Abstract

Background: It is important to develop novel antipsychotics that can effectively treat schizophrenia with minor side-effects. The aim of our work is to develop novel antipsychotics that act on dopamine D2 and D3, serotonin 5-HT1A and 5-HT2A receptors with low affinity for the serotonin 5-HT2C and H1 receptors, which can effectively cure positive symptoms, negative symptoms and cognitive impairment without the weight gain side-effect.

Methodology/Principal Findings: A series of 2-substituted-5-thiopropylpiperazine (piperidine)-1,3,4-oxadiazoles derivatives have been synthesized and the target compounds were evaluated for binding affinities to D2, 5-HT1A and 5-HT2A receptors. Preliminary results indicated that compounds 14, 16 and 22 exhibited high affinities to D2, 5-HT1A and 5-HT2A receptors among these compounds. Further binding tests showed that compound 22 had high affinity for D3 receptor, and low affinity for serotonin 5-HT2C and H1 receptors. In addition, compound 22 inhibited apomorphine-induced climbing behavior and MK-801-induced hyperactivity with no extrapyramidal symptoms liability in mice. Moreover, compound 22 exhibited acceptable pharmacokinetic properties.

Conclusions/Significance: Compound 22 showed an atypical antipsychotic activity without liability for extrapyramidal symptoms. We anticipate compound 22 to be useful for developing a novel class of drug for the treatment of schizophrenia.

Introduction

Schizophrenia is a serious mental disorder that significantly compromises the quality of life of those suffering from it. The early agents for the treatment of psychosis, the “typical” antipsychotics (haloperidol, Figure 1), were therapies for the positive symptoms of schizophrenia, but they failed to manage its negative symptoms and cognitive impairment [1]. Nevertheless, typical antipsychotics carry heavy side effects such as extrapyramidal symptoms (EPS) and hyperprolactinemia [2][3][4].

A breakthrough in the pharmacotherapy of schizophrenia was achieved by the introduction of the “atypical” antipsychotics (e.g., clozapine, ziprasidone, risperidone, quetiapine and olanzapine) which combines a potent antagonism for serotonin 5-HT2A with a dopamine D2 receptors blockade [5]. A major advantage of atypical antipsychotics is their effectiveness in suppressing negative and cognitive symptoms [6][7][8][9][10]. However, it has been proved that atypical antipsychotics cause numerous side effects, such as substantial weight gain and QT interval prolongation [11][12][13]. Therefore, the discovery of novel antipsychotic agents that are effective and free of side effects with different chemical structures remains a challenging.

In the past decade, experimental evidence suggested that a complex binding profile is linked to the clinical efficacy of antipsychotic drugs. Indeed, the importance of designing multitarget G-protein-coupled receptors to deal with schizophrenia has been pointed out by many authors [14][15][16]. The 5-HT1A receptor plays crucial roles in regulating psychoemotional, cognitive and motor functions in the central nervous system [17][18]. Many relevant preclinical data suggested that 5-HT1A receptor activation may contribute to the improved activity of certain atypical antipsychotic drugs, such as treatment cognitive and negative symptoms, and decrease the development of EPS in schizophrenia [19]. Blockade of D2 receptor was the key mechanism for controlling positive symptoms of schizophrenia [20]. The localization of D3 receptor in the limbic regions of brain suggests that this receptor subtype may be a target for developing antipsychotics, and thus, some works suggested that D3 antagonism may improve cognition [21] and reduce the risk of causing extrapyramidal side effect [22]. Compound S33138 (1) was shown...
to be a potent and selective dopamine D3 receptor antagonist, which has been in Phase IIb clinical trials for schizophrenia [23]. Furthermore, two or more receptors may be involved in the weight gain associated with the treatment of schizophrenia via atypical antipsychotic drugs. Blockade of H1 receptor by antipsychotics is more likely to be the primary cause of these adverse reactions [24][25]. Although 5-HT2C receptor blockade has been reported to counteract dopamine D2-mediated extrapyramidal side-effects (EPS) [26] and may also confer anxiolytic/antidepressant properties [27], 5-HT2C receptor may be involved in the risk of obesity under chronic treatment [10][28][29]. Thus, the aim of our work is to develop a novel antipsychotic that acts on dopamine D2 and D3, serotonin 5-HT1A and 5-HT2A receptors with low affinity for the serotonin 5-HT2C and H1 receptors, so that it could effectively cure positive symptoms, negative symptoms and cognitive impairment without the weight gain side-effect.

