Sharp decouplings for three dimensional manifolds in $\mathbb{R}^5$

Ciprian Demeter, Shaoming Guo and Fangye Shi

Abstract

We prove a sharp decoupling for a class of three dimensional manifolds in $\mathbb{R}^5$.

1 Introduction

For two symmetric matrices $A_1, A_2 \in M_3(\mathbb{R})$ consider the quadratic forms

$$Q_i(r, s, t) = [r, s, t] A_i [r, s, t]^T$$

and the associated three dimensional quadratic surface in $\mathbb{R}^5$ given by

$$S = S_{A_1, A_2} := \{(r, s, t, Q_1(r, s, t), Q_2(r, s, t)) : (r, s, t) \in [0, 1]^3\}.$$  \hfill (1.1)

For a measurable subset $R \subset [0, 1]^3$ and a measurable function $g : R \to \mathbb{C}$, define the extension operator associated with $R$ and $S$ by

$$E_R^S g(x) = \int_R g(r, s, t) e^{i (rx_1 + sx_2 + tx_3 + Q_1(r, s, t)x_4 + Q_2(r, s, t)x_5)} drdsdt.$$  \hfill (1.2)

Here and throughout the rest of this paper, we will write

$$e(z) = e^{2\pi iz}, \quad z \in \mathbb{R}.$$  

For a positive weight $w : \mathbb{R}^5 \to (0, \infty)$, define the weighted $L^p$ norm

$$\|f\|_{L^p(w)} = \left( \int_{\mathbb{R}^5} |f(x)|^p w(x) dx \right)^{1/p}.$$  

For a ball $B_N$ centered at $c(B)$ with radius $N$, we let $w_B$ denote the weight

$$w_B(x) = \frac{1}{(1 + \frac{|x-c(B)|}{N})^C}.$$  

The exponent $C$ is a large but unspecified constant.

Given $N \geq 1$, $p \geq 2$ and $S$ as in (1.1), let $D_S(N, p)$ be the smallest constant such that the following so-called $p^\ell p^\ell$ decoupling inequality

$$\|E_{[0, 1]^3} g\|_{L^p(w_{B_N})} \leq D_S(N, p) \left( \sum_{\Delta \subset [0, 1]^3 \atop l(\Delta) = N^{-1/2}} \|E_{\Delta}^g\|_{L^p(w_{B_N})}^p \right)^{1/p}$$  \hfill (1.3)

holds true for each $g : [0, 1]^3 \to \mathbb{C}$ and each ball $B_N \subset \mathbb{R}^5$ of radius $N$. Here the summation runs over a finitely overlapping cover of $[0, 1]^3$ by squares $\Delta$ of side length $l(\Delta) = N^{-1/2}$.

The estimate

$$D_S(N, 2) \sim 1$$  \hfill (1.4)

is an easy consequence of $L^2$ orthogonality, while the estimate

$$D_S(N, \infty) \sim N^{3/2}$$  \hfill (1.5)
follows from the triangle inequality (upper bound) and from testing (1.3) with \( g \equiv 1 \) (lower bound). Also, we will see in the last section that we have the following universal lower bound

\[ D_S(N, p) \geq \max \{ N^{\frac{3}{2}}(\frac{1}{2} - \frac{1}{p}), N^\frac{3}{2} - \frac{5}{p} \} . \]  

(1.6)

Our main result identifies a large class of manifolds for which this universal lower bound is essentially sharp. It may in fact be the case that this is the largest class of quadratic manifolds with this property.

**Theorem 1.1.** Assume that for each nonzero vector \((u, v, w) \in \mathbb{R}^3\), the determinant

\[ \det \begin{bmatrix} \frac{\partial Q_i}{\partial r} & \frac{\partial Q_i}{\partial s} & \frac{\partial Q_i}{\partial t} \\ \frac{\partial Q_2}{\partial r} & \frac{\partial Q_2}{\partial s} & \frac{\partial Q_2}{\partial t} \\ u & v & w \end{bmatrix} \]

is not the zero polynomial, when regarded as a function of \( r, s, t \). Then for each \( \epsilon > 0 \) and each \( p \geq 2 \), there exists \( C_{\epsilon, p} \) such that

\[ D_S(N, p) \leq \begin{cases} C_{\epsilon, p} N^{\frac{3}{2}}(\frac{1}{2} - \frac{1}{p}) + \epsilon, & \text{if } 2 \leq p \leq \frac{14}{3} \\ C_{\epsilon, p} N^{\frac{3}{2} - \frac{5}{p}} + \epsilon, & \text{if } p \geq \frac{14}{3} \end{cases} \]  

(1.7)

The standard consequence of (1.7) for exponential sums is discussed in the last section. There are other interesting applications to the decoupling theory of curves that will appear elsewhere. In the next section we will derive the following corollary.

**Corollary 1.2.** Let \( A_1, A_2 \in M_3(\mathbb{R}) \) be two symmetric matrices, such that there exists an invertible matrix \( M \in \text{GL}_3(\mathbb{R}) \) satisfying

\[ M^T A_i M = \begin{bmatrix} \lambda_{i,1} & 0 & 0 \\ 0 & \lambda_{i,2} & 0 \\ 0 & 0 & \lambda_{i,3} \end{bmatrix}, \quad 1 \leq i \leq 2. \]  

(1.8)

Let \( S \) be the surface defined in (1.1).

(a) Assume that all the two by two minors of the matrix

\[ \begin{bmatrix} \lambda_{1,1} & \lambda_{1,2} & \lambda_{1,3} \\ \lambda_{2,1} & \lambda_{2,2} & \lambda_{2,3} \end{bmatrix} \]  

(1.9)

have nonzero determinant. Then (1.7) holds.

(b) If at least one of the two by two minors of (1.9) is singular then we have

\[ \lim_{N \to \infty} \frac{D_S(N, p)}{N^{\frac{3}{2}(\frac{1}{2} - \frac{1}{p})}} = \infty \]  

(1.10)

for each \( p > 4 \).

The requirement from (1.8) is rather mild, in particular it does not force \( A_1 \) and \( A_2 \) to commute. See [1] for details. But inequality (1.7) also holds true in some cases when \( A_1, A_2 \) do not satisfy (1.8). One such example is the manifold

\[ \{(r, s, t, r^2 + s^2, st) : (r, s, t) \in [0, 1]^3 \}, \]

which certainly falls under the scope of Theorem 1.1.
Due to (1.6), the upper bounds in (1.7) are sharp (apart from the $N^\epsilon$ term). It will suffice to prove the estimate (1.7) at the critical exponent $\frac{14}{13}$, as then we can interpolate it with (1.4) and (1.5). We refer the reader to [4] for details on how to interpolate decoupling inequalities.

The reason we only consider quadratic manifolds is because in some sense they tell the whole story. Indeed, on the one hand (1.6) shows that the decoupling constants for two dimensional manifolds in $\mathbb{R}^2$ do not get smaller in the presence of cubic or higher order terms. In other words, the critical exponent is never larger than $\frac{14}{13}$. On the other hand, each manifold can be locally approximated with quadratic manifolds (Taylor’s formula), and the general theory can be understood by invoking induction on scales as in [13] (see also Section 7 from [4]).

Part (b) of Corollary 1.2 says that if the critical exponent is smaller than $\frac{14}{13}$, it is in fact at most 4. These manifolds exhibit various levels of degeneracy, and classifying them will not be our concern here. A more detailed discussion is included in the next section. One surprising example that falls into this category is the very symmetric manifold

$$\{(r, s, t, r^2 + s^2 + t^2, rs + rt + st) : (r, s, t) \in [0, 1]^3\}.$$

In this case $A_1$ is the identity matrix, so (1.8) is easily satisfied. The second matrix will have two equal eigenvalues.

One difficulty when approaching three dimensional manifolds in $\mathbb{R}^3$, and in general the $d$-dimensional manifolds in $\mathbb{R}^n$ with $d \neq 1, n - 1$, is the lack of an appropriate notion of “curvature”. In the case of hypersurfaces ($d = n - 1$) decouplings are guided by the principal curvatures, while for curves ($d = 1$), by torsion. Similar difficulties have been previously encountered when trying to establish the restriction theory for manifolds with $1 < d < n - 1$. We hope that our current work will reignite the interest in this circle of problems.

This paper follows the methodology developed by the first author with Jean Bourgain in recent related papers. Most of the material in sections 3, 6 and 7 is rather standard. The main new subtleties appear in Section 4. More precisely, Section 4 addresses the lower dimensional contribution from the Bourgain–Guth-type iteration where a new difficulty arises this time. More precisely, on each $B_K$ the lower dimensional contribution is now clustered in the $K^{-1/2}$-neighborhood of a lower dimensional manifold. This scenario also appeared in a simpler context in [5] (see Claim 5.10 there). The difficulty arises due to the fact that the scale $K^{-1/2}$ is too big to be accommodated by the uncertainty principle (since the spatial ball $B_K$ has scale $K$). To address this issue we prove that this $K^{-1/2}$-neighborhood is within $O(K^{-1})$ from a cylinder. We then combine previous decouplings with appropriate cylindrical decouplings. In previous papers the lower dimensional contribution could be localized in $K^{-1}$-neighborhoods of a lower dimensional manifolds. The reason why we need the larger $K^{-1/2}$-neighborhoods here will become more transparent in the proof of Proposition 6.4.

In Section 8 we prove that the only obstructions to transversality are the 2-varieties. With some extra work we could probably reduce the list of enemies to planes and curves, but we do not pursue this approach. Instead, it turns out that we can control the lower dimensional contribution clustered near each 2-variety, once we can do it for planes. This follows via an approximation argument very similar to the one from [12], that we describe in Section 5.

In the last section we describe some related examples and post some open questions.

2 Linear algebra reductions

In this section we demonstrate that the decoupling theory is essentially invariant under certain transformations. This will allow us to give a simple proof of Corollary 1.2 using Theorem 1.1.

**Proposition 2.1.** Let $A_1, A_2 \in M_3(\mathbb{R})$, $M \in GL_3(\mathbb{R})$ and $\beta = [\beta_{ij}]_{1 \leq i, j \leq 2} \in GL_2(\mathbb{R})$. Define

$$B_i := M^T(\beta_{i,1} A_1 + \beta_{i,2} A_2) M, \quad 1 \leq i \leq 2.$$
Let \( D_1(N,p) \) and \( D_2(N,p) \) be the decoupling constants associated with \( S_{A_1,A_2} \) and \( S_{B_1,B_2} \), respectively. Then for each \( p \geq 2 \)

\[ D_1(N,p) \sim_{p,M,\beta} D_2(N',p), \]

where \( N' \sim_{M,\beta} N \).

**Proof.** Denote by \( E^{(1)} \) and \( E^{(2)} \) the extension operators associated with the two surfaces. For each square \( R \subset [0,1]^3 \) we may write, denoting \( v = (r,s,t) \) and using the changes of variables

\[ v = L_M(w) := wM^T \]

and

\[ E_R^{(1)} g(x_1, \ldots, x_5) = \int_R g(v) e(v \cdot (x_1,x_2,x_3) + vA_1v^T x_4 + vA_2v^T x_5) dv = \]

\[ \det(M) \int_{(L_M)^{-1}R} g \circ L_M(w) e(w \cdot (y_1,y_2,y_3) + wM^T A_1 Mw^T x_4 + wM^T A_2 Mw^T x_5) dw = \]

\[ \det(M) \int_{(L_M)^{-1}R} g \circ L_M(w) e(w \cdot (y_1,y_2,y_3) + wB_1w^T y_4 + wB_2w^T y_5) dw = \]

\[ \det(M)E^{(2)}_{(L_M)^{-1}R} g \circ L_M(y_1,y_2,y_3,y_4,y_5). \]

The proposition will now follow once we make two observations. First, since \( \beta \) and \( M \) are nonsingular, the transformation

\[ T(x_1, \ldots, x_5) = (y_1,y_2,y_3,y_4,y_5) \]

has finite distortion. In particular, for each ball \( B \subset \mathbb{R}^5 \)

\[ w_B(T^{-1}y) \sim w_B(y). \]

Second, \( (L_M)^{-1}R \) will be a parallelogram with area comparable to the area of \( R \), and which sits inside a square \( R' \) with side length comparable to that of \( R \). In particular, if \( l(R) = N^{-1/2} \) then

\[ \| E^{(2)}_{(L_M)^{-1}R} h \|_{L^p(w_B \mathcal{N})} \lesssim \| E^{(2)}_R h \|_{L^p(w_B \mathcal{N})} . \]

This can be seen by observing that \( F_1 = E^{(2)}_{(L_M)^{-1}R} h \) and \( F_2 = E^{(2)}_R h \) are related via

\[ \hat{F}_1 = \hat{F}_2 1_P, \]

with \( P \) a rectangular box in \( \mathbb{R}^5 \) having three side lengths comparable to \( N^{-1/2} \) and two of them comparable to \( N^{-1} \).

