We study electron quantum transport through a strongly interacting Anderson quantum dot at finite bias voltage and magnetic field at zero temperature using the real-time renormalization group (RT-RG) in the framework of a kinetic (generalized master) equation for the reduced density operator. To this end, we further develop the general, finite-temperature real-time transport formalism by introducing field super operators that obey fermionic statistics. This direct second quantization in Liouville-Fock space strongly simplifies the construction of operators and superoperators that transform irreducible under the Anderson-model symmetry transformations. The fermionic field superoperators naturally arise from the univalence (fermion-parity) superselection rule of quantum mechanics for the total system of quantum dot plus reservoirs. Expressed in these field superoperators, the causal structure of the perturbation theory for the effective time-evolution superoperator kernel becomes explicit. Using the constraints of the causal structure, we construct a parametrization of the exact effective time-evolution kernel for which we analytically find the eigenvectors and eigenvalues in terms of a minimal set of only 30 independent coefficients. The causal structure also implies the existence of a fermion-parity protected eigenvector of the exact Liouvillian, explaining a recently reported result on adiabatic driving [L.D. Contreras-Pulido et al Phys. Rev. B 85, 075301 (2012)] and generalizing it to arbitrary order in the tunnel coupling $\Gamma$. Furthermore, in the wide-band limit the causal representation exponentially reduces the number of diagrams for the time-evolution kernel. The remaining diagrams can be identified simply by their topology and are manifestly independent of the energy cut-off term-by-term. By an exact reformulation of this series we integrate out all infinite-temperature effects, obtaining an expansion targeting only the non-trivial, finite-temperature corrections, and the exactly conserved transport current follows directly from the time-evolution kernel. From this new series the previously formulated RT-RG equations are obtained naturally. We perform a complete one-plus-two-loop RG analysis at finite voltage and magnetic field, while systematically accounting for the dependence of all renormalized quantities on both the quantum dot and reservoir frequencies. Using the second quantization in Liouville space and symmetry restrictions, we obtain analytical RT-RG equations, which can be solved numerically in an efficient way, and we extensively study the model parameter space, excluding the Kondo regime where the one-plus-two-loop approach is obviously invalid. The incorporated renormalization effects result in an enhancement of the inelastic cotunneling peak, even at a voltage $\sim$ magnetic field $\sim$ tunnel coupling $\Gamma$. Moreover, we find a tunnel-induced non-linearity of the stability diagrams (Coulomb diamonds) at finite voltage, both in the single-electron tunneling and inelastic cotunneling regime.

I. INTRODUCTION

Non-linear transport spectroscopy of nanoscale systems is a key technique in modern day physics. Although the linear (equilibrium) transport regime is well-understood (see Ref. 3 for a review), the theoretical description of non-equilibrium transport, especially at low temperature, remains challenging. Recent progress in this direction has led to an improved understanding of quantum transport through strongly interacting systems (see Ref. 4 for a recent comparative review). Several fully numerical approaches have appeared, such as the scattering-state time-dependent numerical renormalization group (TD-NRG)\textsuperscript{5} relying on the discretization parameter approximation\textsuperscript{6} time-dependent density matrix renormalization group (TD-DMRG)\textsuperscript{7,2} iterative path integrals (IPSI)\textsuperscript{8} numerically exact influence functional path integrals (INFPI)\textsuperscript{9,10} quantum Monte Carlo (QMC) in combination with the Nakajima-Zwanzig projection technique\textsuperscript{11} or with an imaginary-time formalism\textsuperscript{12} and diagrammatic Monte Carlo (diagMC)\textsuperscript{13} Partially analytical approaches involve the non-crossing approximation (NCA)\textsuperscript{14,15} equations of motion for Green’s functions\textsuperscript{16} Bethe ansatz\textsuperscript{17,18} and the flow-equation approach\textsuperscript{19} Fully analytical approaches include the Keldysh perturbation theory to high orders in the Coulomb interaction $U$ (Ref. 20 and Ref. 21) or the dual-fermion superperturbation theory\textsuperscript{22} Finally, perturbative renormalization group studies have mostly started from the Kondo-model mapping of the Anderson model, either working with Keldysh-Green functions\textsuperscript{23} or the reduced density operator approach\textsuperscript{24,25}

The density operator approach has a long history in various fields of physics and chemistry. In the context of nanoscale transport, it is a natural starting point for the
description of systems with large interaction energies in the high temperature, weak-coupling limit, $U \gg T \gg \Gamma$. It can be systematically extended to include high-order tunneling processes using the real-time diagrammatic\cite{32,33} or Nakajima-Zwanzig approach\cite{34} technique, in particular when combined with Liouville space techniques\cite{35}. However, at low temperature this approach becomes problematic due to effect of high-energy contributions that renormalize the effective low-energy physics. In this paper, we show how this approach can be extended to this regime. In particular, we show that much of the insightful structure of generalized the master / kinetic equation approach at high temperature is preserved in this regime. We formulate a real-time renormalization group approach that naturally connects to the generalized quantum master or kinetic equation approach.

For this purpose, we study the simplest possible benchmark model of an interacting quantum dot (QD) coupled to metallic electrodes, the Anderson model. We explicitly set up a general approach to deal with the non-linear transport at very low temperature using a renormalization group formulation in the framework of the real-time perturbation theory. We proceed analytically as far as possible, making this a technically challenging task. In fact, the problem is not really manageable without a different physical approach for dealing with superoperators. The development of this Liouville-Fock space approach is a central topic of this paper. Our approach differs from previous formulations\cite{34,35}, both by its construction and by the scope of its application. The most closely related is that of Prosen\cite{34}, which was used to calculate steady states of quadratic effective Liouvillians. Here, we extend it to the reservoirs with continuous fields as well and further develop it to simplify the microscopic derivation of effective Liouvillians for non-quadratic problems. The approach introduced by Schmutz\cite{32} and used by other authors\cite{33,34} differs from our approach in principal details that are essential for our application. See also the very recent Ref.\cite{35}.

A large part of the paper is devoted to the development of our Liouville-Fock space approach since it allows for general physical insights into the problem and is crucial for overcoming technical difficulties in setting up the real-time renormalization group (RT-RG). We will illustrate its potential in the application to the RT-RG calculation of the non-linear transport at zero temperature. As a result, this paper by necessity is extensive. Further motivation for its length is that several general physical insights into the real-time approach have not been pointed out, although this approach has been developed for some time and has found widespread use (see Ref.\cite{26} for a review). It is therefore required that the approach is set up from scratch, paying special attention to (i) the causal structure and the related Keldysh rotation, (ii) the Liouville space formulation, in particular the second quantization for superoperators, (iii) the spin- and charge-rotation symmetries, and (iv) the infinite-temperature limit, which serves as a reference point, both for the second quantization technique that we develop, as well as for the perturbation theory and RT-RG. Only by fully exploiting these does the application of RT-RG to the Anderson model becomes feasible. Clearly, these developments are best presented coherently in the context of the application to the RT-RG for which it is absolutely crucial.

To indicate the impact of these developments for our study of the Anderson model, we note that the simplest approximation that includes the exact result for the $U = 0$ limit requires an infinite series of diagrams in the standard real-time perturbation theory. Using the RT-RG, this result is recovered only when performing a one- and two-loop analysis for the effective Liouvillian and including one-loop vertex corrections. We emphasize that when applied to the interacting case, this incorporates renormalization effects from strong tunneling, while neglecting spin-fluctuation processes relevant only in the Kondo regime, which enter only in a three-loop RG analysis (the latter has been addressed previously based on a Kondo-model mapping\cite{25}). Naively formulating these RG equations leads to hundreds of non-linear, coupled integro-differential equations for frequency-dependent coupling functions. The central result of this paper is the derivation of 30 coupled differential coupling functions, which systematically incorporate the leading frequency dependence and describe the $U = 0$ limit exactly. On the way, we derive several exact results of general importance. Altogether, this makes an efficient numerical implementation possible and allows experimentally relevant stability diagrams to be calculated from wide ranges of parameters in the non-linear zero-temperature regime (excluding the narrow Kondo regime). Many of the results can be extended to generic models involving local interactions (multiorbital Anderson-type models) with bilinear tunnel coupling to reservoirs. See Ref.\cite{30} for a recent study of non-local interactions using the RT-RG.

The paper is organized in three main parts as follows. In the first part, Sec.\cite{11}, we formulate the model and directly revert to a Liouville space description and develop the kinetic equation approach for the stationary QD density operator. We formulate the perturbation series for the effective Liouvillian $L(z)$ appearing in this equation using what we will call causal representation of field superoperators $G$ with fermionic statistics. We emphasize that this formulation of the perturbation theory, although equivalent to previous formulations\cite{29,30,31} leads to many simplifications beyond the application of interest here, and therefore warrants a proper, extensive discussion. Several of these results have already found application\cite{29} and even provide insights into, and generalization of, recent interesting predictions\cite{30}. Moreover, a renormalized perturbation theory that takes the infinite-temperature limit as a formal reference point, suggests itself. It also connects in a natural way to the renormalization group approach while preserving much of its general perturbative structure. We show how the calculation of the current requires little additional calculation.
and prove that in our non-linear approach the linear current vanishes at zero bias, a fact that is not obvious from the general structure of the theory.

In the second main part of the paper, Sec. (III), the explicit one- and two-loop RT-RG equations are derived, accounting for the energy dependence of both the Liouvillian and the vertices due to the finite non-linear transport voltage. For the non-interacting case, \( U = 0 \), the current is shown to arise naturally as an exact result already in the one-loop RT-RG, implying that all two-loop corrections to this observable arise from the strong local Coulomb interaction. We find, however, that for \( U = 0 \) non-zero, two-loop terms exist, which are relevant when one is interested in, e.g., the density matrix (and not just the current). The non-trivial frequency dependence of two-loop equations is systematically accounted for in powers of the renormalized dimensionless coupling superoperators \( \bar{\mathcal{G}} \), resulting in an effective RG equation for an effective Liouvillian only that accounts for vertex renormalization corrections.

This simplification enables the detailed numerical study of the zero-temperature, non-linear transport in the third part of the paper, Sec. (IV). This covers all regimes, except for the Kondo regime of low applied voltage and magnetic field. The importance of accounting for both one- and two-loop corrections, as well as the non-equilibrium Matsubara axes is demonstrated numerically. Finally, we show that the tunnel-induced renormalization effects incorporated in our one- plus-two-loop approach enhance the inelastic cotunneling resonance at finite magnetic field and voltage and generate non-linearities of the single-electron tunneling (SET) stability diagrams (Coulomb diamonds).

II. MODEL AND REAL-TIME TRANSPORT THEORY

A. Anderson model

In this section we introduce the model and our compact notation, which is crucial to the Liouville space formulation of the theory. The simplest model Hamiltonian of a QD that takes into account Coulomb interaction effects involves just a single orbital:

\[
H = \epsilon n + BS_z + Un_\uparrow n_\downarrow.
\]

where \( n = \sum \sigma n_\sigma \) and \( n_\sigma = d_{\sigma}^\dagger d_\sigma \) are the occupation operators. Here, \( \epsilon \) denotes the energy of the orbital, experimentally controlled by the gate voltage \( V_g \) (we take \( \epsilon = -V_g \)), and \( U \) is the Coulomb charging energy. The index \( \sigma = \pm \) corresponds to spin up (\( \uparrow \)) and down (\( \downarrow \)) and \( S_z = \frac{1}{2} \sum \sigma \sigma n_\sigma \) is the \( z \) component of the spin vector operator \( \mathbf{S} = \sum \sigma \sigma \frac{1}{2} \sigma_\sigma d_\sigma^\dagger d_\sigma \) along the external magnetic field \( \mathbf{B} = B\mathbf{e}_z \) (in units where \( g\mu_B = 1 \)) and \( \sigma \) is the vector of Pauli matrices. The dot is attached to electrodes, treated as free electron reservoirs:

\[
H^R = \sum_{\sigma,r,k} \epsilon_{\tau,k} a_{\sigma,r,k}^\dagger a_{\sigma,r,k},
\]

where the index of the spin \( \sigma = \pm \), quantized along the \( z \)-axis, corresponds to \( \uparrow, \downarrow \), the reservoir index \( r = \pm \) corresponds to \( L, R \) and \( k \) is the orbital index. The reservoir electron number and spin operator can be decomposed as \( n^R = \sum r n^r \) and \( s^R = \sum r s^r \), respectively, into

\[
n^r = \sum_{\sigma,k} a_{\sigma,r,k}^\dagger a_{\sigma,r,k},
\]

\[
s^r = \sum_{\sigma,k} \frac{1}{2} \sigma_{\sigma,\sigma'} a_{\sigma,r,k}^\dagger a_{\sigma',r,k}.
\]

In the continuum limit the reservoirs are described by the density of states \( \nu_r(\omega) = \sum_k \delta(\omega - \epsilon_{\tau,k} + \mu_r) \) and we go to the energy representation of the fermionic operators,

\[
a_{\sigma,r}(\omega) = \frac{1}{\sqrt{\nu_r(\omega)}} \sum_k a_{\sigma,r,k} \delta(\omega - \epsilon_{\tau,k} + \mu_r),
\]

with the anticommutation relations

\[
[a_{\sigma,r}(\omega), a_{\sigma',r',(\omega')}^\dagger]_\pm = \delta_{\sigma,\sigma'} \delta_{\tau,\tau'} \delta(\omega - \omega'), \quad [a_{\sigma',r}(\omega), a_{\sigma,r',(\omega')}^\dagger] = 0,
\]

where we denote (anti)commutators by \([A, B]_\pm = AB \pm BA\). Thus we have for the reservoir Hamiltonian:

\[
H^R = \sum_{\sigma,\tau} \int d\omega (\omega + \mu_r) a_{\sigma,\tau}(\omega) a_{\sigma,\tau}(\omega).
\]

In contrast to \( \epsilon_{\tau,k} \) the energy \( \omega \) is the electron energy relative to \( \mu_r \), i.e., the reference energy depends on which reservoir \( r \) is considered.

The junctions connecting the dot and reservoirs are modeled by the tunneling Hamiltonian

\[
V = \sum_r V^r,
\]

\[
V^r = \sum_{\sigma} \int d\omega \sqrt{\nu_r(\omega)} (t_r(\omega)a_{\sigma,r}(\omega)d_\sigma + \text{h.c.}) .
\]

The Hamiltonian of the total system is denoted by

\[
H^\text{tot} = H + H^R + V.
\]

We assume \( t_r(\omega) \) to be real and introduce the spectral density

\[
\Gamma_r(\omega) = 2\pi \nu_r(\omega) |t_r(\omega)|^2
\]

and rescaled field operators

\[
b_{\sigma,r}(\omega) = \sqrt{\frac{\Gamma_r(\omega)}{2\pi}} a_{\sigma,r}(\omega).
\]
To make the notation more compact we introduce an additional particle-hole index $\eta$:

$$
\begin{align*}
&b_{\eta,\sigma,r}(\omega) = \begin{cases} 
  b^\dagger_{\eta,\sigma,r}(\omega) & \eta = + \\
  b_{\eta,\sigma,r}(\omega) & \eta = - 
\end{cases}, \\
&d_{\eta,\sigma} = \begin{cases} 
  d^\dagger_{\sigma} & \eta = + \\
  d_{\sigma} & \eta = - 
\end{cases}.
\end{align*}
$$

(14)

(15)

Throughout the paper we will denote the inverse value of a two-valued index with a bar, e.g.,

$$
\bar{\eta} = -\eta.
$$

(16)

We combine all indices into a multi-index variable written as a number:

$$
1 = \eta, \sigma, r, \omega, \quad \bar{1} = \bar{\eta}, \sigma, r, \omega.
$$

(17)

By way of exception, the bar denotes inversion of the particle-hole index $\eta$ only. With $b_1 = b_{\eta,\sigma,r}(\omega)$ and $\bar{b}_1 = b_{-\eta,\sigma,r}(\omega)$ the various independent anticommutation relations can be compactly summarized as

$$
[d_1, d_2]_+ = \delta_{12},
$$

(18)

$$
[b_1, b_2]_+ = \frac{\Gamma_1}{2\pi} \delta_{12},
$$

(19)

where $\Gamma_1 = \Gamma_r(\omega)$. The interaction then simply reads as

$$
V = b_1 d_1,
$$

(20)

where we implicitly assume summation over all discrete parts of the multi-index 1 (i.e., $\eta, \sigma, r$) and integration over its continuous part ($\omega$). If we have more than one multi-index, we distinguish their components by corresponding subscripts: $1 = \eta_1, \sigma_1, r_1, \omega_1, 2 = \eta_2, \sigma_2, r_2, \omega_2$. We will often omit these subscripts if only one multi-index appears. Importantly, it can be shown that operators (and, below also superoperators) of the dot and the reservoirs can be treated as if they commute (rather than anticommute), i.e., $[d_1, b_2]_+ = 0$ for all multi-indices 1, 2.