In fact, some of the latest efforts in the development of novel antipsychotic drugs are aimed at obtaining compounds with binding affinities for a certain number of receptors [10][30][31][32]. To validate this multireceptor affinity profile approach to antipsychotics and to achieve an optimum interaction with dopamine and serotonin receptors, in this work, we report the synthesis of compounds 7–26 (Figure 1) that allowed us to understand the SAR (structure-activity relationship) and to evaluate the pharmacological efficacy. The target compounds were subjected to preliminary pharmacological evaluation to determine their affinities for D2, D3, 5-HT1A, 5-HT2A, 5-HT2C and H1 receptors. Among the derivatives prepared, compound 22 exhibited high affinity to D2, D3, 5-HT1A and 5-HT2A receptors, with low affinity for 5-HT2C and H1 receptors. In addition, Compound 22 inhibited apomorphine-induced climbing behavior and MK-801-induced hyperactivity without causing catalepsy in mice. In particular, compound 22 was more potent than clozapine.

**Results and Discussion**

**Synthesis of Compounds 7–26**

The general strategy for the synthesis of compounds 7–26 was summarized in Figure 2. Aromatic acids 2 were esterified with absolute ethanol using conc. sulfuric acid as catalyst and the resulting esters 3 were refluxed with hydrazine hydrate in ethanol to give aroyl hydrazines 4. The acid hydrazides were then subjected to cyclisation with carbon disulphide in the presence of potassium hydroxide in absolute alcohol to afford the corresponding 5-aryl-1,3,4-oxadiazol-2-thiones (5). Compounds 5 reacted with 1,3-dibromopropane, in acetone to give 6. Compounds 6 reacted with an arylpiperazine (piperidine) group, which is one of the important kind of drugs for CNS-activity [33][34][35]. This strategy led to the synthesis of compounds 7–26 (Figure. 1) that allowed us to understand the SAR (structure-activity relationship) and to evaluate the pharmacological efficacy. The target compounds were subjected to preliminary pharmacological evaluation to determine their affinities for D2, D3, 5-HT1A, 5-HT2A, 5-HT2C and H1 receptors. Among the derivatives prepared, compound 22 exhibited high affinity to D2, D3, 5-HT1A and 5-HT2A receptors, with low affinity for 5-HT2C and H1 receptors. In addition, Compound 22 inhibited apomorphine-induced climbing behavior and MK-801-induced hyperactivity without causing catalepsy in mice. In particular, compound 22 was more potent than clozapine.
presence of K₂CO₃ and a catalytic amount of potassium iodide, to give compounds 7–26 (Table 1) with good yields.

**In vitro studies of New Compounds**

Initially, we investigated the effect of different amine moieties (Table 2, compounds 7–12) present in several established CNS agents: arylpiperazines such as N-(2,3-dichlorophenyl)-piperazine present in aripiprazole, and a substituted piperidine (N-(6-fluoro-benzisoxazol-3-yl)piperidine present in risperidone. According to Table 2, compounds 7–10 (phenylpiperazines) showed weak affinities for D₂, 5-HT₁A and 5-HT₂A. It should be noted that compounds 11 [(benzo[d]isothiazol-3-yl)piperazine] and 12 [(6-fluorobenzo[d]isoxazol-3-yl)piperidine] displayed high affinities for 5-HT₁A and 5-HT₂A receptors, and increased D₂ receptor affinity in comparison to compounds 7–10.

In order to improve D₂ receptor affinity, further studies were conducted by introducing flouro, chloro, trifluoromethyl and methoxy substituents on the phenyl of the Ar₁ (Table 2, compounds 13–20). When amine moiety Ar₂ was (benzo[d]isothiazol-3-yl)piperazine (compounds 13, 15, 17 and 19), the order of affinities for the D₂ and 5-HT₂A receptors was OCH₃ > Cl > CF₃ > F, and the high affinity for the 5-HT₁A substituents with Cl, but the affinities for 5-HT₁A receptor were obviously decreased when substituents with OCH₃, CF₃ and F.

When amine moiety Ar₂ was (6-fluorobenzo[d]isoxazol-3-yl)piperidine (compounds 14, 16, 18 and 20), the affinities order for the D₂ receptor was OCH₃ > Cl > CF₃ > F, and the affinities order for the 5-HT₁A and 5-HT₂A receptors was OCH₃ > Cl > F > CF₃. Compounds 14 and 16 exhibited high affinities for D₂ (compound 14, Ki = 14.8 nM; compound 16, Ki = 18.3 nM), 5-HT₁A (compound 14, Ki = 6.8 nM; compound 16, Ki = 10.5 nM) and 5-HT₂A (compound 14, Ki = 0.22 nM; compound 16, Ki = 6.6 nM). Moreover, compounds 14 and 16 had higher affinities for all the three receptors than clozapine (D₂, Ki = 128.7 nM; 5-HT₁A, Ki = 141.6 nM; 5-HT₂A, Ki = 11.6 nM). In particular, compounds 14 and 16 displayed higher affinities to 5-HT₁A receptor than risperidone (Ki = 180 nM). 5-HT₁A receptor implicated in the therapeutic efficacy of atypical antipsychotic drugs in treating the negative symptoms of schizophrenia and decreased the development of EPS in schizophrenia [18]. These results also indicated that compounds bearing a 6-fluorobenzo[d]isoxazol-3-ylpiperidine moiety (14, 16, 18 and 20) showed higher affinities to all three receptors than those with a (benzo[d]isothiazol-3-yl)piperazine fragment (13, 15, 17 and 19).