The details are left to the interested reader. \( \square \)

As a first application of this result, we prove part (b) of Corollary 1.2. It is rather immediate that the existence of a singular two by two minor of (1.9) leads to the existence of a \( \beta \in GL_2(\mathbb{R}) \) so that the matrix

\[ \beta \left[ \begin{array}{ccc} \lambda_{1,1} & \lambda_{1,2} & \lambda_{1,3} \\ \lambda_{2,1} & \lambda_{2,2} & \lambda_{2,3} \end{array} \right] \]

is of one of the following types

\[ \begin{bmatrix} 0 & 0 & 0 \\ a & b & c \end{bmatrix} \]

\[ \begin{bmatrix} 0 & 0 & c \\ a & b & 0 \end{bmatrix} \]
with $a, b, c \in \{0, 1, -1\}$. In the first case, the decoupling constant of $S$ will be comparable to that of the manifold in $\mathbb{R}^4$

$\{(r, s, t, ar^2 + bs^2 + ct^2), 0 \leq r, s, t \leq 1\}$.

The most favorable case is when $a, b, c \neq 0$, when most curvature is present. In [8] it is proved that the critical index for this manifold is $\frac{10}{3}$. In particular,

$$\lim_{N \to \infty} \frac{D_S(N, p)}{N^{\frac{1}{2}(\frac{1}{2} - \frac{1}{p})}} = \infty, \quad p > \frac{10}{3}.$$

The remaining three cases are symmetric, so it suffices to consider the first one. The decoupling constant of $S$ will in this case be comparable to that of the product-type manifold

$S_{\text{prod}} := \{(r, s, t, ar^2 + bs^2, ct^2), 0 \leq r, s, t \leq 1\}$.

Let

$S_1 = \{(r, s, ar^2 + bs^2), 0 \leq r, s \leq 1\}$

and

$S_2 = \{(t, ct^2), 0 \leq t \leq 1\}$.

By testing (1.3) with functions of the form $g(r, s, t) = g_1(r, s)g_2(t)$ we see that

$$D_{S_{\text{prod}}}(N, p) \gtrsim D_{S_1}(N, p)D_{S_2}(N, p).$$

The values of $D_{S_1}(N, p)$ and $D_{S_2}(N, p)$ are smallest when $a, b, c \neq 0$, which guarantees most curvature. But even in this case, the results in [8] show that

$$\lim_{N \to \infty} \frac{D_{S_1}(N, p)}{N^{\frac{1}{2} - \frac{1}{p}}} = \infty, \quad p > 4$$

$$D_{S_2}(N, p) \gtrsim N^{\frac{1}{2}(\frac{1}{2} - \frac{1}{p})}, \quad p \geq 2.$$

Combining these leads to the desired estimate

$$\lim_{N \to \infty} \frac{D_{S_{\text{prod}}}(N, p)}{N^{\frac{1}{2}(\frac{1}{2} - \frac{1}{p})}} = \infty, \quad p > 4$$

Proposition 2.1 also has the following rather immediate consequence.

**Corollary 2.2.** Let $A_1, A_2 \in M_3(\mathbb{R})$ satisfy the requirement of part (a) of Corollary 1.2, and let $S_{A_1, A_2}$ be the associated surface. Then

$$D_{S_{A_1, A_2}}(N, p) \sim_{p, M, \beta} D_S(N', p),$$

where $N' \sim_{A_1, A_2} N$ and

$S := \{(r, s, t, \frac{1}{2}(r^2 + As^2), \frac{1}{2}(t^2 + Bs^2)) : (r, s, t) \in [0, 1]^3\}, \quad (2.1)$

for some $A, B \neq 0$ depending on $A_1, A_2$.

It is now immediate that part (a) of Corollary 1.2 will follow from Theorem 1.1.
**Remark 2.3.** It is easy to see that the requirement in Theorem 1.1 is invariant under nonsingular linear changes of variables. Indeed, assume $Q_1, Q_2$ satisfy this requirement, and let $B \in M_3(\mathbb{R})$ be nonsingular. Define $\tilde{Q}_i(r,s,t) = Q_i(B[r,s,t]^T)$. It now suffices to note that

$$
\begin{bmatrix}
\frac{\partial \tilde{Q}_i}{\partial r}(v) & \frac{\partial \tilde{Q}_i}{\partial s}(v) & \frac{\partial \tilde{Q}_i}{\partial t}(v) \\
\frac{\partial \tilde{Q}_i}{\partial r}(v') & \frac{\partial \tilde{Q}_i}{\partial s}(v') & \frac{\partial \tilde{Q}_i}{\partial t}(v')
\end{bmatrix} = B
\begin{bmatrix}
\frac{\partial Q_i}{\partial r}(v) & \frac{\partial Q_i}{\partial s}(v) & \frac{\partial Q_i}{\partial t}(v) \\
\frac{\partial Q_i}{\partial r}(v') & \frac{\partial Q_i}{\partial s}(v') & \frac{\partial Q_i}{\partial t}(v')
\end{bmatrix}
$$

where $[u, v, w] = [u', v', w']B$ and $v = (r, s, t)$, $v' = B[r, s, t]^T$.

This observation allows us to prove the following result that will be used later.

**Lemma 2.4.** Assume $Q_1, Q_2$ satisfy the requirement in Theorem 1.1. Then for each plane $H \subset \mathbb{R}^3$, one of the restrictions $Q_1|_H$, $Q_2|_H$ is not identically equal to zero. In particular, there exists $\eta > 0$ so that for each $\alpha, \beta, \gamma = O(1)$, at least one of the quadratic polynomials (in $r$ and $s$)

$$Q_i(r, s, \alpha + \beta r + \gamma s)$$

has a quadratic term with coefficient of absolute value at least $\eta$.

**Proof.** The proof of the first part goes by contradiction. The existence of an $H$ such that $Q_1|_H \equiv 0$ and $Q_2|_H \equiv 0$ forces a decomposition

$$Q_i = PP_i$$

with $P, P_1, P_2$ linear factors. By making a nonsingular change of variables we may assume that, say, $P = t$. Then writing

$$\tilde{Q}_i = t(a_i r + b_i s + c_i t)$$

we get

$$
\begin{bmatrix}
\frac{\partial \tilde{Q}_i}{\partial r} & \frac{\partial \tilde{Q}_i}{\partial s} & \frac{\partial \tilde{Q}_i}{\partial t} \\
\frac{\partial Q_i}{\partial r} & \frac{\partial Q_i}{\partial s} & \frac{\partial Q_i}{\partial t}
\end{bmatrix} = t^2 \begin{bmatrix}
a_1 & b_1 & 2c_1 \\
a_2 & b_2 & 2c_2
\end{bmatrix}.
$$

The determinant of this is zero everywhere, for an appropriate choice of $(u, v, w)$. Remark 2.3 now leads to a contradiction.

For the second part, apply first a compactness argument to settle the case when $\alpha = 0$. Note that in this case both polynomials $Q_i(r, s, \alpha + \beta r + \gamma s)$ have purely quadratic terms. It then suffices to note that the purely quadratic part remains unchanged by $\alpha$.

\[\square\]

The rest of the paper will be concerned with the proof of Theorem 1.1.

### 3 Transversality

Let $m$ be a positive integer. For $1 \leq j \leq m$, let $V_j$ be a $d$-dimensional linear subspace of $\mathbb{R}^n$. Let also $\pi_j : \mathbb{R}^n \to V_j$ denote the orthogonal projection onto $V_j$. Define

$$\Lambda(f_1, f_2, ..., f_m) = \int_{\mathbb{R}^n} \prod_{j=1}^m f_j(\pi_j(x)) dx,$$

(3.1)

for $f_j : V_j \to \mathbb{C}$. We recall the following theorem from Bennett, Carbery, Christ and Tao [2].
Theorem 3.1. Given $p \geq 1$, the estimate

$$|\Lambda(f_1, f_2, \ldots, f_m)| \lesssim \prod_{j=1}^{m} \|f_j\|_p,$$  
(3.2)

holds if and only if $np = dm$ and the following Brascamp-Lieb transversality condition is satisfied

$$\dim(V) \leq \frac{1}{p} \sum_{j=1}^{m} \dim(\pi_j(V)), \text{ for each linear subspace } V \subset \mathbb{R}^n.$$  
(3.3)

An equivalent formulation of the estimate (3.2) is

$$\left\| \left( \prod_{j=1}^{m} g_j \circ \pi_j \right)^{1/m} \right\|_q \lesssim \left( \prod_{j=1}^{m} \|g_j\|_2 \right)^{1/m},$$  
(3.4)

with $q = \frac{2n}{d}$. The restriction that $p \geq 1$ becomes $dm \geq n$. The transversality condition (3.3) becomes

$$\dim(V) \leq \frac{n}{dm} \sum_{j=1}^{m} \dim(\pi_j(V)), \text{ for each subspace } V \subset \mathbb{R}^n.$$  
(3.5)

Now let us be more specific about $d, n$ and $m$. In this section, we will take $n = 5$, since we are considering a three dimensional surface $S$ in $\mathbb{R}^5$. We will take $d = 3$, since the tangent space to $S$ has dimension three. The degree $m$ of multilinearity is more complicated. It will not be a fixed integer, but will rather depend on the scale of the sets (cubes) we are using.

With this numerology (3.4) becomes

$$\left\| \left( \prod_{j=1}^{m} g_j \circ \pi_j \right)^{1/m} \right\|_{L^{2n/3}(\mathbb{R}^5)} \lesssim \left( \prod_{j=1}^{m} \|g_j\|_2 \right)^{1/m},$$  
(3.6)

and the condition (3.5) becomes

$$\dim(V) \leq \frac{5}{3m} \sum_{j=1}^{m} \dim(\pi_j(V)), \text{ for each subspace } V \subset \mathbb{R}^5.$$  
(3.7)

Fix now $S$ satisfying the requirement of Theorem 1.1. We will next try to understand what it mean for (3.7) to be satisfied, given that $V_j$ are the tangent spaces to $S$ at the points $(r_j, s_j, t_j) \in [0, 1]^3$. We will see that this means that a rather big fraction of these points should not belong to a 2-variety. By that we will mean the (real) zero set of a nontrivial polynomial $P(r, s, t)$ of degree at most two.

In order to achieve this, we need more notation. Let $\mathcal{M}$ be an $m \times n$ matrix with $m \geq n$. We define $\det(\mathcal{M})$ to be the $l^1$ sum of the determinants of all $n \times n$ sub-matrices of $\mathcal{M}$.

At one point $(r, s, t) \in [0, 1]^3$, we denote by $n_1, n_2$ and $n_3$ the three tangent vectors of the surface $S$ given by

$$n_1 = (1, 0, 0, \frac{\partial Q_1}{\partial r}, \frac{\partial Q_2}{\partial r}),$$
$$n_2 = (0, 1, 0, \frac{\partial Q_1}{\partial s}, \frac{\partial Q_2}{\partial s}),$$
$$n_3 = (0, 0, 1, \frac{\partial Q_1}{\partial t}, \frac{\partial Q_2}{\partial t}).$$  
(3.8)

The tangent space they span will be denoted by $V_{r,s,t}$. The projection onto this space will be denoted by $\pi_{r,s,t}$. 

7
For a one dimensional subspace $V \subset \mathbb{R}^5$ spanned by a unit vector $x$, denote by $M_V(r, s, t)$ the $1 \times 3$ matrix
\[
(x \cdot n_1, x \cdot n_2, x \cdot n_3).
\] (3.9)

For a two dimensional subspace $V \subset \mathbb{R}^5$ spanned by two orthogonal unit vectors $x, y \in \mathbb{R}^5$, denote by $M_V(r, s, t)$ the $2 \times 3$ matrix
\[
\begin{pmatrix}
x \cdot n_1 & x \cdot n_2 & x \cdot n_3 \\
y \cdot n_1 & y \cdot n_2 & y \cdot n_3
\end{pmatrix}
\] (3.10)

Similarly, for a four dimensional subspace $V \subset \mathbb{R}^5$ spanned by four orthogonal unit vectors $x, y, z, \theta \in \mathbb{R}^5$, we denote by $M_V(r, s, t)$ the $4 \times 3$ matrix
\[
\begin{pmatrix}
x \cdot n_1 & x \cdot n_2 & x \cdot n_3 \\
y \cdot n_1 & y \cdot n_2 & y \cdot n_3 \\
z \cdot n_1 & z \cdot n_2 & z \cdot n_3 \\
\theta \cdot n_1 & \theta \cdot n_2 & \theta \cdot n_3
\end{pmatrix}
\] (3.11)

**Remark 3.2.** Note that for $V \subset \mathbb{R}^5$ of dimensions 1, 2 or 4, the condition $\det(M_V(r, s, t)) \neq 0$ is equivalent with $\dim(\pi_{r,s,t}(V))$ being at least 1, 2 or 3, respectively. This is a consequence of the rank-nullity theorem.

Now we are ready to state our transversality condition.

**Definition 3.3** (Transversality). A collection of $m \geq 10^4$ sets $S_1, ..., S_m \subset [0,1]^3$ is said to be $\nu$-transverse if for each
\[
1 \leq i_1 \neq i_2 \neq ... \neq i_{\lceil m/100 \rceil} \leq m,
\]
we have that for each subspace $V \subset \mathbb{R}^5$ of dimension one, two or four,
\[
\max_{1 \leq j \leq \lceil m/100 \rceil} \inf_{(r,s,t) \in S_{ij}} |\det(M_V(r, s, t))| \geq \nu.
\] (3.13)

We next observe that the transversality condition in Definition 3.3 is stronger than the Brascamp-Lieb transversality condition (3.7).

**Proposition 3.4.** Consider $m$ sets $S_j$ which are $\nu$-transverse for some $\nu > 0$. Then for each $(r_j, s_j, t_j) \in S_j$, the $m$ tangent planes $V_j$, $1 \leq j \leq m$ spanned by the vectors $n_i (r_j, s_j, t_j)$, $1 \leq i \leq 3$, satisfy the condition (3.7).

