(Received 5 December 2019; accepted 9 March 2020; published 23 March 2020)

Topological superconductors can host quasiparticle states that offer a promising route for generating quantum entangled states that are protected against decoherence [1]. While many of the approaches that are currently being pursued involve hybrid structures [2–5], the discovery of an intrinsic topological superconductor would be an exciting step forward. One route involves finding superconductors that possess both broken spatial inversion symmetry and spin-orbit interactions, which are expected to exhibit a mix of singlet and triplet pairing due to the lifting of the twofold spin degeneracy [6–9]. The application of a Zeeman field or other microscopic interactions can suppress the $s$-wave channel in favor of odd-parity superconductivity [8].

Bulk, unstrained SrTiO$_3$ is a multiband superconductor [10–12] that exhibits a superconducting dome with a maximum transition temperature ($T_C$) of $\sim 300$ mK at a carrier density of $1 \times 10^{20}$ cm$^{-3}$ [13]. The degeneracy of the three $t_{2g}$-derived conduction bands at the $\Gamma$ point is lifted by the low-temperature tetragonal distortion and by spin-orbit coupling [14,15]. With increasing carrier density, the three bands fill consecutively [15–17]. Quasi-two-dimensional electron systems at interfaces involving SrTiO$_3$, which exhibit signatures of Rashba spin-orbit coupling [18–22], have been suggested as possible candidates for topological superconductivity [8,23]. Bulk SrTiO$_3$ is also a quantum paraelectric [24] that is near a ferroelectric transition. The fixed polarization charge of ferroelectrics, and corresponding electric fields, can easily rival those of high-density two-dimensional electron gases [25]. Early theoretical work already pointed out that ferroelectric order would be a promising route to realize odd-parity superconductivity [6]. Combining the ingredients of multiorbital effects, ferroelectricity, and spin-orbit coupling, a topological superconducting state has been predicted [26,27].

Recently, it was shown that ferroelectric (polar), doped SrTiO$_3$ can become superconducting [28–32]. In particular, doped SrTiO$_3$ films grown on (001) (LaAlO$_3$)$_{0.3}$(Sr$_2$AlTaO$_6$)$_{0.7}$ (LSAT) crystals, which are compressively strained, undergo a transition to a ferroelectric phase prior to becoming superconducting and show enhanced superconducting transition temperatures [28,29]. Because of the broken inversion symmetry, such films are promising candidates in the search for an intrinsic topological superconductor.

A key signature of odd- or mixed-parity superconductors is an enhancement of the upper critical field beyond the paramagnetic (Clogston-Chandrasekhar or Pauli) limit [8]. Here, we show that some polar superconducting SrTiO$_3$ films show anisotropic critical fields above the Pauli limit. Moreover, we find pronounced nonreciprocal charge transport, a signature of a noncentrosymmetric, spin-orbit coupled superconductor that is sensitive to the parity of the superconducting order parameter [33,34]. Taken together, these observations indicate a highly unconventional superconductor.

Doped SrTiO$_3$ films were grown by hybrid metal-organic molecular beam epitaxy [35,36]. Strained films with thicknesses between 160 and 180 nm were grown on (001) (LaAlO$_3$)$_{0.3}$(Sr$_2$AlTaO$_6$)$_{0.7}$ (LSAT) crystals. The lattice mismatch between SrTiO$_3$ ($a = 3.905$ Å) and LSAT ($a = 3.868$ Å) is $-0.95\%$. Some of the films were coherently strained (such as film A discussed below), while others (such as the films denoted B and D in the following) were partially relaxed. Details of the films’ structure can be found in the Supplemental Material [37]. All films were $n$-type doped by substituting Sr$^{2+}$ with either La$^{3+}$ or Sm$^{3+}$. The choice of dopant had no influence on the superconducting parameters, such as critical field ($H_c2$) and critical temperature ($T_c$). Electrical measurements were performed on Hall bar devices with dimensions of $100 \mu m \times 100 \mu m$, which were fabricated by standard optical photolithography, Ar ion milling for mesa definition, and electron beam deposition of ohmic Ti/Au contacts. Hall measurements to extract carrier concentrations

were performed between 300 and 2 K in Quantum Design Dynacool systems. Here, \( n_{3D} \) refers to the volume carrier concentration estimated from the Hall measurements at 300 K and the film thickness. Hall bars were aligned along \( \langle 100 \rangle \) and \( \langle 010 \rangle \), respectively, to facilitate measurements with \( I \parallel H \) and \( \perp H \) in the film plane, where \( H \) is the magnetic field and \( I \) is the excitation current.