The reservoirs are assumed to be in thermal equilibrium, each described by its own grand-canonical density operator with temperature $T$ and electrochemical potential $\mu^r$:

$$
\rho^R = \prod_r \rho^r, \quad \rho^r = \frac{1}{z^r} e^{-\frac{1}{T_r} (H^r - \mu^r n^r)},
$$

(21)

where $z^r = \text{Tr}_{\text{dot}} e^{-\frac{1}{T_r} (H^r - \mu^r n^r)}$. We assume that a symmetric bias is applied to the electrodes, i.e., $\mu_L, R = \pm V/2$. We note the key property

$$
b_1 \rho^R = e^{\iota \omega_1/T} \rho^R b_1.
$$

(22)

In Eq. (12), the density of states varies on the energy scale of the bandwidth $D$, which we assume to be much larger than any other energy scale in the problem. In this wide-band limit, we can assume $\Gamma_r(\omega)$ to be energy independent and cut off all reservoir energy integrals ($\omega$) at the scale $D$. The detailed energy dependence of $\Gamma_r(\omega)$ at high energies is not crucially important for the results. In the actual applications in Sec. (IV), we will assume for simplicity that the tunnel couplings are symmetric, i.e., $\Gamma_L = \Gamma_R = \Gamma$, and consider the low-temperature limit, i.e., $T \ll U, V, \Gamma_r$, by setting $T = 0$. The results of this section and much of Sec. (III), however, do not depend on these assumptions unless explicitly indicated.

For a non-zero magnetic field $B$ and finite Coulomb interaction $U$, the total system possesses two locally and globally conserved quantities that will play an important role. The charge and the spin components along the magnetic field are conserved individually in the dot and in the reservoirs,

$$
[H,n]_- = 0, \quad [H, S_z]_- = 0,
$$

(23)

$$
[H^R, n^R]_- = 0, \quad [H^R, S^R_z]_- = 0.
$$

(24)

These conservation laws extend to the total charge, $N^\text{tot} = n + n^R$, and spin, $S^\text{tot}_z = S_z + S^R_z$, since the interaction $V$ commutes with these operators:

$$
[H^\text{tot}, N^\text{tot}]_- = 0,
$$

(25)

$$
[H^\text{tot}, S^\text{tot}_z]_- = 0.
$$

(26)

**B. Density operator and diagram rules**

The purpose of this section is twofold. First, we briefly review the real-time approach to the calculation of the stationary reduced density operator, introducing the central quantities $\Sigma(z)$, the self-energy superoperator, and $L(z)$, the effective Liouvillian, and their perturbative expansions in vertex superoperators $G$. Second, we introduce a “causal” representation of the perturbation theory, which allows for a compact formulation and derivation of the diagrammatic rules for the self-energy $\Sigma$. Moreover, many general physical insights become explicitly clear in this representation. In particular, this new formulation naturally suggests the possibility of a two-stage, real-time renormalization group (RT-RG), which will be set up in Sec. (III.3.4) and Sec. (III).

1. **Stationary density operator**

In order to find the QD stationary state, we need to consider the evolution of the total system density operator. It evolves according to the Liouville-von Neumann equation,

$$
\partial_t \rho^\text{tot}(t) = -i [H^\text{tot}, \rho^\text{tot}(t)] = -i L^\text{tot} \rho^\text{tot}(t),
$$

(27)

with the superoperator Liouvillian $L^\text{tot} = [H^\text{tot}, \cdot]$. Superoperators are linear transformations of operators and throughout the paper we let the solid bullet ($\bullet$) indicate the operator on which a superoperator acts (if
needed). Explicit matrix representations of superoperators are only required for the QD part and will be discussed later on in Sec. \[11\text{C}\].

The reduced density matrix of the dot is obtained by the reduced density operator. A key idea exploited following. The formal solution of Eq. (27) is:

\[ \rho^{\text{tot}}(t) = e^{-iH^{\text{tot}}(t-t_0)}\rho(t_0)e^{iH^{\text{tot}}(t-t_0)}. \]

We will discuss some properties of \( \rho(t_0) \) further in the following. The formal solution of Eq. (27) is:

\[ \rho^{\text{tot}}(t) = e^{-iL^{\text{tot}}(t-t_0)}\rho^{\text{tot}}(t_0), \]

The reduced density matrix of the dot is obtained by integrating out the reservoir degrees of freedom:

\[ \rho(t) = \text{Tr}_R \rho^{\text{tot}}(t) = \text{Tr}_R \left( e^{-iL^{\text{tot}}(t-t_0)}\rho(t_0)e^{iL^{\text{tot}}(t-t_0)} \right). \]

We now decompose \( L^{\text{tot}} = L + L^R + L^V \), where \( L = [H, \cdot]_\text{−} \) and \( L^R = [H^R, \cdot]_\text{−} \), and set up the perturbation series in the tunnel coupling \( L^V = [V, \cdot]_\text{−} \sim \sqrt{\Gamma} \). It is then more convenient to use the Laplace transform of the dot reduced density matrix for \( \text{Im} z > 0 \):

\[ \rho(z) = \int_{t_0}^{\infty} dt e^{iz(t-t_0)}\rho(t) \]

\[ = \text{Tr}_R \left( \frac{1}{z-L-L^R-L^V} \rho^{\text{tot}}(t_0) \right). \]

We will refer to \( z \) as the dot frequency. We expand the resolvent in \( L^V \), resulting in a geometric series with terms of the form

\[ \text{Tr}_R \left( \frac{1}{z-L-L^R-L^V} \right)^n \rho^{\text{tot}}(t_0). \]

The average over the reservoirs can now be calculated using a Wick theorem for field superoperators (see Eq. (30) and App. \[A\]). Collecting irreducible contractions into the self-energy superoperator \( \Sigma(z) \) (see below, Sec. \[11\text{B}3\]), the perturbation series can be resummed to

\[ \rho(z) = \frac{i}{z-L(z)}\rho(t_0), \]

where we have introduced the effective dot Liouvillian

\[ L(z) = L + \Sigma(z). \]

To keep the notation to a minimum we distinguish this quantity from the “bare” dot Liouvillian \( L = [H, \cdot]_\text{−} \) by simply appending the dependence on the frequency \( z \). \( L(z) \) completely determines the time-evolution of the reduced density operator. A key idea exploited both in the perturbation theory and in the renormalization group as long as their sum remains equal to \( L(z) \). The equation determining the stationary density matrix \( \rho = \lim_{t \to +\infty} \rho(t) = \lim_{t \to -i0}(-iz\rho(z)) \) is now obtained by multiplying Eq. (35) by \(-iz(z-L(z))\) and taking \( z \to i0 \):

\[ L(i0)\rho = 0. \]

Before deriving the perturbation series for \( \Sigma(z) \) in Sec. \[11\text{B}3\], we first introduce a convenient representation of the field superoperators.

2. Causal representation of fermionic field superoperators

In the following, we integrate out explicitly the reservoir degrees of freedom while keeping track of those of the QD. To facilitate this, the tunnel coupling superoperator \( L^V = [V, \cdot]_\text{−} \) should be written as a convenient product of superoperators of the dot and the reservoirs: inserting Eq. (20), we have

\[ L^V = pL^N^{\text{tot}} \mathcal{F}_p \mathcal{G}_p, \]

where we defined the following “naive” field superoperators:

\[ \mathcal{F}_p = \begin{cases} b_1 & p = +, \\ \bar{b}_1 & p = -, \end{cases} \]

\[ \mathcal{G}_p = \begin{cases} d_1 & p = +, \\ \bar{d}_1 & p = -. \end{cases} \]

The superscript \( p = \pm \) keeps track of whether a field operator acts from the left or right and is referred to as the Keldysh index by analogy to the Green’s function and functional integral techniques. In Eq. (38), we implicitly sum over \( p \), in addition to the multi-index \( 1 \). A crucial difference to the formulation of Ref. \[26\] is that we introduced a harmless additional superoperator

\[ pL^N^{\text{tot}} \cdot = pL^N^R \cdot \]

into Eq. (38), where

\[ L^N^{\text{tot}} = [N^{\text{tot}}, \cdot]_\text{−} = L^n + L^{n^R}, \]

\[ L^n = [n, \cdot]_\text{−}, \]

\[ L^{n^R} = [n^R, \cdot]_\text{−}, \]

are the superoperators associated with the total, QD, and reservoir electron numbers, respectively. Clearly, for \( p = +1 \) this factor is trivially equal to 1. However, it may seem at first sight that for \( p = -1 \) this is not the case: when applied to a projector of states of the total system, this superoperator counts the relative parity of the fermion numbers \( N \) and \( N' \):

\[ (-1)^{L^N^{\text{tot}}[N\lambda][N'\lambda']} = \pm |N\lambda\rangle\langle N'\lambda'| \] for \( N - N' = \) even / odd, where \( \lambda \) and \( \lambda' \)
denote further quantum numbers. However, in all calculations we can assume that the total-system density operators on which it acts have even parity, since odd fermion-parity components of states can neither be measured by any physical operator nor be prepared using physical evolutions. This is referred to as the fermion-parity superselection rule of quantum mechanics.\textsuperscript{40,41}

Since the fermion parity plays an important role in what follows but is often not mentioned or used explicitly in density operator approaches, it warrants some discussion, in particular since odd-fermion-parity operators do appear in the renormalization group approach. Physical Hamiltonians and observables (and their corresponding superoperators) always contain only products of even physical evolutions. This is referred to as the fermion-parity superselection rule of quantum mechanics.\textsuperscript{40,41}

The useful implications of this fermion-parity conservation become clear when performing a linear transformation of the field superoperators with respect to their Keldysh indices \(J\) and \(\tilde{J}\). This complicates many calculations as noted, e.g., in Ref.\textsuperscript{42} However, the factorization of the total fermion parity into a dot and reservoir factor in \textsuperscript{41} naturally suggests a transformation of the field operators. By absorbing the fermion parity superoperators of each subsystem into new field superoperators,\textsuperscript{41}

\[
\begin{align*}
\mathcal{G}_1^q &= pL^q \mathcal{G}_1^p, \\
\mathcal{J}_1^q &= pL^q \mathcal{J}_1^p,
\end{align*}
\]

the latter obey definite anticommutation relations

\[
\begin{align*}
[\mathcal{G}_1^q, \mathcal{G}_2^q]^+ &= p \delta_{pp'} \delta_{12}, \\
[\mathcal{J}_1^q, \mathcal{J}_2^q]^+ &= \frac{\Gamma}{2\pi} p \delta_{pp'} \delta_{12}.
\end{align*}
\]

This allows one to prove the Wick theorem directly for the operators \(\mathcal{J}\) using simple algebra\textsuperscript{41} avoiding the need to carefully keep track of sign factors as done in Ref.\textsuperscript{26} However, the non-vanishing anticommutators still depend on the Keldysh index \(p\) on the right-hand side. Moreover, the fields have no simple Hermitian superconjugation relation (see App.\textsuperscript{13}) This can be avoided by a rotation of the QD fields,

\[
\begin{align*}
\tilde{G}_1 &= \frac{1}{\sqrt{2}} \sum_p \mathcal{G}_1^p = \frac{1}{\sqrt{2}} \sum_p pL^q \mathcal{G}_1^p \quad q = + \\
\tilde{G}_1 &= \frac{1}{\sqrt{2}} \sum_p \mathcal{G}_1^p = \frac{1}{\sqrt{2}} \sum_p pL^{q+1} \mathcal{G}_1^p \quad q = - ,
\end{align*}
\]

and a contravariant rotation (cf. Sec.\textsuperscript{13,13,13}) of the reservoir fields

\[
\begin{align*}
\tilde{J}_1^q &= \frac{1}{\sqrt{2}} \sum_p \mathcal{J}_1^p = \frac{1}{\sqrt{2}} \sum_p pL^{q+1} \mathcal{J}_1^p \quad q = + \\
\tilde{J}_1^q &= \frac{1}{\sqrt{2}} \sum_p \mathcal{J}_1^p = \frac{1}{\sqrt{2}} \sum_p pL^{q} \mathcal{J}_1^p \quad q = - .
\end{align*}
\]

To facilitate later discussions, we introduced both an index \(q = \pm\) as well as “tilde” and “overbar” symbols to distinguish the new field components. Now, the anticommutation relations are completely analogous to those of the usual fermionic operators,

\[
\begin{align*}
&& [\mathcal{G}_1^q, \mathcal{G}_1^q]^+ &= \delta_{q,q'} \delta_{1,1'}, \\
&& [\mathcal{G}_1^q, \mathcal{G}_1^q]^+ &= 0 , \quad (53)
\end{align*}
\]

whereas in the reservoirs we incorporate the coupling into the normalization factor:

\[
\begin{align*}
&& [\mathcal{J}_1^q, \mathcal{J}_1^q]^+ &= \frac{\Gamma_1}{2\pi} \delta_{q,q'} \delta_{1,1'}, \\
&& [\mathcal{J}_1^q, \mathcal{J}_1^q]^+ &= 0 . \quad (54)
\end{align*}
\]

This second transformation is known as the Keldysh rotation\textsuperscript{42} and is, e.g., applied to fermionic fields represented by Grassmann numbers in functional integral theories\textsuperscript{42} or in the Green’s-function formalism\textsuperscript{42} Here, we find that it also considerably simplifies the real-time transport theory in which not all degrees of freedom can be integrated out, in contrast to the cited approaches. We note that a transformation similar to Eqs. (47) and (48), which also results in the usual anticommutation and conjugation relations for the fermionic superoperators, was introduced in Ref.\textsuperscript{52,34} however, without performing the Keldysh rotation. This transformation, however, is less convenient since it does not reveal a general structure of the fermionic superoperators that is important for our applications. In the following, this will be related to causality and we will therefore refer to Eqs. (51) and (52) as the causal representation and to the index \(q = \pm\) as the
causal index. Again, we denote its inverse by $\bar{q} = -q$.

The superoperator approach introduced by Prosen is related to ours, but is constructed in a different way by first introducing a Fock basis (see Sec. II C 2). This construction does not allow one to easily see the relations between Prosen’s superoperators and our causal superoperators. See our detailed comparison of the existing approaches in App. C and D. For the dot field superoperators ($\mathcal{G}^D$) this representation was already introduced in Ref. [26], but it was not exploited in the context of the perturbation theory, where it provides many useful additional simplifications that we now address.