**Proof.** The case $\dim(V) = 5$ is trivially true, as we always have $\dim(\pi_j(V)) = 3$ for all $j$. When $\dim(V) = 4$, in order to verify (3.7), it suffices to prove that there are at least $9m/10 V_j$ with $\dim(\pi_j(V)) \geq 3$. This follows from Remark 3.2 and (3.13). The cases $\dim(V) = 1, 2, 3$ can be proved similarly.

An $\alpha$-cube is defined to be a closed cube with side length $\frac{1}{\alpha}$ inside $[0,1]^3$. If $\alpha \in 2^\mathbb{Z}$, the collection of all dyadic $\alpha$-cubes will be denoted by $Cal_\alpha$. We will implicitly assume that various values of $\alpha$ we use are in $2^\mathbb{Z}$.

The following result provides a nice criterium for transversality.

**Theorem 3.5.** Consider an arbitrary collection $C$ of $m(\geq 10^4)$ $K$-cubes such that the $10/K$ neighbourhood of each 2-variety in $\mathbb{R}^3$ intersects no more than $m/100$ of these $K$-cubes. Then the cubes in $C$ are $\nu_K$-transverse, for some $\nu_K > 0$ that depends only on $K$.

**Proof.** The proof will follow from a standard compactness argument combined with Lemma 8.1.

For each subset $R \subset [0,1]^3$ and $0 < \delta < 1$, let $N_{R,\delta}$ be a $\delta$-neighbourhood of $S_R = \{(r, s, t, Q_1(r, s, t), Q_2(r, s, t)) : (r, s, t) \in R\}$.

The following multilinear restriction theorem is a particular case of a result from [3]. Its proof relies on Theorem 3.1 and induction on scales.
Theorem 3.6. Let $R_j$ with $j = 1, ..., m$ be a collection of subsets of $[0,1]^3$ that are $\nu$-transverse. For each $f_j : N_{R_j,1/N} \to \mathbb{C}$, each $\epsilon > 0$ and each ball $B_N \subset \mathbb{R}^5$ of radius $N \geq 1$, we have
\[
\left\| \prod_{j=1}^m |f_j|^{1/m} \right\|_{L^{4\nu}(B_N)} \lesssim_{\epsilon, \nu} N^{-1+\epsilon} \left( \prod_{j=1}^m \left\| f_j \right\|_{L^2(N_{R_j,1/N})} \right)^{1/m}.
\]

(3.14)

We close this section with presenting the following consequence, a direct application of Proposition 6.5 from [6] with $n = 5$, $d = 3$ and
\[
\kappa_p = \frac{p - \frac{10}{3}}{p - 2}, \quad p \geq \frac{10}{3}.
\]

This result will play a key role in the iteration from Section 7.

Proposition 3.7. Let $R_j$ with $j = 1, ..., m$ be a collection of subsets of $[0,1]^3$ that are $\nu$-transverse. For each ball $B_R$ in $\mathbb{R}^5$ with radius $R \geq N \geq 1$, $p \geq \frac{10}{3}$, $\epsilon > 0$, $\kappa_p \leq \kappa \leq 1$ and $g_i : R_1 \rightarrow \mathbb{C}$ we have
\[
\left\| \prod_{i=1}^m \sum_{t \in \{0, 1\}} \left\| E^\tau g_i \right\|^{2p}(w_{BR}) \right\|_{L^{p}(w_{BR})} \lesssim_{\epsilon, \nu}
\]
\[
N^{\epsilon} \left( \prod_{i=1}^m \sum_{t \in \{0,1\}} \left\| E^\Delta g_i \right\|^{2p}(w_{BR}) \right) \lesssim_{\epsilon, \nu} \left( \sum_{i=1}^m \sum_{t \in \{0,1\}} \left\| E^\tau g_i \right\|^{2p}(w_{BR}) \right)^{\frac{1}{p}}.
\]

4 Lower dimensional decoupling

Recall that we are working with a manifold
\[
\mathcal{S} := \{(r,s,t, Q_1(r,s,t), Q_2(r,s,t)) : (r,s,t) \in [0,1]^3\}
\]
satisfying the requirement in Theorem 1.1. Lemma 2.4 shows that there exists $\eta > 0$ such that for any $\alpha, \beta, \gamma = O(1)$, either $Q_1(r,s,\alpha + \beta r + \gamma s)$ or $Q_2(r,s,\alpha + \beta r + \gamma s)$, when viewed as polynomials in $r,s$, will have at least one quadratic coefficient which has absolute value at least $\eta$.

Unless specified otherwise, the extension operator $E$ will refer to $E^S$.

The main result of this section is the following decoupling inequality for cubes clustered near a plane. It will be used in the next section in the proof of Proposition 6.1.

Theorem 4.1. Let $H$ be a plane in $\mathbb{R}^3$ which intersects $[0,1]^3$. Fix a large constant $K \gg 1$. Let $\mathcal{R} \subset \text{Col}_{K^{1/2}}$ be a collection of $K^{1/2}$-cubes, each of which intersects $H$. Then we have the decoupling inequality
\[
\left\| \sum_{R \in \mathcal{R}} E^R g \right\|_{L^p(w_{BR})} \lesssim_{\epsilon} K^{2(\frac{1}{2} - \frac{1}{p}) + \epsilon} \left( \sum_{R \in \mathcal{R}} \left\| E^R g \right\|_{L^p(w_{BR})}^p \right)^{1/p},
\]

for all $4 \leq p \leq 6$.

We will only use this result for $p = \frac{16}{3}$. Let us comment on the strength of this result. It is stronger than what we would get by using only trivial decoupling, and by that we refer to Lemma 6.3 below. Indeed this lemma gives the poor decoupling constant $K^{2(\frac{1}{2} - \frac{1}{p})}$, because it exploits no curvature.

Given a manifold
\[
\mathcal{M} := \{(v, Q(v)) : v \in \mathbb{R}^d\}
\]
associated with $Q : \mathbb{R}^d \rightarrow \mathbb{R}^d$, its extension operator will be defined as follows
\[
E^\nu_{\mathcal{M}} g(x,x') = \int_{\mathcal{M}} g(v) e(xv + x'Q(v)) dv.
\]
Lemma 4.2. Let $p \geq q \geq 2$. Let $Q_i : \mathbb{R}^3 \to \mathbb{R}$, $i = 1, 2$ be measurable. Fix $U_1, \ldots, U_4$, an arbitrary measurable partition of $[0, 1]^3$ and fix $B$, an arbitrary measurable subset of $\mathbb{R}^4$. For $i = 1, 2$, let $E^{(i)} = E^{\mathcal{M}_i}$ denote the extension operators associated with the manifolds $\mathcal{M}_i$ defined as follows

\[
\mathcal{M}_1 = \{(u, Q_1(u)) : u \in \mathbb{R}^3\},
\]
\[
\mathcal{M}_2 = \{(u, Q_1(u), Q_2(u)) : u \in \mathbb{R}^3\}.
\]

Fix a measurable function $h : [0, 1]^3 \to \mathbb{C}$. Let $C$ be a number such that the inequality

\[
\|E_{[0,1]}^{(1)} \hat{h}\|_{L^p(B)} \leq C \left( \sum_i \|E_{U_i}^{(1)} \hat{h}\|_{L^p(B)}^q \right)^{1/q}
\]

holds for all measurable $\hat{h}$ such that $|\hat{h}| = |h|$. Then for each measurable set $B' \subset \mathbb{R}$ we have

\[
\|E_{[0,1]}^{(2)} \hat{h}\|_{L^p(B \times B')} \leq C \left( \sum_i \|E_{U_i}^{(2)} \hat{h}\|_{L^p(B \times B')}^q \right)^{1/q}.
\]

We will also need the following instances of cylindrical decouplings.

Lemma 4.3. Consider the curve $\gamma$ in the $(u_1, u_2)$-plane

\[
\gamma := \{(u_1, \psi(u_1)) : |u_1| \lesssim 1\}.
\]

We assume $|\psi''| \sim 1$. For $K \gg 1$, let $I_1, I_2, \ldots$ be a partition of $|u_1| \lesssim 1$ using intervals of length $\sim K^{-1/2}$. Partition the $O(K^{-1})$-neighborhood of $\gamma$ into sets $R_i$, each of which is an $O(K^{-1})$ neighborhood of $I_1$. Note that each $R_i$ looks like a $\sim K^{-1/2} \times K^{-1}$ rectangle. For each $R_i$ consider the vertical region $P_i$ in $\mathbb{R}^4$ defined as follows

\[
P_i = \{(u_1, u_2, u_3, u_4) : (u_1, u_2) \in R_i, u_3, u_4 \in \mathbb{R}\}.
\]

For each $f : \mathbb{R}^4 \to \mathbb{C}$ with Fourier transform supported in $\bigcup_i P_i$, we will define the Fourier restriction $f_{P_i}$ of $f$ to $P_i$ by

\[
\hat{f}_{P_i} = \hat{f} 1_{P_i}.
\]

Then for each $2 \leq p \leq 6$, each such $f$ and each $B_K$ in $\mathbb{R}^4$ we have

\[
\|f\|_{L^p(w_{B_K})} \lesssim \epsilon K^{\frac{3}{4} - \frac{1}{3p}} (\sum_i \|f_{P_i}\|^p_{L^p(w_{B_K})})^{1/p}.
\]

Proof. The first inequality follows immediately by applying Theorem 1.1 from [4] (in the form from Section 7) combined with a standard Fubini-type argument. The second one follows from the first one combined with Hölder. \hfill \Box

Lemma 4.4. Consider the surface $\Lambda$ where

\[
\Lambda := \{(u_1, u_2, \psi(u_1, u_2)) : |u_1|, |u_2| \lesssim 1\}.
\]

We assume $|D^2(\psi)| \sim 1$ where $D^2(\psi)$ is the Hessian of $\psi$. For $K \gg 1$, let $I_1, I_2, \ldots$ be a partition of $|u_1|, |u_2| \lesssim 1$ using squares of side length $\sim K^{-1/2}$. Partition the $O(K^{-1})$-neighborhood of
A into sets $R_i$, each of which is an $O(K^{-1})$ neighborhood of $I_i$. Note that each $R_i$ looks like a $\sim K^{-1/2} \times K^{-1/2} \times K^{-1}$ rectangular box. For each $R_i$ consider the vertical region $P_i$ in $\mathbb{R}^4$ defined as follows

$$P_i = \{(u_1, u_2, u_3, u_4) : (u_1, u_2, u_3) \in R_i, \ u_4 \in \mathbb{R}\}.$$ 

For each $f : \mathbb{R}^4 \to \mathbb{C}$ with Fourier transform supported in $\cup_i P_i$, we will define the Fourier restriction $\hat{f}_{P_i}$ of $f$ to $P_i$ by

$$\hat{f}_{P_i} = \hat{f}_{1_{P_i}}.$$ 

Then for each $p \geq 4$, each such $f$ and each $B_K$ in $\mathbb{R}^4$ we have

$$\|f\|_{L^p(w_{B_K})} \lesssim K^{-\frac{p}{2}+\varepsilon} \left(\sum_{i} \|\hat{f}_{P_i}\|_{L^p(w_{B_K})}^p\right)^{1/p}. \quad (4.3)$$

Proof. The inequality follows immediately by applying Theorem 1.1 from [8] combined with a standard Fubini-type argument.

\[\square\]

**Remark 4.5.** It may help to realize that the Fourier transform of the function $f$ from the lemmas is supported in the $O(K^{-1})$-neighborhood of the cylinder

$$Cyl = \{(u_1, \psi(u_1), u_3, u_4), |u_1| \leq 1, u_3, u_4 \in \mathbb{R}\}.$$ 

and

$$Cyl = \{(u_1, u_2, \psi(u_1, u_2), u_4), |u_1|, |u_2| \leq 1, u_4 \in \mathbb{R}\},$$

respectively. These cylinders are obtained in the first case by attaching to each point $(u_1, \psi(u_1), 0, 0)$, the plane $\pi$ spanned by $(0, 0, 1, 0)$ and $(0, 0, 0, 1)$, while in the second case by attaching to each point $(u_1, u_2, \psi(u_1, u_2), 0)$ the line $L$ spanned by $(0, 0, 0, 1)$. We will call this plane (line) the “vertical component” of $Cyl$.

The results of the lemmas remain true if the cylinder is replaced with any of its rigid motions.

We will now start the proof of Theorem 4.1.

By symmetry, we could assume our plane is given by $t = \alpha + \beta r + \gamma s$ for some $\alpha, \beta, \gamma = O(1)$. And without loss of generality, we could also assume that

$$\hat{Q}_1(r, s) := Q_1(r, s, \alpha + \beta r + \gamma s) = ar^2 + bs^2 + crs + L(r, s),$$

with $\max\{|a|, |b|, |c|\} > \eta$ and $L$ affine. The value of $L$ is irrelevant (it never influences the curvature) and can be discarded. Now we will analyze three cases. Let us start by briefly explaining the third case, which is conceptually the easiest. When the quantity $c^2 - 4ab$ is away from zero, we can view the relevant manifold (living in $\mathbb{R}^4$) as being close to a cylinder over a two dimensional surface (lying inside a three dimensional space). The requirement on $c^2 - 4ab$ being nonzero is equivalent to the non degeneracy of the cylinder. We will then combine the well established decoupling theory for surfaces\(^1\) with the cylindrical decoupling from Lemma 4.4. On the other hand, when $c^2 - 4ab = 0$ the cylinder is degenerate, it lives inside a copy of $\mathbb{R}^3$. We will then essentially view it as a cylinder over a curve, and will instead invoke Lemma 4.3.