Furthermore, we investigated the effect of replacement of the Ar₁ phenyl ring with naphthalene and heterocyclic (Table 2, compounds 21–26). These results indicated that compounds 21 and 22 with naphthalene showed good affinities for D₂, 5-HT₁A and 5-HT₂A receptors. For example, compound 22 (D₂, Ki = 23.0 nM; 5-HT₁A, Ki = 4.6 nM; 5-HT₂A, Ki = 1.1 nM) showed higher affinities than clozapine (D₂, Ki = 128.7 nM; 5-

HT1A, \( K_i = 141.6 \text{ nM} \); 5-HT2A, \( K_i = 11.6 \text{ nM} \)). Moreover, compound 22 possessed higher affinity to 5-HT1A receptor than risperidone (\( K_i = 180 \text{ nM} \)). However, the introduction of an aromatic heterocycle at Ar 1 (compounds 23–26) resulted in dramatic decrease of affinities for all the three receptors. These results pointed out the importance of the phenyl ring (Ar 1) for the affinities at the D2, 5-HT1A and 5-HT2A receptors.

In line with the multiple receptor-targeting approaches for the development of new antipsychotic agents, compounds 14, 16, and 22 were selected for further binding tests to D3, 5-HT2C, and H1 receptors because they had high affinities for D2, 5-HT1A and 5-HT2A receptors. Previously, the D3 receptor was proposed for the development of new antipsychotic agents, compounds 14, 16 and 22 displayed higher affinities to D3 receptor than risperidone (\( K_i = 180 \text{ nM} \)). However, the introduction of an aromatic heterocycle at Ar 1 (compounds 23–26) resulted in dramatic decrease of affinities for all the three receptors. These results pointed out the importance of the phenyl ring (Ar 1) for the affinities at the D2, 5-HT1A and 5-HT2A receptors.

In vivo Studies

An initial behavioral screening was performed on compound 22 based on their multiple receptors affinity profile. The atypical antipsychotics have been used for relieving positive symptoms at doses without EPS [10]. In this study, the side-effect liability was evaluated by the horizontal bar test, which is very sensitive for catalepsy induced by dopamine D2 receptor blockade [10]. Antipsychotic potential of these compounds was assessed by apomorphine-induced climbing and dizocilpine (MK-801) induced hyperactivity. Apomorphine-induced climbing was potently reduced by D2 receptor antagonists [36], while selective antagonism of the effect of the noncompetitive N-methyl-D-aspartate (NMDA) antagonist MK-801 had been proposed as a

**Table 2.** Binding affinities for \( D_2 \), \( D_3 \), 5-HT\(_{1A} \), 5-HT\(_{2A} \), 5-HT\(_{2C} \) and \( H_1 \) receptors of compounds 7–26 and reference antipsychotics.

Potential Multireceptor Atypical Antipsychotics

Acute Toxicity

The above results led to the conclusion that compound 22 exhibited high affinity for dopamine D2 and D3, serotonin 5-HT1A and 5-HT2A receptors, with low affinity for the serotonin 5-HT2C and H1 receptors. We then assayed the acute toxicity of the new compound by determining their LD\(_{50} \) value. Compound 22 showed good safety profiles even at the highest dose tested (LD\(_{50} \) > 2000 mg/kg).
Compound 22 exhibited a low potential to induce catalepsy with ED50 values of 0.02, 7.99 and 0.09 mg/kg, respectively. Haloperidol produced reversal of apomorphine-induced climbing with ED50 value of 3.68 mg/kg (Table 3). In comparison, risperidone, clozapine and haloperidol evidenced high capacity of this drug to block D2 receptor [38]. In contrast, these results indicated that compound 22 was more potent than clozapine. This was also consistent with their estimated Ki values at the D2 receptor.

In the apomorphine-induced climbing model, compound 22 produced the significant reversal of apomorphine-induced climbing, with ED50 value of 3.68 mg/kg (Table 3). In comparison, risperidone, clozapine and haloperidol produced reversal of apomorphine-induced climbing with ED50 values of 0.02, 7.99 and 0.09 mg/kg, respectively. These results suggested that compound 22 was slightly more potent at blocking the D2 receptors in vivo than clozapine. This was also consistent with their estimated Ki values at the D2 receptor.

The MK-801-induced hyperactivity model has been used to indirectly evaluate the ability of compounds to oppose cortical dopaminergic hypofunction induced by NMDA receptor blockade [37]. In this test, compound 22 significantly inhibited MK-801-induced hyperactivity with ED50 value of 3.58 mg/kg (Table 3). In comparison, risperidone, clozapine and haloperidol yielded ED50 values of 0.02, 7.99 and 0.19 mg/kg, respectively. These results indicated that compound 22 was more potent than clozapine.