Measurements between 1 K and 12 mK were performed in an Oxford Instruments Triton dilution refrigerator using low-frequency lock-in techniques. For measurements of the first harmonic resistances, cryogenically filtered measurements were used on the current and voltage lines to reduce the temperature of the electron bath (see Supplemental Material [37]). Superconducting transitions were recorded on different devices and/or contact configurations for all samples to ensure reproducibility.

A nonlinear voltage response to an applied current is a manifestation of nonreciprocal currents in noncentrosymmetric Rashba superconductors [34,38]. The voltage \( V \) response is given as \( V = RI + \gamma RBL^2 \) for \( I \parallel H \), where \( R \) is the resistance and \( B \) is the magnetic flux density [39]. In contrast, \( V = 0 \) for \( I \perp H \) [39]. Here, \( \gamma \) is a coefficient that describes the strength of the magnetochiral anisotropy [39,40]. Given an applied AC current \( I = \sqrt{2}I_0 \sin \omega t \), where \( \omega \) and \( t \) are angular frequency and time, respectively, it follows that

\[
V = \sqrt{2}RI_0 \sin \omega t - \gamma RBL_0 \cos 2\omega t + \gamma RBL_0^2. \tag{1}
\]

Nonreciprocal currents were measured by detecting the amplitudes of first and second harmonic resistances with a lock-in amplifier. Following the Eq. (1), the first and second harmonic resistances are defined as \( R^0 = R + \gamma RBL_0 \sqrt{2} \), respectively. The cutoff frequency of the cryogenic filters is on the order of a few tens of Hz, so they were not used for measurements of the second harmonics. For these measurements, lock-in amplifier measurements at a higher frequency were used to enhance the signal-to-noise ratio [37].

We investigated films with a range of carrier densities. Figure 1 shows \( T_C \), \( H_{c2} \), and their ratio as a function of \( n_{3D} \) with \( H \) oriented either in or out of the film plane, respectively. Here, \( T_C \) is the temperature for which the resistance reaches 5% of normal-state resistance and \( H_{c2} \) is defined as the magnetic field value when the resistance reaches 95% of the normal-state resistance. The sharp drop in \( T_C \) at lower concentrations is due to effects from surface depletion [41].

The \( T_C \) values [Fig. 1(a)] are in agreement with values previously reported for strained, doped films on LSAT [28]. Enhanced \( T_C \) values (up to 600 mK) near the peak of the superconducting dome relative to unstrained, doped SrTiO\(_3\) are directly connected to the ferroelectric normal state, as shown elsewhere [28,29]. The films are polar (point group 4mm) with the electric polarization vector pointing normal to the film plane [29]. Partially relaxed films, such as films B and D (see Supplemental Material [37]), show a slightly reduced \( T_C \), which is, however, still larger than that of unstrained, doped SrTiO\(_3\). In the following we will focus on slightly underdoped films with \( n_{3D} \) tuned between 5.5 × 10\(^{19}\) and 8 × 10\(^{19}\) cm\(^{-3}\).

Figure 1(b) shows \( H_{c2} \), as a function of \( n_{3D} \). In general, \( H_{c2} \) increases with \( n_{3D} \), as expected for films on the underdoped side of the dome. When \( H \) is in-plane, \( H_{c2} \) is strongly enhanced; some samples only enter the normal conducting state at \( \mu_0 H > 2T \) (\( \mu_0 \) is the vacuum permeability). These \( H_{c2} \) values are comparable to the largest values previously reported for doped SrTiO\(_3\) [21]. Figure 1 also shows the values of an unusual sample (film D) with an even more strongly enhanced in-plane \( H_{c2} \). Film D only enters the normal conducting state at \( \mu_0 H > 3.5T \). The main difference between films B and D is the presence of a thin layer near the interface with the substrate (see Supplemental Material [37]). It is likely that the very large in-plane \( H_{c2} \) of film D is associated with the presence of this layer.

The ratio of \( H_{c2} \) over \( T_C \) is shown in Fig. 1(c). The dotted line marks the Clogston-Chandrasekhar (Pauli) limit, at which the condensation energy of the Cooper pairs \( \Delta = 1.78k_B T_C \) equals the magnetic polarization energy of a spin singlet Cooper pair \( E = \frac{\mu_0 H}{4\pi}, \) where \( \mu_0 \) is the Bohr magneton, \( g \approx 2 \) is the Landé factor, and \( k_B \) is Boltzmann’s constant [42]. Expressed in units of \( \mu_0 H/T \), this ratio is 1.85 T/K. For measurements with \( H \) normal to the film plane, the ratio is below the Pauli limit for most films, while for \( H \) in plane, the ratio is above the limit for several films, and especially so for film D. While the breaking of the Pauli limit and a