Case 1. Assume $|a| > \eta/4$. Suppose $Q_1(r, s, t) = Ar^2 + Bs^2 + Ct^2 + Drs + Ert + Fst$ for some $A, B, C, D, E, F \in \mathbb{R}$. Then by a direct computation,

$$a = A + C\beta^2 + E\beta. \quad (4.4)$$

Tile the unit square $\{(r, s) \in [0, 1] \times [0, 1]\}$ with $K^{1/2}$-squares, and call this collection $\mathcal{R}_{tile}$. By allowing another $O(1)$ loss, we may in fact assume that there is at most one $R \in \mathcal{R}$ whose $(r, s)$–projection is any given square in $\mathcal{R}_{tile}$.\(^1\)

\(^1\)What matters in all three cases is that at least one principal curvature of the surface is away from zero. We can afford to perform a trivial decoupling in the direction corresponding to small curvature.
Let 
\[ h = g \sum_{R \in \mathcal{R}} 1_R. \]

With this in mind, it suffices to prove that for \( 2 \leq p \leq 6 \) (note that in this case we can afford a more generous range than \( 4 \leq p \leq 6 \))
\[ \| E_{[0,1]}^3 h \|_{L^p(w_B^K)} \lesssim e^{K^{\frac{1}{2} - \frac{1}{p}}} (\sum_{I,J \in [0,1]} \| E_{I \times [0,1]}^3 h \|_{L^p(w_B^K)})^{1/p}. \]

By invoking Lemma 4.2, it will suffice to prove the following inequality for each \( \tilde{h} \) with \( |\tilde{h}| = |h| \)
\[ \| E_{[0,1]}^3 \tilde{h} \|_{L^p(w_B^K)} \lesssim e^{K^{\frac{1}{2} - \frac{1}{p}}} (\sum_{I,J \in [0,1]} \| E_{I \times [0,1]}^3 \tilde{h} \|_{L^p(w_B^K)})^{1/p}, \] (4.5)

where \( E^{(1)} \) is the extension operator for the manifold
\[ \mathcal{M}_1 = \{(r, s, t, Q_1(r, s, t)), (r, s, t) \in \mathbb{R}^3 \}. \]

Of course, our estimates need to be uniform over \( \alpha, \beta, \gamma \). As a first step towards proving (4.5), we perform a trivial decoupling in the \( s \) direction (Lemma 6.3), to write for each \( p \geq 2 \)
\[ \| E_{[0,1]}^3 \tilde{h} \|_{L^p(w_B^K)} \lesssim K^{\frac{1}{2} - \frac{1}{p}} (\sum_{I \in [0,1]} \| E_{I \times [0,1]}^3 \tilde{h} \|_{L^p(w_B^K)})^{1/p}. \]

Fix \( I = [s_0, s_0 + K^{-1/2}] \) from the summation. It remains to prove the following inequality, for \( 2 \leq p \leq 6 \)
\[ \| E_{[0,1] \times I \times [0,1]}^3 \tilde{h} \|_{L^p(w_B^K)} \lesssim K^{\frac{1}{2} - \frac{1}{p}} (\sum_{J \in [0,1]} \| E_{I \times [0,1]}^3 \tilde{h} \|_{L^p(w_B^K)})^{1/p}. \] (4.6)

Consider the following strip on \( \mathcal{M}_1 \)
\[ \mathcal{M}_{1,I} = \{(r, s, t, Q_1(r, s, t)), (r, s, t) \in [0, 1] \times I \times [0, 1], |t - (\alpha + \beta r + \gamma s)| \lesssim K^{-1/2} \}. \]

This lies in the \( O(K^{-1/2}) \)-neighborhood of the parabola
\[ \mathbb{P} = \{(r, s_0, \alpha + \beta r + \gamma s_0, ar^2 + b^2 + cr^2 s_0) : r \in [0, 1] \}, \]
whose curvature satisfies
\[ \kappa \sim 1. \] (4.7)

because \( |a| \) is away from zero by assumption. This parabola lies in a translate of the plane spanned by \( w_1 = (1, 0, \beta, 0) \)
and \( w_2 = (0, 0, 0, 1) \).

Tile \( \mathcal{M}_{1,I} \) with caps
\[ \mathcal{M}_{1,I,J} = \{(r, s, t, Q_1(r, s, t)), (r, s, t) \in J \times I \times [0, 1], |t - (\alpha + \beta r + \gamma s)| \lesssim K^{-1/2} \}. \]

Note that the Fourier transform of \( E_{J \times I \times [0,1]}^3 \tilde{h} \) is supported on the cap \( \mathcal{M}_{1,I,J} \). By loosing \( O(1) \) we may assume that the \( K^{-1} \)-neighborhoods \( N_{I,J} \) of these caps are pairwise disjoint. Thus (4.6) will follow if we prove that for each \( f \) Fourier supported in \( \bigcup J N_{I,J} \) we have
\[ \| f \|_{L^p(w_B^K)} \lesssim K^{\frac{1}{2} - \frac{1}{p}} (\sum_{J \subset [0,1]} \| f_{N_{I,J}} \|_{L^p(w_B^K)})^{1/p}, \] (4.8)

where \( f_{N_{I,J}} \) is the Fourier restriction of \( f \) to \( N_{I,J} \).

In order to prove (4.8) we need to prove the following claim.
Proof. (of the claim) The tangent space $T_r$ to $M_{1,1}$ at the point from $P$ indexed by $r$ is spanned by the vectors

$$v_1 = (1, 0, 0, 2Ar + Ds_0 + Et) = (1, 0, 0, (2A + E\beta)r + Ds_0 + E\gamma s_0 + E\alpha)$$

$$v_2 = (0, 1, 0, 2Bs_0 + Dr + Ft) = (0, 1, 0, (D + F\beta)r + 2Bs_0 + F\gamma s_0 + F\alpha)$$

and

$$v_3 = (0, 0, 1, 2Ct + Er + Fs_0) = (0, 0, 1, (E + 2C\beta)r + Fs_0 + 2C\gamma s_0 + 2C\alpha).$$

Recall that $|a| = |A + C\beta^2 + E\beta| > \eta/4$. Therefore, by the triangle inequality, either $|2A + E\beta| > \eta/4$ or $|2C\beta^2 + E\beta| > \eta/4$. So we split into two cases here.

First, assume $|2A + E\beta| > \eta/4$. Note that for each $r$, $T_r$ contains the fixed plane $\pi$ spanned by

$$u_3 =\ndots$$

$$u_4 =$$

and

Consider the cylinder $Cyl$ in $\mathbb{R}^4$ obtained by attaching the plane $\pi$ to each point of the parabola $P$. In other words, $\pi$ will be the “vertical component” of $Cyl$. In general, the plane $\pi$ is not perpendicular to the plane of the parabola. However, since $|\det[u_1, u_2, u_3, u_4]| = |2A + E\beta||2A + 2C\beta^2 + 2E\beta| > \eta/4 \times \eta/2$ (4.9)

is away from zero, the cylinder is non-degenerate. Its cross section with the plane $\pi^\perp$ is the projection of $P$ onto $\pi^\perp$. Due to (4.7) and (4.9) this projection will be a curve given by $u_2 = \psi(u_1)$, with $|\psi''| \sim 1$, for some appropriate orthonormal basis $(u_1, u_2)$ in $\pi^\perp$. In other words, $Cyl$ is a cylinder like the one in Lemma 4.3, modulo a rigid motion. Taylor’s approximation of second order finishes the proof of the claim in this case, as $M_{1,1}$ lies within $O(K^{-1/2})$ from $P$.

In the second case, assume $|2C\beta^2 + E\beta| > \eta/4$. The proof is similar to the first case, but this time we use

$$u_3 =$$

$$u_4 =$$

and

$$(0, \beta + 2C\beta^2, -(D + F\beta^2)(2Bs_0 + F\gamma s_0 + F\alpha) - (D + F\beta^2)(Fs_0 + 2C\gamma s_0 + 2C\alpha)).$$

It follows that $\bigcup_i N_{I_{1,1}}$ lies in the $O(K^{-1})$-neighborhood of $Cyl$. Let now $P_1, P_2, \ldots$ be the partition of this neighborhood like in Lemma 4.3. By choosing $P_i$ wide enough (still of order $O(K^{-1/2})$) we may arrange so that each $N_{I_{1,1}}$ is inside some $P_i$ and moreover, each $P_i$ contains at most one $N_{I_{1,1}}$. This can be seen via simple geometry, using the orientation of $Cyl$.

Thus, if $f$ is Fourier supported in $\bigcup_i N_{I_{1,1}}$, it is automatically Fourier supported in $\bigcup_i P_i$ and moreover

$$\hat{f}_{N_{I_{1,1}}} = \hat{f}_{P_i},$$

whenever $N_{I_{1,1}} \subset P_i$. With all these observations, inequality (4.8) is an immediate consequence of (4.2). This finishes the analysis of Case 1.
Case 2. Assume $|b| > \eta/4$. Then the proof is similar to the proof of Case 1 with the role of $r, s$ swapped.

Case 3. Since we are not in Case 1 or 2, we may assume that $|a| \leq \eta/4, |b| \leq \eta/4, |c| > \eta$. Suppose $Q_1(r, s, t) = Av^2 + Bs^2 + Ct^2 + Drs + Estr + Fst$ for some $A, B, C, D, E, F \in \mathbb{R}$. Then by a direct computation,
\[
c = 2\beta_1C + D + E\gamma + F\beta, \quad a = A + C\beta^2 + E\beta, \quad b = B + C\gamma^2 + F\gamma.
\] (4.10)

Our approach here is similar to what we did before, we will use a cylindrical decoupling. But this time, the base would be a two dimensional surface in $\mathbb{R}^3$ with nonzero Gaussian curvature.

Tile the unit square $\{(r, s) \in [0, 1] \times [0, 1]\}$ with $K^{1/2}$—squares, and call this collection $\mathcal{R}_{tile}$. By allowing another $O(1)$ loss, we may in fact assume that there is at most one $R \in \mathcal{R}$ whose $(r, s)$—projection is any given square in $\mathcal{R}_{tile}$. Let
\[
h = g \sum_{R \in \mathcal{R}} 1_{R}.
\]
We will prove that for each $p \geq 4$,
\[
\|E_{[0,1]}^1 h\|_{L^p(w_{BK})} \lesssim \varepsilon K^{1-\frac{a}{2} + \delta}(\sum_{I,J \subseteq [0,1]} \|E_{I \times J \times [0,1]} h\|_{L^p(w_{BK})}^p)^{1/p}.
\] (4.11)

By invoking Lemma 4.2, it will suffice to prove the following inequality for each $\tilde{h}$ with $|\tilde{h}| = |h|$,
\[
\|E_{[0,1]}^{(1)} \tilde{h}\|_{L^p(w_{BK})} \lesssim \varepsilon K^{1-\frac{a}{2} + \delta}(\sum_{I,J \subseteq [0,1]} \|E_{I \times J \times [0,1]} \tilde{h}\|_{L^p(w_{BK})}^p)^{1/p},
\] (4.12)

where $E^{(1)}$ is the extension operator for the manifold
\[
\mathcal{M}_1 = \{(r, s, t, Q_1(r, s, t)) : |t - (\alpha + \beta r + \gamma s)| \lesssim K^{-1/2}\}.
\]

Note that $\mathcal{M}_1$ lies in the $O(K^{-1/2})$—neighborhood of the surface
\[
\mathbb{S} = \{(r, s, \alpha + \beta r + \gamma s, ar^2 + bs^2 + crs) : r, s \in [0, 1]\},
\]
whose Gaussian curvature satisfies
\[
k \sim 1,
\] (4.13)
since $|c^2 - 4ab| \geq |c|^2 - 4|a||b| \geq \eta^2 - 4\eta/4 \times \eta/4 = 3\eta^2/4$ is away from zero by assumption. This surface lies in a translate of the three dimensional space spanned by
\[
w_1 = (1, 0, \beta, 0),
\]
\[
w_2 = (0, 1, \gamma, 0),
\]
and
\[
w_3 = (0, 0, 0, 1).
\]
Tile $\mathcal{M}_1$ with caps
\[
\mathcal{M}_{1,I,J} = \{(r, s, t, Q_1(r, s, t)) : (r, s, t) \in I \times J \times [0, 1], |t - (\alpha + \beta r + \gamma s)| \lesssim K^{-1/2}\}.
\]

Note that the Fourier transform of $E_{I \times J \times [0,1]} \tilde{h}$ is supported on the cap $\mathcal{M}_{1,I,J}$. By loosing $O(1)$ we may assume that the $K^{-1}$—neighborhoods $N_{I,J}$ of these caps are pairwise disjoint. Thus (4.12) will follow if we prove that for each $f$ Fourier supported in $\cup_{I,J} N_{I,J}$ we have
\[
\|f\|_{L^p(w_{BK})} \lesssim \varepsilon K^{1-\frac{a}{2} + \delta}(\sum_{I,J \subseteq [0,1]} \|f_{N_{I,J}}\|_{L^p(w_{BK})}^p)^{1/p},
\] (4.14)

where $f_{N_{I,J}}$ is the Fourier restriction of $f$ to $N_{I,J}$.