First, the property that for any multiindex $1$,  
\[  \text{Tr}_D(\bar{G}_1 \bullet) = 0 \]  
ensures the probability conservation on the dot during the time-evolution [see Eq. (60)]. This property of $\bar{G}_1$ is extremely important for the formulation of the RT-RG in Sec. II I and is preserved during renormalization. We note that probability conservation in the Liouville space to construct a convenient basis for this space that includes the left and right zero dot equal to the product of pair contractions summed over all contractions of pairs $\langle ik \rangle$.

\[  \text{Tr}_R \left( J_1^{q_1} \ldots J_m^{q_m} \rho^R \right) = \prod_{i<k} (-1)^P \langle J_i^{q_i} J_k^{q_k} \rangle_R, \]

with the usual fermionic sign $(-1)^P$ of the permutation $P$ that disentangles the contractions.

b. Causal structure. The number of possible pair-contractions appearing on the right-hand side of Eq. (60) is strongly limited by the causal structure. Applying $\text{Tr}_R \bar{G}_1$ to Eq. (59) written for the operator $\bar{J}_2$ we obtain a relation between two of the possible four pair contractions:

\[  \langle \bar{J}_1 \bar{J}_2 \rangle_R = \tanh(\eta_2 \omega_2/2T) \langle \bar{J}_1 \bar{J}_2 \rangle_R. \]

This is actually a statement of the equilibrium fluctuation-dissipation theorem for each reservoir separately (see, e.g., Ref. [45]). In close analogy to Eq. (59), one proves that

\[  \text{Tr}_R \left( J_1^{q_1} \ldots J_m^{q_m} \rho^R \right) = \prod_{i<k} (-1)^P \langle J_i^{q_i} J_k^{q_k} \rangle_R, \]

This is analogous to the absence of the so-called “quantum-quantum” contractions and of the “classical-classical” term in the action in the Keldysh functional integral approach and has been referred to as the “causal” structure of the Green functions. However, Eq. (62) entails an additional simplification: $\langle \bar{J}_1 \bar{J}_2 \rangle_R = 0$. This is particular to our real-time superoperator approach, and is most explicitly related to causality. To see this, note that we keep track of the left and right action of operators using superoperator notation and that these superoperators inherit their ordering in the Laplace representation from their forward time-ordering in the time-evolution [cf. Eq. (43)]. We never have to introduce a fictitious backward time-propagation as in the Keldysh technique. Therefore, no advanced reservoir Green functions can appear in our theory, which is expressed by $\langle \bar{J}_1 \bar{J}_2 \rangle_R = 0$. 

a. Wick theorem. First, we note that due to the local interactions on the QD, Eq. (53) cannot be used to formulate a Wick theorem for the vertices $G$. In contrast to this, for the reservoir field superoperators this is possible due to the relation

\[  \bar{J}_1 \rho^R = \tanh(\eta_1 \omega_1/2T) \bar{J}_1 \rho^R. \]
c. Energy and temperature dependence. The only reservoir correlation functions that can appear in the Wick expansion (60) for the causal fields have a simpler energy ($\omega$) and temperature ($T$) dependence than in the representations (39)-(40) and (47)-(48). This correlates with the physical information incorporated in these functions, i.e., in the retarded function
\[ \tilde{\gamma}_{1,2}(n_2\omega_2) := \langle \tilde{J}_1, \tilde{J}_2 \rangle_R = \frac{\Gamma_2}{2\pi} \delta_{1,2}, \] (63)
and in the Keldysh function
\[ \tilde{\gamma}_{1,2}(n_2\omega_2) := \langle \tilde{J}_1, \tilde{J}_2 \rangle_K = \frac{\Gamma_2}{2\pi} \tanh(n_2\omega_2/2T) \delta_{1,2}. \] (64)

In the causal representation, the superoperator ordering explicitly shows that the retarded contraction $\tilde{\gamma}$ contains no information about the distribution function of the reservoirs and is therefore temperature independent. Equation (63) follows directly from the anticommutation relation (Eq. (54)) and the property (62), and is indeed independent of the reservoir density operator $\rho^R$. In contrast, for the Keldysh contraction $\tilde{\gamma}$, one first needs to use the property (59) specific to the equilibrium state of the non-interacting reservoirs, before Eq. (54) and Eq. (62) can be applied. The above shows that the representation (62) reflects most explicitly the causal structure of the perturbation theory, motivating its denotation. It thereby automatically achieves the decomposition of the reservoir Fermi distribution function into its symmetric (trivial) and antisymmetric (non-trivial) parts with respect to the energy $\omega$ that was introduced in Ref. 24, where it was crucial for setting up the RT-RG. In the following, we show that in the causal representation for the QD fields the perturbation theory also drastically simplifies and that in this formulation the RT-RG appears quite naturally.

3. Perturbation series and diagram rules

a. Diagram rules. When defining the causal representations (83) and (84), we performed opposite Keldysh rotations for the dot and the reservoirs. This is motivated by the form of the tunneling Liouvillian Eq. (38), which in the causal representation can be written compactly as
\[ L^V = \tilde{G}_1 \tilde{J}_i + \tilde{G}_2 \tilde{J}_i = \sum_{q \neq \pm} G^V_q J^q_q. \] (65)

We note the convenient absence of a minus sign on the right-hand side: we can treat the dot superoperators $G^V_q$ as if their commute (rather than anticommute) with the reservoir superoperators $J^q_q$ as mentioned in the remark after Eq. (24). We can now integrate out the reservoir degrees of freedom in each term of the expansion (38) in the way discussed in Ref. 24 by commuting all reservoir superoperators to the right side using the relation
\[ J^q_q L^R = (L^R - \eta_1(\omega_1 + \mu_1)) J^q_q. \] (66)
The nth-order contributions to $\Sigma(z)$ then read as
\[
\frac{1}{z - L} G^q_1 \frac{1}{z - X_1 - L} G^q_2 \frac{1}{z - X_2 - L} \ldots \quad (67)
\]
\[
\frac{1}{z - X_{m-1}} G^m_m \frac{1}{z - L} \rho(t_0) \text{Tr} \left( J^q_1 J^q_2 \ldots J^q_m \rho^R \right).
\]

Here, $X_i = \sum_{k \leq i} x_k$, where the summation runs over the reservoir frequencies $x_k = \eta_k(\omega_k + \mu_k)$ of the $G^q_k (J^q_k)$ originally standing to the left of resolvent $i$. Applying the Wick theorem (60), we can represent the terms diagrammatically by propagator-lines connecting vertices that are contracted in pairs by lines with frequencies $x_k$. The irreducible parts of these diagrams, i.e., those parts which cannot be cut without hitting at least one reservoir contration, are collected into the irreducible kernel or self-energy superoperator $\Sigma(z)$. In Fig. 4 we show the diagrams for $\Sigma(z)$ to one- and two-loop order. Leaving implicit the sum over all indices, all possible combinations of pair contractions and all orders $m$, we can write:
\[
\Sigma(z) = (-1)^P \left( \prod \gamma_{ij} \right)_{\text{irr}} \times \quad (68)
\]
\[
\frac{1}{z - X_1 - L} G^q_1 \frac{1}{z - X_{m-1}} G^m_m \frac{1}{z - X_1 - L} G^q_2 \ldots \frac{1}{z - X_{m-1}} G^m_m.
\]
Here, $\gamma$ denotes the function $\tilde{\gamma} (\tilde{\gamma})$, given by Eq. (64) (Eq. (63)), should be written for pair contraction connecting a $\tilde{G}_i$ vertex on the left with a $\tilde{G}_j (\tilde{G}_j)$ vertex on the right. By Eq. (63) it is the earliest vertex (rightmost) that decides the type of contraction, i.e., its indices appear as the argument of the contraction function. Here, $X_i$ is now the sum over the frequencies of all reservoir contractions which go over $i$-th resolvent (since contractions that start and end to the left or right cancel out).

Importantly, since on the left we always have $\tilde{G}$ (i.e., $G^R$ with $q_1 = -\pi$), the property (65) of the causal field of type $\tilde{G}$ is seen to guarantee the conservation of probability:
\[
\text{Tr}_D \Sigma(z) = 0. \quad (69)
\]

Another general property restricts the frequency dependence:
\[ K \Sigma(z) K = -\Sigma(-z^*). \] (70)

Here, $K = K^{-1}$ is the antilinear superoperator that effects the Hermitian conjugation of an operator, see App. C (Such a transformation of an arbitrary superoperator $S \to KSK := S^\ast$ was referred to as “c-conjugation” in Ref. 24). This guarantees through Eq. (65)- (66) that the reduced density operator remains Hermitian during the time-evolution, i.e., $\rho(z) = \rho(-z^*)$. The property (70) derives from the conjugation properties (113) below and from $K L K^{-1} = -L$. The causal representation (38) of the diagrammatic perturbation theory is very useful in general and has been extended to time-dependent problems in Ref. 38,47. We now discuss the main advantages that will be important for setting up the RG and the construction of a convenient supervector basis in Sec. 11 C.
\[ \Sigma(z) = \sum_{G_1} + \sum_{G_2} + \sum_{G_3} + \sum_{G_4} \sim \Gamma/D \ll 1 \]

\[ \sum_{G_1} \sum_{G_2} \sum_{G_3} \sum_{G_4} \sim \Gamma^2/D^2 \ll 1 \]

FIG. 1: One- and two-loop contributions to the self-energy kernel \( \Sigma \). The full black line denotes the free dot propagation, the arrow indicates the ordering of superoperators ("late goes left") in Laplace space that is "inherited" from the time ordering. The curves denote the contraction of dot superoperators. Here, the line connects the dot superoperators whose corresponding reservoir superoperators are contracted: \( \langle GJ \cdots GJ \rangle_R = \langle J \rangle_R^G G \cdots G \rightarrow G \cdots G \). This is in contrast to the standard technique, where a contraction line connects contracted operators themselves. The full blue line denotes a Keldysh contraction \( \gamma \) of two \( G \) type vertices (cf. Eq. (64)) whereas the dashed blue contraction corresponds to the retarded contraction \( \tilde{\gamma} \) of a \( G \) with an earlier \( \tilde{G} \) vertex to the right (cf. Eq. (22)). Diagrams with vanishing contractions, i.e., where \( \tilde{G} \) is contracted to the right (cf. Eq. (22)), are not drawn. Furthermore, the 2 loop diagrams in the light and dark gray boxes contain a \( \gamma \) contraction enclosing \( k = 1 \) and respectively \( k = 2 \) other vertices and therefore scale with \( \Gamma^k/D^k \) and can be neglected in the wide band limit. In the causal representation only 5 diagrams remain, in contrast to formulations using "naive" superoperators where 20 terms remain, which partially cancel out.

b. Wide-band limit. First of all, the number of contributing terms in Eq. (58) is strongly reduced since the trivial \( \gamma \) and non-trivial \( \tilde{\gamma} \) energy dependence of the contractions is automatically separated, which in other representations has to be done separately. Here, terms that do not contribute in the wide bandwidth limit can be identified using the diagram topology as illustrated in Fig. 1. All diagrams where one or more vertices are enclosed between contracted vertices \( \tilde{G}_1 \) and \( \tilde{G}_1 \) give contributions of order \( \Gamma/D \ll 1 \) or smaller and can be neglected. This can be proved by careful examination of the poles appearing when closing all integrals in the complex upper half plane (see Ref. 38), or argued in the time-representation. As a result \( \tilde{\gamma} \) contractions can only occur inside \( \gamma \) contractions in diagrams with more than one loop, see Fig. 1. This results in an exponential reduction in the number of contributing terms.

This feature also naturally suggests a starting point for a two-stage RG approach. First, all terms that contain retarded contractions \( \gamma \) can be integrated out explicitly by a one-step diagram resummation, leading to a renormalization of \( L \) discussed in Sec. (II B 3). The remaining diagrams will then contain only \( \tilde{G} \) superoperators with non-trivial contractions \( \tilde{\gamma} \), which can be eliminated by a second, continuous RG. This approach will be worked out in detail in Sec. (III).

c. Infinite-temperature limit. The choice of the superoperator basis is simplified very much by noting that the superoperator structure of \( \Sigma(z) \) is strongly restricted in the causal representation: in the wide-band limit (see above), there is only one diagram that starts with \( \tilde{G} \) on the right and ends with \( G \) on the left. We denote this special one-loop diagram by \( \Sigma \). Importantly, all other diagrams start and end with a \( G \) vertex. The \( \omega \) integral for the \( \Sigma \) diagram can be performed by closing the integration contour in the upper/lower half-plane of the complex plane for \( \eta = \mp \) and neglecting small corrections of order \( \Gamma/D \ll 1 \):

\[ \Sigma(z) = \int d\omega \tilde{G}_1(z-L-\eta \omega-\eta \mu_i) \tilde{G}_1 = -i \frac{\Gamma_1}{2} \tilde{G}_1 \tilde{G}_1. \]

(71)

where \( \Gamma_1 = \Gamma \), for multiindex \( 1 = \eta, \sigma, r, \omega \). The self-energy \( \Sigma \) has a clear physical meaning: it is the self-energy one obtains in the infinite temperature limit. This follows from its definition since all contractions \( \tilde{\gamma} = 0 \) for \( T = \infty \), and \( \Sigma \) is the only diagram in wide-band limit without this contraction function. As discussed in Sec. (II B 2), the retarded correlation function of the reservoirs \( \tilde{\gamma} \) contains only spectral information (see the discussion of Eq. (63)) and is therefore independent of \( T \). Therefore, \( \Sigma = \Sigma \) at \( T = \infty \). Since at \( T = \infty \) no energy scale matters any more, \( \Sigma \) is independent of the QD frequency \( z \) or any QD energy scale in the problem as well as the cutoff \( D \). The dependence on \( \Gamma \) remains, however: in the high-temperature limit all quantum dot states are equally accessible by tunneling processes. This is described by the self-energy \( \Sigma \).

The action of \( \Sigma \) is very different from that of the Liouvillian \( L \) of the isolated QD: it is not super-Hermitian, as \( L \) is, but rather anti-super-Hermitian,

\[ \Sigma^\dagger = -\Sigma, \]

(72)

which simply follows from the Hermitian conjugation property of the causal field superoperators [Eq. (67)]. For \( T = \infty \), the effective Liouvillian thus reduces to \( L(z) = L + \Sigma(z) \) with stationary state

\[ \rho = \frac{1}{Z} \rho, \]

(73)

which is the maximal entropy state. This follows directly from the causal representation of \( \Sigma \) [Eq. (71)], which shows that \( \Sigma \) and \( \tilde{G} \) share the same right eigenvectors, combined with the probability conservation Eq. (65). By the same argument it is clear that in this limit the current vanishes: anticipating the result of Sec. (III C), we find for the self-energy required for the current equals

\[ \Sigma^\dagger(z) = -i \frac{\Gamma_1}{2} \tilde{G}_1 \tilde{G}_1 \mid_{\gamma = r} = 0, \]

(74)

where in the sum over 1 we exclude the reservoir index \( r \). This also vanishes by Eq. (65) and therefore \( \langle I^r \rangle = 0. \)
d. Cutoff dependence and complete basis Another advantage of the causal representation is that the cutoff dependence of integrals in the individual diagrams that do contribute in the wide-band limit can be analyzed on the level of superoperators. These self-energy contributions seem to depend on the energy integral cutoff $D$. However, using the causal structure of the perturbation theory, one can explicitly see that such dependence cancels out due to the superoperator structure of the vertices (i.e., the matrices multiplying the $D$-dependent contributions to the integrals vanish). The condition for this is that one keeps the complete basis of many-body eigenstates of the dot Hamiltonian. To see this, however, one needs to consider the entire Liouville space, including all off-diagonal density operator elements and not restrict the analysis to only diagonal density matrix elements based on symmetry properties as is often done. The idea is best illustrated by considering the one-loop contributions in Fig. 1. By Eq. (77), the one-loop diagram with a $\tilde{\gamma}$ contraction is explicitly independent of $D$. For the $\tilde{\gamma}$ contraction of two $\tilde{G}$-type vertices,

$$\int d\omega_1 \tilde{G}_1 \frac{\tilde{\gamma}_{11}(\eta_1 \omega_1)}{z - L - \eta_1 \omega_1 - \eta_1 \mu_1} \tilde{G}_1,$$

(75)

the $D$ dependence enters through the most divergent part of the integral, obtained by neglecting $L_D$ in the denominator. This part is thus proportional to a superoperator that is identically zero due to anticommutation relations $\mathcal{A}$. 

$$\tilde{G}_1 \tilde{G}_1 = -\tilde{G}_1 \tilde{G}_1 = \tilde{G}_2 \tilde{G}_2 = 0,$$

(76)

Here, we renamed the dummy summation indices $1 = \eta_1, \sigma_1, r_1, \omega_1$; in fact, only the implicit summation over $\eta_1$ is relevant here. Importantly, this argument breaks down as soon as many-body states have been excluded from the Hilbert space basis, e.g., based on their large energy. For example, in the limit $U \to \infty$, one can exclude the doubly occupied QD state $|2\rangle$ and thereby eliminate Liouville-space elements with eigenvalues exceeding $D$. This simplifies the calculations, but for vertex operators projected onto this subspace the relation (74) does not hold anymore (since it is a non-linear relation). As a result, the explicit $D$ dependence remains and does not cancel out from such expressions, and the cutoff should be set to $D \sim U$ if one makes this approximation.