Catalepsy is often used as the method for predicting the incidence of extrapyramidal motor disorders. In this model (Table 3), it was clear that haloperidol had the highest propensity to induce catalepsy (ED50 0.22 mg/kg), in agreement with the high capacity of this drug to block D2 receptor [38]. In contrast, compound 22 exhibited a low potential to induce catalepsy with ED50 value>300 mg/kg (Table 3), similar to those of risperidone and clozapine (ED50 risperidone 0.3 mg/kg, clozapine 92.73 mg/kg). Moreover, these results suggested that the therapeutic indices of compound 22 calculated between their efficacy (apomorphine and MK-801 models) and side effects (catalepsy) were in the range 81–83, while the therapeutic indices of risperidone and clozapine were roughly 11–30. Thus, in contrast to risperidone and clozapine, compound 22 had a high threshold for inducing catalepsy which might, by analogy, translate into lower clinical EPS liability.

Overall, compound 22 significantly inhibited apomorphine-induced climbing behavior and MK-801-induced hyperactivity without causing catalepsy. These results suggested a preferential ability of compound 22 to modulate mesolimbic instead of nigrostriatal dopaminergic neurotransmission, highlighting their atypicality and low propensity to induce unwanted extrapyramidal motor disturbances at therapeutically useful doses.

**Pharmacokinetic Properties of Compound 22**

Compound 22 was selected based on its in vitro profile for in vivo characterization. Table 4 highlights the pharmacokinetic parameters of compound 22 in the rat using both intravenous and oral administration. Intravenous administration of compound 22 to rats (5 mg/kg, n = 6) resulted in detectable plasma levels (half-life (t1/2) = 9.3 h), and oral administration of compound 22 to rats (20 mg/kg, n = 6) resulted in a t1/2 of 8.6 h. The area under the curve (AUC) value of compound 22 was 6239.0 ng·h/mL after intravenous administration versus 13602.7 ng·h/mL after oral administration. The Cmax value after oral dosing was 723.6 mg/mL and the Tmax value was 5.0 h. The bioavailability of compound 22 was 54.5%.

In summary, we described the synthesis and pharmacological evaluation of a series of 2-substituted-5-thiopropypiperazin-1,3,4-oxadiazoles derivatives as potential multi-target antipsychotics. Among the derivatives synthesized, compound 22 showed high affinity for dopamine D2 and D3, serotonin 5-HT1A and 5-HT2A receptors, with low affinity for the serotonin 5-HT2C and H1 receptors. In vivo animal models showed that compound 22 had high potential for treating symptoms of schizophrenia without causing catalepsy. Moreover, compound 22 exhibited acceptable pharmacokinetic properties.

**Materials and Methods**

**Synthesis of Compounds 7–26**

Melting points were determined in open capillary tubes and are uncorrected. 1H NMR spectra were recorded at 400 MHz on a Varian Inova Unity 200 spectrometer in CDCl3 solution. Chemical shifts were given in δ values (ppm), using tetramethylsilane (TMS) as the internal standard; coupling constants (J) were given in Hz. Signal multiplicities were characterized as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad signal). Reagents were all of analytical grade or of chemical purity. Analytical TLC was performed on silica gel GF254. Column chromatographic purification was carried out using silica gel.

**Table 4. Plasma pharmacokinetic data following administration of compound 22 (i.v. dose of 5 mg/kg and p.o. dose of 20 mg/kg) in rats (n = 6/group).**

General procedure for the synthesis of aroyl hydrazines 4 (a–h) [39]. A mixture of aromatic acids 2 (10 mmol), ethanol (20 mL) and a catalytic amount of conc. H₂SO₄ were refluxed for 8 h. The reaction mixture was evaporated under reduced pressure. The residue was dissolved in ice-cold water and acidified with dilute hydrochloric acid. The precipitate was filtered off, washed with chilled ethanol (1 mL) to give the corresponding aroyl hydrazines 4 (a–h).

4-methoxybenzohydrazide (4b). Yield: 85%; mp: 133–135°C [lit [41], mp: 135–137°C].

4-chlorobenzohydrazide (4c). Yield: 82%; mp: 115–117°C [lit [41], mp: 117–118°C].

4-trifluoromethylbenzohydrazide (4d). Yield: 87%; mp: 114–116°C [lit [40], mp: 115–116°C].

4-fluorobenzohydrazide (4e). Yield: 80%; mp: 159–162°C [lit [41], mp: 160–163°C].

1-naphthohydrazide (4f). Yield: 80%; mp: 161–163°C [lit [41], mp: 160–163°C].

thiophene-2-carbohydrazide (4g). Yield: 84%; mp: 136–138°C [lit [42], mp: 135–137°C].

isonicotinohydrazide (4h). Yield: 84%; mp: 136–138°C [lit [43], mp: 172°C].

