}^{t} \gamma^T(s)\hat{Q}_a\gamma(s) \, ds
$$

$$
\hat{h}(t) \begin{bmatrix}
\gamma^T(t)Q_a\gamma(t) - \gamma^T(t-h(t))Q_a\gamma(t-h(t)) \\
- 2 \int_{t-h(t)}^{t} \gamma^T(s)Q_a\gamma(s) \, ds + \gamma^T(t-h(t)) \\
\times Q_b\gamma(t-h(t)) - \gamma^T(t-h(t))Q_b\gamma(t-h(t)) \\
- 2 \int_{t-h(t)}^{t} \gamma^T(s)Q_b\gamma(s) \, ds
\end{bmatrix},
$$

$$
0 = h_d \begin{bmatrix}
\gamma^T(t)R_a\gamma(t) - \gamma^T(t-h(t))R_a\gamma(t-h(t)) \\
- 2 \int_{t-h(t)}^{t} \gamma^T(s)R_a\gamma(s) \, ds
\end{bmatrix},
$$

(13)

(14)

(15)

(16)

(17)
\[
\leq h_2 \xi^T(t) \begin{bmatrix} H_1 \\ H_2 \end{bmatrix}^T \begin{bmatrix} h(t)X_3\tilde{R}_a^{-1}X_3^T & X_5G_1 \\ \frac{1}{3}Y_3\tilde{R}_a^{-1}Y_3^T & -\text{Sym}[Y_5H_5] \end{bmatrix} \times \begin{bmatrix} H_1 \\ H_2 \end{bmatrix} \xi(t),
\]
(18)
\[
- \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{R}_b\gamma(s) \, ds
\]
\[
\leq \xi^T(t) \begin{bmatrix} H_1 \\ H_3 \end{bmatrix}^T \begin{bmatrix} (h-h(t))X_4\tilde{R}_b^{-1}X_4^T & X_4G_1 \\ \frac{1}{3}Y_4\tilde{R}_b^{-1}Y_4^T & -\text{Sym}[Y_4G_2] \end{bmatrix} \times \begin{bmatrix} H_1 \\ H_3 \end{bmatrix} \xi(t).
\]
(19)

For any appropriately dimensioned matrices \( N \in \mathbb{R}^{m \times 2n} \), \( \tilde{U}^T = [U_1^T \ U_2^T \ U_3^T] \), it is true that
\[
0 = 2[v_1(t) v_2(t) \varphi(t)] = -\varepsilon_{11} (h-h(t)) \varepsilon_5 \xi(t),
\]
(20)
\[
0 = 2[\dot{v}_1(t) \ x^T(t-h(t)) + \dot{\varphi}(t) \tilde{x}(t)].
\]
(21)

Finally, from the above derivation, we have
\[
\dot{V}(t)
\leq \xi^T(t) \begin{bmatrix} P^T(h(t),\hat{h}(t)) & h(t)h_2H_1^T X_3\tilde{R}_a^{-1}X_3^T H_1 \\ H_1^T X_3\tilde{R}_a^{-1}X_3^T H_1 & \bar{\mu}H_2^T X_2\tilde{R}_b^{-1}X_2^T H_2 + h(t) \bar{\mu}\frac{1}{3}H_3^T Y_3\tilde{R}_a^{-1}Y_3^T H_2 + \bar{\mu}\frac{1}{3}H_3^T Y_4\tilde{R}_b^{-1}Y_4^T H_2 \\ \end{bmatrix} \xi(t).
\]
(22)

Therefore, LMIs (11)–(12) hold for \([ h(t), \hat{h}(t) ] \in [0, h] \times [-\mu, \mu] \), which together with Schur complement equivalence imply that \( V(t) < 0 \). This shows that system (1) is stable from Lyapunov stability theory. This completes the proof.

**Remark 3.1:** It is important to reduce the conservativeness of stability conditions by introducing some delay-dependent matrices into the single-integral terms of LKF \([35]\). Unfortunately, the main result of \([35]\) was incorrect due to the neglect of the terms with \( h^2(t) \) even \( h^3(t) \) discussed in the section 1. In this paper, all matrices inequations of Theorem 3.1 are LMI by introducing additional state variables \( \hat{h}(t) v_1(t), (h-h(t)) v_2(t) \) and a zero equation (20), which can remove the terms with \( h^2(t) \) even \( h^3(t) \). Moreover, the double integral items \( V_4(t) \) of the LKF (10) divide the time delay interval \([0, h] \) into two subintervals \(([0, h(t)] \) and \([h(t), h] \) instead of using the item \( \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{R} \gamma(s) \, ds \) directly. It further makes full use of the information of time-varying delays \( h(t), h - h(t) \) and their derivative. Thus, the QGFMI technique can be fully used in each subinterval, which can further reduce the conservativeness of the stability conditions.