The above analysis can be extended to higher-order diagrams, and one finds that also there the $D$ dependence drops out. Here one uses that diagrams containing $\tilde{G}$ vertices are always expressible in terms of the cutoff-independent $\Sigma$ skeleton (see also Sec. III B 3). This analysis confirms the observation, made previously after explicit calculations of the kernel $\Sigma(0)$, e.g., in Ref. 18, that the cutoff $D$ drops out. Here, however, the cutoff dependence can be completely assessed on a very general level, based on the fermionic superoperator algebra, without any need for the explicit calculation of matrix-elements.

4. Finite temperature perturbation theory: Elimination of infinite-temperature contractions

As already mentioned at the end of Sec. III B 3, the causal structure of the perturbation theory naturally suggests to proceed in two stages. We first eliminate all diagrams containing the retarded contraction $\tilde{\gamma}$, i.e., the skeleton diagram (74). As discussed in Sec. III B 2, the function $\tilde{\gamma}$, given by Eq. (53), only contains spectral information about the reservoirs. Since this contraction always occurs isolated and inside other Keldysh contractions (cf. Sec. III B 3), we can use (71) as a skeleton diagram and on each propagator line resum the series,

$$\frac{1}{z - L - X} \sum_{n=0}^{\infty} \left( \tilde{\Sigma} \frac{1}{z - L - X} \right)^n = \frac{1}{z - L - X},$$

(77)

thereby renormalizing the dot Liouvillian to

$$\tilde{L} = L + \tilde{\Sigma}.$$  

(78)

This is illustrated in Fig. 2. As discussed in Sec. III B 3, $\tilde{\Sigma}$ equals the QD self-energy in the limit of infinite temperature in all reservoirs. The lack of energy dependence of $\Sigma$ reflects that in the high-temperature limit, all QD states are equally accessible via transitions induced by the electrodes. Physically, one expects that the Keldysh contractions $\tilde{\gamma}$, describing the non-trivial, temperature dependent part of the distribution function, will drop out in this limit.

In a second stage, we calculate the finite temperature effects, which are all incorporated through the self-energy $\Sigma(z)$. Its diagrammatic perturbation series has the same structure as for $\Sigma$, but is expressed entirely in terms of the contraction $\tilde{\gamma}$, the vertex $\tilde{G}$ and the Liouvillian $\tilde{L}$:

$$\Sigma(z) = (-1)^p \left( \prod \tilde{\gamma}_{ij} \right)_{\text{irr}} \times$$

$$G_1 \frac{1}{z - X_1 - L} G_2 \ldots \frac{1}{z - X_{n-1} - L} G_n.$$  

(79)

Summing this renormalized perturbation theory, one obtains, of course, the same exact result (50) for the effective Liouvillian, which, however, is now decomposed in a different way:

$$L(z) = \tilde{L} + \Sigma(z).$$  

(80)

All contractions $\tilde{\gamma}$ have been eliminated simultaneously in the above transformation of the perturbation series. This was previously referred to as the discrete step of the real-time renormalization group procedure. In the Anderson model in the wide-band limit, only one skeleton diagram contributes to $\tilde{L}$ through $\Sigma$ and no renormalization of vertex $\tilde{G}$ is required to eliminate $\tilde{\gamma}$. This discrete first step is a necessary preparation for the second-step RG in which we will integrate out the $\tilde{\gamma}$ contractions as well in a continuous RG flow. In contrast to the $\tilde{G}$, the vertices $\tilde{G}$ do not share the left zero eigen-supervector.
(Z_L) with the effective Liouvillian [cf. Eq. (80)]. If they were still present during a process of continuous renormalization, this would lead to divergences whenever the zero eigenvalue of L would appear in the resolvent (z - X - L)^{-1} (see also Ref. 51). The vertices G must therefore be integrated out before any continuous RG can be formulated. This is a characteristic feature of an RG for dissipative systems that exhibits a stationary state (a zero eigen-superoperator). The causal structure of the renormalized perturbation theory (79) makes clear that this elimination has been achieved: the zero eigenvalue term of L always drops out due to the presence of G's adjacent to the propagator (z - X - L)^{-1}.

At this point, we can already make an observation that is important for the construction of an explicit expansion for the effective Liouvillian L(z) later on in Sec. III C 5: no continuous RG scheme, which reorganizes the perturbation series Eq. (79) involving only G vertices, can ever generate terms of the form G...G, i.e., with a G superoperator standing on the far right. In the notation of Sec. III C 5 this implies that the coefficient of the term |Z_R|Z_L in the expansion Eq. (80) is not changed during a RG flow (or any non-perturbative approximation to the series (79)).

What was done so far can be understood as a formal expansion around the infinite-temperature limit as a reference point. We start from the exact solution for the stationary non-equilibrium state from appearing (see Sec. II C 5) this implies that the coefficient of the term of |Z_R|Z_L in the expansion Eq. (136) is not changed during a RG flow [or any non-perturbative approximation to the series (79)].

To obtain explicit RG equations that can be solved numerically in an efficient way we need to construct a basis that exploits the advantages of (i) selection rules for the self-energy superoperator induced by the global symmetries (ii) the causal structure of Σ(z) and (iii) the fermion-parity superselection rule. Again, these can be useful in the perturbation theory as well, so we discuss them here.

1. Liouville space bra-ket formalism

By Eq. (88) and (74) the QD self-energy Σ (Σ) is a functional of the QD Liouvillian L (L) and the vertex superoperators G^0 (G), which linearly act on the QD Hilbert space of many-body states. To explicitly calculate these superoperators, it is convenient to introduce a “bra-ket” formalism analogous to that of standard quantum mechanics: we write a 16-component supervector (representing an operator acting on the 4-dimensional Hilbert space) as a rounded superket A (|A>) and introduce its dual supervector (A) = Tr(A^†) as a linear functional acting on operators. An operator A is orthogonal to B if (A|B) = Tr(A^†B) = 0 (see, e.g., Ref. 51). The dual vector may be written as the Hermitian conjugate of a superket:

(A| = |A>)†, |A) = (A|^†),

where † is not to be confused with the supervector corresponding to the Hermitian conjugate of the operator A, A^† = |A>)†. An operator basis |A_i>, i = 1, ..., 16 of mutually orthonormal operators Tr(A^†_iA_j) = δ_i,j is complete if any operator B can be expanded as B = ∑(A_i|B)A_i with coefficients (A_i|B) = Tr(A^†_iB). Any superoperator S acting on such operators can then be expressed in general as a sum of 256 terms:

S = ∑_{i,j=1}^{16} (A_i|S|A_j)|A_i)(A_j|.

2. Liouville Fock-space basis

To maximally reduce the number of terms in the expansion (82) of physical superoperators, we now exploit...
the close analogy between our Liouville field superoperators in the causal representation and the usual fermionic field operators. In this section we will first construct a suitable orthonormal basis of operators (supervectors) in which any QD operator can be expanded. In Sec. (II C 3) we analyze their transformation properties under the symmetry transformations of the Anderson model. In this basis we can then in Sec. (II C 5) easily construct supervector expansions compatible with these symmetries.

We start from the key property (55) of the vertex operators in the causal representation. In bra-ket notation the trace operation corresponds to the action

\[ \text{Tr}_D \circ = \text{Tr}_D \mathbb{1} = 2 |Z_L| \]  

(83)
of the dual of the normalized supervector

\[ |Z_L\rangle = \frac{1}{2} \mathbb{1}. \]  

(84)

Therefore, by Eq. (55), \(|Z_L\rangle\) is a left zero eigensupervector of \(\bar{G}\) and by (57) it follows that \(|Z_L\rangle\) must be a right eigen-supervector of \(G\):

\[ (\bar{G} |Z_L\rangle |G_1\rangle = 0, \quad \hat{G}_1 |Z_L\rangle = 0. \]  

(85)

We can formally consider the state annihilated by operators \(\bar{G}\) as a “supervacuum”. (Note that the “supervacuum” state is the most symmetric dot operator similar to standard field theories where the vacuum state usually is the most symmetric one). This vacuum supervector is proportional to the physical infinite temperature density operator \([\text{cf. Eq. (73)}]\) with maximal von Neumann entropy \(S = -\text{Tr}_D \{ \rho \ln(\rho) \}\). It is then also natural to construct the corresponding right zero eigen-supervector of \(\bar{G}_1\) whose dual is the left zero eigen-supervector of \(\bar{G}_1\):

\[ \bar{G}_1 |Z_R\rangle = 0, \quad (\bar{G}_R |\bar{G}_1\rangle = 0. \]  

(86)

Since \(\bar{G}_1\) is a non-Hermitian superoperator these eigen-supervectors are not simply related by Hermitian conjugation in Liouville space, \(|Z_R\rangle \neq (Z_L|\) [cf. Eq. (81)].

The operator \(Z_R\) will be found to play a key role throughout this work. In App. E we discuss its many interesting properties, most prominently, its relation to the fermion-parity, its similarity to Grassmann numbers, and its relation to the spin- and charge-rotations of Sec. (II C 3). To construct \(|Z_R\rangle\) we now exploit the close analogy to the usual field operators: \(G_1\) is a creation operator in Liouville Fock-space, since its Hermitian superconjugate \(\bar{G}_1\) annihilates the supervacuum state \(|Z_L\rangle\) by Eq. (55). The state annihilated by \(\bar{G}_1\) is therefore simply the maximally occupied state in the QD Liouville Fock-space, starting from the vacuum:\n
\[ |Z_R\rangle = \prod_{\sigma} \left( \prod_{\eta} \bar{G}_{\eta \sigma} \right) |Z_L\rangle. \]  

(87)

As for the usual fermionic field operators, the action of creation operators preserves the normalization: this follows directly from Eq. (51) and the anticommutation relations (53):

\[ (Z_R |Z_R\rangle = (Z_L | \prod_{\sigma} \left( \prod_{\eta} \bar{G}_{\eta \sigma} \bar{G}_{\eta' \sigma'} \right) |Z_L\rangle \]

\[ = (Z_L |\bar{Z}_L\rangle = 1. \]  

(88)

Note that by Eq. (53), reordering the \(G_i\)’s in the definition of \(Z_R\) only amounts to an unimportant redefinition of the overall sign. Using Eq. (51), we can write for the explicit action on any operator (denoted by \(\bullet\)) with even fermion-parity

\[ \bar{G}_{i+} \bar{G}_{-i} |\bullet\rangle = \frac{1}{2} \left( \{ n_{\sigma}, \bullet \} - 1 + d^\dagger_{\sigma} \bullet d_{\sigma} - d_{\sigma} \bullet d^\dagger_{\sigma} \right). \]  

(89)

Inserting this into Eq. (51), we obtain

\[ |Z_R\rangle = \frac{1}{2} \prod_{\sigma} (2 n_{\sigma} - 1). \]  

(90)

Since \(|Z_L\rangle\) is a left eigenvector of \(\bar{G}\) [cf. Eq. (51)], we immediately see that the two zero eigen-supervectors are orthonormal, \((Z_L |Z_R\rangle = 0. \) Therefore, it is natural to include \(|Z_R\rangle\) into the orthonormal Liouville space basis. By successively acting on the supervacuum state \(|Z_L\rangle\) we can generate more normalized, orthogonal operators. There are in total eight bosonic operators:

\[ |Z_L\rangle = \frac{1}{2} \mathbb{1}, \]

\[ |\chi_{\sigma}\rangle = \bar{G}_{+\sigma} \bar{G}_{-\sigma} |Z_L\rangle, \]

\[ |T_{\eta}\rangle = \eta \bar{G}_{\eta} \bar{G}_{\eta \uparrow} |Z_L\rangle, \]

\[ |S_{\sigma}\rangle = \bar{G}_{+\sigma} \bar{G}_{-\sigma} |Z_L\rangle, \]

\[ |Z_R\rangle = \bar{G}_{+\uparrow} \bar{G}_{-\downarrow} \bar{G}_{+\downarrow} \bar{G}_{-\uparrow} |Z_L\rangle, \]  

(91)

(92)

(93)

(94)

(95)

and there are eight fermionic operators:

\[ |a_{i,\sigma}^+\rangle = \bar{G}_{+\sigma} |Z_L\rangle, \]

\[ |a_{i,\sigma}^-\rangle = \sigma \bar{G}_{-\sigma} |Z_L\rangle, \]

\[ |\alpha_{+,-\sigma}^+\rangle = \bar{G}_{+\sigma} \bar{G}_{+\sigma} \bar{G}_{-\sigma} |Z_L\rangle, \]

\[ |\alpha_{+,-\sigma}^-\rangle = \sigma \bar{G}_{-\sigma} \bar{G}_{-\sigma} \bar{G}_{+\sigma} |Z_L\rangle. \]  

(96)

The labeling of these basis supervectors is motivated by their explicit expressions in terms of the field operators \(d_{\sigma}, d^\dagger_{\sigma}\) (see Eq. (103)-(114)) and their behavior under symmetry transformations, which will be discussed in the next section. We see that the index \(\nu\) of the operators \(|\alpha_{\nu\sigma}\rangle\) only has a meaning in Liouville space: it distinguishes \(\nu = +\) states with one excess excitation relative to the supervacuum \(|Z_L\rangle\) (superparticles), from \(\nu = -\) states with one deficit particle with respect to the maximally occupied superstate \(|Z_R\rangle\) (superholes). By construction, these 16 operators form a complete orthonormal basis of the QD Liouville space. This basis includes only one operator that has non-zero trace, namely,
\( |Z_L | = \frac{1}{2} \mathbb{1} \). Since all other supervectors are orthogonal to \( |Z_L | \), their corresponding operators are traceless according to Eq. \( (88) \).

We emphasize that the choice of basis supervectors \( |Z_L | \) and \( |Z_R | \) relies on two general physical properties of the problem, the probability conservation (cf. Eq. \( (69) \) and Eq. \( (55) \)) and the fermion-parity (cf. App. \( E \)). The choice of the signs of the remaining operators, however, is motivated by considering the symmetry transformations of the Anderson model. These will be discussed in the next section. The related approach of Prosen was also introduced by an explicit construction of the Liouville-Fock space\( ^{3} \) (see App. \( C \)).

Before we proceed, we emphasize the necessity of working with a complete basis for the QD Liouville space, which includes operators that are non-diagonal in both spin and / or charge quantum numbers. In perturbation theory, one can disregard all matrix elements of the self-energy \( \Sigma(z) \) involving the latter operators (cf. Sec. \( II \ B \ 3)\), due to the conservation laws \( (101) \). How-

the self-energy \( \Sigma(z) \), due to the conservation laws (101). How-

ever, the states propagating in the inner part of a diagram contributing to \( \Sigma(z) \) (i.e., a virtual intermediate state) are less restricted by the conservation laws, requiring the matrix elements of the vertices and the QD Liouvil-

lL \( \) between all the off-diagonal operators\( ^{22} \). In the RT-

to RG that we set up below such matrix elements involving odd-fermion-parity operators cannot be avoided for \( \Sigma(z) \) as well since one needs to describe the renormalization of all virtual intermediate states, both fermionic as well as bosonic ones.

