Deciding the existence of cut-off in parameterized rendez-vous networks

Florian Horn\textsuperscript{1} and Arnaud Sangnier\textsuperscript{1}

\textsuperscript{1}IRIF, CNRS, Universite de Paris, France

Abstract

We study networks of processes which all execute the same finite-state protocol and communicate thanks to a rendez-vous mechanism. Given a protocol, we are interested in checking whether there exists a number, called a cut-off, such that in any networks with a bigger number of participants, there is an execution where all the entities end in some final states. We provide decidability and complexity results of this problem under various assumptions, such as absence/presence of a leader or symmetric/asymmetric rendez-vous.

1 Introduction

Networks with many identical processes. One of the difficulty in verifying distributed systems lies in the fact that many of them are designed for an unbounded number of participants. As a consequence, to be exhaustive in the analysis, one needs to design formal methods which takes into account this characteristic. In [21], German and Sistla introduce a model to represent networks with a fix but unbounded number of entities. In this model, each participant executes the same protocol and they communicate between each other thanks to rendez-vous (a synchronization mechanism allowing two entities to change their local state simultaneously). The number of participants can then be seen as a parameter of the model and possible verification problems ask for instance whether a property holds for all the values of this parameter or seeks for some specific value ensuring a good behavior. With the increasing presence of distributed mechanisms (mutual exclusion protocols, leader election algorithms, renaming algorithms, etc) in the core of our computing systems, there has been in the last two decades a regain of attention in the study of such parameterized networks.

Surprisingly, the verification of these parameterized systems is sometimes easier than the case where the number of participants is known. This can be explained by the following reason: in the parameterized case the procedure can adapt on demand the number of participants to build a problematic execution. It is indeed what happens with the liveness verification of asynchronous shared-memory systems. This problem is PSPACE-complete for a finite number of processes and in NP when this number is a parameter [14]. It is hence worth studying the complexity of the verification of such parameterized models and many recent works have attacked these problems considering networks with different means of communication. For instance in [16] [13] 7 8 the participants communicate thanks to broadcast of messages, in [11] [2] they use a token-passing mechanism, in [10] a message passing mechanism and in [18] the communication is performed through shared registers. The relative expressiveness of some of those models has been studied in [1]. Finally in his survey [15], Esparza shows that minor changes in the setting of parameterized networks, such as the presence of a controller (or equivalently a leader), might drastically change the complexity of the verification problems.

\textsuperscript{*}Partly supported by ANR FREDDA (ANR-17-CE40-0013).
**Cut-off to ease the verification.** When one has to prove the correctness of a distributed algorithm designed to work for an unbounded number of participants, one technique consists in proving that the algorithm has a cut-off, i.e. a bound on the number of processes such that if it behaves correctly for this specific number of processes then it will still be correct for any bigger networks. Such a property allows to reduce the verification procedure to the analysis of the algorithm with a finite number of entities. Unfortunately, as shown in [3], many parameterized systems do not have a cut-off even for basic properties. Instead of checking whether a general class of models admits a cut-off, we propose in this work to study the following problem: given a representation of a system and a class of properties, does it admit a cutoff? To the best of our knowledge, looking at the existence of a cutoff as a decision problem is a subject that has not received a lot of attention although it is interesting both practically and theoretically. First, in the case where this problem is decidable, it allows to find automatically cutoffs for specific systems even though they belong to a class for which there is no general results on the existence of cutoff. The search of cutoffs has been studied in [1] where the authors propose a semi-algorithm for verification of parameterized networks with respect to safety properties. This algorithm stops when a cutoff is found. However it is not stated how to determine the existence of this cutoff, neither if this is possible or not. In [24], the authors propose a way to compute dynamically a cutoff, but they consider systems and properties for which they know that a cutoff exists. Second, from the theoretical point of view, the cutoff decision problem is interesting because it goes beyond the classical problems for parameterized systems that usually seek for the existence of a number of participants which satisfies a property or check that a property hold for all possible number of participants. Note that in the latter case, one might be in a situation that for a property to hold a minimum number of participants is necessary (and below this number the property does not hold), such a situation can be detected with the existence of a cutoff but not with the simple universal quantification.

**Rendez-vous networks.** We focus on networks where the communication is performed by rendez-vous. There are different reasons for this choice. First, we are not aware of any technique to decide automatically the existence of a cut-off in parameterized systems, it is hence convenient to look at this problem in a well-known setting. Another aspect which motivates the choice of this model is that the rendez-vous communication corresponds to a well-known paradigm in the design of concurrent/distributed systems (for instance rendez-vous in the programming languages C or JAVA can be easily implemented thanks to wait/notify mechanisms). Rendez-vous communication seems as well a natural feature for parameterized systems used to model for instance crowds or biological systems (at some point we consider symmetric rendez-vous which can be seen less common in computing systems but make sense for these other applications). Last but not least, rendez-vous networks are very close to population protocols [5] for which there has been in the last years a regain of interest in the community of formal methods [17, 8, 9]. Population protocols and rendez-vous networks are both based on rendez-vous communication, but in population protocols it is furthermore required that all the fair executions converge to some accepting set of configurations (see [17] for more details). In our case, we seek for the existence of an execution ending with all the processes in a final state. The similarities between the two models let us think that the formal techniques we use could be adapted for the analysis of some population protocols.

**Our contributions.** We study the Cut-off Problem (C.O.P.) for rendez-vous networks. It consists in determining whether, given a protocol labeled with rendez-vous primitives, there exists a bound \( B \), such that in any networks of size bigger than \( B \) where the processes all run the same protocol there is an execution which brings all the processes to a final state. We assume furthermore that in our network, there could be one extra entity, called the leader, that runs its own specific protocol. We first show that C.O.P. is decidable by reducing it to a new decision problem on Petri nets. Unfortunately we show as well that it is non elementary thanks to a reduction from the reachability problem in Petri nets[12]. We then show that better complexity bounds can be obtained if we assume the rendez-vous to be symmetric (i.e. any process that requests a rendez-vous can as well from the same state accept one and vice-versa) or if we assume that there is no leader. For each of these restrictions, new algorithmic techniques for the analysis of rendez-vous networks are proposed. The following table sums up the complexity bounds we obtain.
Due to lack of space, omitted details and proofs can be found in Appendix.

2 Modeling networks with rendez-vous communication

We write \( \mathbb{N} \) to denote the set of natural numbers and \([i,j]\) to represent the set \( \{k \in \mathbb{N} \mid i \leq k \text{ and } k \leq j\} \) for \( i, j \in \mathbb{N} \). For a finite set \( E \), the set \( \mathbb{N}^E \) represents the multisets over \( E \). For two elements \( m, m' \in \mathbb{N}^E \), we denote \( m + m' \) the multiset such that \( (m + m')(e) = m(e) + m'(e) \) for all \( e \in E \). We say that \( m \leq m' \) if and only if \( m(e) \leq m'(e) \) for all \( e \in E \). If \( m \leq m' \), then \( m' - m \) is the multiset such that \( (m' - m)(e) = m'(e) - m(e) \) for all \( e \in E \). The size of a multiset \( m \) is given by \( |m| = \sum_{e \in E} m(e) \). For \( e \in E \), we use sometimes the notation \( m(e) \) for the multiset \( m \) verifying \( m(e) = 1 \) and \( m'(e) = 0 \) for all \( e' \in E \setminus \{e\} \) and the notation \( \langle\langle e1, e1, e2, e3\rangle\rangle \) to represent the multiset with four elements \( e1, e1, e2 \) and \( e3 \).

2.1 Rendez-vous protocols

We are now ready to define our model of networks. We assume that all the entities in the network (called sometimes processes) behave similarly following the same protocol except one entity, called the leader, which might behave differently. The communication in the network is pairwise and is performed by rendez-vous through a communication alphabet \( \Sigma \). Each entity can either request a rendez-vous, with the primitive \(?a\), or answer to a rendez-vous, with the primitive \(!a\) where \( a \) belongs to \( \Sigma \). The set of actions is hence \( RV(\Sigma) = \{?a, !a \mid a \in \Sigma\} \).

Definition 1 (Rendez-vous protocol). A rendez-vous protocol \( \mathcal{P} \) is a tuple \( (Q, Q_P, Q_L, \Sigma, q_i, q_f, q_0^i, q_f^i, E) \) where \( Q \) is a finite set of states partitioned into the processes states \( Q_P \) and the leader states \( Q_L \), \( \Sigma \) is a finite alphabet, \( q_i \in Q_P \) [resp. \( q_0^i \in Q_L \)] is the initial state of the processes [resp. of the leader], \( q_f \in Q_P \) [resp. \( q_f^i \in Q_L \)] is the final state of the processes [resp. of the leader], and \( E \subseteq (Q_P \times RV(\Sigma) \times Q_P) \cup (Q_L \times RV(\Sigma) \times Q_L) \) is the set of edges.

A configuration of the rendez-vous protocol \( \mathcal{P} \) is a multiset \( C \in \mathbb{N}^Q \) verifying that there exists \( q \in Q_L \) such that \( C(q) = 1 \) and \( C(q') = 0 \) for all \( q' \in Q_L \setminus \{q\} \), in other words there is a single entity corresponding to the leader. The number of processes in a configuration \( C \) is given by \( |C| - 1 \). We denote by \( C^{(n)} \) the set of configurations \( C \) involving \( n \) processes, i.e. such that \( |C| = n + 1 \). The initial configuration with \( n \) processes \( C^{(n)}_i \) is such that \( C^{(n)}_i(q_i) = n \) and \( C^{(n)}_i(q_0^i) = 1 \) and \( C^{(n)}_i(q) = 0 \) for all \( q \in Q \setminus \{q_i, q_0^i\} \). Similarly the final configuration with \( n \) processes \( C^{(n)}_f \) verifies \( C^{(n)}_f(q_f) = n \) and \( C^{(n)}_f(q_f^i) = 1 \) and \( C^{(n)}_f(q) = 0 \) for all \( q \in Q \setminus \{q_f, q_f^i\} \). Hence in an initial configuration all the entities are in their initial state and in a final configuration they are all in their final state. The notation \( C \) represents the whole set of configurations equals to \( \bigcup_{n \in \mathbb{N}} C^{(n)} \).

