Abstract

Diarrhea and cholera are major health problems. *Vibrio cholera*, the causative agent of cholera, infects the small intestine, resulting in vomiting, massive watery diarrhea and dehydration. Reduced water and electrolyte absorption is also due to zinc deficiency. Zinc has an important role in recovery from the disease. The combination of zinc with cholera vaccine and oral rehydration solutions has a positive impact on cholera and diarrhea. It has led to a decrease in the mortality and morbidity associated with diarrhea.

Key words: Diarrhea; Cholera; *Vibrio cholera*; Zinc; Oral rehydration solutions

Core tip: In diarrhea and cholera, reduced water and electrolyte absorption is due to zinc deficiency. Therefore, zinc has an important role in recovery from the symptoms. The use of zinc with cholera vaccine and oral rehydration solutions has been shown to affect positive impacts in cholera and diarrhea.

INTRODUCTION

Diarrhea and cholera are major global health problems. Cholera toxin produced by the causative agent increases cyclic adenosine monophosphate (cAMP) production. This result in massive electrolyte and water secretion into the intestinal lumen, resulting in severe dehydration[1]. *Vibrio cholera*, the causative agent of cholera, infects the small intestine. Vomiting, massive watery diarrhea and dehydration (Figure 1) are associated with cholera and may lead to death if not managed properly[2]. Reduced water and electrolyte absorption is also due to zinc deficiency[3]. Zinc has an important role in recovery from the disease[4] and can reduce the morbidity and mortality, associated with diarrhea, in the population[5].

ZINC WITH CHOLERA VACCINE

Clinically, zinc has positive effect in children with complications of diarrhea[6]. Young children are immunized with oral inactivated whole cell cholera vaccine containing recombinant cholera toxin B subunit. This vaccine induces T-cell responses that are further enhanced by zinc supplementation[7]. Zinc combined with oral cholera vaccine shows increased vibriocidal antibody effects and suppresses cholera toxin antibody response[8]. Zinc supplementation enhances oral cholera vaccine efficacy and also improves seroconversion to vibriocidal antibody[9]. Oral administration improves immune response to antigens applied to mucosal surfaces and also improves antibacterial response in serum and reduces antitoxin levels[10].

Administration of two doses of oral inactivated cholera vaccine, containing cholera B subunit and killed cholera vibrios, combined with zinc supplementation, to 6-8 mo old children was found to be safe and immunogenic[11].
ZINC WITH ORAL REHYDRATING SOLUTIONS

Diarrhea and cholaera are major global health problem and have caused seven pandemics. Cholera toxin produced by *Vibrio cholera* increases cAMP production. This results in massive electrolyte and water secretion into intestinal lumen, leading to severe dehydration. The World Health Organization emphasises the use of oral rehydration solutions (ORS) in the treatment of diarrhea. Various modifications have been made to standard ORS, to treat non cholera diarrhea and cholera diarrhea. These include addition of zinc, amino acids and amylase-resistant starch, to decrease the morbidity and mortality associated with acute diarrhea. Zinc with ORS is an attempt to improve ORS for cholera diarrhea management. The presence of zinc in ORS improves physiological condition, reduces the risk of recurrent diarrhea attacks and also has positive effects in dehydrating acute diarrhea in malnourished children. Studies in various countries showed that the duration and severity of diarrhea can be reduced by zinc addition and this also allows limitation of the use of antibacterials and antimicrobials (Figure 2).

**WATER SOLUBLE ACTIVE ZnTe NANOCOMPOSITES**

Water soluble active ZnTe nanocomposites (average size range of 2.9-6.0 nm) show potential against enteropathogenic bacteria including enterotoxigenic *Escherichia coli* (E. coli) and *Vibrio cholera* serogroup 01, having positive effects in diarrhea and cholaera without toxic effects on humans.

**EFFECT OF ZINC**

A study on an animal model showed that zinc deficiency in the intestine resulted in reduced water and electrolyte absorption. Cholera toxin increases cAMP production, thereby causing electrolyte and water secretion. Zinc reduces cAMP concentration and cholera toxin-induced ion secretion, as well as increasing ion absorption, but does not inhibit *E. coli* heat stable enterotoxin-induced ion secretion.

In children suffering from acute diarrhea and persistent diarrhea, the effect of zinc on intestinal integrity is unknown. However, in patients with acrodematitis enteropathica infection, zinc induced more mucosal repair. Zinc also effects excretion of urinary probe sugars, increasing lactulose excretion and decreasing mannitol excretion.

**EFFECT OF SCHEDULED DOSES OF ZINC**

Children and older patients both show zinc deficiency in cholera. Zinc supplementation showed beneficial impact on diarrhea in infants but its impact was masked by the protective action of breastfeeding.

Zinc supplementation administered on a daily or weekly schedule is effective in decreasing diarrhoal morbidity without adverse reactions.

Children with cholera supplemented with zinc show reduction in stool output and in the duration of diarrhea. Children with diarrhea may benefit from zinc supplementation but its cost effectiveness and optimal mode of delivery are not yet clear.

**CONCLUSION**

In diarrhea and cholaera, reduced water and electrolyte absorption is due to zinc deficiency. Therefore, zinc has an important role in recovery from the symptoms. Zinc combined with cholera vaccine and ORS has been shown to have positive impacts in cholera and diarrhea.