3. Irreducible transformation under symmetry operations

For the total system of QD and reservoirs both the charge and spin components along the magnetic field are conserved [cf. Eqs. \( (22) \) and \( (26) \)]. The particle number conservation on the dot is conveniently expressed using the charge-polarization operator

\[ T_z = \frac{1}{2} (n - 1), \]

which measures the difference of the occupation probabilities of the empty and doubly occupied QD states \(|0 \rangle \) and \(|2 \rangle \). It follows from Eq. \( (26) \) and \( (26) \) that the dot superv operators for charge polarization (cf. Eq. \( (19) \)) and spin,

\[ L^T_z = [T_z, \bullet]_-, \]
\[ L^S_z = [S_z, \bullet]_- \]

respectively, commute with each other as well as with the Liouvilian \( L \) and the self-energy \( \Sigma(z) \). Therefore, the effective Liouvilian \( L(z) = L + \Sigma(z) \), which determines the time-evolution of the reduced density operator, conserves these superobservables (see App. \( E \) for a derivation):

\[ [L(z), L^T_z]_- = 0, \]
\[ [L(z), L^S_z]_- = 0. \]

Thus \( L(z) \) can be simultaneously block diagonalized with the superv operators for charge- and spin-polarization and they have common eigen-supervectors. In the basis of Sec. \( \text{II C} \ 3)\), the initial dot Hamiltonian operator Eq. \( (11) \) has the form

\[ H = (2\epsilon + U/2) |Z_L | + U/2 |Z_R | + 2 \epsilon \left( \epsilon + \frac{U}{2} \right) |T_z \rangle + B |S_z \rangle. \]

In two special cases the total system has a higher symmetry: for \( \epsilon = -U/2 \) and \( \mu_L = \mu_R \) it exhibits full charge-rotation symmetry, whereas for \( B = 0 \) it has full spin-rotation symmetry. These full symmetry groups are obtained by adding the operators \( S_x \) and \( S_y \) to \( S_z \) (cf. Eq. \( (107) \)), giving the SU(2) spin-algebra, and by adding \( T_x \) and \( T_y \) to \( T_z \) (cf. Eq. \( (111) \)), giving another SU(2) algebra generating “charge-rotations” (see below). The construction of superv operators that transform in the simplest possible way under these symmetry operations is greatly simplified by first constructing basis operators that can be classified with respect to the corresponding irreducible representations. Importantly, the Liouville Fock basis \( \{ 13 \} \) that we constructed using the causal field superv operators is already very close to a symmetry-adapted basis and we merely need to complete the classification. We first group these operators according to their even or odd fermion parity, and refer to these as bosonic, respectively, fermionic operators. We subsequently classify them according to the transformation behavior under the two SU(2) rotation groups as an irreducible tensor operator (ITO). This allows us to identify supervectors corresponding to Hilbert-space operators that are diagonal with respect to the QD charge and / or the QD spin. In perturbation theory, one only needs the self-energies connecting such diagonal components of the density matrix. In the RG that we set up below this is no longer true. Still, it is important to single out this block of matrix elements of \( \Sigma(z) \), \( \Sigma(z) \) and \( L(z) \).

One half of the Liouville space is then spanned by eight bosonic operators with integer charge- and spin-ITO ranks:

- The zero-eigenvectors of the vertex superv operators are scalars (rank-0 spin and charge ITOs) with respect to both spin- and charge-rotations since the zero-eigenvale equations Eq. \( (55) - (56) \) are invariant under these transformations. They are therefore charge- and spin-diagonal operators. This is also clear from their explicit form in terms of the Casimir operators of the spin- \( (S^2 = \sum_i S_i^2) \) and charge-rotation \( (T^2 = \sum_i T_i^2) \) SU(2) Lie algebras:

\[ |Z_L | = \frac{1}{2} \mathbb{1} = \frac{4}{3} (T^2 + S^2), \]
\[ |Z_R | = 2 n_L n_R - n + \frac{1}{2} \mathbb{1} = \frac{2}{3} (T^2 - S^2). \]
The generators of rotations in spin space are
\[ |S_{0}\rangle = \frac{1}{\sqrt{2}} \sum_{\sigma} \chi_{\sigma} |\chi_{\sigma}\rangle = \frac{1}{\sqrt{2}} \sum_{\sigma} \sigma n_{\sigma}, \quad (105) \]
\[ |S_{\sigma}\rangle = d_{\sigma}^\dagger d_{\sigma}, \quad \sigma = \uparrow, \downarrow = \pm. \quad (106) \]

The operators \(-|S_{+}\rangle, |S_{0}\rangle, |S_{-}\rangle\) transform as the components of a rank-1 spin-ITO (vector), i.e., simpler than the more familiar Cartesian components of the spin-operator,
\[ |S_{x,y}\rangle = \frac{1}{\sqrt{2}} (|S_{+}\rangle \pm |S_{-}\rangle), \quad |S_{z}\rangle = \frac{1}{\sqrt{2}} |S_{0}\rangle, \quad (107) \]
which satisfy \([|S_{i}\rangle, |S_{j}\rangle] = i \epsilon_{ijk} |S_{k}\rangle\). They transform as a rank-0 ITO (scalar) with respect to charge-rotations and are therefore charge-diagonal.

The generators of rotations in charge space are
\[ |T_{0}\rangle = \frac{1}{\sqrt{2}} \sum_{\sigma} |\chi_{\sigma}\rangle = \frac{1}{\sqrt{2}} (n - 1), \quad (108) \]
\[ |T_{+}\rangle = d_{\uparrow}^\dagger d_{\uparrow}, \quad (109) \]
\[ |T_{-}\rangle = d_{\downarrow}^\dagger d_{\downarrow}. \quad (110) \]

The operators \(-|T_{+}\rangle, |T_{0}\rangle, |T_{-}\rangle\) transform as a rank-1 ITO (vector) under rotations in charge space, and as a rank 0 ITO (scalar) with respect to spin-rotations. Therefore, they are all spin-diagonal. They are more convenient than the Cartesian components
\[ |T_{x,y}\rangle = \frac{1}{\sqrt{2}} (|T_{+}\rangle \pm |T_{-}\rangle), \quad |T_{z}\rangle = \frac{1}{\sqrt{2}} |T_{0}\rangle, \quad (111) \]
satisfying the SU(2) algebra \([|T_{i}\rangle, |T_{j}\rangle] = i \epsilon_{ijk} |T_{k}\rangle\). In contrast to the spin-operators, here the indices \(x, y, z\) are not related to the axes in the real space, but merely label the components of the SU(2) generators.

In the bosonic sector, we can thus use either
\[ |\chi_{\sigma}\rangle = n_{\sigma} - \frac{1}{2} |1\rangle = \frac{1}{\sqrt{2}} \{ |T_{0}\rangle \pm \sigma |S_{0}\rangle \}, \quad (112) \]
or \(|S_{0}\rangle\) and \(|T_{0}\rangle\) as basis vectors. Only the latter two are adapted to charge- and spin-rotation symmetry, but the former two allow for greater notational simplicity. Both will be used.

The other half of the QD Liouville space is spanned by eight more, fermionic operators with half-integer charge- and spin-ITO ranks:
- The fermionic operators, denoted by \(\alpha_{\eta,\sigma}^{\nu}\), act in three subspaces of dimension 2 labeled by \(\sigma = \pm\) (spin), \(\eta = \pm\) (particle-hole) and, additionally, \(\nu = \pm\). These basis operators are ITos of rank \(\frac{1}{2}\) with respect to both charge (\(\eta\)) and spin-rotations (\(\sigma\)). For \(\nu = +\) these are the rank \(\frac{1}{2}\) spin-ITOs constructed from creation and annihilation operators:
  \[ |\alpha_{+,\sigma}^{+}\rangle = \sqrt{2} d_{\sigma}^\dagger, \quad |\alpha_{+,\sigma}^{-}\rangle = \sqrt{2} \sigma d_{\sigma}, \quad (113) \]
  \[ |\alpha_{-,\sigma}^{-}\rangle = 2 |Z_{R} \alpha_{+,\sigma}^{-}\rangle, \quad |\alpha_{-,\sigma}^{+}\rangle = 2 |Z_{R} \alpha_{+,\sigma}^{+}\rangle. \quad (114) \]

| Operator | fermion \(-\)parity | S-ITO \((\text{rank, index})\) | T-ITO \((\text{rank, index})\) |
|----------|------------------|----------------|----------------|
| \(|Z_{i}\rangle\) | + | (0,0) | (0,0) | \(i = L, R\) |
| \(|S_{m}\rangle\) | | (1, m) | (0, 0) | \(m = 0, \pm 1\) |
| \(|T_{m}\rangle\) | + | (0, 0) | (1, m) | \(m = 0, \pm 1\) |
| \(|\alpha_{\eta,\sigma}^{\nu}\rangle\) | | (\(\frac{1}{2}, \frac{1}{2}\)) | (\(\frac{1}{2}, \frac{1}{2}\)) | \(\eta, \sigma, \nu = \pm 1\) |

**TABLE I**: Fermion-parity and irreducible transformation behavior of basis operators under spin- and charge-rotations. Schematically denoting these operators by \(|s, m; t, m_{t}\rangle\), these transform as (i) spin-irreducible tensor operators \((S\text{-ITOs})\) with rank \(s\) and index \(m_{s}, L^{S}|s, m_{s}; t, m_{t}\rangle = m_{s}|s, m_{s}; t, m_{t}\rangle\) and \(L^{S}|s, m_{s}; t, m_{t}\rangle = \sqrt{(s + 1) - m_{s}(m_{s} \pm 1)}|s, m_{s} \pm 1; t, m_{t}\rangle\) and (ii) as charge-ITOs \((T\text{-ITOs})\) with rank \(t\) and index \(m_{t}, L^{T}|s, m_{s}; t, m_{t}\rangle = m_{t}|s, m_{s}; t, m_{t}\rangle\) and \(L^{T}|s, m_{s}; t, m_{t}\rangle = \sqrt{(t + 1) - m_{t}(m_{t} \pm 1)}|s, m_{s}; t, m_{t}\rangle\). All zero-index \(S\text{-ITOs} (T\text{-ITOs})\) correspond to operators acting on Hilbert space that are diagonal in spin (charge).

The above simple transformation behavior of the basis superoperators motivates all the relative signs that we anticipated in writing Eq. (111)-(116). The basis is therefore completely fixed up to irrelevant phases by general physical properties (probability conservation, symmetries) together with the supervector normalization. Table I summarizes the transformation properties.

Finally, we note the transformation behavior under Hilbert-space Hermitian conjugation, corresponding to an antilinear superoperator \(K\) (see Eq. (110)). For all diagonal basis operators \(D = Z_{L}, Z_{R}, \chi_{\sigma}, S_{0}, T_{0}\)
\[ K|D\rangle = |D\rangle, \quad (116) \]
whereas for the off-diagonal operators
\[ K|S_{\pm}\rangle = |S_{\mp}\rangle, \quad K|T_{\pm}\rangle = |T_{\mp}\rangle, \quad (117) \]
\[ K|\alpha_{\eta,\sigma}^{\nu}\rangle = -\nu \eta \sigma |\alpha_{\eta,\sigma}^{\nu}\rangle. \]

4. **Expansion of the vertex**

The calculation of the bra-ket representation of the vertex superoperators in the basis Eq. (111)-(116) reduces
entirely to the calculation of
\[ \tilde{G}_{\sigma} = \alpha_{\sigma}^+(Z_L) + \sigma[Z_R](\alpha_{\sigma}^-) \]
(118)
\[ + \sigma[T_+(\alpha_{\sigma}^+) + |\alpha_{\sigma}^-|T_- + |\alpha_{\sigma}^+|\chi_\sigma] \]
\[ - \sigma[\chi_\sigma](\alpha_{\sigma}^+) + \sigma[S_\sigma](\alpha_{\sigma}^+ - |\alpha_{\sigma}^-|)(S_\sigma). \]

This is easily performed using the second quantization technique that we introduced in Liouville Fock space, i.e., using algebra rather than the explicit matrix representations of Sec. [II C 3]. All other vertices follow from general relations: first, using the transformation under Hermitian conjugation [see Eq. (70)],
\[ G_{\eta\sigma} = (-1)^{L+1} K \tilde{G}_{\eta\sigma} K, \]
the result for opposite charge index \( \eta \) follows from Eqs. [110] and [117]:
\[ \tilde{G}_{-\sigma} = - \sigma[\alpha_{\sigma}^+(T_L - |\alpha_{\sigma}^-|T_- + |\alpha_{\sigma}^+|\chi_\sigma] \]
\[ - |\alpha_{\sigma}^+ - |\alpha_{\sigma}^-| - S_\sigma)(\alpha_{\sigma}^+ + \sigma[\alpha_{\sigma}^-]S_\sigma). \]

The vertex superoperators \( \tilde{G}_{\eta\sigma} \) are obtained from \( \tilde{G}_{\eta\sigma} \) by the Hermitian conjugation rule [57] between the field superoperators. In the Liouville bra-ket formalism, this simply means that we can interchange bra and ket vectors in the expansions [118] and [120] to obtain \( \tilde{G}_{\eta\sigma} \).

We point out that under the two-loop RG flow to be discussed in Sec. [III], the structure of the vertex operators is changed and the above relations cease to hold [\( \tilde{G} \) will be modified whereas \( \tilde{G} \) is not changed, implying that Eq. [57] breaks down]. However, in Sec. [IV C 2], we show how such vertex corrections can be incorporated effectively into the flow of the effective Liouvillian only, allowing us to work with the “bare” vertices having the nice properties discussed above. Two properties of the bare vertices that remain valid under the RG-flow are
\[ \alpha_{\eta\sigma}^+|G_1 \propto (Z_L) \text{ or } 0, \]
(121)
\[ \tilde{G}_1\alpha_{\eta\sigma}^- \propto |Z_R) \text{ or } 0, \]
(122)
Equation [121] follows since \( |\alpha_{\eta\sigma}^+ \) is obtained from the vacuum \( |Z_L) \) by the action of a single creation superoperator (cf. Eq. [58]). Using Eq. [57]
\[ (\alpha_{\eta\sigma}^+) = \sigma^{(1-n)/2}(Z_L)|\tilde{G}_{\eta\sigma}(\eta\sigma). \]
(123)
When inserted in the left-hand side of Eq. [121], this \( \tilde{G} \) can be anticommutated past the \( \tilde{G} \) using Eq. [58] and the supervacuum property [85], \( (Z_L)|\tilde{G} = 0. \) Analogously, Eq. [122] follows by noting that Eq. [58] for the \( |\alpha_{\eta\sigma}^- \) can be rewritten as a single destruction superoperator acting on the maximally occupied state in Liouville-Fock space:
\[ |\alpha_{\eta\sigma}^- = \sigma^{(1-n)/2}\tilde{G}_{\eta\sigma}(\eta\sigma)|Z_R). \]
(124)

Commuting the \( \tilde{G} \) to the right and using \( \tilde{G}_1|Z_R) = 0 \) [Eq. [59] on the right of each term we obtain Eq. [122].