We are now ready to formalize the behavior of a rendez-vous protocol. In this matter, we define the relation \( \rightarrow \subseteq \bigcup_{n \geq 1} C^{(n)} \times C^{(n)} \) as follows: \( C \rightarrow C' \) if, and only if, there is \( a \in \Sigma \) and two edges \( (q_1, ?a, q_2), (q_1', !a, q_2') \in E \) such that \( C(q_1) > 0 \) and \( C(q_1') > 0 \) and \( C(q_1) + C(q_1') \geq 2 \) and \( C' = C - (q_1 + q_1') + (q_2 + q_2') \). Intuitively it means that in \( C \) there is one entity in \( q_1 \) that requests a rendez-vous and one entity in \( q_1' \) that answers to it and they both change their state to respectively \( q_2 \) and \( q_2' \). We need the hypothesis \( C(q_1) + C(q_1') \geq 2 \) in case \( q_1 = q_1' \). We use \( \rightarrow^* \) to represent the reflexive and transitive closure of \( \rightarrow \). Note that if \( C \rightarrow^* C' \) then \( |C| = |C'| \), in other words there is no deletion or creation of processes during an execution.
Example 1. Figure \[\text{1}\] provides an example of rendez-vous protocol where the process states are represented by circles and the leader states by diamond.

2.2 The cut-off problem

We can now describe the problem we address. It consists in determining given a protocol whether there exists a number of processes such that if we put more processes in the network it is always possible to find an execution which brings all the entities from their initial state to their final state. This cut-off problem (C.O.P.) can be stated formally as follows:

- **Input:** A rendez-vous protocol \( \mathcal{P} \);
- **Output:** Does there exist a cut-off \( B \in \mathbb{N} \) such that \( C_i^{(n)} \rightarrow* C_f^{(n)} \) for all \( n \geq B \)?

Example 2. The rendez-vous network represented in Figure \[\text{1}\] admits a cut-off equal to 3. For \( n = 3 \), we have indeed an execution \( C_i^{(3)} \rightarrow* C_f^{(3)} : \langle\langle q_i^L, q_i, q_i, q_i \rangle\rangle \xrightarrow{d} \langle\langle q_i^L, q_i, q_i, q_i, q_f \rangle\rangle \xrightarrow{a} \langle\langle q_i^L, q_i, q_i, q_i, q_f \rangle\rangle \xrightarrow{b} \langle\langle q_i^L, q_i, q_i, q_f, q_f \rangle\rangle \) (we indicate for each transition the label of the corresponding rendez-vous). For \( n = 4 \), the following sequence of rendez-vous leads to an execution \( C_i^{(4)} \rightarrow* C_f^{(4)} : \langle\langle q_i^L, q_i, q_i, q_i, q_i \rangle\rangle \xrightarrow{d} \langle\langle q_i^L, q_i, q_i, q_i, q_i, q_f \rangle\rangle \xrightarrow{a} \langle\langle q_i^L, q_i, q_i, q_i, q_i, q_f \rangle\rangle \xrightarrow{b} \langle\langle q_i^L, q_i, q_i, q_i, q_f, q_f \rangle\rangle \xrightarrow{b} \langle\langle q_i^L, q_i, q_i, q_f, q_f, q_f \rangle\rangle \). Then for any \( n > 4 \), we can always come back to the case where \( n = 3 \) (if \( n \) is odd) or \( n = 4 \) (if \( n \) is even). In fact, we can always let 3 or 4 processes in \( q_i \) and move pairwise the other processes, one in \( q \) and one in \( q_f \). Then the processes in \( q \) can be brought in \( q_f \) thanks to the rendez-vous \( a \) and \( b \) and the leader loop between \( q_i^L \) and \( q_i^R \). Note that if we delete the edge \( (q, a, q_i) \), this protocol does not admit anymore a cut-off but for all odd number \( n \geq 3 \), we have \( C_i^{(n)} \rightarrow* C_f^{(n)} \).

2.3 Petri nets

As we shall see there are some strong connections between rendez-vous protocols and Petri nets, this is the reason why we recall the definition of this latter model.

Definition 2 (Petri net). A Petri net \( \mathcal{N} \) is a tuple \( \langle P, T, \text{Pre}, \text{Post} \rangle \) where \( P \) is a finite set of places, \( T \) is a finite set of transitions, \( \text{Pre} : T \rightarrow \mathbb{N}^P \) is the precondition function and \( \text{Post} : T \rightarrow \mathbb{N}^P \) is the postcondition function.

A marking of a Petri net is a multiset \( M \in \mathbb{N}^P \). A Petri net defines a transition relation \( \Rightarrow \subseteq \mathbb{N}^P \times T \times \mathbb{N}^P \) such that \( M \xrightarrow{t} M' \) for \( M, M' \in \mathbb{N}^P \) and \( t \in T \) if and only if \( M \geq \text{Pre}(t) \) and \( M' = M - \text{Pre}(t) + \text{Post}(t) \). The intuition behind Petri nets is that marking put tokens in some places and each transition consumes with \( \text{Pre} \) some tokens and produces others thanks to \( \text{Post} \) in order to create a new marking. We write \( M \Rightarrow M' \) iff there exists \( t \in T \) such that \( M \xrightarrow{t} M' \). Given a marking \( M \in \mathbb{N}^P \), the reachability set of \( M \) is the set \( \text{Reach}(M) = \{ M' \in \mathbb{N}^P \ | \ M \Rightarrow* M' \} \) where \( \Rightarrow^* \) is the reflexive and transitive closure of \( \Rightarrow \). One famous problem in Petri nets is the reachability problem:
• **Input:** A Petri net \( \mathcal{N} \) and two markings \( M \) and \( M' \);

• **Output:** Do we have \( M' \in \text{Reach}(M) \)?

This problem is decidable \([31, 26, 27, 28]\) and non elementary \([12]\). Another similar problem that we will refer to and which is easier to solve is the **reversible reachability problem**:

• **Input:** A Petri net \( \mathcal{N} \) and two markings \( M \) and \( M' \);

• **Output:** Do we have \( M' \in \text{Reach}(M) \) and \( M \in \text{Reach}(M') \)?

It has been shown in \([30]\) to be \( \text{EXPSpace} \)-complete.

## 3 Back and forth between rendez-vous protocols and Petri nets

### 3.1 From Petri nets to rendez-vous protocols

We will see here how the reachability problem for Petri nets can be reduced to the C.O.P. which gives us a non-elementary lower bound for this latter problem. We consider in the sequel a Petri net \( \mathcal{N} = (P, T, \text{Pre}, \text{Post}) \) and two markings \( M, M' \in \mathbb{N}^P \). Without loss of generality we can assume that \( M \) and \( M' \) are of the following form: there exists \( p_i \in P \) such that \( M(p_i) = 1 \) and \( M(p) = 0 \) for all \( p \in P \setminus \{p_i\} \) and there exists \( p_f \in P \) such that \( M'(p_f) = 1 \) and \( M'(p) = 0 \) for all \( p \in P \setminus \{p_f\} \). Taking these restrictions on the markings does not alter the complexity of the reachability problem.

![Figure 2: A Petri net \( \mathcal{N} \) and its associated rendez-vous network \( \mathcal{P}_N \)](image)

We build from \( \mathcal{N} \) a rendez-vous protocol \( \mathcal{P}_N \) which admits a cut-off if and only if \( M' \in \text{Reach}(M) \). The states of the processes in \( \mathcal{P}_N \) are matched to the places of \( \mathcal{N} \), the number of processes in a state corresponding to the number of tokens in the associated place, and the leader is in charge to move the processes in order to simulate the changing on the number of tokens. The protocol is equipped with an extra state \( R \), the reserve state, where the leader stores at the beginning of the simulation the number of processes which will simulate the tokens: when a transition produces a token in a place \( p \), the leader moves a process from \( R \) to \( p \) and when it consumes a token from a place \( p \), the leader moves a process from \( p \) to \( q_f \). Formally, we have: \( \mathcal{P}_N = (Q, Q_P, Q_L, \Sigma, q_i, q_f, q_i^L, q_f^L, E) \) where:

- \( Q_P = \{q_i, q_f, R\} \cup \{p \mid p \in P\} \),
- \( Q_L = \{q_i^L, q_f^L, q_s^L\} \cup Q_{L}^{aux} \) (the states \( Q_{L}^{aux} \) are extra states use by the leader while simulating transitions),
• $\Sigma = \{a, b\} \cup \{\text{co}(p), \text{pr}(p) \mid p \in P\}$,

• $E \subseteq (Q_P \times RV(\Sigma) \times Q_P) \times (Q_L \times RV(\Sigma) \times Q_L)$ is the smallest relation such that:
  
  - $(q_i, ?a, R) \in E$ and $(q_L^i, !a, q_L^i) \in E$ (the leader send some processes in $R$),
  
  - $(R, ?\text{pr}(p), p) \in E$ and $(p, ?\text{co}(p), q_f) \in E$ for all $p \in P$ (a production of a token moves a process from $R$ to $p$ and a consumption moves it from $p$ to $q_f$),
  
  - $(q_L^i, !\text{pr}(p_i), q_L^i) \in E$ (the leader moves a process to $p_i$ and is in state $q_L^i$ where he simulates the transition),
  
  - for each transition $t \in T$, there is in $E$ a sequence of edges: $(q_L^i, !\text{co}(p_1), q_L^i)(q_L^i, !\text{co}(p_2), q_L^i) \ldots (q_L^i, !\text{co}(p_k), q_L^i)(q_L^{i+1}, !\text{pr}(p_1'), q_L^{i+1}) \ldots (q_L^{k+m-1}, !\text{pr}(p_{m-1}), q_L^m)(q_L^m, !\text{pr}(p_m), q_L^f)$ such that $\text{Pre}(t) = p_1 + p_2 + \ldots + p_k$ and $\text{Post}(t) = p_1' + p_2' + \ldots + p_m'$,
  
  - $(q_i, ?b, q_f) \in E$ and $(q_L^i, ?b, q_L^i) \in E$ (the leader can move the remaining processes in $q_f$),
  
  - $(q_L^i, !\text{co}(p_f), q_L^f) \in E$ (the leader ends the simulation).