General procedure for the preparation of 5-aryl-1,3,4-oxadiazol-2-thiones 5 (a–h) [44]. A mixture of aromatic acids 2 (10 mmol), ethanol (25 mL), and the mixture was refluxed for 12 h. After filtering, the resulting mixture was refluxed for 12 h. After filtering, the resulting filtrate was evaporated to dryness under reduced pressure. The residue was suspended in water (10.0 mL) and the resulting mixture was refluxed for 12 h. After filtering, the resulting filtrate was evaporated to dryness under reduced pressure. The residue was suspended in water (10.0 mL) and the resulting filtrate was evaporated to dryness under reduced pressure. The residue was suspended in water (10.0 mL) and the resulting filtrate was evaporated to dryness under reduced pressure. The residue was suspended in water (10.0 mL) and the resulting filtrate was evaporated to dryness under reduced pressure.

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(3-fluorophenyl)-1,3,4-oxadiazole (11): Yield: 69.1%; mp: 69–71°C. 1H-NMR (CDCl3) δ 2.11–2.14 (m, 2H), 2.64 (t, 2H, J = 13.6 Hz), 2.72–2.74 (m, 4H), 3.40 (t, 2H, J = 14 Hz), 3.50–3.60 (m, 4H), 7.33–7.37 (m, 1H), 7.44–7.52 (m, 4H), 7.60 (d, 1H, J = 8 Hz), 7.89 (d, 1H, J = 8.4 Hz), 7.99 (d, 2H, J = 2 Hz). MS (ESI) m/z 458.2 ([M+H]+).

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(methoxyphenyl)-1,3,4-oxadiazole (12): Yield: 81.6%; mp: 106–107°C. 1H-NMR (CDCl3) δ 2.05–2.18 (m, 8H), 2.57 (t, 2H, J = 13.6 Hz), 3.05–3.09 (m, 3H), 3.40 (t, 2H, J = 14.4 Hz), 7.05 (m, 1H), 7.24 (dd, 1H, J1 = 2 Hz, J2 = 2 Hz), 7.49–7.51 (m, 3H), 7.68–7.71 (m, 1H), 7.99–8.02 (m, 2H). MS (ESI) m/z 493.2 ([M+H]+).

2-(4-(benzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-methoxyphenyl)-1,3,4-oxadiazole (13): Yield: 70.6%; mp: 88–89°C. 1H-NMR (CDCl3) δ 2.08–2.11 (m, 2H), 2.61 (t, 2H, J = 13.6 Hz), 2.69 (t, 4H, J = 9.6 Hz), 3.38 (t, 2H, J = 14 Hz), 3.57 (t, 4H, J = 9.6 Hz), 3.87 (s, 3H), 6.99 (d, 2H, J = 8.8 Hz), 7.35 (t, 1H, J = 8.4 Hz), 7.46 (t, 1H, J = 8.8 Hz), 7.80 (d, 1H, J = 8.4 Hz), 7.89–7.95 (m, 3H). MS (ESI) m/z 468.2 ([M+H]+).

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-methoxyphenyl)-1,3,4-oxadiazole (14): Yield: 78.3%; mp: 103–104°C. 1H-NMR (CDCl3) δ 2.04–2.17 (m, 8H), 2.57 (t, 2H, J = 13.6 Hz), 3.04–3.08 (m, 3H), 3.37 (t, 2H, J = 14 Hz), 3.86 (s, 3H), 6.99–7.07 (m, 3H), 7.21–7.30 (m, 1H), 7.68–7.71 (m, 1H), 7.91–7.95 (m, 2H). MS (ESI) m/z 469.2 ([M+H]+).

2-(4-(benzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-chlorophenyl)-1,3,4-oxadiazole (15): Yield: 79.8%; mp: 99–101°C. 1H-NMR (CDCl3) δ 2.08–2.12 (m, 2H), 2.59–2.71 (m, 6H), 3.40 (t, 2H, J = 14 Hz), 3.55–3.58 (m, 4H), 7.33–7.36 (m, 1H), 7.44–7.47 (m, 3H), 7.79–7.89 (m, 1H), 7.90–7.94 (m, 3H). MS (ESI) m/z 472.2 ([M+H]+).

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-chlorophenyl)-1,3,4-oxadiazole (16): Yield: 80.3%; mp: 115–117°C. 1H-NMR (CDCl3) δ 2.08–2.20 (m, 8H), 2.56–2.59 (m, 2H), 3.06–3.09 (m, 3H), 3.42 (t, 2H, J = 14 Hz), 7.04–7.06 (m, 1H), 7.22–7.24 (m, 1H), 7.46–7.49 (m, 2H), 7.68–7.72 (m, 1H), 7.94–7.96 (m, 2H). MS (ESI) m/z 473.2 ([M+H]+).