In order to prove (4.14) we need to prove the following claim.
Claim 4.7. \( \mathcal{M}_1 \) lies within \( O(K^{-1}) \) from a cylinder like the one from Lemma 4.4 (modulo rigid motions).

Proof. (of the claim) The tangent space \( T_{r,s} \) to \( \mathcal{M}_1 \) at the point from \( S \) indexed by \( r, s \) is spanned by the vectors

\[
v_1 = (1, 0, 0, 2Ar + Ds + Et) = (1, 0, 0, (2A + E\beta)r + (D + E\gamma)s + E\alpha)
\]

\[
v_2 = (0, 1, 0, 2Bs + Dr + Ft) = (0, 1, 0, (D + F\beta)r + (2B + F\gamma)s + F\alpha)
\]

and

\[
v_3 = (0, 0, 1, 2Ct + Er + Fs) = (0, 0, 1, (E + 2C\beta)r + (F + 2C\gamma)s + 2C\alpha).
\]

By a direct computation, we have the following identity:

\[
|\det\begin{pmatrix} 2A + E\beta & D + F\beta \\ D + E\gamma & 2B + F\gamma \end{pmatrix}| - \beta |\det\begin{pmatrix} D + F\beta & E + 2C\beta \\ 2B + F\gamma & F + 2C\gamma \end{pmatrix}| - \gamma |\det\begin{pmatrix} D + E\gamma & F + 2C\beta \\ 2A + E\beta & E + 2C\beta \end{pmatrix}|
\]

\[
= |(2\gamma C + D + E\gamma + F\beta)^2 - 4(A + C\beta^2 + E\beta)(B + C\gamma^2 + F\gamma)|
\]

(4.15)

Since the right hand side of the equation is equal to \(|c^2 - 4ab|\) which is away from 0, at least one term from the left hand side of the equation must be away from 0. In particular, this tells us that the rank of

\[
\begin{pmatrix} 2A + E\beta & D + F\beta & E + 2C\beta \\ D + E\gamma & 2B + F\gamma & F + 2C\gamma \end{pmatrix}
\]

is two.

From this, we could deduce that for each \( r, s \), \( T_{r,s} \) contains a line \( L \) parallel to the vector

\[
u_4 = (\det\begin{pmatrix} D + F\beta & E + 2C\beta \\ 2B + F\gamma & F + 2C\gamma \end{pmatrix}, \det\begin{pmatrix} D + E\gamma & F + 2C\gamma \\ 2A + E\beta & E + 2C\beta \end{pmatrix}, \det\begin{pmatrix} 2A + E\beta & D + F\beta \\ D + E\gamma & 2B + F\gamma \end{pmatrix}, * )
\]

where

\[
* = \det\begin{pmatrix} D + F\beta & E + 2C\beta \\ 2B + F\gamma & F + 2C\gamma \end{pmatrix} \times ((2A + E\beta)r + (D + E\gamma)s + E\alpha) + \frac{\det\begin{pmatrix} D + E\gamma & F + 2C\gamma \\ 2A + E\beta & E + 2C\beta \end{pmatrix} \times ((D + F\beta)r + (2B + F\gamma)s + F\alpha)}{\det\begin{pmatrix} 2A + E\beta & D + F\beta \\ D + E\gamma & 2B + F\gamma \end{pmatrix} \times ((E + 2C\beta)r + (F + 2C\gamma)s + 2C\alpha)}.
\]

(4.16)

The main point is that \( * \) is independent of \( r, s \) (after simplification, the coefficient of \( r, s \) is 0), so that \( u_4 \) is independent of \( r, s \).

Consider the cylinder \( Cyl \) in \( \mathbb{R}^4 \) obtained by attaching the line \( L \) parallel to \( u_4 \) to each point of the surface \( S \). In other words, \( L \) will be the “vertical component” of \( Cyl \). In general, the line \( L \) is not perpendicular to the three dimensional space where the surface lies. However, since

\[
|\det[w_1, w_2, w_3, u_4]| =
\]

(4.17)

\[
|\det\begin{pmatrix} 2A + E\beta & D + F\beta \\ D + E\gamma & 2B + F\gamma \end{pmatrix} \times (|\det\begin{pmatrix} D + F\beta & E + 2C\beta \\ 2B + F\gamma & F + 2C\gamma \end{pmatrix} - \beta |\det\begin{pmatrix} D + E\gamma & F + 2C\beta \\ 2A + E\beta & E + 2C\beta \end{pmatrix}|)
\]

is away from zero by formula (4.15), the cylinder is non-degenerate. Its cross section with the space \( L^\perp \) is the projection of \( S \) onto \( L^\perp \). Due to (4.13) and (4.17) this projection will be a surface.
given by $u_3 = \psi(u_1, u_2)$, with $|D^2(\psi)| \sim 1$, for some appropriate orthonormal basis $(u_1, u_2, u_3)$ in $L^1$. In other words, $Cyl$ is a cylinder like the one in Lemma 4.4, modulo a rigid motion. Taylor’s approximation of second order finishes the proof of the claim, as $M_1$ lies within $O(K^{-1/2})$ from $S$.

It follows that $\cup I,J N_{I,J}$ lies in the $O(K^{-1})$-neighborhood of $Cyl$. Let now $P_1, P_2, \ldots$ be the partition of this neighborhood like in Lemma 4.4. By choosing $P_i$ wide enough (still of order $O(K^{-1/2})$) we may arrange so that each $N_{I,J}$ is inside some $P_i$ and moreover, each $P_i$ contains at most one $N_{I,J}$. This can be seen via simple geometry, using the orientation of $Cyl$.

Thus, if $f$ is Fourier supported in $\cup I,J N_{I,J}$, it is automatically Fourier supported in $\cup_i P_i$ and moreover

$$f_{N_{I,J}} = f_{P_i}$$

whenever $N_{I,J} \subset P_i$. With all these observations, inequality (4.14) is an immediate consequence of (4.3).

Thus, since $1 - \frac{2}{p} \leq \frac{2}{2} - \frac{1}{p} = \frac{1}{2} - \frac{1}{p}$ when $p \leq 6$, we have that (4.1) is a consequence of (4.11).

This ends the analysis of Case 3 and thus the proof of Theorem 4.1.

5 From planes to arbitrary surfaces

Throughout this section we will fix $p \in (2, \infty)$ and will assume that the inequality

$$\|E_\gamma g\|_{L^p(w_{BM})} \lesssim M^7 \left( \sum_{Q \subset S \cap \{\gamma(Q) = M^{-1/2}\}} \|E_Q g\|_{L^p(w_{BM})}^p \right)^{1/p} \tag{5.1}$$

holds true for all $M \geq 1$ and for all rectangular boxes $S \subset [0,1]^3$ with size $\sim M^{-1/2} \times 1 \times 1$. In our applications, we will take $p = \frac{14}{3}$.

The forthcoming discussion is following very closely the arguments from [12]. This is a variant of the induction on scales that was used in [13] and then in [4] to prove the sharp decoupling for the cone. The intriguing aspect in the present context is that we approximate curved surfaces with zero curvature manifolds (planes). To bridge the gap between zero curvature and nonzero curvature we use the following rescaling argument.

**Lemma 5.1.** For each rectangular box $R \subset [0,1]^3$ with size $\sim M^{-1} \times M^{-1/2} \times M^{-1/2}$ we have

$$\|E_\gamma g\|_{L^p(w_{BM^2})} \lesssim M^7 \left( \sum_{Q \subset R \cap \{\gamma(Q) = M^{-1}\}} \|E_Q g\|_{L^p(w_{BM^2})}^p \right)^{1/p}. \tag{5.2}$$

**Proof.** The argument is a standard parabolic rescaling. Rescale $t, r, s$ by $M^{1/2}$. The ball $BM^2$ from $\mathbb{R}^5$ will turn into a set that resembles a box with size $M^{3/2} \times M^{3/2} \times M$ in $M \times M$. Cover it with balls $BM$, apply (5.1) on each $BM$, then sum up all these contributions.

The key observation is that (5.1) forces a similar inequality for curved boxes.

**Proposition 5.2.** The inequality

$$\|E_\gamma g\|_{L^p(w_{UBK})} \lesssim K^{\gamma + \epsilon} \left( \sum_{Q \subset U \cap \{\gamma(Q) = K^{-1/2}\}} \|E_Q g\|_{L^p(w_{BK})}^p \right)^{1/p} \tag{5.3}$$

holds true for all $K \geq 1$ and $\epsilon > 0$, where $U \subset [0,1]^3$ is the $K^{-1/2}$ neighborhood of a smooth surface in $\mathbb{R}^3$ (the graph of a smooth function). The implicit constant is uniform over surfaces with principal curvatures of magnitude $O(1)$.
Proof. Fix $\epsilon > 0$ of the form $\epsilon = 2^{-n-1}$ with $n \in \mathbb{N}$. We may assume that $g$ is supported on $U$. Cover $U$ with $\sim K^{2\epsilon}$ rectangular boxes $R_1$ of size $K^{-2\epsilon} \times K^{-\epsilon} \times K^{-\epsilon}$, then write using Hölder’s inequality
\[
\|E_R g\|_{L^p(w_B K)} \lesssim K^{2\epsilon(1-\frac{1}{p})} \left( \sum_{R_1} \|E_{R_1} g\|_{L^p(w_B K)}^p \right)^{1/p}.
\] (5.3)
Next we apply Lemma 5.1 with $M = K^{2\epsilon}$ on each ball $B_{K^{4\epsilon}}$ in a finitely overlapping cover of $B_K$ and then sum over these balls to get
\[
\|E_{R_1} g\|_{L^p(w_B K)} \leq CK^{2\epsilon\gamma} \left( \sum_{Q_1 \subset R_1} \|E_{Q_1} g\|_{L^p(w_B K)}^p \right)^{1/p}.
\] (5.4)

We repeat this argument as follows. Fix a $Q_1$ as above and note that $E_{Q_1} g = E_{Q_1 \cap U} g$. Note also that $Q_1 \cap U$ is contained in a rectangular box $R_2$ with size $\sim K^{-4\epsilon} \times K^{-2\epsilon} \times K^{-2\epsilon}$, and we may thus write
\[
E_{Q_1} g = E_{R_2} g.
\]
Apply Lemma 5.1 as above with $M = K^{4\epsilon}$ to write
\[
\|E_{Q_1} g\|_{L^p(w_B K)} = \|E_{R_2} g\|_{L^p(w_B K)} \leq CK^{4\epsilon\gamma} \left( \sum_{Q_2 \subset R_2} \|E_{Q_2} g\|_{L^p(w_B K)}^p \right)^{1/p}.
\] (5.5)

We iterate this procedure. In the final step, we are faced with cubes $Q_n-1$ with side length $K^{-2^{n-1}\epsilon} = K^{-\frac{1}{2}}$. Since $Q_n-1 \cap U$ is inside a rectangular box $R_n$ with size
\[
\sim K^{-2^{n-1}\epsilon} \times K^{-2^{n-2}\epsilon} \times K^{-2^{n-1}\epsilon} = K^{-1/2} \times K^{-1/4} \times K^{-1/4}
\]
we may apply Lemma 5.1 one last time with $M = K^{1/2}$ to write
\[
\|E_{Q_{n-1}} g\|_{L^p(w_B K)} = \|E_{R_n} g\|_{L^p(w_B K)} \leq CK^{\frac{1}{2}\gamma} \left( \sum_{Q_n \subset R_n} \|E_{Q_n} g\|_{L^p(w_B K)}^p \right)^{1/p}.
\] (5.6)
Collecting (5.3) through (5.6) we conclude that
\[
\|E_{U} g\|_{L^p(w_B K)} \lesssim C^n K^{2\epsilon(1-\frac{1}{p})} K^{\gamma(\frac{1}{2} + \frac{1}{4} + \ldots)} \left( \sum_{Q_n \subset U} \|E_{Q_n} g\|_{L^p(w_B K)}^p \right)^{1/p}
\]
which is equivalent to (5.2).

We can now prove the following consequence of Theorem 4.1.

Corollary 5.3. Let $H$ be a $2$-variety in $\mathbb{R}^3$ which intersects $[0,1]^3$. Fix a large constant $K \gg 1$. Let $\mathcal{R} \subset Col_{K^{1/2}}$ be a collection of $K^{1/2}$-cubes, each of which intersects $H$. Then we have the decoupling inequality
\[
\left\| \sum_{\beta \in \mathcal{R}} E_{\beta} g \right\|_{L^p(w_B K)} \lesssim C \left( \sum_{\beta \in \mathcal{R}} \|E_{\beta} g\|_{L^p(w_B K)}^p \right)^{1/p},
\] (5.7)
for all $4 \leq p \leq 6$.