Figure 2 provides an example of a Petri net and its associated rendez-vous network. In this net, the transition letter $a$ is used to put as many processes as necessary to simulate the number of tokens in the places in the reserve state $R$. The letters $\text{pr}(p_j)$ are used to simulate the production of a token in the place $p_j$ by moving a process from $R$ to $p_j$ and the letter $\text{co}(p_j)$ are used to simulate the consumption of a token in the place $p_j$ by moving a process from $p_j$ to $q_f$. It is then easy to see that each loop on the state $q_L^i$ simulates a transition of the Petri net whereas the transition from $q_L^i$ to $q_L^i$ is used to build the initial marking and the transition from $q_L^i$ to $q_L^f$ is used to delete one token from the single place $p_f$ and move the corresponding process to $q_f$. Finally, the letter $b$ is used to ensure the cutoff property by moving from $q_i$ to $q_f$ the extra processes not needed to simulate the tokens. This construction ensures the following Lemma.

**Lemma 1.** $M' \in \text{Reach}(M)$ in $\mathcal{N}$ iff there exists $B \in \mathbb{N}$ such that for all $n \geq B$, we have $C_i^{(n)} \rightarrow^* C_f^{(n)}$ in $\mathcal{NP}$.

**Sketch of proof:** If $M' \in \text{Reach}(M)$, then the cut-off is equal to $N + 1$ where $N$ is the number of tokens produced during the execution from $M$ to $M'$. The leader first brings $N + 1$ processes to $R$ thanks to the rendez-vous $a$ (the processes which remains in $q_i$ will be moved later from $q_i$ to $q_f$ thanks to the rendez-vous $b$). Then the leader moves to $q_L^i$ putting one process in $p_i$ (corresponding to one token in $p_i$) and from this state it simulates one by one the transitions of the execution by taking the corresponding loop on $q_L^i$. Each such loop simulates in fact a transition as follows: it first consumes the tokens of the transition (by making processes move from a state $p$ to $q_f$) and then produces the corresponding tokens (by making processes move from $R$ a place $p$). When the leader has simulated all the transitions of the run, no more processes are in $R$, one process is in $p_f$ and some processes are left in $q_i$, the leader first empties $q_i$ (thanks to $b$) and then it moves the last process in $p_f$ to $q_f$ going himself to $q_f$.

Assume now that there exists $n$ such that $C_i^{(n)} \rightarrow^* C_f^{(n)}$ in $\mathcal{NP}$. Then such an execution is necessarily at each step a move of the leader and of one process. According to the shape of the leader edges, we deduce that after having put some processes in $R$, it moves to $q_L^i$ where it will take a certain number of times some of the loops and finally it will move to $q_L^f$. Following the reverse reasoning as above this allows us to retrieve in the Petri net an execution from $M$ to $M'$ (each loop taken from $q_L^i$ corresponding to a fired transition).

We can hence obtain a hardness result for the C.O.P. thanks to the fact that the reachability problem in Petri nets is non-elementary [12].

**Theorem 1.** The C.O.P. is non-elementary.
3.2 From rendez-vous protocols to Petri nets

We now show how to encode the behavior of a rendez-vous protocol into a Petri net and give a reduction from the C.O.P. to a problem on the built Petri net. We consider a rendez-vous protocol \( \mathcal{P} = (Q, Q_L, \Sigma, q_1, q_2, q_1^t, q_2^t, E) \). From \( \mathcal{P} \), we build a Petri net \( \mathcal{N}_\mathcal{P} = \langle P, T, \text{Pre}, \text{Post} \rangle \) with the following characteristics:

- \( P = \{ p_q \mid q \in Q \} \),
- \( T = \{ t_i, t_f^L \} \cup \{ t_{(q_1, q_2, a, q_1', q_2')} \mid q_1, q_2, q_1', q_2' \in Q \text{ and } a \in \Sigma \text{ and } (q_1, !a, q_1'), (q_2, ?a, q_2') \in E \} \),
- the precondition function \( \text{Pre} \) is such that:
  - \( \text{Pre}(t_i(p)) = 0 \) for all \( p \in P \),
  - \( \text{Pre}(t_f^L(p_{q_1})) = 1 \) and \( \text{Pre}(t_f^L(p)) = 0 \) for all \( p \in P \setminus \{ p_{q_1} \} \),
  - \( \text{Pre}(t_{(q_1, q_2, a, q_1', q_2')}(p_{q_1})) = \text{Pre}(t_{(q_1, q_2, a, q_1', q_2')}(p_{q_2})) = 1 \) and \( \text{Pre}(t_{(q_1, q_2, a, q_1', q_2')}(p)) = 0 \) for all \( p \in P \setminus \{ p_{q_1}, p_{q_2} \} \),
- the postcondition function \( \text{Post} \) is such that:
  - \( \text{Post}(t_i(p_{q_i})) = 1 \) and \( \text{Post}(t_i(p)) = 0 \) for all \( p \in P \setminus \{ p_{q_i} \} \),
  - \( \text{Post}(t_f^L(p)) = 0 \) for all \( p \in P \),
  - \( \text{Post}(t_{(q_1, q_2, a, q_1', q_2')}(p_{q_i})) = \text{Post}(t_{(q_1, q_2, a, q_1', q_2')}(p_{q_2})) = 1 \) and \( \text{Post}(t_{(q_1, q_2, a, q_1', q_2')}(p)) = 0 \) for all \( p \in P \setminus \{ p_{q_i}, p_{q_2} \} \).

Intuitively in \( \mathcal{N}_\mathcal{P} \), we have a place for each state of \( \mathcal{P} \), the transition \( t_i \) puts tokens corresponding to new processes in the place corresponding to the initial state \( q_i \), the transition \( t_f^L \) consumes a token in the place corresponding to the final state of the leader \( q_2^t \) and each transition \( t_{(q_1, q_2, a, q_1', q_2')} \) simulates the protocol respecting the associated semantics (it checks that there is one process in \( q_1 \) another one in \( q_2 \) and that they can communicate thanks to the communication letter \( a \in \Sigma \) moving to \( q_1' \) and \( q_2' \)). Figure 3 represents the Petri net \( \mathcal{N}_\mathcal{P} \) for the protocol \( \mathcal{P} \) of Figure 1 (the transitions are only labeled with the letter of the rendez-vous).

![Figure 3: The Petri net \( \mathcal{N}_\mathcal{P} \) for the protocol \( \mathcal{P} \) of Figure 1](image)

Unfortunately we did not find a way to reduce directly the C.O.P. to the reachability problem in Petri nets which would have lead directly to the decidability of C.O.P. However we will see how the C.O.P. on \( \mathcal{P} \) can lead to a decision problem on \( \mathcal{N}_\mathcal{P} \). We consider the initial marking \( M_0 \in \mathbb{N}^P \) such that \( M_0(p_{q_i}) = 1 \) and \( M_0(p) = 0 \) for all \( p \in P \setminus \{ p_{q_i} \} \) and the family of markings \( (M_f^{(n)})_{n \in \mathbb{N}} \) such that \( M_f^{(n)}(p_{q_i}) = n \) and \( M_f^{(n)}(p) = 0 \) for all \( p \in P \setminus \{ p_{q_i} \} \). From the way we build the Petri net \( \mathcal{N}_\mathcal{P} \), we deduce the following lemma:
Lemma 2. For all \( n \in \mathbb{N} \), \( C_i^{(n)} \to^* C_f^{(n)} \) in \( \mathcal{P} \) iff \( M_f^{(n)} \in \text{Reach}(M_0) \) in \( \mathcal{N}_\mathcal{P} \).

This leads us to propose a cut-off problem for Petri nets, which asks whether given an initial marking and a specific place, there exists a bound \( B \in \mathbb{N} \) such that for all \( n \geq B \) it is possible to reach a marking with \( n \) tokens in the specific place and none in the other. This single place cut-off problem (single place C.O.P.) can be stated formally as follows:

- **Input:** A Petri net \( \mathcal{N} \), an initial marking \( M_0 \) and a place \( p_f \);
- **Output:** Does there exist \( B \in \mathbb{N} \) such that for all \( n \geq B \), we have \( M^{(n)} \in \text{Reach}(M_0) \) in \( \mathcal{N} \) where \( M^{(n)} \) is the marking verifying \( M^{(n)}(p_f) = n \) and \( M^{(n)}(p) = 0 \) for all \( p \in P \setminus \{p_f\} \)?