2-(4-(benzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(3,4-trifluoromethyl)phenyl)-1,3,4-oxadiazole (17): Yield: 71.8%; mp: 106–107°C. 1H-NMR (CDCl3) δ 2.10–2.14 (m, 2H), 2.60–2.71 (m, 6H), 3.43 (t, 2H, J = 14 Hz), 3.58 (br, 4H), 7.33–7.37 (m, 1H), 7.44–7.48 (m, 1H), 7.75–7.82 (m, 3H), 7.90 (d, 1H, J = 8 Hz), 8.13 (d, 2H, J = 8 Hz). MS (ESI) m/z 506.2 ([M+H]+).

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-trifluoromethyl)phenyl)-1,3,4-oxadiazole (18): Yield: 64.4%; mp: 122–124°C. 1H-NMR (CDCl3) δ 2.08–2.19 (m, 8H), 2.59 (t, 2H, J = 13.6 Hz), 3.06–3.12 (m, 3H), 3.43 (t, 2H, J = 14 Hz), 7.06–7.08 (m, 1H), 7.23–7.27 (m, 1H), 7.68–7.72 (m, 1H), 7.77 (d, 2H, J = 8.4 Hz), 8.14 (d, 1H, J = 8 Hz). MS (ESI) m/z 507.2 ([M+H]+).

2-(4-(benzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-fluorophenyl)-1,3,4-oxadiazole (19): Yield: 71.2%; mp: 89–91°C. 1H-NMR (CDCl3) δ 2.06–2.10 (m, 2H), 2.57–2.68 (m, 6H), 3.38 (t, 2H, J = 14 Hz), 3.53–3.56 (m, 4H), 7.13–7.17 (m, 2H), 7.32–7.43 (m, 2H), 7.77–7.99 (m, 4H). MS (ESI) m/z 456.2 ([M+H]+).

2-(4-(6-fluorobenzyl)[isoazol-3-yl]piperidin-1-yl)propylthio)-5-(4-fluorophenyl)-1,3,4-oxadiazole (20): Yield: 61.9%; mp: 118–120°C. 1H-NMR (CDCl3) δ 2.03–2.17 (m, 8H), 2.57 (t, 2H, J = 13.6 Hz), 3.05–3.07 (m, 3H), 3.40 (t, 2H, J = 14 Hz), 7.05–7.06 (m, 1H), 7.16–7.25 (m, 3H), 7.68–7.71 (m, 1H), 8.00–8.05 (m, 2H). MS (ESI) m/z 457.2 ([M+H]+).

Potential Multireceptor Atypical Antipsychotics

All the research involving animals in this study follows the guidelines of the bylaw of experiments on animals, and has been approved by the Ethics and Experimental Animal Committee of Jiangsu Nhwa Pharmaceutical Co., Ltd.
In Vitro Binding Assays

General procedures. All the new compounds were dissolved in 5% DMSO. The following specific radioligands and tissue sources were used: (a) serotonin 5-HT1A receptor, [3H]8-OH-DPAT, rat brain cortex; (b) serotonin 5-HT2A receptor, [3H]ketanserin, rat brain cortex; (c) serotonin 5-HT2C receptor, [3H]mesulergine, rat brain cortex; (d) dopamine D2 receptor, [3H]spiperone, rat striatum; (e) dopamine D3 receptor, [3H]spiperone, rat olfactory tubercle (β) histamine H1 receptor, [3H]pyrilamine, guinea pig cerebellum.

Total binding was determined in the absence of non-specific binding and compounds. Specific binding was determined in the presence of compounds. Non-specific binding was determined as the difference between total and specific binding.

Percentage of inhibition (%) = (total binding – specific binding)/(total binding – non-specific binding).

Blank experiments were carried out to determine the effect of 5% DMSO on the binding and no effects were observed.

Compounds were tested at least three times over a 6 concentration range (10^-3 M to 10^-10 M), IC50 values were determined by nonlinear regression analysis using Hill equation curve fitting. Ki values were calculated based on the Cheng and Prussoff equation: $Ki = IC50/(1+C/Kd)$ where C represents the concentration of the hot ligand used and $Kd$ its receptor dissociation constant were calculated for each labeled ligand. Mean Ki values and SEM were reported for at least three independent experiments.

5-HT1A binding assay [49]. Rat cerebral cortex was homogenized in 20 volumes of ice-cold Tris-HCl buffer (50 mM, pH 7.7) using an ULTRA TURAX homogeniser, and was then centrifuged at 32000 g for 20 min. The resulting pellet was then resuspended in the same buffer, incubated for 10 min at 37 °C, and centrifuged at 32000 g for 10 min. The final pellet was resuspended in Tris-HCl buffer containing 10 μM Pargyline, 4 mM CaCl2 and 0.1% ascorbic acid.

Total binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]8-OH-DPAT (187.4 Ci/mmol, Perkin Elmer Life Sciences, Boston, MA, USA), 50 μL Tris-HCl buffer containing 10 μM Pargyline, 4 mM CaCl2 and 0.1% ascorbic acid.