5. Expansion of the effective Liouvillian

a. Causal structure

By the general properties [58] and [59], the vertices must have an expansion of the form (confirmed by the explicit results Eq. [118]-[120]):
\[ \tilde{G} = -(Z_R)(\bullet + \ldots)(Z_L) + ..., \]
(125)
\[ \tilde{G} = -(\bullet)(Z_R) + \ldots(Z_L)(\bullet + ..., \]
(126)
where the remaining terms involve neither \( Z_L \) nor \( Z_R. \) Therefore, the terms in the expansion of the effective Liouvillian involving these vectors are strongly restricted. Combined with the general causal structure of the perturbative series, i.e., the way \( \tilde{G} \) and \( \tilde{G} \) can appear, this imposes further constraints (cf. Sec. [IIIB 3]):

- Terms of the form \( |Z_L)(\bullet| \) are prohibited by probability conservation, since otherwise the trace condition [59] would be violated:
\[ (Z_L)|\tilde{L} = (Z_L)|L(z) = (Z_L)|\Sigma(z) \]
(127)
\[ = (Z_L)|\tilde{\Sigma} = (Z_L)|\Sigma(z) = 0. \]
(128)
This is guaranteed by the causal structure, which requires that the leftmost vertex is always of the type \( \tilde{G} \), with expansion Eq. [125].

- Terms of form \( \bullet)(Z_R| \) can only appear due to the diagrams collected in \( \tilde{\Sigma} = -i4\Gamma^1_1^1_1 \Gamma_1^1 \).
Expanding Eq. [71] in the basis [91]-[96], one finds that only the term \( |Z_R)(Z_R| \) with coefficient \(-i4\Gamma \) can appear [see also Eq. [134]]. Importantly, this implies that \( |Z_R) \) is a right eigenvector of both \( \tilde{L} \) as well as the exact effective Liouvillian \( L(z) \) and the kernel \( \Sigma(z) \) [see the discussion of Eq. [138]]:
\[ \tilde{L}(z)|Z_R) = L(z)|Z_R) = \Sigma(z)|Z_R), \]
(129)
\[ = \Sigma(z)|Z_R) = -4i\Gamma|Z_R). \]
(130)
In contrast,
\[ \Sigma(z)|Z_R) = 0. \]
(131)
Note that this eigenvector and eigenvalue are independent of the QD frequency \( z \).

- The term \( |Z_R)(Z_L| \) is not forbidden by general considerations. However, such terms always drop out in the calculation of the transport current, which interest us here (see Sec. [II B 1]). This happens because in all required expressions, the renormalized Liouvillian \( L, \) parametrized as [159], is evaluated between two \( \tilde{G} \) vertices cf. Eq. [79]. Therefore, by Eq. [125] the term \( |Z_R)(Z_L| \) with coefficient \( \zeta \) always drops out. We emphasize, however, that \( \zeta \) does enter into the stationary state (cf. Eq. [141]) and other physical quantities, such as the average dot energy, and may therefore be important for, e.g., thermal transport problems.
• Terms of the form $|\alpha_{\eta,\sigma}^+\rangle\langle\bullet|$ and $|\bullet\rangle\langle\alpha_{\eta,\sigma}^-|$ can appear only in the bare Liouvillian $L = [H, \bullet]_-$ or the infinite-temperature kernel $\Sigma = \frac{1}{2}i\Gamma\hat{G}_1\hat{G}_1$, but not in the non-trivial kernel $\Sigma(z)$:

$$\langle\alpha_{\eta,\sigma}^+\rangle\Sigma(z) = 0, \quad (132)$$
$$\Sigma(z)|\alpha_{\eta,\sigma}^-\rangle = 0. \quad (133)$$

Both relations follow from the fact that $\Sigma(z)$ contains only vertices of the type $\hat{G}$ in the expansion of $\Sigma$, Eq. (132) follows from Eq. (124) applied to Eq. (79) and then using $(Z_L|L = 0$ and $(Z_L|G = 0$, the vacuum property [55]. Analogously, Eq. (133) follows from Eq. (122) using our general result (130), $L|Z_R) = -4i\Gamma|Z_R)$, and $\hat{G}|Z_R) = 0$, Eq. (50). Eq. (132) - (133) allow us to make general predictions about the excitation spectrum of the exact dot Liouvillian, $L(z)$ [see Sec. (II D 3) and (III B 4)]

b. Spin- and charge-rotation symmetry

We now first expand the infinite-temperature self-energy $\Sigma$ and the renormalized Liouvillian $\hat{L}$ in the basis $\{|\pm\rangle\}$. Substituting the above bra-ket expansions of the superoperators $\hat{G}_1$ and $\hat{G}_1$ into Eq. (71) we get:

$$\hat{\Sigma} = -i\Gamma\left[4|Z_R)(Z_R| + 2 \sum_{\sigma = \pm} |\chi_\sigma)(\chi_\sigma| + 2 \sum_{\sigma = \pm} |T_\sigma)(T_\sigma| + 2 \sum_{\sigma = \pm} |S_\sigma)(S_\sigma| + \sum_{\sigma = \pm} \sum_{\eta = \pm} \sum_{\nu = \pm} (2 - \nu)|\alpha_{\eta,\sigma}^\nu\rangle\langle\alpha_{\eta,\sigma}^\nu| \right] \tag{134}$$

Clearly, $\hat{\Sigma}$ is explicitly anti-Hermitian in the superoperator sense (cf. Eq. (72)). Combining this with the bare dot Liouvillian, obtained by expanding the commutator $L = [H, \bullet]_-$ of (102) we obtain:

$$\hat{\Lambda}_{\Delta \lambda = \infty} := \hat{\Lambda} = L + \hat{\Sigma} = -i\Gamma|Z_R)(Z_R| - 2i\Gamma\chi_0 + \sum_{\sigma} \left[(\sigma B - 2i\Gamma)|S_\sigma)(S_\sigma| + (\sigma U + 2\epsilon - 2i\Gamma)|T_\sigma)(T_\sigma| + \sum_{\eta,\nu} \left(\eta + \frac{U}{2}\right) + \frac{B}{2} - i(2 - \nu)\Gamma) |\alpha_{\eta,\sigma}^\nu\rangle\langle\alpha_{\eta,\sigma}^\nu|\right.\right.$$  

$$+ \frac{U}{2} \sum_{\eta,\nu} |\alpha_{\eta,\sigma}^\nu\rangle\langle\alpha_{\eta,\sigma}^\nu| \right]. \tag{135}$$

where for later reference we introduced the notation $\hat{\Lambda}_{\Delta \lambda = \infty} := \hat{\Lambda}$ of Sec. (III). All non-zero eigenvalues of $\hat{\Lambda}$ have negative imaginary parts, thereby automatically regularizing all resolvents that can appear $\hat{\Lambda}(z - \hat{L} - X)^{-1}\hat{G}$ in the perturbation theory for $\Sigma(z)$ for $z \to i0$. This can be seen explicitly since all terms are already in diagonal superoperator form, with the exception of the odd-fermion terms (the last two lines in Eq. (135)) whose eigenvalues are given below (set $\Delta F_{\eta,\sigma}^+ = 0$ in Eq. (163)). Note that the right zero eigenvector of $\hat{\Lambda}_{\Delta = \infty}$ is $\frac{1}{2}(Z_L)$ — it is the only basis vector missing in Eq. (135) — in agreement with the result (73) in Sec. (III B 4). We further note that the infinite-temperature kernel $\Sigma$ (134) contributes terms to Eq. (135) that are diagonal in the index $\nu$, whereas contributions off-diagonal in $\nu$ are produced in Eq. (135) by the Coulomb interaction included in the bare dot Liouvillian $L$. We will show in Sec. (III B 4) that the continuous RT-RG produces only contributions to the effective Liouvillian $L(z)$ that are off-diagonal in $\nu$, which has important consequences.

We can now write down the exact form of the QD effective Liouvillian $L(z)$ taking into account all general restrictions that we have derived above. In the most general case that we consider only spin- and charge-rotation symmetry about the $z$-axis: this implies that the effective Liouvillian must be a sum of superoperators that (i) transform as an irreducible tensor of any rank but with index zero with respect to both the charge- and spin-rotation group (i.e., by pairing only bras and kets of basis supervectors with the same charge and spin indices) and (ii) preserve the fermion-parity (i.e., by avoiding combinations of fermion and boson kets and bras). Using Table I which lists the transformation properties of the basis supervectors $|\pm\rangle$, we can readily construct the most general form of superoperators of this kind, which are furthermore compatible with the causal structure of the perturbative series [68]. In Table I we have classified all these superoperators according to their irreducible transformation properties under the full symmetry group of both spin- and charge-rotations. This makes it easy to impose further restrictions on the expansion coefficients in the special cases of higher symmetry ($B = 0$ and / or $\epsilon = -U/2, \mu_L = \mu_R$), see Sec. (II D 4). The most general form of the exact QD effective Liouvillian $L(z) = L + \Sigma(z) = L + \Sigma(z)$ then reads:

$$iL_{\alpha}(z) = 4|Z_R)(Z_R| + \chi|Z_R)(Z_L| + |Z_R|\phi + |Z_L|\phi^+$$

$$+ \xi + \sum_{\eta,\sigma} \left[M_{\eta \sigma}|T_\sigma)(T_\sigma| + E_{\eta \sigma}|S_\sigma)(S_\sigma| + \sum_{\eta,\sigma} F_{\eta,\sigma} \right],$$

where $G = \frac{1}{2} \sum_{\Gamma} \Gamma$ and $F_{\eta,\sigma}$ are superoperators acting in the two-dimensional $\nu$ space spanned by $|\alpha_{\eta,\sigma}|$ (see below). This is a central result of the paper, and before discussing the occurring coefficients in detail, we point out its importance.

By exploiting only its general properties we have reduced the number of terms contributing to $L(z)$ from 256 [cf. Eq. (52)] down to just 30. The key simplification came by using the causal field superoperators to construct the Liouville Fock space. The resulting general Liouvillian can be easily diagonalized as we show in the next section. Furthermore, because of its general nature, the parametrization (160) is useful in applications other than those considered here and may be extended to more
superoperator acting on the \( \chi \)-subspace

\[
\xi = \sum_{\eta,\sigma} \xi_{\eta,\sigma} |\chi_{\eta,\sigma}\rangle \langle \chi_{\eta,\sigma}'| = \sum_{i=0,1,2,3} \xi_i \chi_i.
\]

Here, after the second equality, the matrix \( \xi_{\eta,\sigma} \) is decomposed in the standard basis \( \tau_i \) of the unit \( (i = 0) \) and three Pauli matrices \( (i = 1,2,3) \), giving another \( \chi \)-subspace superoperator-basis:

\[
\chi_i = \sum_{\eta,\sigma} (\tau_i)_{\eta,\sigma} |\chi_{\eta,\sigma}\rangle \langle \chi_{\eta,\sigma}'|.
\]

Four superoperators acting on the 2 dimensional \( \alpha_{\eta,\sigma} \)-subspaces spanned by \( |\alpha_{\eta,\sigma}^\pm\rangle \)

\[
F_{\eta,\sigma} = \sum_{\nu,\nu'} F_{\nu,\nu'}^{\eta,\sigma} |\alpha_{\eta,\sigma}'\rangle \langle \alpha_{\eta,\sigma}'| = \sum_{i=0,1,2,3} F_{i,\eta,\sigma}^{\eta,\sigma} |\alpha_{\eta,\sigma}_i\rangle \langle \alpha_{\eta,\sigma}^i|.
\]

with unit and Pauli-vector superoperators

\[
\alpha_{\eta,\sigma}^i = \sum_{\nu,\nu'} (\tau_i)_{\eta,\sigma} |\alpha_{\eta,\sigma}'\rangle \langle \alpha_{\eta,\sigma}'|,
\]

for each fixed \( \sigma = \pm \) and \( \eta = \pm \).

It is convenient to use the four-vector as well as the \( 2 \times 2 \) matrix representations for the superoperators \( \xi \) and \( F_{\eta,\sigma} \).

All the above expansion coefficients depend on the QD frequency \( z \) (not written) and satisfy the following conjugation relations, which derives from the Hermicity condition \( \{iL(z)\} K = iL(-z^*) \). For the charge and spin diagonal operators these are

\[
\overrightarrow{\xi}(z) = \overrightarrow{\xi}^*(-z^*), \quad \overrightarrow{\psi}(z) = \overrightarrow{\psi}^*(-z^*), \quad \xi(z) = \xi^*(-z^*), \quad (144)
\]

implying that these coefficients are real only for zero frequency \( z = 0 \). For the charge or spin nondiagonal operators we have

\[
F_{\eta,\sigma}^{\nu,\nu'}(z) = \nu \nu' F_{\eta,\sigma}^{\nu,\nu'}^*(-z^*), \quad \nu, \nu' = \pm, \quad (145)
\]
\[
M_{\sigma}(z) = M_{\sigma}^*(z), \quad (146)
\]
\[
E_{\sigma}(z) = E_{\sigma}^*(z). \quad (147)
\]
Therefore, at finite dot frequency $z$ all parameters are in general complex and all $2 \times 2$ coefficient matrices are non-Hermitian.

Note that in Eq. (136) we have parametrized $iL(z)$, rather than $L(z)$, i.e., including the imaginary factor $i$. This anticipates the application to the RT-RG, where a renormalized version of the Liouvillian $\bar{L}$ appears in the final RG equations only as the combination $i\bar{L}$ (cf. Sec. (III C 1) and (III D 1)). Finally, we emphasize that the simplifications that led up to the parametrization Eq. (136) remain valid for the RT-RG: Eq. (69), as well as Eq. (83) and Eq. (84) do not change under the continuous renormalization, as will be shown in Sec. (III).

D. Effective Liouvillian

1. Spectral decomposition of $L(z)$ and $\bar{L}$

Above we have reduced $L(z)$ to block-diagonal form as far as possible by using symmetry and general properties. In Sec. (III), we will see that $L(z)$ is closely related to a renormalized version of the QD Liouvillian $L$ that we will denote by $\bar{L}_\Lambda$. To make this clear, we have to anticipate a result: $\bar{L}_\Lambda$ interpolates between $L$ and $\bar{L}(z)$ as the flow parameter $\Lambda$ varies from 0 to 1: $L(z) = L + \int_0^1 \frac{d\Lambda}{2\pi} \frac{dL(\Lambda)}{d\Lambda}$. This is done by redistributing diagrams of $\Sigma$ in Eq. (84) and including a fraction of them into a redefinition of the Liouvillian $\bar{L}$. By construction $\bar{L}(z)$ is thus decomposed into “pieces” $\frac{dL(\Lambda)}{d\Lambda}$ with the same matrix structure that are accumulated during the flow. At the end of the flow, $\bar{L}_\Lambda$ equals $L(z)$. Therefore, $\bar{L}_\Lambda$ has an expansion of the same form [Eq. (136)] as $L(z)$. For notational simplicity, we denote the expansion coefficients of $\bar{L}_\Lambda$ by the same variables as for $L(z)$. In cases where this leads to confusion, the coefficients of $\bar{L}_\Lambda$ are distinguished from those of $L(z)$ by indicating their $\Lambda$ dependence, e.g., $F_{\eta \eta'}^{F'}$ vs. $F_{\eta \eta'}^{\eta \eta'}$, which can, however, often be omitted. All results obtained in this section thus apply to both the exact $L(z)$ as well as the renormalized $\bar{L}_\Lambda$. This explicit form of $\bar{L}_\Lambda$ is required since later on it needs to be inserted into resolvent superoperators that appear in the RG equations.

We therefore need to completely diagonalize $\bar{L}_\Lambda$ such that it can be expanded into its eigenprojectors $P^k = |\lambda^k\rangle\langle\lambda^k| = (P^k)^2$:

$$\bar{L}_\Lambda = \sum_k \lambda^k P^k, \quad (148)$$

where the sum runs over the labels $k$ of the eigenvalues. Here, $|\lambda^k\rangle$ and $\langle\lambda^k|$ are the left and right eigen-supervectors of $\bar{L}_\Lambda$ for the same eigenvalue $\lambda^k$: $\bar{L}_\Lambda P^k = P^k \bar{L}_\Lambda = \lambda^k P^k$. Using this complete and orthogonal set of projectors, one can then easily resolvent superoperators in Eq. (79) explicitly:

$$\frac{1}{z - X} \bar{L}_\Lambda \bar{G} = ... \sum_i \frac{1}{z - X - \lambda^i} G P^i \bar{G} ... \quad (149)$$

We note that the diagonalization of Eq. (136) can also be useful for higher orders of (renormalized) perturbation theory Eq. (69) (Eq. (79)): when expanding the QD $L$ and $\bar{L}$ in the form $\bar{L}_\Lambda$, it is directly adapted to all symmetries of the problem and one can efficiently construct explicit matrix representation of the self-energies $\Sigma(z)$ and $\bar{\Sigma}(z)$, respectively.