Thanks to Lemma 2 we can then conclude the following proposition which justifies the introduction of the single place C.O.P. in our context.

**Proposition 1.** The C.O.P. reduces to the single place C.O.P.

### 4 Solving C.O.P. in the general case

We show how to solve the C.O.P. by solving the single place C.O.P. To the best of our knowledge this latter problem has not yet been studied and we do not see direct connections with existing studied problems on Petri nets. It amounts to check if for some \( B \in \mathbb{N} \) we have \( \{ M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \} \subseteq \text{Reach}(M_0) \). We know from \([25]\) that the projection of the reachability set on the single place \( p_f \) is semilinear (that can be represented by a Presburger arithmetic formula), however this does not help us since we furthermore require the other places different from \( p_f \) to be empty.

#### 4.1 Formal tools and associated results

For \( P, P' \subseteq \mathbb{N}^n \), we let \( P + P' = \{ p + p' \mid p \in P \text{ and } p' \in P' \} \) and we shall sometimes identify an element \( p \in \mathbb{N}^n \) with the singleton \( \{ p \} \). A subset \( P \) of \( \mathbb{N}^n \) for \( n > 0 \) is said to be **periodic** iff \( 0 \in P \) and \( P + P \subseteq P \). Such a periodic set \( P \) is **finitely generated** if there exists a finite set of elements \( \{p_1, \ldots, p_k\} \subseteq \mathbb{N}^n \) such that \( P = \{ \lambda_1p_1 + \ldots + \lambda_kp_k \mid \lambda_i \in \mathbb{N} \text{ for all } i \in [1,k] \} \).

A **semilinear set** of \( \mathbb{N}^k \) is then a finite union of sets of the form \( b + P \) where \( b \in \mathbb{N}^k \) and \( P \) is finitely generated. Semilinear sets are particularly useful tools because they are closed under the classical operations (union, complement and projection) and they provide a finite representation of infinite sets of vectors of naturals. Furthermore they can be represented by logical formulae expressed in Presburger arithmetic which is the decidable first-order theory of natural numbers with addition. A formula \( \phi(x_1, \ldots, x_k) \) of Presburger arithmetic with free variables \( x_1, \ldots, x_k \) defines a set \( \llbracket \phi \rrbracket \subseteq \mathbb{N}^k \) given by \( \{ v \in \mathbb{N}^k \mid v \models \phi \} \) (here \( \models \) is the classical satisfiability relation for Presburger arithmetic and it holds true if the formula holds when replacing each \( x_i \) by \( v[i] \)).

In \([22]\), it was proven that a set \( S \subseteq \mathbb{N}^k \) is semilinear iff there exists a Presburger formula \( \phi \) such that \( S = \llbracket \phi \rrbracket \). Note that the set \{ \( M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \} \) has a single interesting component, the other being \( 0 \). In \([25]\), to prove that the projection of the reachability set of a Petri net on a single place is semilinear, the authors need the following lemma.

**Lemma 3.** \([27]\) Let \( S \subseteq \mathbb{N} \). If there exist \( m, t \in \mathbb{N} \) such that for all \( s \in S \), \( s + t \in S \), then \( S \) is semilinear.

This allows us to deduce the following result on periodic subsets of \( \mathbb{N} \).

**Lemma 4.** Every periodic subset \( P \subseteq \mathbb{N} \) is semilinear.

**Proof.** If \( P = \emptyset \) or \( P = \{0\} \) then it is semilinear. Otherwise, let \( m \) be the minimal strictly positive element of \( P \). Then for any \( s \in P \) such that \( s \geq m \), since \( P \) is periodic, we have \( s + m \in P \). By Lemma 3 we get that \( P \) is semilinear. \( \square \)
We now recall some connections between Petri nets and semilinear sets. Let $N = \langle P, T, \text{Pre}, \text{Post} \rangle$ be a Petri net with $P = \{p_1, \ldots, p_k\}$, this allows us to look at the markings as elements of $\mathbb{N}^k$ or of $\mathbb{N}^P$. Given a language of finite words of transitions $L \subseteq T^*$ and a marking $M$, let $\text{Reach}(M, L)$ be the reachable markings produced by $L$ from $M$ defined by $\{M' \subseteq \mathbb{N}^k \mid \exists w \in L \text{ such that } M \xrightarrow{w} M'\}$ where we extend in the classical way the relation $\Rightarrow$ over words of transitions by saying $M \Rightarrow M$ and if $w = t.w'$, we have $M \Rightarrow M'$ iff there exists $M''$ such that $M \Rightarrow M'' \Rightarrow M'$. A flat expression of transitions is a regular expression over $T$ of the form $T_1T_2\ldots T_k$ where each $T_i$ is either a finite word in $T^*$ or of the form $w^*$ with $w \in T^*$. For a flat expression $FE$, we denote by $L(\text{FE})$ its associated language. In [20], the following result relating flat expressions of transitions and their produced reachability set is given (it has then been extended to more complex systems [19]).

Proposition 2. Let $N = \langle P, T, \text{Pre}, \text{Post} \rangle$ be a Petri net, $FE$ a flat expression of transitions and $M \in \mathbb{N}^P$ a marking. Then $\text{Reach}(M, L(\text{FE}))$ is semilinear (and the corresponding Presburger formula can be computed).

4.2 Deciding if a bound is a single-place cut-off

We prove that if one provides a bound $B \in \mathbb{N}$, we are able to decide whether it corresponds to a cut-off as defined in the single place C.O.P. Let $N = \langle P, T, \text{Pre}, \text{Post} \rangle$ be a Petri net with an initial marking $M_0 \in \mathbb{N}^P$, a specific place $p_f \in P$ and a bound $B \in \mathbb{N}$. We would like to decide whether the following inclusion holds $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0)$. An important point to decide this inclusion lies in the fact that the set $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\}$ is semilinear and this allows us to use a method similar to the one proposed in [23] to check whether the reachability set of a Petri net equipped with a semilinear set of initial markings is universal. One key point is the following result which is a reformulation of a Lemma in [29]. This result was originally stated for Vector Addition System with States (VASS), but it is well known that a Petri net can be translated into a VASS with an equivalent reachability set.

Proposition 3. Let $N = \langle P, T, \text{Pre}, \text{Post} \rangle$ be a Petri net, $M \in \mathbb{N}^P$ a marking and $S \subseteq \mathbb{N}^P$ a semilinear set of markings. If $S \subseteq \text{Reach}(M)$ then there is a flat expression $FE$ of transitions such that $S \subseteq \text{Reach}(M, L(\text{FE}))$.

Following the technique used in [23], this proposition provides us a tool to solve our inclusion problem. We use two semi-procedures, one searches for a $M' \in \{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\}$ but not in $\text{Reach}(M_0)$ and the other one searches a flat expression of transitions $FE$ such that $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0, L(\text{FE}))$.

Proposition 4. For a Petri net $N = \langle P, T, \text{Pre}, \text{Post} \rangle$, a marking $M_0 \in \mathbb{N}^P$, a place $p_f \in P$ and a bound $B \in \mathbb{N}$, testing whether $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0)$ is decidable.

Proof. The two semi-procedures to decide the inclusion are the following ones:

1. If $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \not\subseteq \text{Reach}(M_0)$ then there exists $b' \geq B$ such that $M' \notin \text{Reach}(M_0)$ and $M'(p_f) = b'$ and $M'(p) = 0$ for all $p \in P \setminus \{p_f\}$. Hence a semi-procedure for non-inclusion enumerates such $b'$ and check for non-reachability of the marking $M'$.

2. If $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0)$, then, from Proposition 3, there exists a flat expression $FE$ of transitions such that $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0, L(\text{FE}))$ because the set $\{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\}$ is clearly semilinear (it can be described easily by a Presburger formula). Hence the semi-procedure for inclusion enumerates the
flat expressions of transitions $FE$, computes the semilinear set $\text{Reach}(M_0, L(FE))$ thanks to Proposition 3 and tests whether $\{M \in \mathbb{N}^P | M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \text{ and } M(p_f) \geq B\} \subseteq \text{Reach}(M_0, L(FE))$ which amounts to test the inclusion of two semilinear sets which is decidable.

\[ \square \]

4.3 Finding the bound

We now show why the single-place C.O.P. is decidable. Let $\mathcal{N} = \langle P, T, \text{Pre}, \text{Post} \rangle$ be a Petri net with a marking $M_0 \in \mathbb{N}^P$ and a place $p_f \in P$. One key aspect is that the set of markings reachable from $M_0$ with no token in the other places except $p_f$ is semilinear. This is a consequence of the following proposition.

Proposition 5. [24, Lemma IX.1] Let $S \subseteq \mathbb{N}^P$ be a semilinear set of markings. Then the set $\text{Reach}(M_0) \cap S$ is a finite union of sets $b + P$ where $b \in \mathbb{N}^P$ and $P \subseteq \mathbb{N}^P$ is periodic.

From this proposition and Lemma 4, we can deduce the following result.

Proposition 6. $\text{Reach}(M_0) \cap \{M \in \mathbb{N}^P | M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \}$ is semilinear.

Proof. From Proposition 5, we know that the set $\text{Reach}(M_0) \cap \{M \in \mathbb{N}^P | M(p) = 0 \text{ for all } p \in P \setminus \{p_f\} \}$ is equal to $\bigcup_{1 \leq i \leq \ell} b_i + P_i$ where $b_i \in \mathbb{N}^P$ and $P_i \subseteq \mathbb{N}^P$ is periodic for each $i \in [1, \ell]$. Now note that by definition for each $p \in P \setminus \{p_f\}$, we have $b_i(p) = 0$ and for each element $v \in P_i$, we have $v(p) = 0$ for all $i \in [1, \ell]$. It means that the only relevant data in this union of sets is the projection over the place $p_f$. From Lemma 4 we hence have that each $P_i$ is a semilinear set and as a direct consequence each $b_i + P_i$ is as well semilinear.