Non-specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]8-OH-DPAT, 50 μL of 10 μM serotoni.

Specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]8-OH-DPAT, 50 μL of new compounds or reference drug.

The tubes were incubated at 37 °C for 30 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

5-HT2A binding assay [49]. Rat cerebral cortex was homogenized in 20 volumes of ice-cold Tris-HCl buffer (50 mM, pH 7.7) using an ULTRA TURAX homogeniser, and centrifuged at 32000 g for 20 min. The resulting pellet was then resuspended in the same quantity of the buffer centrifuged for 20 min. The final pellet was resuspended in 50 volumes of the Tris-HCl buffer.

Total binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.6 nM [3H]ketanserin, 60.0 Ci/mmol, Perkin Elmer Life Sciences, Boston, MA, USA), 50 μL Tris-HCl buffer.

Non-specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.6 nM [3H]ketanserin, 50 μL of 10 μM methisergide.

Specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.6 nM [3H]ketanserin, 150 μL of new compounds or reference drug.

The tubes were incubated at 37 °C for 15 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

5-HT2C binding assay [49]. Rat cerebral cortex was homogenized in 20 volumes of ice-cold Tris-HCl buffer (50 mM, pH 7.7) using ULTRA TURAX homogeniser, and centrifuged at 32000 g for 20 min. The resulting pellet was resuspended in the same quantity of the buffer centrifuged for 20 min. The final pellet was resuspended in 50 volumes of the Tris-HCl buffer.

Total binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 1 nM [3H]mesulergine (35.4 Ci/mmol; Perkin Elmer Life Sciences, Boston, MA, USA), 50 μL Tris-HCl buffer.

Non-specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 1 nM [3H]mesulergine, 50 μL of 10 μM mianserin.

Specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 1 nM [3H]mesulergine, 50 μL of new compounds or reference drug.

The tubes were incubated at 37 °C for 15 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

D2 dopaminergic binding assay [49]. Rat striatum was homogenized in 20 volumes of ice-cold 50 mM Tris-HCl buffer (pH 7.7) using an ULTRA TURAX homogeniser, and centrifuged twice for 10 min at 48,000 g resuspension of the pellet in fresh buffer. The final pellet was resuspended in 50 mM ice-cold Tris-HCl containing 120 mM NaCl, 5 mM KCl, 2 mM CaCl2, 1 mM MgCl2, 0.1% ascorbic acid and 5 μM pargyline.

Total binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]spiperone (16.2 Ci/mmol; Perkin Elmer Life Sciences, Boston, MA, USA), 50 μL Tris-HCl buffer containing 120 mM NaCl, 5 mM KCl, 2 mM CaCl2, 1 mM MgCl2, 0.1% ascorbic acid and 5 μM pargyline.

Non-specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]spiperone, 50 μL of 10 μL (+)-butaclamol.

Specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.5 nM [3H]spiperone, 50 μL of new compounds or reference drug.

The tubes were incubated at 37 °C for 15 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

D3 Dopaminergic Binding Assay [37].

Rat olfactory tubercle was homogenized in 20 volumes of ice-cold 50 mM Hepes Na (pH 7.5) using an ULTRA TURAX homogeniser and centrifuged at 32000 g for 20 min. The resulting pellet was resuspended in 50 volumes of the Tris-HCl buffer.

Total binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.1 nM [3H]mesulergine, 50 μL of 10 μM fluphenazine.

Non-specific binding each assay tube was added 900 μL of the tissue suspension, 50 μL of 0.1 nM [3H]mesulergine, 50 μL of new compounds or reference drug.

The tubes were incubated at 37 °C for 15 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.
homogeniser, and centrifuged twice for 10 min at 48,000 g with resuspension of the pellet in fresh buffer. The final pellet was resuspended in 50 mM Hapes Na, pH 7.5, containing 1 mM EDTA, 0.005% ascorbic acid, 0.1% albumin, 200 nM eliprodil.

Total binding each assay tube was added 900 nL of membranes, 50 nL of 0.6 nM [3H]piperazine (16.2 Ci/nmol; Perkin Elmer Life Sciences, Boston, MA, USA), 50 nL of 50 mM Hapes Na, pH 7.5, containing 1 mM EDTA, 0.005% ascorbic acid, 0.1% albumin, 200 nM eliprodil.

Non-specific binding each assay tube was added 900 nL of membranes, 50 nL of [3H]piperazine, 50 nL of 1 μM dopamine. Specific binding each assay tube was added 900 nL of Membranes, 50 nL of [3H]piperazine, 50 nL of new compounds or reference drug.