**Remark 3.2:** It is worth noting that in \([35]\), to bound the integral item for \(-\mu \leq h(t) \leq \mu, (\mu > 0) \)
\[
- \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_a \gamma(s) \, ds - \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{Q}_b \gamma(s) \, ds
\]
via the QGFMI technique, the following addition zero equation is introduced
\[
0 = \mu \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_a \gamma(s) \, ds - \mu \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{Q}_b \gamma(s) \, ds + \mu \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{Q}_b \gamma(s) \, ds.
\]
(23)

Then, the above integral item can be rewritten as the following form:
\[
\tilde{\psi} = -(\mu + \hat{h}(t)) \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_a \gamma(s) \, ds - \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{Q}_b \gamma(s) \, ds + \mu \int_{t-h}^{t-h(t)} \gamma^T(s)\tilde{Q}_b \gamma(s) \, ds.
\]
(24)

The first two items on the right can be bounded via the QGFMI technique (for details see Equation (17) of this paper), however there are fewer proper techniques for obtaining a tight upper bound of the integral terms
\[
\mu \int_{t-h}^{t} \gamma^T(s)\tilde{Q}_a \gamma(s) \, ds
\]
due to their positive definiteness. Thus, to avoid introducing the two positive definite integral terms, we give the modified LKF (10) with a double integral term \( V_3(t) \).

To illustrate the effectiveness of delay-dependent matrices in reducing the conservativeness of stability conditions, we give the following corollary by choosing
the following LKF:

\[
\bar{V}(t) = \sum_{i=1}^{3} \bar{V}_i(t)
\]

(25)

with

\[
\bar{V}_1(t) = \zeta^T(t)P\zeta(t),
\]

\[
\bar{V}_2(t) = \int_{h-h(t)}^{t} \gamma^T(s)Q_1\gamma(s) \, ds
\]

\[
+ \int_{h-h(t)}^{t} \gamma^T(s)Q_2\gamma(s) \, ds,
\]

\[
\bar{V}_3(t) = \int_{h-h(t)}^{t} \int_{h-h(t)}^{t} \gamma^T(s)R_1\gamma(s) \, ds \, d\theta
\]

\[
+ \int_{h-h(t)}^{t} \int_{h-h(t)}^{t} \gamma^T(s)R_2\gamma(s) \, ds \, d\theta,
\]

where, \( P, Q_1, Q_2, R_1 \) and \( R_2 \) are positive definite matrices.

**Corollary 3.1:** The system (1) satisfying the conditions (2) is stable for given values of \( h \geq 0, \mu < 1 \), if there exist real positive definite matrices \( P \in \mathbb{R}^{3n \times 3n}, (R_1, R_2, Q_1, Q_2 \in \mathbb{R}^{2n \times 2n}), \) symmetric matrices \( (R_a, R_b \in \mathbb{R}^{n \times n} \) and any matrices \( (\bar{U} \in \mathbb{R}^{3n \times n}), N \in \mathbb{R}^{4n \times 2n}, X_i \in \mathbb{R}^{2n \times 2n}, Y \in \mathbb{R}^{4n \times 2n}, (i = 1, 2) \) such that \( R_a > 0, R_b > 0 \) and the following LMIs hold

\[
\begin{bmatrix}
\hat{F}^0[0, h(t)] & \tilde{\Omega}_{[1,2]} & h_d \tilde{\Omega}_{[3,2]} \\
* & -hR_b & 0 \\
* & * & -3h_d hR_b
\end{bmatrix} < 0, \quad (26)
\]

\[
\begin{bmatrix}
\hat{F}^0[h, h(t)] & \tilde{\Omega}_{[1,1]} & h_d \tilde{\Omega}_{[2,1]} \\
* & -hR_a & 0 \\
* & * & -3h_d hR_a
\end{bmatrix} < 0, \quad (27)
\]

where the definitions of some symbols are shown in Appendix 2.