Another key point for the decidability of the single-place C.O.P. is the ability to test whether the intersection of the reachability set of a Petri net with a linear set is empty. In fact, it reduces to the reachability problem.

Lemma 5. If $S \subseteq \mathbb{N}^P$ is a linear set of the form $b + P$ where $P$ is finitely generated, then testing whether $\text{Reach}(M_0) \cap S = \emptyset$ is decidable.

Proof. We assume $P = \{\lambda_1, v_1, \ldots, \lambda_k, y_k | \lambda_i \in \mathbb{N} \text{ for all } i \in [1, k]\}$. From $\mathcal{N} = \langle P, T, \text{Pre}, \text{Post} \rangle$, we build another Petri net $\mathcal{N}' = \langle P', T', \text{Pre}', \text{Post}' \rangle$ such that:

- $P' = P \cup \{p_{\text{sim}}, p_{\text{lin}}\}$,
- $T' = T \cup \{t_{\text{lin}}, t_{\text{cons}1}, \ldots, t_{\text{cons}k}, t_{\text{end}}\}$.

Intuitively, while there is a token in place $p_{\text{sim}}$ then $\mathcal{N}'$ simulates $\mathcal{N}$ (and let the token in $p_{\text{sim}}$). Then at some point $\mathcal{N}'$ fires $t_{\text{lin}}$ which consumes the token in $p_{\text{sim}}$, consumes $b[p]$ token in each place $p \in P$ and produces a token in $p_{\text{lin}}$. Then each transition $t_{\text{cons}}$, while there is a token in $p_{\text{lin}}$ (it tests the presence but does not consume it) consumes $p_i(p)$ token in each place $p \in P$. Finally, the transition $t_{\text{end}}$ consumes the token in $t_{\text{end}}$ and does not produce any token.

- for all $t \in T$, we have $\text{Pre}'(t)(p_{\text{sim}}) = 1$, $\text{Pre}'(t)(p_{\text{lin}}) = 0$ and $\text{Pre}'(t)(p) = \text{Pre}(t)(p)$ for all $p \in P$,
- for all $t \in T$, we have $\text{Post}'(t)(p_{\text{sim}}) = 1$, $\text{Post}'(t)(p_{\text{lin}}) = 0$ and $\text{Post}'(t)(p) = \text{Post}(t)(p)$ for all $p \in P$,
- For what concerns the transition $t_{\text{lin}}$:
  - $\text{Pre}'(t_{\text{lin}})(p_{\text{sim}}) = 1$, $\text{Pre}'(t_{\text{lin}})(p_{\text{lin}}) = 0$ and $\text{Pre}'(t_{\text{lin}})(p) = b(p)$ for all $p \in P$,
  - $\text{Post}'(t_{\text{lin}})(p_{\text{sim}}) = 0$, $\text{Post}'(t_{\text{lin}})(p_{\text{lin}}) = 1$ and $\text{Post}'(t_{\text{lin}})(p) = 0$ for all $p \in P$,
The decidability of the single place C.O.P. is decidable.

Proof. We consider a Petri net \( \langle P, T, Pre, Post \rangle \), an initial marking \( M_0 \) and a place \( p_f \). We solve the single-place C.O.P. with the two following semi-procedures:

1. If there exists \( B \in \mathbb{N} \) such that for all \( n \geq B \), we have \( M^{(n)} \in \text{Reach}(M_0) \) where \( M^{(n)} \) is a marking verifying \( M^{(n)}(p_f) = n \) and \( M^{(n)}(p) = 0 \) for all \( p \in P \setminus \{p_f\} \), the first semi-procedure terminates and outputs \( B \).

The previous results allow us to design two semi-procedures to decide the single place C.O.P.

Theorem 2. The single place C.O.P. is decidable.
enumerate the $b'$ of $\mathbb{N}$ and tests whether for all $n \geq b'$, we have $M^{(n)} \in \text{Reach}(M_0)$.

According to Proposition 4, this test is possible and hence eventually the procedure finds $B$.

2. Assume there does not exist $B \in \mathbb{N}$ such that for all $n \geq B$, we have $M^{(n)} \in \text{Reach}(M_0)$ where $M^{(n)}$ is a marking verifying $M^{(n)}(p_f) = n$ and $M^{(n)}(p) = 0$ for all $p \in P \setminus \{p_f\}$. Let $F = \text{Reach}(M_0) \cap \{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\}\}$. By Proposition 5, this set is semilinear. Hence $F = \{M \in \mathbb{N}^P \mid M(p) = 0 \text{ for all } p \in P \setminus \{p_f\}\} \setminus F$ is as well semilinear. Furthermore, the hypothesis holds iff $F$ is infinite. As a consequence, there exists $b \in \mathbb{N}^P$ and a period $p \in \mathbb{N}^P$ such that $p > 0$ and $\{b + \lambda \cdot p \mid \lambda \in \mathbb{N}\} \subseteq F$. In that case, we have $\{b + \lambda \cdot p \mid \lambda \in \mathbb{N}\} \cap \text{Reach}(M_0) = \emptyset$. Hence the second semi-procedure enumerates such two vectors $b$ and $p$ in $\mathbb{N}^P$ until $\{b + \lambda \cdot p \mid \lambda \in \mathbb{N}\} \cap \text{Reach}(M_0) = \emptyset$. This test can be performed thanks to Lemma 5.

\[\square\]

Thanks to Proposition 4, we obtain the result which concludes this section.

**Corollary 1.** The C.O.P. is decidable.

## 5 The specific case of symmetric rendez-vous

Even though the C.O.P. is decidable, the lower bound is quite bad as mentioned in Theorem 2 and the decision procedure presented in the proof of Theorem 2 is quite technical. We show here that for a specific family of rendez-vous protocols, solving C.O.P. is easier.

### 5.1 Definition and basic properties

A rendez-vous protocol $P = \langle Q, Q_F, Q_L, \Sigma, q_i, q_f, q_i^L, q_f^L, E \rangle$ is symmetric if it respects the following property: for all $q, q' \in Q$ and $a \in \Sigma$, we have $(q, a, q') \in E$ iff $(q', a, q) \in E$. In this context we denote such transitions by $(q, a, q')$. We furthermore assume w.l.o.g. that in the underlying graph of $P$ for every states $q$ in $Q_F$ there is a path from $q_i$ to $q$ and a path from $q$ to $q_f$ (otherwise an initial configuration can never reach a configuration with a process in $q$ or from a configuration with a process in $q$ a final configuration can never been reached). We now work under these hypotheses.

In symmetric rendez-vous protocols, it is always possible to bring in any state as many pairs of processes one desires from the initial state $q_i$ and to remove as many pairs of processes (and bring them to the final state $q_f$). To perform such actions, it is enough to move pairs of processes following the same path (as the rendez-vous are symmetric, this is allowed by the semantics of rendez-vous protocols). We now state these properties formally. Let $P = \langle Q, Q_F, Q_L, \Sigma, q_i, q_f, q_i^L, q_f^L, E \rangle$ a symmetric rendez-vous protocol.

**Lemma 6.** Let $C \in \mathcal{C}$ verifying $C_i^{(|C_i| - 1)} \rightarrow^* C$. Then:

1. for all $C' \in \mathcal{C}$ such that $C(q) \leq C'(q)$ and $(C(q) = C'(q)) \mod 2$ for all $q \in Q$, we have $C_i^{(|C_i| - 1)} \rightarrow^* C'$, and,

2. for all $C' \in \mathcal{C}$ such that $|C'| = |C|$ and $C'(q) \leq C(q)$ for all $q \in Q \setminus \{q_f\}$ and $(C(q) = C'(q)) \mod 2$ for all $q \in Q$, we have $C_i^{(|C_i| - 1)} \rightarrow^* C'$.

**Proof.** To prove Point 1, we consider $C' \in \mathcal{C}$ such that $C(q) \leq C'(q)$ and $(C(q) = C'(q)) \mod 2$ for all $q \in Q$. And we let $n = |C| - 1$ and $m = |C'| - 1$. First note that $n \leq m$. We want to show that $C_i^{(m)} \rightarrow^* C'$. To do this we first execute from $C_i^{(m)}$ the same set of actions as in the execution $C_i^{(n)} \rightarrow^* C$. We reach then a configuration $C''$ having the following properties: $C''(q) = C(q)$ for all $q \in Q \setminus \{q_i\}$ and $C''(q_i) = C(q_i) + m - n$. Then for each $q \in Q$ such that $C(q) < C'(q)$, we can bring pairwise $C'(q) - C(q)$ processes from $q_i$ to $q$ following the path from $q_i$ to $q$. This is
possible because the considered protocol is symmetric. Note that \( C'(q) \) is necessarily even since \( (C(q) = C'(q)) \mod 2 \). This leads us to the configuration \( C'' \). To prove Point 2 we proceed similarly by bringing pairwise processes from a state \( q \) to \( q_f \).

As a consequence, we show that there is a cut-off in \( P \) iff a final configuration with an even number and another one with an odd number of processes are reachable in \( P \).