FIG. 1. Superconducting properties as a function of \( n_{3D} \) for different field orientations (IP = H in the film plane; OOP = H normal to the film plane). (a) \( T_C \), (b) \( H_{c2} \), and (c) the ratio of \( \mu_0 H_{c2}/T_C \) over \( T_C \). The dotted line in (c) indicates the Pauli limit. Arrows point to data from the four films (A, B, C, D) discussed in more detail. The open symbols are films doped with Sm, and all others are doped with La.
An independent measurement supporting an unconventional superconducting state, we measured nonreciprocal transport. Figure 3(a) shows second harmonic resistances of film B. The second harmonic signal is purely imaginary, in agreement with Eq. (1). An antisymmetric component emerges in the second harmonic signal, only if $\mathbf{I} \parallel \mathbf{H}$ (see Supplemental Material for a measurement with $\mathbf{I} \parallel \mathbf{H}$ [37]). The extracted $\gamma$ parameter for this sample is $(1.6 \pm 0.5) \times 10^{3} \text{T}^{-1} \text{A}^{-1}$. The error was calculated using error propagation and a conservative estimate of the errors in $R^{2}\omega$, $R^{\omega}$, and in determining the $\mathbf{H}$ position of the peak. Figures 3(b) and 3(c) show the temperature dependence of the second harmonic signal and the extracted $\gamma$ parameter of sample D. The signal decreases in strength with increasing temperature and vanishes at temperatures above 300 mK. $R^{\omega}$ was recorded in the same measurement setup and used to extract the $\gamma$ parameter [Fig. 3(c)]. Here, $\gamma$ increases with decreasing temperature and reaches values of $(4.7 \pm 0.5) \times 10^{3} \text{T}^{-1} \text{A}^{-1}$, which is larger by a factor of 6 than values found in the noncentrosymmetric superconductor MoS$_2$ [39] and two orders of magnitude higher than that of an interfacial electron gas in SrTiO$_3$ [38]. The difference in $\gamma$ parameters between films B and D is mainly due to strongly enhanced $H_{c2}$ of film D. Thus, at the field where $R^{2}\omega$ peaks, which is similar for both films, $R^{\omega}$ of film D is smaller.

In spin-orbit coupled, noncentrosymmetric Rashba superconductors, $\gamma$ is proportional to the product of the strength of spin-orbit coupling and the ratio between the odd- and even-parity pairing [34]. Unlike films B and D, several other strained (and thus noncentrosymmetric) films, such as film A, showed no detectable nonreciprocal currents (see Supplemental Material [37]). A main result of this study is therefore that the lack of inversion symmetry alone is insufficient to produce a large nonreciprocal current and $\gamma$ value in polar doped SrTiO$_3$ films whose normal-state ferroelectric polarization is normal to the film plane [29]. Additional microscopic parameters appear to play a role in determining the nature of the superconductivity. As discussed above, the superconducting properties of film D appear to have contributions from an interface region, resulting in the strongly enhanced in-plane $H_{c2}$ and $\gamma$ parameter. The nonreciprocal signal is, however, not solely an interface effect because it is also observed in film B, which does not have an interfacial layer. A common feature of both films B and D is partial strain relaxation [37]. Theoretical studies that clarify the role of interfaces, electronic structure, dimensionality, and strain gradients would be an important step in further understanding and tuning the superconducting properties of these films.

To briefly summarize, we find that some doped polar SrTiO$_3$ films show signatures characteristic of spin-orbit coupled, noncentrosymmetric superconductors. Such a superconductor will exhibit a spin-triplet pairing component and thus has the potential to host non-Abelian Majorana bound states. Further development of existing models of topological superconductivity in SrTiO$_3$ [8,23,26,27] to describe the polar films studied here would be very desirable. Ultimately, the topological nature of the superconducting phase(s) should be characterized using techniques that can discern the nature of edge states or bound states in the vortex cores.

FIG. 3. (a) Asymmetric component of the second-order harmonic $R_{\text{ asym}}^{2\omega}$ for film B ($\eta_{\text{2D}} = 6.2 \times 10^{15}$ cm$^{-2}$). The magnetic field is in the sample plane and perpendicular to the applied current. The solid lines are obtained by smoothing over 50 data points. The antisymmetric component was obtained via $R_{\text{ asym}}^{2\omega} = (1/2)[R^{2\omega}(+H) - R^{2\omega}(-H)]$. (b) $R_{\text{ asym}}^{2\omega}$ for film D as a function of temperature. Traces are offset by 30 mΩ for clarity. (c) Extracted values for the $\gamma$ parameter [see Eq. (1)] as a function of temperature for film D. Error bars were obtained via error propagation from standard deviations on the values of $R^{2\omega}$ and the position of the peak.