Proof. Write $H$ as the union of $O(1)$ many manifolds of dimension at most two. It suffices to prove our inequality pretending $H$ is one of these manifolds. The case of zero dimension is trivial. If $H$ is one dimensional, the inequality follows from trivial decoupling (Lemma 6.3), since the result from [14] implies that $H$ intersects at most $O(K^{1/2})$ cubes from $Col_{K^{1/2}}$. Finally, if $H$ is a surface, we combine Theorem 4.1 with Proposition 5.2. \qed
6 Equivalence between linear and multilinear decoupling

In this subsection we run a version of the Bourgain-Guth argument from [11] to prove that the linear decoupling inequality (1.3) is equivalent to a certain multilinear one. Recall that we work with a fixed \( S \) as in (2.1). We continue to use the simplified notation \( E \) to denote the extension operator \( E_S \), while \( D(N,p) \) will refer to \( D_S(N,p) \). Define the multilinear decoupling constant \( D_{\text{multi}}(N,p,\nu) \) to be the smallest number such that

\[
\| \prod_{i=1}^{m} |E_{R_i}g_i|^{1/m} \|_{L^p(w_{B_N})} \leq D_{\text{multi}}(N,p,\nu)\left( \prod_{i=1}^{m} \| E_{\Delta_i}g_i \|_{L^p(w_{B_{N_i}})} \right)^{1/m}. \tag{6.1}
\]

holds for all \( \nu \)-transverse cubes \( R_i \subset [0,1]^3 \) (both \( m \) and the side lengths of the cubes can be arbitrary), all \( g_i : R_i \to \mathbb{C} \) and all balls \( B_N \subset \mathbb{R}^5 \). Hölder’s inequality proves that

\[
D_{\text{multi}}(N,p,\nu) \leq D(N,p).
\]

In the rest of this section, we will show that the reverse inequality is also essentially true. More precisely, we will prove the following result.

**Proposition 6.1.** For each \( K \gg 1 \), \( 4 \leq p \leq 6 \) and \( \epsilon > 0 \), there exists \( \beta(p,K,\epsilon) > 0 \) and \( C(p,K) \) such that for each \( \epsilon, p \) we have

\[
\lim_{K \to \infty} \beta(p,K,\epsilon) = 0, \tag{6.2}
\]

and for each \( N \geq K \) we have

\[
D(N,p) \leq N^{\beta(p,K,\epsilon)} N^{\frac{3}{2}(\frac{1}{2} - \frac{1}{p})}
+ C(p,K) N^{\beta(p,K,\epsilon)} \max_{1 \leq M \leq N} \left( \frac{M}{N} \right)^{-\frac{3}{2}(\frac{1}{2} - \frac{1}{p})} D_{\text{multi}}(M,p,\nu_K). \tag{6.3}
\]

Here \( \nu_K \) is the quantity appearing in Theorem 3.5.

**Remark 6.2.** In light of the expected values for \( D(N,p) \), see (1.7), the inequality (6.3) shows that the value of \( D(N,p) \) can not be significantly larger than that of \( D_{\text{multi}}(N,p,\nu_K) \), if \( K \) is large enough.

To prove the above proposition, we need several auxiliary lemmas. The first one is a “trivial” decoupling estimate. It makes use of the orthogonality among functions with frequencies supported on different caps, however it does not take advantage of the curvature of the surface \( S \) from (1.1).

**Lemma 6.3.** Let \( R_1, \ldots, R_M \) be pairwise disjoint cubes in \([0,1]^3\) with side length \( K^{-1} \). Then for each \( 2 \leq p \leq \infty \), we have

\[
\| \sum_j E_{R_j}g \|_{L^p(w_{B_{K^2}})} \lesssim_p M^{1-\frac{2}{p}} \left( \sum_j \| E_{R_j}g \|_{L^p(w_{B_{K^2}})}^p \right)^{1/p}. \tag{6.4}
\]

**Proof.** When \( p = 2 \), we use the fact that the functions \( E_{R_j}g \) have essentially disjoint frequency supports. At \( p = \infty \), we use the triangle inequality. The rest follows from interpolation. See the proof of Lemma 5.1 from [9] for details.

Now we are ready to start the proof of Proposition 6.1. The main step is the proof of the following result.
Proposition 6.4. For each $4 \leq p \leq 6$, each $\epsilon > 0$ and $N \geq K \gg 1$, we have that
\[
\|E_{[0,1]^3}g\|_{L^p(w_{B_N})} \lesssim_{\epsilon} K^{\frac{1}{2} + \frac{1}{p} + \epsilon} \left( \sum_{R \in \text{Col}_K} \|E_Rg\|_{L^p(w_{B_N})}^p \right)^{1/p}
\]

\[
+ K^{\frac{1}{2} + \frac{1}{p} + \epsilon} \left( \sum_{\beta \in \text{Col}_{K^{1/2}}} \|E_{\beta}g\|_{L^p(w_{B_N})}^p \right)^{1/p}
\]

\[
+ C(p, K) D_{\text{multi}}(N, p, \nu_K) \left( \sum_{\Delta \in \text{Col}_{K^{1/2}}} \|E_\Delta g\|_{L^p(w_{B_N})}^p \right)^{1/p}.
\]

Here $\nu_K$ is the quantity appearing in Theorem 3.5, and $C(p, K)$ is a constant depending on $p$.

Proof. Partition $[0,1]^3$ into cubes $R$ from $\text{Col}_K$. Following Bourgain and Guth [11], we may assume that $|E_R(x)|$ is essentially constant on each ball $B_K$ of radius $K$. This value will be denoted as $|E_Rg(B_K)|$. Write
\[
E_{[0,1]^3}g(x) = \sum_{R \in \text{Col}_K} E_Rg(x), \quad x \in B_K.
\]

For a fixed $B_K$, let $R^* \in \text{Col}_K$ be the cube that maximizes $|E_Rg(B_K)|$. Let $\text{Col}^*_K$ be those cubes $R \in \text{Col}_K$ such that
\[
|E_Rg(B_K)| \geq K^{-3}|E_{R^*}g(B_K)|.
\]

Before we proceed, let us first explain the ideas. We will deal with three cases. The first case is when $\text{Col}^*_K$ contains a “small” amount of cubes. In this case, applying only the triangle and the Cauchy–Schwarz inequality will suffice. The second case is when the cardinality of $\text{Col}^*_K$ is large, but the cubes in $\text{Col}^*_K$ are not clustered near any 2-variety in $\mathbb{R}^3$. By Theorem 3.5, we know that these cubes are transverse, which allows us to invoke multilinear estimates. The last case is when a big percentage of the cubes in $\text{Col}^*_K$ intersect a 2-variety in $\mathbb{R}^3$. In this case, we will rely on a lower dimensional decoupling inequality, that is (4.1) from Theorem 4.1.

**Case 1:** Suppose
\[
\#(\text{Col}^*_K) < 10^4.
\]

In this case we combine the triangle and the Cauchy–Schwarz inequality, to get a very favorable estimate. First we observe that for $x \in B_K$
\[
|E_{[0,1]^3}g(x)| \leq \left| \sum_{R \in \text{Col}^*_K} E_Rg(x) \right| + |E_{R^*}g(B_K)|
\]

\[
\lesssim \left( \sum_{R \in \text{Col}_K} |E_Rg(x)|^p \right)^{1/p}
\]

Integrating on $B_K$ we get
\[
\|E_{[0,1]^3}g\|_{L^p(w_{B_K})} \lesssim \left( \sum_{R \in \text{Col}_K} \|E_Rg\|_{L^p(w_{B_K})}^p \right)^{1/p}.
\]

Note that we get a better estimate than needed in this case.

**Case 2:** Assume
\[
\text{m} := \#(\text{Col}^*_K) \geq 10^4.
\]

Moreover, assume there does not exist any 2-variety in $\mathbb{R}^3$ whose $10/K$ neighbourhood intersects more than $m/100$ of the cubes from $\text{Col}^*_K$. Then by Theorem 3.5, these $m$ cubes are $\nu_K$-transverse.
We may write
\[
\|E_{[0,1]^3} g\|_{L^p(B_K)} \lesssim K^6 \max_{\nu K - \text{transverse}} \prod_{i=1}^m |E_{\nu K} g|^{1/m}_{L^p(B_K)}^{1/p} = K^6 \left( \sum_{R_1, \ldots, R_m} \prod_{i=1}^m |E_{\nu K} g|^{1/m}_{L^p(B_K)}^{p} \right)^{1/p}.
\] (6.11)

**Case 3:** Suppose that there is a 2-variety in \( \mathbb{R}^3 \) whose 10/K neighbourhood intersects more than \( m/100 \) of the (at least 10^4) cubes from \( \text{Col}_K^* \). Call this 2-variety \( H_1 \). Consider the 10K^{-1/2} neighbourhood \( N_{K^{-1/2}}(H_1) \) of \( H_1 \). Denote
\[
\text{Col}_K^{(1)} := \text{Col}_K \setminus \{ R \in \text{Col}_K^* : R \subset N_{K^{-1/2}}(H_1) \}.
\] (6.12)
Moreover, define
\[
m_1 = \#(\text{Col}_K^{(1)}).
\] (6.13)
We cover \( N_{K^{-1/2}}(H_1) \) using cubes \( \beta \) from \( \text{Col}_{K^{1/2}} \). By Corollary 5.3
\[
\left\| \sum_{\beta \in \text{Col}_{K^{1/2}}, \beta \subset N_{K^{-1/2}}(H_1)} E_{\beta} g \right\|_{L^p(B_K)} \lesssim \epsilon K^{6 \left( \frac{1}{2} - \frac{1}{p} \right) + \epsilon} \left( \sum_{\beta \in \text{Col}_{K^{1/2}}, \beta \subset N_{K^{-1/2}}(H_1)} \|E_{\beta} g\|_{L^p(B_K)}^p \right)^{1/p}.
\] (6.14)
This takes care of the cubes inside \( N_{K^{-1/2}}(H_1) \). For cubes outside, we repeat the whole procedure, with \( \text{Col}_K^* \) replaced by \( \text{Col}_K^{(1)} \) and \( m \) by \( m_1 \). This procedure will terminate in at most \( \log K \) many steps, as \( \text{Col}_K^{(i+1)} \) is at least one percent smaller than \( \text{Col}_K^{(i)} \). The \( \log K \) will be harmlessly absorbed into the \( K^6 \) term.

We collect all the contributions of the type (6.9), (6.11) and (6.14) from each step,
\[
\|E_{[0,1]^3} g\|_{L^p(B_K)} \lesssim \epsilon \left( \sum_{R \in \text{Col}_K} \|E_{\nu K} g\|_{L^p(B_K)}^p \right)^{1/p} + K^{6 \left( \frac{1}{2} - \frac{1}{p} \right) + \epsilon} \left( \sum_{\beta \in \text{Col}_{K^{1/2}}} \|E_{\beta} g\|_{L^p(B_K)}^p \right)^{1/p}.
\] (6.15)
Raising to the \( p \)-th power and summing over \( B_K \subset B_N \), we obtain
\[
\|E_{[0,1]^3} g\|_{L^p(B_K)} \lesssim \epsilon \left( \sum_{R \in \text{Col}_K} \|E_{\nu K} g\|_{L^p(B_K)}^p \right)^{1/p} + K^{6 \left( \frac{1}{2} - \frac{1}{p} \right) + \epsilon} \left( \sum_{\beta \in \text{Col}_{K^{1/2}}} \|E_{\beta} g\|_{L^p(B_K)}^p \right)^{1/p}.
\] (6.16)
Note that there are only $O_K(1)$ choices of squares. By the definition of the multilinear decoupling constant in (6.1), we conclude (6.5), as desired. Note that the first term in (6.16) has a more favorable estimate than the one stated in (6.5). We prefer to work with the latter estimate, as it makes the rest of the argument more symmetric.

Given a cube $R \subset [0, 1]^3$ and $\alpha^{-1} < l(R)$, we denote by $Col_n(R)$ the collection of all dyadic cubes inside $R$ with side length $\frac{1}{\alpha}$.