**Lemma 7.** There exists \( B \in \mathbb{N} \) such that \( C_{i}^{(n)} \rightarrow^* C_{f}^{(n)} \) for all \( n \geq B \) iff there exists an even \( n_E \in \mathbb{N} \) and an odd \( n_O \in \mathbb{N} \) such that \( C_{i}^{(n_E)} \rightarrow^* C_{f}^{(n_E)} \) and \( C_{i}^{(n_O)} \rightarrow^* C_{f}^{(n_O)} \).

**Proof.** First obviously if there exists \( B \in \mathbb{N} \) such that for all \( n \geq B \), we have \( C_{i}^{(n)} \rightarrow^* C_{f}^{(n)} \) then there exists an even natural \( n_E \) and an odd natural \( n_O \) such that \( C_{i}^{(n_E)} \rightarrow^* C_{f}^{(n_E)} \) and \( C_{i}^{(n_O)} \rightarrow^* C_{f}^{(n_O)} \). We are hence interested in showing the other direction. Assume there exists an even natural \( n_E \) and an odd natural \( n_O \) such that \( C_{i}^{(n_E)} \rightarrow^* C_{f}^{(n_E)} \) and \( C_{i}^{(n_O)} \rightarrow^* C_{f}^{(n_O)} \). Let \( B = \max(n_E, n_O) \) and \( n \geq B \). Suppose \( n \) is even. Since \( C_{i}^{(n_E)} \rightarrow^* C_{f}^{(n_E)} \) and since \( C_{i}^{(n_O)} \) is such that \( C_{f}^{(n)}(q) = C_{f}^{(n)}(q) \) for all \( q \in Q \setminus \{q_f\} \) and \( C^{(n)}(q_f) \leq C^{(n)}(q_f) \), using 1. from Lemma 7, we have \( C_{i}^{(n)} \rightarrow^* C_{f}^{(n)} \). The same technique applies when \( n \) is odd.

### 5.2 The even-odd abstraction

We now present our tool to decide C.O.P. for a symmetric rendez-vous protocol \( P = (Q, Q_P, Q_L, \Sigma, q_1, q_f, q_1^L, q_f^L, E) \). We build an abstraction of the transition system \( (C, \rightarrow) \) where we only remember the state of the leader and whether the number of processes in each state is even (denoted by \( E \)) or odd (\( O \)). Let \( \hat{E} = O \) and \( \hat{E} = E \). The set of even-odd configurations is \( \Gamma_{EO} = Q_L \times \{E, O\}^{Q_P} \). To an even-odd configuration \((q^L, \gamma) \in \Gamma_{EO}\), we associate the set of configurations \([([q^L, \gamma]] \subseteq C\) such that \([[q^L, \gamma]] = \{C \in C \mid C(q^L) = 1 \text{ and } C(q) = 0 \mod 2 \} \). We now define the even-odd transition relation \( \rightarrow_{EO} \subseteq \Gamma_{EO} \times E \times E \times \Gamma_{EO} \). We have \((q_1^L, \gamma_1) \rightarrow_{EO} (q_2^L, \gamma_2) \) iff one the following conditions holds:

1. \( e = (q_1^L, a, q_2^L) \) and \( e' = (q_1, a, q_2) \) belongs to \( Q_P \times RV(\Sigma) \times Q_P \) and if \( q_1 = q_2 \) then \( \gamma_2 = \gamma_1 \) else \( \gamma_2(q_1) = \gamma_1(q_1), \gamma_2(q_2) = \gamma_1(q_2) \) and \( \gamma_2(q) = \gamma_1(q) \) for all \( q \in Q_P \setminus \{q_1, q_2\} \).

2. \( e, e' \in Q_P \times RV(\Sigma) \times Q_P \) and \( q_1^L = q_2^L \) and \( e = (q_1, a, q_2) \) and \( e' = (q_3, a, q_4) \) and there exists \( \gamma' \in \{E, O\}^{Q_P} \) such that:
   - if \( q_1 = q_2 \) then \( \gamma' = \gamma_1 \) else \( \gamma'(q_1) = \gamma_1(q_1), \gamma'(q_2) = \gamma_1(q_2) \) and \( \gamma'(q) = \gamma_1(q) \) for all \( q \in Q_P \setminus \{q_1, q_2\} \), and,
   - if \( q_3 = q_4 \) then \( \gamma_2 = \gamma' \) else \( \gamma_2(q_3) = \gamma'(q_3), \gamma_2(q_4) = \gamma'(q_4) \) and \( \gamma_2(q) = \gamma'(q) \) for all \( q \in Q_P \setminus \{q_3, q_4\} \).

The relation \( e \rightarrow_{EO} e' \) reflects how the parity of the number of processes changes when performing a rendez-vous involving edges \( e \) and \( e' \). For instance, the first case illustrates a rendez-vous between the leader and a process, hence the parity of the number of states in \( q_1 \) and in \( q_2 \) changes except when these two control states are equal. The second case deals with a rendez-vous between two processes and it is cut in two steps to take care of the cases like for instance \( q_1 \neq q_2 \) and \( q_3 \neq q_4 \) and \( q_1 \neq q_4 \) and \( q_2 = q_3 \); in fact here the parity of the number of processes in \( q_2 \) should not change, since the first transition adds one process to \( q_2 \) and the second one removes one from it. We write \((q_1^L, \gamma_1) \rightarrow_{EO} (q_2^L, \gamma_2) \) if there exists \( e, e' \in E \) such that \((q_1^L, \gamma_1) \rightarrow_{EO} (q_2^L, \gamma_2) \) and \( \rightarrow_{EO} \) denotes the reflexive and transitive closure of \( \rightarrow_{EO} \).

As said earlier, \((\Gamma_{EO}, \rightarrow_{EO}) \) is an abstraction of \((C, \rightarrow)\). We will prove that this abstraction is enough to solve the C.O.P. For this, we define the following abstract configurations in \( \Gamma_{EO} \):
• \((q_i^L, \gamma_i^E)\) and \((q_i^F, \gamma_i^F)\) are such that \(\gamma_i^E(q) = \gamma_i^F(q) = E\) for all \(q \in Q_P\);

• \((q_i^L, \gamma_i^O)\) and \((q_i^F, \gamma_i^O)\) are such that \(\gamma_i^O(q) = \gamma_i^F(q) = O\) for all \(q \in Q_P \setminus \{q_i, q_f\}\) and \(\gamma_i^O(q_i) = \gamma_i^F(q_i) = E\) and \(\gamma_i^O(q_f) = \gamma_i^F(q_f) = O\).

Note that we have then \(\{C_i^{(n)} | n \text{ is even}\} \subseteq \{(q_i^L, \gamma_i^E)\}\) and \(\{C_i^{(n)} | n \text{ is odd}\} \subseteq \{(q_i^F, \gamma_i^F)\}\) and \(\{C_i^{(n)} | n \text{ is even}\} \subseteq \{(q_i^F, \gamma_i^F)\}\) and \(\{C_i^{(n)} | n \text{ is odd}\} \subseteq \{(q_i^F, \gamma_i^F)\}\). According to the definitions of the relations \(\rightarrow\) and \(\rightarrow^*\), we can easily deduce this first result.

**Lemma 8 (Completeness).** Let \(n \in \mathbb{N}\). If \(C_i^{(n)} \rightarrow^* C_i^{(n)}\) and \(n\) is even \(\text{[resp. } n\text{ is odd] then} \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^F, \gamma_i^F)\) \text{[resp. } (q_i^L, \gamma_i^O) \rightarrow^* (q_i^F, \gamma_i^O)\].

The two next lemmas show that our abstraction is sound for C.O.P. The first one can be proved by induction on the length of the path in \((\Gamma_{EO}, \rightarrow)\) using Point 1. of Lemma 6.

**Lemma 9.** If \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^L, \gamma)\) \text{[resp. } (q_i^L, \gamma_i^O) \rightarrow^* (q_i^L, \gamma)\] then there exists \(n \in \mathbb{N} \setminus \{0\}\) such that \(n\) is even \(\text{[resp. } n\text{ is odd]} and \(C_i^{(n)} \rightarrow^* C\) with \(C \in \{(q_i^L, \gamma)\}\).

**Proof.** Assume \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^L, \gamma_1) \rightarrow^* (q_i^L, \gamma_2) \rightarrow^* \cdots \rightarrow^* (q_i^L, \gamma_k)\) with \((q_i^L, \gamma_k) = (q_i^L, \gamma)\).

We reason by induction on \(k\). For \(k = 0\), we have \(C_i^{(2)} \in \{(q_i^L, \gamma_i^E)\}\), hence the property holds. Now suppose \(k > 1\) and that the property holds for \(k - 1\). Hence there exists \(C' \in \{(q_i^{k-1}, \gamma_i^{E_{k-1}})\}\) and \(n \in \mathbb{N} \setminus \{0\}\) such that \(n\) is even and \(C_i^{(n)} \rightarrow^* C'\). We have two cases:

1. \(e_k = (q_i^{k-1}, a, q_i^L)\) and \(e'_k = (q_i^L, a, q_i^L)\) (in other words the pair \((e_k, e'_k)\) involves a transition of the kind \(\rightarrow\)). Then to take this rendez-vous from \(C'\), we need to have \(C'(q_i^L) > 0\) but it might not be the case. However by 1. of Lemma 6 if we consider the configuration \(C''\) such that \(C''(q) = C'(q)\) for all \(q \in Q \setminus \{q_i\}\) and \(C''(q_i) = C'(q_i) + 2\) then \(C_i^{(n+2)} \rightarrow C''\). Note that by definition \(C'' \in \{(q_i^L, \gamma_i^E)\}\). From \(C''\) the rendez-vous between edges \(e_k\) and \(e'_k\) can take place and it leads to a configuration \(C\), hence \(C_i^{(n+2)} \rightarrow^* C'' \rightarrow C\), and by definition \(\rightarrow^*\) we have necessarily that \(C \in \{(q_i^L, \gamma)\}\).