The application of the above spectral decomposition to the continuous RG in Sec. (III) involves two assumptions that should be pointed out here. First, we always assume that the zero eigenvalue of $L_\Lambda$ is non-degenerate, corresponding to the unique stationary state for the density operator. This is always found to be the case for the numerically calculated RG flows discussed in Sec. (III). However, in principle, it may also happen that two (or more) non-zero eigenvalues of $L_\Lambda$ become degenerate during this flow. If this is the case, and additionally the supermatrix $\bar{L}_\Lambda$ has non-zero elements on its diagonal in the normal Jordan form in the degenerate subspace, then no complete eigenprojector basis exists. For the Anderson model, this presents no crucial complication: the eigenbasis can in principle be circumvented for the calculation of the two dimensional superoperators. However, numerically we never meet this problem in the application of the RG theory presented below.

2. Eigenvalues, eigen-supervectors and the stationary state

We now explicitly diagonalize $L(z)$ or $\bar{L}_\Lambda$, parametrized as in Eq. (136), in each of its block-diagonals. We first list the eigenvalues and projectors in the block spanned by the charge- and spin-diagonal bosonic operators $|Z_L⟩, |Z_R⟩|S⟩, \text{ and } |T⟩$, which contains the stationary non-equilibrium state:

- Eigenvalue $\lambda^{Z_L} = 0$ with projector

$$P^{Z_L} = 2|\rho⟩⟨Z_L|, \quad (150)$$

with the stationary density operator

$$|\rho⟩ = -\left(\frac{1}{2\xi} \psi - \frac{1}{2} |Z_L⟩\right) - \frac{\zeta}{8\Gamma} \left(\psi - \langle\phi|\bar{\psi}|Z_R⟩\right) |Z_R⟩. \quad (151)$$

We note that the coefficient $\zeta$ appears only in the stationary state and the next projector, $P^{Z_R}$, but not in any other eigenprojector or eigenvalue.

- Eigenvalue $\lambda^{Z_R} = -i4\Gamma$ with projector

$$P^{Z_R} = \left(\frac{\phi}{4\Gamma(4\Gamma - \xi)} \bar{\psi}⟩|Z_R⟩\left(\psi - \langle\phi|\bar{\psi}|Z_R⟩\right) + \frac{\zeta}{4\Gamma} |Z_R⟩Z_L⟩ + |Z_R⟩\left(\frac{\phi}{4\Gamma - \xi} \bar{\psi}⟩\right) \quad (152)$$

We note that the diagonalization of Eq. (136) can also be useful for higher orders of (renormalized) perturbation theory Eq. (69) (Eq. (79)): when expanding the QD $L$ and $\bar{L}$ in the form $\bar{L}_\Lambda$, it is directly adapted to all symmetries of the problem and one can efficiently construct explicit matrix representation of the self-energies $\Sigma(z)$ and $\bar{\Sigma}(z)$, respectively.
• Eigenvalues $\lambda^{\pm}$ with projectors

$$P^{3,4} = P^{x,\pm} + \frac{\tilde{\phi}[P^{x,\pm} \phi]}{(\lambda^{x,\pm} - 4\Gamma)}|Z_R\rangle(Z_L)$$

(153)

$$+ \frac{1}{\lambda^{x,\pm} - 4\Gamma}|Z_R\rangle(\phi)P^{x,\pm} + \frac{1}{\lambda^{x,\pm}}P^{x,\pm}\phi)(Z_L).$$

The eigenvalues $\lambda^{x,\pm}$ are determined by first diagonalizing $\xi$ in the $\chi$-subspace, i.e., by finding eigen-projectors $P^{x,\sigma}$ of $\xi$

$$\xi P^{x,\sigma} = P^{x,\sigma} \xi = \lambda^{x,\sigma} P^{x,\sigma}. \quad (154)$$

Since $\xi_{\sigma,\sigma'}$ is a $2 \times 2$ non-Hermitian matrix, it can be expressed in the vector $\xi = (\xi_1, \xi_2, \xi_3)$ and coefficient $\xi_0$ (cf. Eq. (139)), all of which are complex:

$$\lambda^{x,\sigma} = -i\left(\xi_0 + \sigma\sqrt{\xi^2}\right) \quad (155)$$

$$P^{x,\sigma} = \frac{1}{2}\lambda^{x,\sigma} + \sigma\frac{\chi^* \xi}{2\sqrt{\xi^2}} \quad (156)$$

Here, the square root of the complex argument is defined such that the branch cut lies in the lower-half complex plane since the effective Liouvillian must be regular in the upper half-plane according to Eq. (32) and (35).

The remaining block-diagonals acting on bosonic subspaces are one-dimensional: for $\sigma = \pm$

$$\lambda^{T,\sigma} = -iM_\sigma, \quad P^{T,\sigma} = |T_\sigma\rangle\langle T_\sigma|$$

(157)

$$\lambda^{S,\sigma} = -iE_\sigma, \quad P^{S,\sigma} = |S_\sigma\rangle\langle S_\sigma| \quad (158)$$

Finally, in the four remaining, two-dimensional, fermionic subspaces labeled by $\alpha_{\eta,\sigma}$ (for fixed $\eta$ and $\sigma$), the eigenvalues and projectors can be calculated in the same way as for the bosonic $\chi$ block:

$$\lambda^{\alpha_{\eta,\sigma},\pm} = -i\left(F_{\eta,\sigma}^{0} \pm \sqrt{F_{\eta,\sigma}^{2}}\right)$$

(159)

$$P^{\alpha_{\eta,\sigma},\pm} = \frac{1}{2}\lambda^{\alpha_{\eta,\sigma},\pm} \pm \frac{F_{\eta,\sigma}^{1} - \alpha_{\eta,\sigma}}{2\sqrt{F_{\eta,\sigma}^{2}}} \quad (160)$$

where the coefficients $F_{\eta,\sigma}^{0}$ and $F_{\eta,\sigma} = (F_{\eta,\sigma}^{1}, F_{\eta,\sigma}^{2}, F_{\eta,\sigma}^{3})$ are again complex (cf. Eq. (142)).

We note that it is in principle possible that $\xi^2 = 0$ while $\xi \neq 0$. In this case, the supermatrix representation of $\chi$ has non-zero diagonal element in its normal Jordan form. In this case, $\xi$ has no eigenbasis and Eq. (160) does not apply. Still, the required matrix valued functions of $\xi$ can be calculated using the Hamilton-Cayley theorem. The same remarks apply to $F_{\eta,\sigma}$ and Eq. (160). However, in practical applications, we never meet such a situation. We also note that during the RG flows discussed in Sec. (111), we never run into points where $\lambda^{x,\pm} = -4i\Gamma$ and one therefore need not worry about the vanishing of the denominators in Eq. (153) or the existence of the inverse of $(4\Gamma - \xi)$ in Eq. (152).

An important simplification applies to the first four bosonic projectors $P^{Z_L}, P^{Z_R}, P^{3,4}$ that involve the vectors $|Z_L\rangle$ and $|Z_R\rangle$, analogous to the corresponding terms in the expansion (139) of the effective Liouvillian (cf. Sec. (111C.5.a)). When inserting projectors into Eq. (149) between two vertices $G$, (i) The projectors $P^{Z_L}, P^{Z_R}$ give no contributions; (ii) The projectors $P^{3,4}$ only contribute through the first term $P^{x,\pm}$ in Eq. (153). As a result, in all applications below we can replace Eq. (148) with the simpler expansion

$$\tilde{L}_\Lambda \frac{\tilde{g}}{\xi} \quad (161)$$

$$\lambda^{x} P^{x} = \sum_{\sigma} \left[\lambda^{S,\sigma} P^{S,\sigma} + \lambda^{T,\sigma} P^{T,\sigma} + \sum_{n,\sigma} \lambda^{\alpha_{\eta,\sigma}} P^{\alpha_{\eta,\sigma}}\right].$$

Here, we leave implicit the sum over the two eigenvalues $\lambda^{x,\pm}$ and $\lambda^{\alpha_{\eta,\sigma},\pm}$ in the $\chi$ and $\alpha_{\eta,\sigma}$-subspace, respectively. A crucial stability requirement for the RG in Sec. (111) is thereby explicitly satisfied: the zero eigen-projector (150), corresponding to the physical stationary state, never appears in the resolvents.

3. Fermionic excitations: Spectral decomposition of $\Sigma$

The expansion (136) can of course also be applied to $\Sigma(z) = \tilde{L}(z) - L$. This, however, involves additional simplifications causing certain terms appearing in the expansion of $L(z)$ and $\tilde{L}_{\Lambda}$ to be absent. First, due to Eq. (131) the term $|Z_R\rangle (Z_R)$ is missing. Second, since Eqs. (132) and (133) derive from the causal structure (cf. Sec. (111C.5.a)), most of the coefficients of the fermionic sector of $\Sigma$, denoted by $-i\Delta F^{\nu_{\eta,\nu'}}_{\eta,\nu'}$, vanish: $\Delta F^{\nu_{\eta,\nu'}}_{\eta,\nu'} = \delta_{\nu,\nu'} - \delta_{\nu,\nu} + \Delta F^{\nu_{\eta,\nu}}_{\eta,\nu}$. We can express the coefficient matrices $F^{\nu_{\eta,\nu}}_{\eta,\nu}$ of $L(z) = \tilde{L} + \Sigma(z)$ using Eq. (135), in terms of those of $\Sigma(z)$, i.e., in terms of the $\Delta F_{\eta,\nu}^{\nu'}$:

$$-i \left(F_{\eta,\nu}^{+,+} F_{\nu,\nu}^{-,-} - F_{\eta,\nu}^{-,-} F_{\nu,\nu}^{+,+}\right)$$

(162)

$$= \left[\eta (\epsilon + \frac{U}{2}) + \sigma \frac{B}{2} - i\Gamma\right] \left[\eta (\epsilon + \frac{U}{2}) + \sigma \frac{B}{2} - i\Gamma\right].$$

Converting to spherical coefficients $F_{\eta,\sigma}^{0}$ and $F_{\eta,\sigma}$ and using Eq. (159), we find

$$\lambda^{\alpha_{\eta,\sigma},\pm} = \eta \left(\epsilon + \frac{U}{2}\right) + \sigma \frac{B}{2} - 2i\Gamma$$

(163)

$$\pm \eta \sqrt{U^2 - \Gamma^2 - iU \Delta F^{\nu_{\eta,\nu}}_{\eta,\nu}} \quad (164)$$

$$\frac{1}{2} \left[\alpha_{\eta,\sigma}^{0} + \frac{U}{2} \alpha_{\eta,\sigma}^{1} + i\Gamma \alpha_{\eta,\sigma}^{2} - i \Delta F^{\nu_{\eta,\nu}}_{\eta,\nu}\right]$$

$$= \frac{1}{2} \left[\alpha_{\eta,\sigma}^{0} + \frac{U}{2} \alpha_{\eta,\sigma}^{1} + i\Gamma \alpha_{\eta,\sigma}^{2} - i \Delta F^{\nu_{\eta,\nu}}_{\eta,\nu}\right].$$

(164)
We thus find that the functional form of the fermionic eigenvalues of $L(z)$ is severely restricted by the casual structure of $\bar{\Sigma}$: all the frequency-dependent renormalization effects enter into the projectors and eigenvalues solely through the four complex numbers $\Delta F_{\eta,\sigma}^{-}$ in the four $\alpha_{\eta,\sigma}$ blocks ($\eta, \sigma = \pm$).

For a QD decoupled from the reservoirs, $\Gamma = 0$, we have $\bar{\Sigma} = 0 = \bar{\Sigma}(z) = 0$ and thus $\Delta F_{\eta,\sigma}^{-} = 0$:

$$\lambda^{\alpha_{\eta,\sigma}^+} = \eta (\epsilon + U) + \sigma B/2, \quad (165)$$

$$\lambda^{\alpha_{\eta,\sigma}^-} = \eta \epsilon + \sigma B/2. \quad (166)$$

This is the spectrum of many-body energy excitations when adding a single electron, starting from either an empty QD ($\lambda^{\alpha_{\eta,\sigma}^+}$) or a singly occupied QD with spin $\sigma$ ($\lambda^{\alpha_{\eta,\sigma}^-}$). This is confirmed by the eigenprojectors in the limit $\Gamma \to 0$ for finite $U$:

$$P^{\alpha_{\eta,\sigma}^\pm} = \frac{1}{2} (\alpha_{\eta,\sigma}^0 \pm \alpha_{\eta,\sigma}^1) = \left\{ (\sigma, 0)(\sigma, 0)|^{+}, \right. \left. (2, \bar{\sigma})(2, \bar{\sigma})|^{-}, \right. \left. (2, \bar{\sigma})(2, \bar{\sigma})\right\}, \quad (167)$$

where $|\sigma, 0\rangle = |\sigma\rangle|0\rangle = (1/2 - Z_R) d_{\sigma}^0$ and $|2, \bar{\sigma}\rangle = (1/2 + Z_R) d_{\sigma}^2$. These are the virtual intermediate states and energies that enter through $L$ into the perturbation expansion for $\bar{\Sigma}(z)$.

For any finite coupling $\Gamma$, but infinite temperature, we have $\bar{\Sigma} = 0$ and therefore again $\Delta F_{\eta,\sigma}^{-} = 0$. In this case, however, $\bar{\Sigma} \propto \Gamma \neq 0$ and the eigenvalues obtained from Eq. (165) depend qualitatively on the interaction strength $U$: for $U < 2\Gamma$, the coupling to the reservoirs $\bar{\Sigma}$ adds different imaginary parts to the degenerate real eigenvalues $\eta(\epsilon + U/2) + \sigma B/2$, whereas for $U > 2\Gamma$ it adds a uniform imaginary part $-i\Gamma$ to these eigenvalues while differently shifting their real parts. This dependence on $U$ is plotted in Fig. 3 and shows a bifurcation at $U = 2\Gamma$. These are the energies and projectors that enter through $\bar{\Sigma}$ into the renormalized perturbation theory.

Finally, for both finite coupling $\Gamma$ and finite temperature $T$, the complex coefficients $\Delta F_{\eta,\sigma}^{-}$ are non-trivial functions that need to be calculated, e.g., perturbatively or using the RG, see Sec. III B 3. However, even in this case Eq. (165) provides an exact relation: the average of the complex particle and hole excitation eigenvalues in each $\alpha_{\eta,\sigma}$-block is independent of $\Delta F_{\eta,\sigma}^{-}$ and thereby, also independent of the frequency $\epsilon$:

$$\frac{1}{2} \sum_{\pm} \lambda^{\alpha_{\eta,\sigma}^\pm} = \eta \left( \frac{\epsilon + U}{2} \right) + \sigma \frac{B}{2} - 2i\Gamma. \quad (168)$$

Physically speaking, both the renormalized energies of single particle fermionic excitation energies (real parts) as well as their decay rates / broadenings (imaginary parts) lie symmetric with respect to the above average values. For example, if the particle excitation broadens, the hole excitation must sharpen up and vice versa.

Finally, we can infer an important physical stability constraint on the functions $\Delta F_{\eta,\sigma}^{-}$: they must be such that the imaginary part of the square root is less than $2\Gamma$.