A standard rescaling gives (see Proposition 5.6 in [4] for details)

**Proposition 6.5.** Let $R \subset [0, 1]^3$ be a cube with side length $\delta$. Then for each $\epsilon > 0$, $K \geq 1$ and $N > \delta^{-2}$, we have

$$
\|E_R g\|_{L^p(w_B)}^p \leq C_{p, \epsilon} \left[ K^{\frac{1}{2}(p-2)+\epsilon} \sum_{R' \in Col_{K/\delta}(R)} \|E_R g\|_{L^p(w_B)}^p \right] + K^{\frac{3}{2}(\frac{p}{2}-1)+\epsilon} \sum_{\beta \in Col_{K/2\delta}(R)} \|E_R g\|_{L^p(w_B)}^p (6.17)
$$

$$
+ C(p, K) D_{multi}^p (N^{\delta^2}, p, \nu K) \sum_{\Delta \in Col_{K/2}(R)} \|E_{\Delta} g\|_{L^p(w_B)}^p \right].
$$

We have arrived at the final stage of the proof of Proposition 6.1. We iterate the above result, from scale one, until scale $K^n$ is reached, where $n$ is such that

$$
K^n = N^{1/2}. \tag{6.18}
$$

In other words, the iteration of each term terminates exactly when it equals the last term in (6.17). At the end of the iteration, we will get many copies of the last term in (6.17), each of which comes with a certain coefficient. Let us trace the iteration history of such a term. Suppose that throughout the iteration history the scale gets smaller by a factor of $\delta$ exactly $\lambda_1$ times and by a factor of $\delta^{1/2}$ exactly $\lambda_2$ times. Then

$$
\lambda_1 + \lambda_2 \leq n = \frac{1}{2} \log_K N. \tag{6.19}
$$

The corresponding coefficient of the final term corresponding to this $(\lambda_1, \lambda_2)$ pattern of iterations is

$$(C_{p, \epsilon})_{\lambda_1+\lambda_2} K^{(\lambda_1+\lambda_2)+\epsilon} K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2} \tag{6.20}
$$

Notice that

$$
K^{(\lambda_1+\lambda_2)+\epsilon} \leq K^{c \log_K N} \leq N^c,
$$

$$(C_{p, \epsilon})_{\lambda_1+\lambda_2} \leq N^{\log_K C_{p, \epsilon}},
$$

$$
K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2} \leq N^{\frac{1}{2}(\frac{p}{2}-1)}.
$$

It is easy to see that there are at most $2^n$ terms corresponding to a given $(\lambda_1, \lambda_2)$ pattern. We write $2^n = N^{\log_K 2}$. Hence we obtain

$$
D(N, p)^p \leq N^{c+\log_K C_{p, \epsilon}} N^{\log_K 2} \sum_{\lambda_1 + (\lambda_2/2) = \frac{1}{2} \log_K N} K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2}
$$

$$
+ C(p, K) N^{c+\log_K C_{p, \epsilon}} N^{\log_K 2} \sum_{\lambda_1 + (\lambda_2/2) < \frac{1}{2} \log_K N} K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2} D_{multi}^p (NK^{-2\lambda_1 - \lambda_2}, p, \nu K) \leq N^{c+\log_K (2C_{p, \epsilon})} \log_K N \left[ N^{\frac{1}{2}(p-2)} + C(p, K) \sum_{j < \log_K N} K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2} D_{multi}^p (NK^{-j-p}, \nu K) \right] \leq N^{c+\log_K (2C_{p, \epsilon})} \log_K N \left[ N^{\frac{1}{2}(p-2)} + C(p, K) \max_{j < \log_K N} K^{\frac{1}{2}(p-2)\lambda_1 + \frac{3}{2}(\frac{p}{2}-1)\lambda_2} D_{multi}^p (NK^{-j-p}, \nu K) \right].
$$

This finishes the proof of Proposition 6.1, using

$$
\beta(p, K, \epsilon) = \frac{1}{p} \log_K (2C_{p, \epsilon}).
$$
7 The final iteration

In this section we finish the proof of (1.7). The argument here is entirely standard, and it appears in all recent papers related to decouplings.

Let $4 \leq p \leq 6$. Fix $K \gg 1$ and $\nu_K$ transverse cubes $R_1, \ldots, R_m \subset [0, 1]^3$. Fix also $g_i : R_i \to \mathbb{C}$. Combining the inequality in Proposition 3.7 with Hölder’s inequality we derive the following critical inequality, valid for $\kappa_p = \frac{p-m}{p-2} \leq \kappa \leq 1$

$$\|\left(\prod_{i=1}^{m} \sum_{l(\tau) = N^{-1/4}} |E_{\tau} g_i|^2\right)^{1/m}\|_{L^p(w_{BR})} \lesssim_{\rho, K} N^{\frac{1}{2} + \frac{(1/2 - 1/4)}{m} \sum_{i=1}^{m} |E_{\tau} g_i|^2_{L^p(w_{BR})} \left(\prod_{i=1}^{m} \sum_{l(\tau) = N^{-1/4}} \|E_{\tau} g_i\|_{L^p(w_{BR})}^\rho\right)^{1/m}. \tag{7.1}$$

By the Cauchy-Schwarz inequality, we have for $s \geq 1$

$$\|\left(\prod_{j=1}^{m} |E_{R_j g_j}|^{1/m}\right\|_{L^p(w_{BR})} \leq N^{\frac{1}{2} - \frac{1}{2s}} \left(\prod_{j=1}^{m} \sum_{l(\tau) = N^{-1/2}} |E_{\tau} g_j|^2_{L^p(w_{BR})} \right)^{1/2m} \|E\|_{L^p(w_{BR})} \tag{7.2}$$

We start with (7.2), and apply the estimate (7.1) until we reach the scale $N^{-1/2}$. We control the last term in (7.1) that appears in each step of the iteration by parabolic rescaling. That is, for each cube $R \subset [0, 1]^3$ with side length $L$, we have

$$\|E_{Rg}\|_{L^p(w_{BR})} \leq D \left(\frac{N}{L^2}, p\right) \left(\sum_{\Delta \subset R} \|E\|_{L^p(w_{BR})} \right)^{1/p}. \tag{7.3}$$

In the end, we obtain

$$\left(\prod_{j=1}^{m} \sum_{l(\Delta) = N^{-1/2}} |E_{\Delta} g_j|^2\right)^{1/2m} \left(\prod_{j=1}^{m} \sum_{l(\tau) = N^{-1/4}} \|E_{\tau} g_j\|_{L^p(w_{BR})}^\rho\right)^{1/m} \lesssim_{\rho, K} N^{\frac{1}{2} - \frac{1}{2s} - \frac{1}{2m} \sum_{j=1}^{m} |E_{\Delta} g_j|^2_{L^p(w_{BR})} \left(\prod_{j=1}^{m} \sum_{l(\tau) = N^{-1/4}} \|E_{\tau} g_j\|_{L^p(w_{BR})}^{\rho}\right)^{1/m}} \tag{7.4}$$

By Hölder’s and Minkowski’s inequality, we bound the second to last term by

$$N^{\frac{1}{2} - \frac{1}{2s} - \frac{1}{2m} \sum_{j=1}^{m} |E_{\Delta} g_j|^2_{L^p(w_{BR})} \left(\prod_{j=1}^{m} \sum_{l(\tau) = N^{-1/4}} \|E_{\tau} g_j\|_{L^p(w_{BR})}^{\rho}\right)^{1/m}}. \tag{7.5}$$

By taking supremum over all $\nu_K$-transverse cubes $R_i$ and all $g_i : R_i \to \mathbb{C}$, these observations lead to

$$D_{multi}(N, p, \nu_K) \leq \left(C_{p, K, \nu} N^s \sum_{i=1}^{N^{1/2 - \frac{1}{2s} + \frac{1}{2} \left(\frac{1}{2} - \frac{1}{4}\right)}} \left\|E_{\Delta} g_j\|_{L^p(w_{BR})}^{\rho}\right)^{1/m}} \right) \times D \left(N^{1-2^{-s+1}}, p\right)^{\kappa(1-\kappa)} \times \cdots \times D \left(N^{1-2^{-s+2}}, p\right)^{\kappa(1-\kappa)} \tag{7.6}$$

Now we come to the final step of the proof Theorem 1.1. Recall that we have shown that the linear decoupling constant $D(N, p)$ is essentially controlled by the multilinear decoupling constant
See the estimate (6.3) from Proposition 6.1. The estimate (7.6) also reveals a connection between these two constants. We will see that these two estimates together lead to the final conclusion.

Let \( \gamma_p \) be the unique positive constant such that

\[
\lim_{N \to \infty} \frac{D(N, p)}{N^{\gamma_p + \delta}} = 0, \text{ for each } \delta > 0,
\]

and

\[
\limsup_{N \to \infty} \frac{D(N, p)}{N^{\gamma_p - \delta}} = \infty, \text{ for each } \delta > 0.
\]

By substituting the estimate \( D(N, p) \lesssim N^{\gamma_p + \delta} \) into (7.6), we obtain

\[
\limsup_{N \to \infty} \frac{D_{\text{multi}}(N, p, \nu_K)}{N^{\gamma_p, \delta, s, \epsilon}} < \infty.
\]

Here

\[
\gamma_{\kappa, p, \delta, s, \epsilon} = \epsilon(s - 1) + 3 \cdot 2^{-s} + 3 \cdot \left(\frac{1}{2} - \frac{1}{p}\right)(1 - \kappa)^{s - 1} + 3 \kappa 2^{-s} \left(\frac{1}{2} - \frac{1}{p}\right) \frac{1 - (2(1 - \kappa))^{s - 1}}{2 \kappa - 1}
\]

\[
+ \kappa(\gamma_p + \delta) \left(\frac{1 - (1 - \kappa)^{s - 1}}{\kappa} - 2^{-s + 1} \frac{1 - (2(1 - \kappa))^{s - 1}}{2 \kappa - 1}\right).
\]

By invoking interpolation, it suffices to prove that

\[
\gamma_{\frac{14}{3}} \leq \frac{3}{2} \left(\frac{1}{2} - \frac{3}{14}\right) = \frac{3}{7}.
\]

We observe that

\[
2(1 - \kappa_{\frac{14}{3}}) = 1.
\]

This is precisely the relation that shows that \( \frac{14}{3} \) is the critical exponent for our decoupling. It suffices to prove that for each \( \kappa > \frac{1}{2} \),

\[
\gamma_{\frac{14}{3}} \leq \frac{3}{2} \left(\frac{2 \kappa - 1}{2 \kappa} + \frac{1}{2} - \frac{3}{14}\right).
\]

Assume for contradiction that there exists \( \kappa > \frac{1}{2} \) such that

\[
\gamma_{\frac{14}{3}} > \frac{3}{2} \left(\frac{2 \kappa - 1}{2 \kappa} + \frac{1}{2} - \frac{3}{14}\right).
\]

Using (7.13), multiplying both side of (7.10) by \( 2^s \), letting \( s \) be large enough, and then \( \epsilon \) and \( \delta \) be small enough, we obtain

\[
\gamma_{\kappa, \frac{14}{3}, \delta, s, \epsilon} < \gamma_{\frac{14}{3}}.
\]

Fix small enough \( \epsilon, \delta \) and large enough \( s \), then choose \( K \) so large that

\[
\frac{3}{2} \left(\frac{1}{2} - \frac{3}{14}\right) + \epsilon + \beta(\frac{14}{3}, K, \epsilon) < \frac{3}{2} \left(\frac{2 \kappa - 1}{2 \kappa} + \frac{1}{2} - \frac{3}{14}\right),
\]

and

\[
\gamma_{\kappa, \frac{14}{3}, \delta, s, \epsilon} + \epsilon + \beta(\frac{14}{3}, K, \epsilon) < \gamma_{\frac{14}{3}}.
\]

Here \( \beta(\frac{14}{3}, K, \epsilon) \) is the constant that appears in Proposition 6.1. Now combining Proposition 6.1 with (7.13) and (7.15), we find that

\[
D(N, \frac{14}{3}) \lesssim_{K, \epsilon} N^{\epsilon + \beta(\frac{14}{3}, K, \epsilon)} \max_{1 \leq M \leq N} \left[ \left(\frac{M}{N}\right)^{-\frac{1}{2} - \frac{3}{14}} D_{\text{multi}}(M, \frac{14}{3}, \nu_K) \right].
\]
We distinguish two cases, each of which will lead to a contradiction.

Case 1. Assume $\gamma, \kappa, 14, \delta, s, \epsilon < \frac{3}{2}(\frac{1}{2} - \frac{3}{14})$. Then by (7.9) and (7.17), we obtain
\begin{equation}
D(N, \frac{14}{3}) \lesssim K, \epsilon N^{\frac{3}{2}}\left(\frac{1}{2} - \frac{3}{14}\right).
\end{equation}
By (7.15), this contradicts the assumption (7.13).

Case 2. Assume $\gamma, \kappa, 14, \delta, s, \epsilon \geq \frac{3}{2}(\frac{1}{2} - \frac{3}{14})$. Substitute this into (7.17), we obtain
\begin{equation}
D(N, \frac{14}{3}) \lesssim K, \epsilon N^{\frac{3}{2}}\left(\frac{1}{2} - \frac{3}{14}\right).
\end{equation}
By (7.16), this contradicts the definition of the constant $\gamma_{14}$.

The analysis of these cases shows that (7.13) can not be true. This finishes the proof of the estimate $\gamma_{14} \leq \frac{3}{7}$, and thus, of Theorem 1.1.

8 Some linear algebra

Let us start by recalling some notation. We are concerned with the surface
\begin{equation}
S := \{(r, s, t, Q_1(r, s, t), Q_2(r, s, t)) : (r, s, t) \in [0, 1]^3\}
\end{equation}
satisfying the requirement of Theorem 1.1. In this section, we will say that a property $\Omega = \Omega(\xi)$ (here $\xi \in \mathbb{R}^3$) holds almost surely if $\{\xi : \Omega(\xi) \text{ does not hold}\} \neq \mathbb{R}^3$. We will write $V_{r,s,t}$ to denote the tangent space to $S$ at $(r, s, t, Q_1(r, s, t), Q_2(r, s, t))$ and $\pi_{r,s,t}$ to denote the orthogonal projection onto it.

The main purpose of this section is to prove the following lemma.

Lemma 8.1. 1) Let $V$ be a one dimensional linear subspace of $\mathbb{R}^5$. Then the set
\begin{equation}
\{(r, s, t) : \dim(\pi_{r,s,t}(V)) = 0\}
\end{equation}
is contained in a 2-variety.

2) Let $V$ be a two (resp. four) dimensional linear subspace of $\mathbb{R}^5$. Then the set
\begin{equation}
\{(r, s, t) : \dim(\pi_{r,s,t}(V)) \leq 1(\text{ resp. } 2)\}
\end{equation}
is contained in a 2-variety.