**Proof:** The steps of proof are similar to those of Theorem 3.1, so it is omitted here.

## 4. Numerical example

In this section, two numerical examples will be provided to illustrate the effectiveness and superiority of Theorem 3.1, in which the maximum allowable upper bounds (MAUBs) are carefully compared, including the numbers of decision variables (NoVs).

**Remark 4.1:** In this paper, the strict LMIs (11) and (12) can be solved easily by using the Matlab LMI-toolbox. The search steps are:

- Step 1. For given values of \( h \geq 0, \mu < 1 \), LMIs (11) and (12) can be solved to find the MAUB \( h \triangleq h_1; \)

**Table 1. MAUBs \( h \) for different \( \mu \) (Example 4.1).**

| Methods | \( 0.05 \) | \( 0.1 \) | \( 0.3 \) | \( 0.5 \) | NoVs |
|---------|-----------|-----------|-----------|-----------|-----|
| [36] (Th. 1) | 2.613 | 2.424 | 2.131 | 1.793 | 27n^2 + 4n |
| [33] (Th. C2) | 2.598 | 2.397 | 2.128 | 1.787 | 23n^2 + 4n |
| [37] (Th. 1) | 2.573 | 2.420 | 2.133 | 2.005 | 142n^2 + 18n |
| [38] (Th. 1) | 2.575 | 2.425 | 2.230 | 2.019 | 114n^2 + 18n |
| [39] (Th. 3) | 2.590 | 2.438 | 2.240 | 2.026 | 70n^2 + 12n |

**Example 4.1:** Consider the following systems:

\[
\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ -1 & -1 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix} x(t - h(t)).
\]

(28)

The comparative results among some previous stability conditions, Theorem 3.1 and Corollary 3.1 are listed in Table 1. It is clear that the MAUBs obtained by Theorem 3.1 and Corollary 3.1 are all larger than those obtained by other conditions proposed in [33,35–39]. As expected, the MAUBs obtained by Theorem 3.1 are the largest for different values \( \mu \), which matches the explanation in Remark 3.1. On the other hand, the number of decision values in our criteria is larger than those in [33,35,36,39] but less than those in [37,38]. To confirm the obtained result \( h = 3.006 \), the simulation result is shown in Figure 2, which shows that the state responses of the system (28) with \( h(t) = \frac{3.006}{2} + \frac{3.006}{2} \sin\left(\frac{0.1t}{3.006}\right) \) converge to zero under the random initial state.

**Example 4.2:** Consider the following systems:

\[
\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ -1 & -2 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ -1 & 1 \end{bmatrix} x(t - h(t)).
\]

(29)
Table 2. MAUBs \( h \) for different \( \mu \) (Example 4.2).

| Methods/\( \mu \) | 0.1 | 0.2 | 0.5 | 0.8 | NoVs |
|-------------------|-----|-----|-----|-----|------|
| [33]              | 6.6103 | 4.0034 | 1.6875 | 1.0287 | 23.92 + 4n |
| [37]              | 7.1672 | 4.5179 | 2.4158 | 1.8384 | 142n + 18n |
| [38]              | 7.1765 | 4.5438 | 2.4963 | 1.9225 | 114n + 18n |

| [12]              | 4.942 | 4.234 | 3.309 | 2.882 | 108.5n + 12n |
| Corollary 3.1     | 4.835 | 4.149 | 3.192 | 2.836 | 81.5n + 11.5n |
| Theorem 3.1       | 4.968 | 4.346 | 3.725 | 3.470 | 104.5n + 9.5n |

and 2, which can show our stability criterion is less conservative than some existing ones.

5. Conclusions

In this paper, the stability of time-varying delay systems is studied. A modified Lyapunov functional with delay-dependent matrices is proposed and used to derive the stability criterion. Based on delay decomposition method, the integral items of the LKF divide the time delay interval \([0, h]\) into two subintervals \([0, h(t)]\) and \([h(t), h]\) instead of using the item \(\int_{t-h}^{t} Y(s)R Y(s) ds\) directly. The Lemma 2.1 (QGFM1 technique) can be fully used in each subinterval, which further reduces the conservatism of the stability condition. Three numerical examples illustrate the effectiveness of the proposed method.

The novel stability condition can also be generalized to some other time-delayed control systems, for example, time-delayed Lur’e systems, time-delayed neural networks, time-delayed neutral-type systems, and so on. However, there is still some distances from practical application because of the complexity of the control theory, which can be something that we will continue to study in the future.