2. The case where \(e_k, e'_k \in Q_P \times RV(\Sigma) \times Q_P\) can be treated similarly always thanks to Point 1. of Lemma 6.

The proof for the case where \(n\) is odd is identical.

Using Point 2. of Lemma 6 we obtain the soundness of our abstraction.

**Lemma 10 (Soundness).** If \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^F, \gamma_f^E)\) \text{[resp. } (q_i^L, \gamma_i^O) \rightarrow^* (q_i^F, \gamma_f^O)\] then there exists \(n \in \mathbb{N}\) such that \(n\) is even \(\text{[resp. } n\text{ is odd]} and \(C_i^{(n)} \rightarrow^* C_i^{(n)}\).

**Proof.** Assume \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^F, \gamma_f^E)\). Then thanks to Lemma 6 we know that there exists \(n \in \mathbb{N} \setminus \{0\}\) such that \(n\) is even and \(C_i^{(n)} \rightarrow^* C\) with \(C \in \{(q_i^L, \gamma_i^E)\}\). Note that by definition of \(\rightarrow\), we have \(|C| = n + 1\). Consider the configuration \(C''\) such that \(C''(q_i^L) = 1\) and \(C''(q_f) = n\) and \(C''(q) = 0\) for all \(q \in Q \setminus \{q_i^L, q_f\}\), then using Point 2. of Lemma 6 we have \(C_i^{(n)} \rightarrow^* C''\) and \(C'' = C_i^{(n)}\). The case where \(n\) is odd can be treated similarly.

Thanks to the Lemmas 7, 8 and 10 to solve the C.O.P. when the considered rendez-vous protocol is symmetric it is enough to check whether \((q_i^L, \gamma_i^E) \rightarrow^* (q_i^F, \gamma_f^E)\) and \((q_i^L, \gamma_i^O) \rightarrow^* (q_i^F, \gamma_f^O)\). But since the transition system \((\Gamma_{EO}, \rightarrow)\) has a finite number of vertices whose number is bounded by \(|Q_L| \cdot 2^{Q_P}|\), these two reachability questions can be solved in \(\text{NPSPACE}\) in \(|Q|\). By Savitch’s theorem, we obtain the following result.

**Theorem 3.** C.O.P. restricted to symmetric rendez-vous protocols is in \(\text{PSPACE}\).
6 Supressing the leader

6.1 Definition and properties

A rendez-vous protocol \( P = (Q, Q_P, Q_L, \Sigma, q_i, q_f, E) \) has no leader when \( Q_L = \{q_f^1\} \) and \( q_f^1 = q_f^1 \) and the transition relation does not refer to the state in \( Q_L \), i.e. \( E \subseteq Q_P \times RV(\Sigma) \times Q_P \).

We can then assume that \( P = (Q, \Sigma, q_i, q_f, E) \) and delete any reference to the leader state. We suppose again w.l.o.g. that in the considered rendez-vous protocols without leader there is a path from \( q_i \) to \( q \) and a path from \( q \) to \( q_f \) for all \( q \in Q_P \). Rendez-vous protocols with no leader enjoy some properties easing the resolution of the C.O.P.

**Lemma 11.** Let \( P = (Q, \Sigma, q_i, q_f, E) \) be a rendez-vous protocol with no leader. Then the following properties hold:

1. If \( C_i^{(n)} \rightarrow^* C_f^{(n)} \) and \( C_i^{(m)} \rightarrow^* C_f^{(m)} \) for \( m, n \in \mathbb{N} \), then \( C_i^{(n+m)} \rightarrow^* C_f^{(n+m)} \).

2. There exists \( B \in \mathbb{N} \) such that \( C_i^{(n)} \rightarrow^* C_f^{(n)} \) for all \( n \geq B \) iff there exists \( N \in \mathbb{N} \) such that \( C_i^{(N)} \rightarrow^* C_f^{(N)} \) and \( C_i^{(N+1)} \rightarrow^* C_f^{(N+1)} \).

**Proof.**

1. This point is a direct consequence of the semantics of rendez-vous protocols associated with the fact that there is no leader. In fact assume \( C_i^{(n)} \rightarrow^* C_f^{(n)} \) and \( C_i^{(m)} \rightarrow^* C_f^{(m)} \). And consider the configuration \( C \) such that \( C(q_i) = m, C(q_f) = n \) and \( C(q) = 0 \) for all \( q \in Q_P \setminus \{q_i, q_f\} \). Then it is clear that we have \( C_i^{(n+m)} \rightarrow^* C \rightarrow^* C_f^{(n+m)} \), the first part of this execution mimicking the execution \( C_i^{(n)} \rightarrow^* C_f^{(n)} \) and the last part mimics the execution \( C_i^{(m)} \rightarrow^* C_f^{(m)} \) on the \( m \) processes left in \( q_i \) in \( C \).

2. If there exists \( B \in \mathbb{N} \) such that \( C_i^{(n)} \rightarrow^* C_f^{(n)} \) for all \( n \geq B \), then we have \( C_i^{(B)} \rightarrow^* C_f^{(B)} \) and \( C_i^{(B+1)} \rightarrow^* C_f^{(B+1)} \). Assume now that there exists \( N \in \mathbb{N} \) such that \( C_i^{(N)} \rightarrow^* C_f^{(N)} \) and \( C_i^{(N+1)} \rightarrow^* C_f^{(N+1)} \). We show that for all \( n \geq N^2 \), we have \( C_i^{(n)} \rightarrow^* C_f^{(n)} \). Let \( n \geq N^2 \) and let \( R \in [0, N - 1] \) be such that \( (n = R) \mod N \). By definition of the modulo, there exists \( A \geq 0 \) such that \( n = A \cdot N + R \). Since \( n \geq N^2 \), we have necessarily \( A \geq N \). As a consequence we can rewrite \( n \) as: \( n = R \cdot (N + 1) + (A - R) \cdot N \). But then since \( C_i^{(N)} \rightarrow^* C_f^{(N)} \), by 1. we have \( C_i^{((A-R) \cdot N)} \rightarrow^* C_f^{((A-R) \cdot N)} \) and since \( C_i^{(N+1)} \rightarrow^* C_f^{(N+1)} \), by 1. we have \( C_i^{(R \cdot (N+1))} \rightarrow^* C_f^{(R \cdot (N+1))} \). By a last application of 1. we get \( C_i^{(n)} \rightarrow^* C_f^{(n)} \).

6.2 The symmetric case

We will now see how the procedure proposed in the proof of Theorem 3 to solve in polynomial space the C.O.P. for symmetric rendez-vous protocols can be simplified when there is no leader. Let \( P = (Q, \Sigma, q_i, q_f, E) \) be a symmetric rendez-vous protocol with no leader and let \((\Gamma_{EO}, \rightarrow^*)\) be the abstract transition system of \((C, \rightarrow)\) as defined in Section 5.2. If we adapt the results of Lemmas 4, 8 and 11 to the no leader case, we deduce that to solve the C.O.P. it is enough to check whether \( \gamma_i^E \rightarrow^* \gamma_f^E \) and \( \gamma_i^O \rightarrow^* \gamma_f^O \) (we have deleted the leader states from these results). Note that by definition \( \gamma_i^E = \gamma_i^E \), hence the only thing to verify is if \( \gamma_i^O \rightarrow^* \gamma_f^O \) holds. This check can be made effortlessly using the fact that there is no leader, because any reordering of a path is still a path in \((\Gamma_{EO}, \rightarrow^*)\) (since we do not need to worry anymore about the leader state) and we can delete the pairs of edges that consecutively repeat since they have the same action on the parity.

**Lemma 12.** If \( \gamma \rightarrow^* \gamma' \) then there exists \( k \leq |E|^2 \) and \( e_1, e'_1, e_2, e'_2, \ldots, e_k, e'_k \in E \) such that \( \gamma \rightarrow^* \gamma_1 \rightarrow^* \ldots \rightarrow^* \gamma_k \rightarrow^* \gamma' \).
Proof. Assume $\gamma_{e_1,e_1'} \to \gamma_{e_1,e_2} \to \ldots \to \gamma_{e_k,e_k'} \to \gamma'$ with $k > |E|^2$. Consequently there exists $i, j \in [1, k]$ such that $i \neq j$ and $(e_i, e_i') = (e_j, e_j')$. Note that according to the semantics of $\to$, when there is no leader, if we have $\gamma'' \to_{e_e} \gamma_1 \to_{e_2} \gamma_2$ then we also have $\gamma'' \to_{e} \gamma_3 \to_{e} \gamma_2$ and furthermore if $(e, e') = (d, d')$ then $\gamma'' = \gamma_2$. As a consequence, we can assume that $j = i + 1$ (otherwise we can reorder the run) and that $\gamma_i = \gamma_{i+2}$. This allows us to shorten the execution from $\gamma$ to $\gamma'$ by deleting the edges $e_i生活的enlE_{i+1}$. We can repeat this operation until we obtain a run of length strictly smaller that $|E|^2$. \hfill \Box

It means that if $\gamma \xrightarrow{\delta_0} \gamma'$ then there is a path of polynomial length (in the size of $\mathcal{P}$) between these two abstract configurations. It is hence enough to guess such a sequence of polynomial length and to check that it effectively corresponds to a path in $(\Gamma_{EO}, \to)$. 