The tubes were incubated at 25°C for 60 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

Histamine H3 Binding Assay [50]

Guinea pig cerebellum was homogenized in volumes of ice-cold 50 mM phosphate buffer (pH 7.4) using an ULTRA TURAX homogeniser, and centrifuged twice for 10 min at 50,000 g with resuspension of the pellet in fresh buffer. The final pellet was resuspended in phosphate buffer.

Total binding each assay tube was added 900 nL of membranes 50 nL of 1 nM [3H]pyrilamine (20.0 Ci/nmol; Perkin Elmer Life Sciences, Boston, MA, USA), 50 nL phosphate buffer.

Non-specific binding each assay tube was added 900 nL of membranes, 50 nL of [3H]pyrilamine, 50 nL of 1 μM promethazine.

Specific binding each assay tube was added 900 nL of Membranes, 50 nL of [3H]pyrilamine, 50 nL of new compounds or reference drug.

The tubes were incubated at 30°C for 60 min. The incubation was followed by a rapid vacuum filtration through Whatman GF/B glass filters, and the filtrates were washed twice with 5 mL cold buffer and transferred to scintillation vials. Scintillation fluid (3.0 mL) was added and the radioactivity bound was measured using a Beckman LS 6500 liquid scintillation counter.

Acute toxicity study. Mice (5 mice in each group) were orally dosed with increasing doses of the compound 22 (200, 500, 1000, 1500 and 2000 mg/kg). The number of surviving animals was recorded after 24 h of drug administration, and the percent mortality in each group was calculated. The LD50 value was calculated by using the program SPSS (Statistical Package for the Social Science).

MK-801-induced hyperactivity [51]. Mice (10 mice in each group) were orally dosed with vehicle or increasing doses of the haloperidol (0.06, 0.2, 0.6, 2.0 and 6.0 mg/kg), clozapine (1, 2.5, 7, 20 and 60 mg/kg), risperidone (0.01, 0.03, 0.1, 0.3 and 1.0 mg/ kg) and compound 22 (3, 5, 10, 20 and 30 mg/kg). Animals were placed in Plexiglas cages for evaluating locomotor activity. After 30 min, the animals were challenged with 0.3 mg/kg (sc) of MK-801 and the locomotor activity of each animal was recorded for 90 min.

Behavioral Tests

Apomorphine-induced climbing [36]. Mice (10 mice in each group) were orally dosed with vehicle or increasing doses of the haloperidol (0.1, 0.13, 0.17, 0.23 and 0.3 mg/kg), clozapine (4.0, 7.5, 9.5 and 12.5 mg/kg), risperidone (0.01, 0.03, 0.1 and 0.3 mg/kg), compound 22 (0.8, 2.5, 8, 25 and 80 mg/kg). Animals were then challenged at 30 minutes post-injection with 1.0 mg/kg of the apomorphine in 0.9% NaCl+0.1% ascorbic acid, placed in cylindrical wire cages (12 cm in diameter, 14 cm in height), and observed for climbing behavior at 10, 20 and 30 min post dose. The climbing behaviour was scored as follows: 3–4 paws on the cage floor = 0 score; 2 and 3 paws on the cage = 1 score; 4 paws on the cage = 2 score.

Catalepsy test [38]. Mice (10 mice in each group) were orally dosed with vehicle or increasing doses of the haloperidol (0.18, 0.35, 0.75, 1.5 and 3.0 mg/kg), clozapine (25, 50, 100, 150 and 200 mg/kg), risperidone (0.1, 0.6, 1.2, 2.5 and 5.0 mg/kg), compound 22 (50, 150 and 300 mg/kg). Catalepsy was evaluated on a metal bar 0.6 cm in diameter positioned 4.5 cm above the tabletop. The test consisted in positioning the animal with its forepaws on the bar and recording how long it remained hanging onto the bar; the end-point was 60 s and an all-or-none criterion was used.

Pharmacokinetics study in rat. The HPLC conditions were as follows: column, Shim-pack ODS 5.0 μm×150 mm×2.0 mm ID (SHIMADZU, Japanese); mobile phase, 0.0167% HCOOH (TEDIA Company, USA)/acetonitrile (Merck Company, Germany)/50; flow rate, 0.2 mL/min; column temperature, 40°C.

For routine compound 22 screening rats (n = 6/group) were dosed via the lateral tail vein at the indicated dose for intravenous administration (5 mg/kg, 100% saline) or via oral gavage (20 mg/kg, suspension in 0.5% methylcellulose). At 30 min, 1 h, 2 h, 3 h, 4 h, 5 h, 6 h, 7 h and 24 h after administration, serial blood samples were collected from the lateral tail vein into heparinized collection tubes (approximately 0.25 mL). The plasma was separated by centrifugation, and the sample was prepared for analysis HPLC/MS by protein precipitation with acetonitrile. The plasma samples were analyzed for drug and internal standard via HPLC-MS/MS protocol.

Statistics. To estimate the potency of test and reference compounds, the ED50 values and their 95% confidence limits were calculated by using the program SPSS (Statistical Package for the Social Science).