Proof. First, we will observe one consequence of the condition imposed in Theorem 1.1. Take $(u, v, w) = (1, 0, 0), (0, 1, 0)$ and $(0, 0, 1)$, we see that
\[
\begin{vmatrix}
\partial_s Q_1 & \partial_t Q_1 \\
\partial_s Q_2 & \partial_t Q_2 \\
\end{vmatrix}, \begin{vmatrix}
\partial_s Q_1 & \partial_t Q_1 \\
\partial_s Q_2 & \partial_t Q_2 \\
\end{vmatrix}, \begin{vmatrix}
\partial_s Q_1 & \partial_t Q_1 \\
\partial_s Q_2 & \partial_t Q_2 \\
\end{vmatrix}
\]
are nonzero polynomials in $r, s, t$. Thus in particular,
\begin{equation}
\text{rank } \begin{pmatrix}
\partial_s Q_1(\xi) & \partial_s Q_1(\xi) & \partial_s Q_1(\xi) \\
\partial_s Q_2(\xi) & \partial_s Q_2(\xi) & \partial_s Q_2(\xi) \\
\end{pmatrix} = 2
\end{equation}
almost surely.

We start by proving the first statement. Notice that $V_{r,s,t}$ is given by the span of the three vectors
\begin{align}
n_1 &= (1, 0, 0, \partial_s Q_1, \partial_t Q_2), \\
n_2 &= (0, 1, 0, \partial_s Q_1, \partial_t Q_2), \\
n_3 &= (0, 0, 1, \partial_s Q_1, \partial_t Q_2).
\end{align}
Let $V \subset \mathbb{R}^5$ be a one-dimensional subspace. Suppose that $V = \text{span}\{x\}$ for some non-zero vector $x = (x_1, x_2, x_3, x_4, x_5) \in \mathbb{R}^5$. The dimension of $\pi_{r,s,t}(V)$ is equal to the rank of the matrix

$$
(x \cdot n_1, x \cdot n_2, x \cdot n_3).
$$

(8.5)

Moreover, if we view $x \cdot n_i$ with $i = 1, 2, 3$ as affine functions in $r, s$ and $t$, we will show that at least one of them does not vanish constantly. Suppose this is not the case. Then $x_1 = x_2 = x_3 = 0$ and

$$
x_4 \partial_r Q_1 + x_5 \partial_s Q_2 = x_4 \partial_s Q_1 + x_5 \partial_s Q_2 = x_4 \partial_t Q_1 + x_5 \partial_t Q_2 = 0.
$$

(8.6)

Since $x$ is a nonzero vector, $(x_4, x_5) \neq (0, 0)$. Hence by (8.6),

$$
\text{rank} \begin{pmatrix}
\partial_r Q_1(\xi) & \partial_s Q_1(\xi) & \partial_t Q_1(\xi) \\
\partial_r Q_2(\xi) & \partial_s Q_2(\xi) & \partial_t Q_2(\xi)
\end{pmatrix} \leq 1.
$$

for every $\xi$. This contradicts (8.3).

We turn to the proof of the second statement. The following approach is in the spirit of [5]. Define the vector spaces of polynomials

$$
S_0 = [1], S_1 = [r, s, t] \text{ and } S_2 = [Q_1(r,s,t), Q_2(r,s,t)].
$$

(8.7)

For $\xi = (r_0, s_0, t_0) \in \mathbb{R}^3$, let

$$
P_\xi f(r, s, t) = f(\xi) + \partial_r f(\xi)(r - r_0) + \partial_s f(\xi)(s - s_0) + \partial_t f(\xi)(t - t_0)
$$

(8.8)

be the first order Taylor expansion of the function $f$ at the point $\xi$. Hence $P_\xi$ is a projection onto $S_0 \oplus S_1$. Moreover, we have

$$
\pi_{S_1}P_\xi f(r, s, t) = \partial_r f(\xi)r + \partial_s f(\xi)s + \partial_t f(\xi)t.
$$

(8.9)

Define $S = S_1 \oplus S_2$. Let $V$ be a subspace of $\mathbb{R}^5$. We could think of $V$ as a subspace of same dimension in $S$ by defining the isomorphism $(x_1, x_2, x_3, x_4, x_5) \mapsto (x_1 r + x_2 s + x_3 t + x_4 Q_1 + x_5 Q_2)$ from $\mathbb{R}^5$ to $S$. Under this correspondence, it is easy to see that $\dim(\pi_\xi(V)) = \dim(\pi_{S_1}P_\xi(V))$, where $\pi_\xi(V)$ is the projection of $V$ onto the tangent space to $S$ at $\xi$ when $V$ is considered as a subspace of $\mathbb{R}^5$. Thus, we need to prove that almost surely in $\xi$,

$$
\dim(\pi_{S_1}P_\xi(V)) = \dim([\partial_r f(\xi), \partial_s f(\xi), \partial_t f(\xi)] : f \in V) \geq \begin{cases} 
2, & \text{if } \dim(V) = 2 \\
3, & \text{if } \dim(V) = 4
\end{cases}
$$

(8.10)

This will imply that the set (8.2) is contained in a 2-varietiy because the “bad” set where the dimension is smaller than what we need is contained in the zero set of some nonzero polynomial of degree at most 2.

We first consider the case $\dim(V) = 2$. By contradiction, we assume that

$$
\dim(\pi_{S_1}P_\xi(V)) \leq 1 \text{ for every } \xi.
$$

(8.11)

Taking $\xi = (0, 0, 0)$, we have $\pi_{S_1}P_\xi(V) = \pi_{S_1}(V)$. Hence $\dim(\pi_{S_1}(V)) \leq 1$. This further implies $\dim(\pi_{S_2}(V)) \geq 1$. We will consider two cases.

**Case 1.** $\dim(\pi_{S_2}(V)) = 2$. In this case we have $\pi_{S_2}(V) = S_2$. By a direct calculation,

$$
\dim(\pi_{S_1}P_\xi(V)) \geq \dim(\pi_{S_1}P_\xi(\pi_{S_2}(V))) =
$$

$$
\dim(\pi_{S_1}P_\xi(S_2)) = \text{rank} \begin{pmatrix}
\partial_r Q_1(\xi) & \partial_s Q_1(\xi) & \partial_t Q_1(\xi) \\
\partial_r Q_2(\xi) & \partial_s Q_2(\xi) & \partial_t Q_2(\xi)
\end{pmatrix}
$$

which equals 2 almost surely in $\xi$, by (8.3). This is a contradiction to (8.11).
Case 2. \( \dim(\pi_S(V)) = 1 \). In this case \( \dim(\pi_S(V)) = 1 \). Also, \( \pi_S, P_\xi(V) \) is a subspace of \( \pi_S, P_\xi(S_2) \) of co-dimension at most one. Observe that \( \pi_S, P_\xi(S_2) = \pi_S(V) \). Suppose that \( \pi_S(V) \) is spanned by the non-zero vector \((u, v, w) \in \mathbb{R}^3 \). Then the dimension of the space \( \pi_S(V) + \pi_S, P_\xi(S_2) \) is given by

\[
\begin{pmatrix}
\partial_1 Q_1(\xi) & \partial_2 Q_1(\xi) & \partial_3 Q_1(\xi) \\
\partial_1 Q_2(\xi) & \partial_2 Q_2(\xi) & \partial_3 Q_2(\xi)
\end{pmatrix}
\]

which, by the assumption of Theorem 1.1, equals three almost surely in \( \xi \). Hence \( \pi_S, P_\xi(V) \) is at least 2 almost surely in \( \xi \). This is again a contradiction to (8.11).

We have finished the proof of the case \( \dim(V) = 2 \).

In the end we consider the case \( \dim(V) = 4 \). We will again argue by contradiction. Suppose that

\[
\dim(\pi_S, P_\xi(V)) \leq 2 \text{ for every } \xi.
\]

Then we obtain \( \pi_S(V) \leq 2 \) as before. Therefore \( \dim(\pi_S(V)) = 2 \). Hence \( \dim(\pi_S(V)) = 2 \) and \( V = \pi_S(V) \oplus S_2 \). Take a non-zero vector \((u, v, w) \in \pi_S(V) \). Then the dimension of \( \pi_S, P_\xi(V) \) is at least equal to the rank from (8.12), which, by the assumption of Theorem 1.1, is three almost surely in \( \xi \). This leads to a contradiction to (8.13). Thus we have finished the proof of the case \( \dim(V) = 4 \).

9 Other related manifolds

Let \( D_M(N, p) \) be the \( pLp \) decoupling constant associated with a \( d \)-dimensional manifold \( M \) in \( \mathbb{R}^n \)

\[
M = \{ (t_1, \ldots, t_d, \phi_1(t_1, \ldots, t_d), \ldots, \phi_{n-d}(t_1, \ldots, t_d) ), t_i \in [0,1] \}.
\]

The functions \( \phi_i \) need not necessarily be quadratic, just continuous. We claim the following universal lower bound

\[
D_M(N, p) \gtrsim_M \max\{N^{\frac{2}{p} - \frac{2}{p}}, N^{\frac{2}{p} - \frac{n}{p}}\}, \quad p \geq 2.
\]

Let us see why this holds true. Theorem 2.2 in [6] extends easily to our generality here. It implies that for each \( p \geq 2 \) and each \( a_{i_1, \ldots, i_d} \in \mathbb{C}, 0 \leq i_1, \ldots, i_d \leq N \) we have

\[
\left( \frac{1}{N^{2n}} \int_{[0,N^2]^n} \left| \sum_{i_1=0}^N \cdots \sum_{i_d=0}^N a_{i_1,\ldots,i_d} e\left( x_1 \frac{i_1}{N} + \cdots + x_d \frac{i_d}{N} \right) + \sum_{j=d+1}^n x_j \phi_j\left( \frac{i_1}{N}, \ldots, \frac{i_d}{N} \right) \right|^p dx_1 \cdots dx_n \right)^\frac{1}{p}
\leq D_M(N^2, p) \|a_{i_1,\ldots,i_d}\|_{L^p}.
\]

Let us now specialize to the case \( a_{i_1,\ldots,i_d} \equiv 1 \). We get

\[
\left( \frac{1}{N^{2n}} \int_{[0,N^2]^n} \left| \sum_{i_1=0}^N \cdots \sum_{i_d=0}^N e\left( x_1 \frac{i_1}{N} + \cdots + x_d \frac{i_d}{N} \right) + \sum_{j=d+1}^n x_j \phi_j\left( \frac{i_1}{N}, \ldots, \frac{i_d}{N} \right) \right|^p dx_1 \cdots dx_n \right)^\frac{1}{p}
\leq D_M(N^2, p) N^\frac{2}{p}.
\]

We present two lower bounds for (9.3). The first is obtained by rewriting (9.3) (using periodicity) as follows

\[
\left( \frac{1}{N^{2n-d}} \int_{[0,N]^d \times [0,N^2]^{n-d}} \left| \sum_{i_1=1}^N \cdots \sum_{i_d=1}^N e\left( x_1 \frac{i_1}{N} + \cdots + x_d \frac{i_d}{N} \right) + \sum_{j=d+1}^n x_j \phi_j\left( \frac{i_1}{N}, \ldots, \frac{i_d}{N} \right) \right|^p dx_1 \cdots dx_n \right)^\frac{1}{p}.
\]
and by restricting $|x_1|, \ldots, |x_n| \lesssim_\mathcal{M} 1$. This restriction will almost align the phases of exponentials and will produce the lower bound

$$N^d N^{-\frac{2n-d}{p}}.$$ 

Using Hölder provides the following second lower bound for (9.3)

$$\left( \frac{1}{N^{2n}} \int_{[0,N^2]^n} | \sum_{i_1=1}^N \cdots \sum_{i_d=1}^N e^{x_1 \frac{i_1}{N} + \cdots + x_d \frac{i_d}{N}} + \sum_{j=d+1}^n x_j \phi_j(\frac{i_1}{N}, \ldots, \frac{i_d}{N})|^2 dx_1 \cdots dx_n \right)^{\frac{1}{p}}.$$ 

This term is of order $N^{\frac{d}{p}}$, which can be seen by invoking $L^2$ quasi-orthogonality. Now (9.1) follows by combining these two lower bounds.

These considerations suggest the following question.

**Question 9.1.** Is it true that for each $n > d \geq 1$ there exists a $d$-dimensional manifold in $\mathbb{R}^n$ whose decoupling constant satisfies

$$D_M(N,p) \lesssim N^d \max\{N^{\frac{d}{p}(\frac{1}{2} - \frac{1}{p})}, N^{\frac{d}{p} - \frac{1}{p}}\} \quad (9.5)$$

for all $p \geq 2$?

Note that this upper bound is trivially true for $p = 2, \infty$. By invoking interpolation as in [4], (9.5) is equivalent with the inequality

$$D_M(N,p) \lesssim N^{\frac{d}{p}(\frac{1}{2} - \frac{1}{p}) + \epsilon} \quad (9.6)$$

for $2 \leq p \leq p_c = \frac{4n}{d} - 2$. The largest $p_c$ for which (9.6) holds for $2 \leq p \leq p_c$ is the so-called critical exponent for the $l^p L^p$ decoupling for $\mathcal{M}$. The question we asked is whether there is a manifold for which $p_c = \frac{4n}{d} - 2$. It seems likely that the answer is “yes” at least when $d \geq \frac{4n}{d}$.

By combining all previous results on decouplings, we have a positive answer in the case $(d,n) = (n - 1, n)$ (hypersurfaces, see [4]) for all $n \geq 2$. Other known cases are $(d,n) = (2,4)$ (see [9]), $(2,5)$ (see [6]) and $(2,9)$ (see [5]). And of course, we can now add $(3,5)$. An interesting case for which the above question is open is $d = 1$. In particular, it proves that (9.5) holds in some range $2 \leq p \leq p_n$, for some $p_n < 4n - 2$.