**Theorem 4.** C.O.P. for symmetric rendez-vous protocols with no leader is in NP.

### 6.3 Upper bound for the C.O.P. with no leader

We now prove that the C.O.P. for rendez-vous protocols with no leader reduces to the reversible reachability problem in Petri nets. Let $\mathcal{P} = (Q, \Sigma, q_i, q_f, E)$ be a rendez-vous protocol with no leader and such that w.l.o.g., there is no edge going out of $q_f$.

Let $N_\mathcal{P} = (P, T, Pre, Post)$ be the Petri net whose construction is provided in Section 5.2 (where we have removed all the places corresponding to leader states as well as the transition $t_f$). From $N_\mathcal{P}$, we build the reverse Petri net $N^R_\mathcal{P}$ obtained by keeping the same set of places and reversing all the transitions. Formally $N^R_\mathcal{P} = (P^R, T^R, Pre^R, Post^R)$, where $P^R = \{p^R | p \in P\}$, $T^R = \{t^R | t \in T\}$ and for all $p^R \in P^R$ and $t^R \in T^R$, we have $Pre^R(t^R)(p^R) = Post(t)(p)$ and $Post^R(t^R)(p^R) = Pre(t)(p)$. Let $M_0^R$ be the marking such that $M_0^R(p^R) = 0$ for all $p^R \in P^R$ and $(M^R_f(n))_{n \in \mathbb{N}}$ be the family of markings verifying $M^R_f(n)(p^R) = n$ and $M^R_f(n)(p) = 0$ for all $p \in P^R \setminus \{p_f^R\}$. A direct consequence of Lemma 2 and of the definition of $N^R_\mathcal{P}$ is that $C_i(n) \rightarrow C_f(n)$ iff $M_0^R \in Reach(M^R_f(n))$ for all $n \in \mathbb{N}$.

From $N_\mathcal{P}$ and $N^R_\mathcal{P}$, we build the Petri net $N'_\mathcal{P}$ obtained by taking the disjoint unions of places and transitions of the two nets except for the place $p_{q_i}$ and $p_{q_f}^R$ which are merged in a single place $p_1$. Formally, $N'_\mathcal{P} = (P', T', Pre', Post')$ where $P' = (P \cup P^R) \setminus \{p_{q_i}^R\}$, $T' = T \cup T^R$, $Pre'(t)(p) = Pre(t)(p)$ and $Post'(t)(p) = Post(t)(p)$ and $Pre'(t)(p^R) = Pre'(t)(p^R)$ and $Post'(t)(p^R) = Post'(t)(p^R)$ and $Pre'(t^R)(p^R) = Post'(t^R)(p^R) = Post'(t^R)(p^R)$ and $Pre'(t^R)(p) = Post'(t^R)(p) = 0$ for all $p \in P$, $p^R \in P^R$ and $t \in T$, $Pre'(t^R)(p^R) = Pre'(t^R)(p^R)$ and $Post'(t^R)(p^R) = Post'(t^R)(p^R)$ and $Pre'(t^R)(p) = 0$ for all $p \in P^R$, $p \in P \setminus \{p_{q_i}\}$ and $t \in T$, and $Pre'(t^R)(p_{q_i}) = 0$ and $Post'(t^R)(p_{q_i}) = Post'(t^R)(p_{q_i})$. Figure 5 provides an example of this latter Petri net.

We now explain why this new net is useful to solve the C.O.P. when there is no leader. First remember that thanks to Point 2. of Lemma 11 it is enough to check whether there exists $N \in \mathbb{N}$ such that $C_i(N) \rightarrow C_f(N)$ and $C_i(N+1) \rightarrow C_f(N+1)$. Intuitively, in $N'_\mathcal{P}$ this property will be witnessed by the fact that we can bring $N + 1$ tokens in $p_{q_i}$ using transitions in $T$ and remove $N$ tokens from $p_{q_i}$ thanks to the transitions in $T^R$ letting hence one token in $p_{q_i}$, and similarly if there is already a token in $p_{q_i}$ we can bring $N$ others and remove afterwards $N + 1$. As for $N_\mathcal{P}$, we let $M_0$ be the marking with no token, and $(M(n))_{n \in \mathbb{N}}$ be the family of markings such that $M(n)(p_{q_i}) = n$ and $M(n)(p) = 0$ for all $p \in P' \setminus \{p_{q_i}\}$. Note that since there is no leader, we have here $M_0 = M^{(0)}$. The next lemma states the correctness of our reduction to the reversible reachability problem.

**Lemma 13.** There exists $N \in \mathbb{N}$ such that $C_i(N) \rightarrow C_f(N)$ and $C_i(N+1) \rightarrow C_f(N+1)$ iff $M^{(1)} \in \overline{Reach(M_0)}$ and $M_0 \in \overline{Reach(M^{(1)})}$ in the Petri net $N'_\mathcal{P}$.

---

1To achieve this, we can simply duplicate $q_f$ adding a new final state $q'_f$ and for each edge going into $q_f$ we add an edge from the same state to $q'_f$. 

---

16
Theorem 5. C.O.P. restricted to rendez-vous protocols with no leader is in EXPSPACE.

Proof. Assume that there exists $N \in \mathbb{N}$ such that $C_i^{(N)} \rightarrow^* C_f^{(N)}$ and $C_i^{(N+1)} \rightarrow^* C_f^{(N+1)}$ then in $N'_p$ from $M^{(0)}$ we can reach $M^{(N+1)}$ taking only transitions in $T$ (thanks to Lemma 2) and from $M^{(N+1)}$ we can reach $M^{(1)}$ letting one token in $p_{q_1}$ and removing all the other tokens using only transitions in $T^R$ (and again using Lemma 2 and the fact that $C_i^{(N)} \rightarrow^* C_f^{(N)})$. Hence $M^{(1)} \in \text{Reach}(M_0)$. Similarly we can show that $M_0 \in \text{Reach}(M^{(1)})$ by from $M^{(1)}$ reaching $M^{(N+1)}$ using transitions in $T$ and the fact that $C_i^{(N)} \rightarrow^* C_i^{(N)}$. And then from $M^{(N+1)}$ we can reach $M_0$ using transitions in $T^R$ and the fact that $C_i^{(N+1)} \rightarrow^* C_f^{(N+1)}$.

Assume now that $M^{(1)} \in \text{Reach}(M_0)$. Note that in the execution from $M_0$ to $M^{(1)}$, we can assume that first the only transitions that occur are in $T$ and then the only used transitions belong to $T^R$, because the only common place between these two sets of transitions is $p_{q_1}$ and transitions from $T$ only produce tokens in this place whereas transitions in $p_{q_1}$ only consume them (remember we assume that in $P$ no transition goes out of $q_f$). Hence in $N'$ we have an execution of the form $M_0 \overset{t_0}{\Rightarrow} \ldots \overset{t_k}{\Rightarrow} M \overset{t'_0}{\Rightarrow} \ldots \overset{t'_l}{\Rightarrow} M^{(1)}$ where $\{t_0, \ldots, t_k\} \subseteq T$ and $\{t'_0, \ldots, t'_l\} \subseteq T^R$. Since the transitions in $T$ only consume and produce tokens in $P$ and the one in $T^R$ only consume tokens in $P^R$. From Lemma 2, we deduce that there exists some $N$ such that $M \in M^{(N+1)}$. Using Lemma 2 we deduce from $M^{(N+1)} \in \text{Reach}(M_0)$ that $C_i^{(N+1)} \rightarrow^* C_f^{(N+1)}$ and from the fact that $M^{(1)} \in \text{Reach}(M^{(N+1)})$ in $N'_p$ using only transitions in $T^R$ that we have as well $M_0 \in \text{Reach}(M^{(N)})$ in $N'^R$ and consequently $C_i^{(N)} \rightarrow^* C_f^{(N)}$.

Since we know that the reversible reachability problem for Petri net is EXPSPACE-complete [30], we obtain the following complexity result.

Theorem 5. C.O.P. restricted to rendez-vous protocols with no leader is in EXPSPACE.

We were not able to propose a lower bound for the C.O.P. apart for the general case, but when there is no leader, we know that there is a protocol which admits a cut-off whose value is exponential in the size of a protocol. This protocol is shown on Figure 6. To bring a process in $q_1$, we need in fact two processes, to bring a process in $q_2$ and empty $q_1$, we need four processes and so on. The letter $a$ is then used to ensure that as soon as we have processes only in $q_a$ and in $q_i$ (and at least one of them in each of these states), there is a way to bring all of them in $q_f$.

7 Conclusion

We have shown here that the C.O.P. is decidable for rendez-vous networks. Furthermore we have provided complexity upper bounds when considering restrictions on the networks such as symmetric rendez-vous or absence of leader. Unfortunately, we did not succeed in finding matching lower bounds. Reducing other problems to the C.O.P. is in fact tedious without leader or when allowing only symmetric rendez-vous, because it is then quite hard to enforce that a specific number of processes are in some states which is a property that is in general needed to design
reductions. However we have some hope to either improve our upper bounds or find matching lower bounds. We wish as well to understand in which matters the techniques we used could be adapted to other parameterized systems and more specifically to population protocols. Finally, one of the justification to consider the cutoff problem is that in some distributed systems it could be the case that a correctness property does not hold for any number of processes, but that a minimal number of participants is needed to reach a goal. It could be interesting to study a variant of our cutoff problem where we do not require all the processes to reach a final state but we want to know given a number of processes how many among them can be brought in such a state. An interesting property could be to check whether there exists a bound $b$ such that for any number of processes, the minimal number that can not be brought to a final state by any execution is always lower than $b$. In such networks, it would mean that at most $b$ entities have to be sacrificed to let the others reach the final state.