**FIG. 3:** Fermionic excitation energies and widths of the infinite-temperature Liouvillian $\bar{L}$ plotted as function of the tunnel coupling strength $\Gamma/U$ for $\epsilon = B = 0$. The energy and widths are given by the real and imaginary parts of the fermionic eigenvalues $\lambda^{\alpha_{\eta,\sigma}^\pm}$ [Eq. (165)] with $\Delta F_{\eta,\sigma}^{-} = 0$. The real parts for $\nu = +1$ (red) and $\nu = -1$ (green), respectively, are given by the full lines, and the imaginary parts are indicated by the shaded width of the level with the corresponding color. For $U > 2\Gamma$, the excitations have different energies, split by $U$, but with the same width $2\Gamma$, whereas for $2\Gamma > U$ they have the same energies but different widths: for $\Gamma > U - \text{Im} \lambda^{\alpha_{\eta,\sigma}^\pm} \approx \Gamma$ (red) $3\Gamma$ (green).

4. High-symmetry stationary states

As a cross-check on the results of Sec. III D 2, we now analyze the stationary density operator in the two special parameter regimes where the model has a higher symmetry than in general. In both cases, the superoperator $\xi$ has no off-diagonal terms in the basis of $|S_0\rangle$ and $|T_0\rangle$,

$$\xi = \xi_{TT}|T_0\rangle\langle T_0| + \xi_{SS}|S_0\rangle\langle S_0|, \quad (169)$$

because there are no scalars with respect to spin- or charge-rotations that contain such terms as components (see Table III). If either symmetry is broken, charge and / or spin-rotations allow for mixing terms $|T_0\rangle\langle S_0|$ and $|S_0\rangle\langle T_0|$ in Eq. (169). For this reason, we work with the $|\chi_\nu\rangle$ basis in the general case.

a. Full spin-rotation symmetry, $B = 0$. At zero magnetic field, all terms in the Liouvillian must be rank-0 ITSOs (scalars) with respect to spin rotations, i.e., the terms $|S_0\rangle\langle S_0|$ and $|S_\pm\rangle\langle S_\pm|$ must have the same coefficients, $E_+ = E_- = \xi_{SS}$ and the coefficients of the rank-1 and -2 spin ITSOs must vanish, i.e., in the $\chi$ subspace.
that there is no summation over the electrode index $r$.

| \[ iL_A = ... + \phi_T|Z_R\rangle|T_0\rangle + \psi_T|T_0\rangle(Z_L| + M_+|T_+\rangle(T_+ + M_-|T_-\rangle(T_-) + \xi_{TT}|T_0\rangle(T_0) + \xi_{SS}(|S_+\rangle(S_+| + |S_-\rangle(S_-| + |S_0\rangle(S_0)|) + \ldots. \]  

See Table 4 where the ITSOs are listed. The expression for the stationary state $\rho$ obtained using Eq. (151) is then independent of $\xi_{SS}$ and is therefore explicitly invariant under spin-rotations, as required:

\[ \rho = -\frac{1}{2}|\psi_S|S_0\rangle + \frac{1}{2}|Z_L\rangle - \frac{\zeta - \phi_T\psi_T/\xi_{TT}}{8\Gamma}|Z_R\rangle. \]  

b. Full charge-rotation symmetry, $\epsilon = -U/2$ and $\mu_L = \mu_R$. At the particle-hole symmetric point, a similar reduction must take place: here $M_+ = M_- = \xi_{TT}$, $\phi_S = \phi_S|S_0\rangle$ and $\psi = \psi_S|S_0\rangle$:

\[ iL_A = ... + \phi_S|Z_R\rangle|T_0\rangle + \psi_S|T_0\rangle(Z_L| + \xi_{TT}(|T_+\rangle(T_+ + |T_-\rangle(T_-) + |T_0\rangle(T_0)) + \xi_{SS}(|T_0\rangle(|T_0\rangle|S_+\rangle(S_+| + |S_-\rangle(S_-| + |S_0\rangle(S_0)|) \quad (172) \]

and the stationary state is explicitly invariant under charge rotations:

\[ \rho = -\frac{1}{2}|\psi_S|S_0\rangle + \frac{1}{2}|Z_L\rangle - \frac{\zeta - \phi_S\psi_S/\xi_{SS}}{8\Gamma}|Z_R\rangle. \]  

E. Current superoperator and its irreducible self-energy

Our main objective is to calculate the stationary current that flows through the QD. Having set up the perturbation theory formalism for the density operator, the expression for the average current can now be compactly derived. Moreover, we give a general proof that in general at zero bias the current vanishes, as it should, independent of the way the self-energy is calculated.

The current flowing out of reservoir $r = L$ or $R$ is obtained using Heisenberg operators (with index $H$):

\[ iH^H = -\frac{\partial}{\partial n^H} = -i[H^{tot}, n^H]_-- = -i[H^L, n^H]_+. \]

Note that there is no summation over the electrode index $r$ [cf. Eq. (139)]. The expectation value of the Schrödinger-picture current operator

\[ I^r = -i[V^r, n^r]_-, \]  

can be expressed in superoperators using the cyclic invariance of the total system trace:

\[ \langle I^r \rangle(t) = \text{Tr}_D\text{Tr}_R \langle I^r \rho^{tot}(t) \rangle \]

\[ = -i\text{Tr}_D\text{Tr}_R \left( L^r e^{-iL^{tot}(t-t_0)}\rho(t_0)\rho^R \right). \]  

We note that observable averages involve anticommutators of the corresponding operator (see, e.g., Ref. [42]):

\[ L^r = \frac{i}{2}[I^r, \bullet]_. \]  

This is in contrast to time-evolution superoperators, which involve commutators of the Hamiltonian operator. This difference is exploited below. If one uses Eq. (174) in Eq. (175), the evaluation of the reservoir trace is unnecessarily complicated, since Eq. (174) involves two operators acting on the reservoir, $V^r$ and $n^r$. Here, we proceed differently: we first use that the tunneling through junction $r$ conserves the particle number of the dot and the reservoir $r$, i.e., $[n^r + n, V^r]_- = 0$, to eliminate one electrode operator:

\[ I^r = i[V^r, n]_-- = i[n, V^r]_-. \]  

Then, using the identity: $[[A, B]_-, \bullet]_+ = [A, [B, \bullet]_-]_+ - [B, [A, \bullet]_+]_-$ the current superoperator anticommutator can be decomposed as

\[ L^r = \frac{1}{2}(L^{n+r}V^r - L^Vn^rL^{n+r}). \]  

Here, we introduced the anticommutator superoperator for the particle number (cf. Eq. (176)),

\[ L^{n+r} = [n, \bullet]_+. \]  

and decomposed the tunneling interactions into the junction contributions, $L^V = \sum_r L^{V,r}$. Importantly, the last term of Eq. (178) is irrelevant when inserted into Eq. (175) since $\text{Tr}_D\text{Tr}_R L^{V,r} \bullet = 0$ due to the commutator form of $L^{V,r}$. We obtain

\[ \langle I^r \rangle(t) = -i\frac{1}{2}\text{Tr}_D L^{n+r} \left( \text{Tr}_R L^{V,r} \rho^{tot}(t) \right). \]  

Integrating out of the reservoirs and collecting terms into irreducible blocks [cf. Sec. (113)], one now obtains

\[ \langle I^r \rangle(z) = \frac{1}{2}\text{Tr}_D L^{n+r} \Sigma^r(z) \frac{1}{1 - L^L(z)}\rho(t_0) \]

\[ = -i\frac{1}{2}\text{Tr}_D L^{n+r} \Sigma^r(z)\rho(z). \]  

where $\Sigma^r$ is just that part of the irreducible self-energy $\Sigma$ for which the latest (leftmost) vertex is associated with reservoir $r$. We can thus decompose

\[ \Sigma(z) = \sum_r \Sigma^r(z). \]  

For the stationary current $\langle I^r \rangle = \lim_{t \to \infty} \langle I^r \rangle(t) = \lim_{t \to \infty} -iz\langle I^r \rangle(z)$, we then obtain the central result of this subsection:

\[ \langle I^r \rangle = -i\frac{1}{2}\text{Tr}_D L^{n+r} \Sigma^r(i0)\rho, \]  

where $\rho$ is the stationary density operator (cf. Eq. (151)).
The first advantage of the Eq. (183) is that it allows one to explicitly see that the current is always zero at zero bias. For any number of electrodes, at zero voltage bias all electrochemical potentials are equal, \( \mu_r = 0 \), implying that all partial self-energies \( \Sigma^r \) are proportional to the total self-energy:

\[
\Sigma^r \propto \sum_r \Gamma_r \Sigma(i0). \tag{184}
\]

Next, we add \( L \) to \( \Sigma(i0) \) in Eq. (183) without changing its value since by local charge conservation, Eq. (103), \( \text{Tr}_D L^{n+} \bullet = \text{Tr}_D n[H, \bullet] = \text{Tr}_D [n, H] \bullet = 0 \) when acting on any dot operator. We can thus express the stationary, zero-bias current in terms of the effective Liouvillian \( \bar{L}(z) = L + \Sigma(z) \) and directly see that it must vanish,

\[
\langle I^r \rangle \propto -i \text{Tr} L^{n+} L(i0) \rho = 0, \tag{185}
\]

since the stationary state \( \rho \) is the zero eigen-supervector of \( L(i0) \) (cf. Eq. (37)). We note, however, that the relation (185) relies on the assumption of reservoir-frequency independent spectral densities \( \Gamma_r(\omega) = \Gamma_r \) which we make throughout this paper. Apart from that, the above proof holds no matter what approximations one makes for the calculation of the self-energy \( \Sigma(i0) \) as long as all reservoirs are treated in the same way. This applies to perturbation theory up to any finite order, as well as to the RT-RG approach that we set up in Sec. (III).

A second advantage of Eq. (183) is that we can directly relate the current to just a few supermatrix elements of the RT-RG approach that we set up in Sec. (III).

\[
\frac{1}{2} \text{Tr}_D (L^{n+} \bullet) = \text{Tr}_D (n \bullet) = \left( \sqrt{2} |T_0| + 2 |Z_L| \right) \bullet. \tag{186}
\]

Equation (186) implies probability conservation, Eq. (69), but also, more strongly, that \( (Z_L) \Sigma^r(i0) \bullet = 2 \text{Tr}_D \Sigma^r(i0) \bullet = 0 \) for fixed \( r \). From this, we obtain

\[
\langle I^r \rangle = -\sqrt{2} i \langle T_0 | \Sigma^r | \rho \rangle. \tag{187}
\]

Clearly, the partial self-energy \( \Sigma^r \) has the same general form as Eq. (130) and we distinguish its parameters (except \( \Gamma_r \)) by an additional reservoir superscript \( r \):

\[
i \Sigma^r = 2 \Gamma_r |Z_R| (Z_R) + \xi^r (Z_R) (Z_L) + |Z_R| (\bar{\phi}^r) + |\bar{\psi}^r| (Z_L) + \sum_\sigma E^r_\sigma |T_\sigma| + \sum_\sigma (\xi^r S_\sigma + \sum_\eta F^r_{\eta, \sigma}). \tag{188}
\]

Inserting this form and the explicit expression for the stationary state Eq. (151) into Eq. (187), we obtain the final explicit expression for the average stationary current in terms of the self-energy expansion coefficients:

\[
\langle I^r \rangle = \frac{1}{\sqrt{2}} \left[ (T_0 | \phi^r \rangle - (T_0 | \xi^r \xi^{-1} \psi \rangle \right]. \tag{189}
\]

We emphasize that this equation is exact, given that the coefficients \( \psi^r \) and \( \xi^r \) of the partial self-energies \( \Sigma^r \) are known, from which \( \psi^r = \sum_r \psi^r_\sigma \) and \( \xi = \sum_r \xi^r \) also follow. We can thus calculate the current easily if we perform all self-energy calculations separately for each fixed value of the reservoir index \( r \) at the latest (leftmost) vertex and sum over \( r \) to obtain Eq. (183). Finally, we note that using Eq. (189), one can check explicitly that if one imposes particle-hole symmetry on the expansion coefficients in Eq. (188), then the current (187) vanishes: one finds that \( |\psi^r \rangle \) and \( \xi^r \) have no components involving \( |T_0 \rangle \). This is in agreement with the result (185) obtained above making explicit use of \( \mu_L = \mu_R \).

### III. REAL-TIME RENORMALIZATION GROUP

In this section we set up the real-time renormalization group (RT-RG) calculation of the effective Liouvillian \( \bar{L}(z) \). It is based on the perturbative expansion of the “finite-temperature” self-energy \( \Sigma \) in the causal representation introduced in the previous section, cf. Sec. (III.D). The procedure is to calculate \( \bar{L}(z) \) by introducing an RG flow of the “infinite-temperature” Liouvillian \( \bar{L} \) and the vertex \( \bar{G} \) as function of a decreasing energy scale cutoff \( \Lambda \), with the initial conditions given by \( \bar{L} = \bar{\Sigma} + L \) (thereby including the vertex of the type \( \bar{G} \) and \( \bar{G} \), the vertex of the perturbation theory. There are a number of motivations for performing such an RG treatment of the perturbative series for \( \Sigma \).

- First of all, treating \( \bar{\Sigma} \) perturbatively in \( \bar{G} \), while infinite orders of \( \bar{G} \) have already been resummed into \( \bar{\Sigma} \), would amount to an inconsistent treatment. We note that even in the non-interacting case \( \bar{G} = 0 \) we already need to do a renormalized perturbation theory (79) up to two-loop terms to recover the exact result for all quantities (i.e., not just the current). For strong interaction \( U \), higher-order corrections in \( \bar{G} \) become increasingly important: at finite and especially at low \( T \) the strong interaction \( U \) leads to different lifetime broadening for single-(SET) and two-electron inelastic cotunneling (ICT) excitations, with a non-trivial voltage dependence. This is not described by \( \bar{\Sigma} \): it leads to a broadening of the various excitations of the QD that is energy independent and \( \sim \Gamma \). The nontrivial, energy-dependent corrections due to quantum fluctuations contained in the high-order contributions to \( \bar{\Sigma}(z) \) are required.

- Second, although the bare perturbation theory breaks down at these resonances as \( T \to 0 \), in the
renormalized perturbation theory \cite{79}, the low energy cutoff \( T \) is replaced by the imaginary parts \( \sim \Gamma \) in \( \bar{L} \). Still, the resonance due to the Kondo effect causes even the renormalized perturbation theory to break down and three-loop corrections result in the enhancement of Kondo exchange processes. These have been studied extensively using the RT-RG based on an effective Kondo model obtained by a Schrieff-Wolff transformation from the Anderson model \cite{27} in the regime of large applied bias voltage and/or magnetic field such three-loop corrections can be neglected due to the dephasing of the Kondo correlations. This is the regime of interest in this work for which we expect the one-plus-two-loop RG approach to give a good first approximation that deserves to be studied.

- In order to study the Kondo effect in the Anderson model beyond the Ref. \cite{27}, at least a three-loop treatment is necessary. The renormalization of the one- and two-loop terms that we study here will then couple to the 3-loop terms and still play an important role. Therefore, our study of the two-loop RG provides an important starting point for such a much more involved study, which in particular can address the low bias and low magnetic field regime.

A. Flow of Keldysh contractions: Continuous RG

In general, RG approaches to transport aim to eliminate the effect of reservoir states, starting at high energies, by incorporating it into a redefinition of the system parameters. Typically, one eliminates the states themselves. Here, in contrast, we successively suppress the occupations of the states using an RG procedure while keeping the states. Before we specify the details and advantages of this cutoff scheme, we first outline the main idea of the functional renormalization group approach when applied to the real-time perturbation series \cite{79}. By our causal reformulation of the perturbation theory (cf. Sec. \textit{II B 2}), it is clear that all the information about the occupations of the reservoir states is contained in the Keldysh components of the correlation functions, i.e., in the \( \bar{\gamma} \) contraction. Therefore, we introduce a cutoff-dependent contraction function \( \bar{\gamma}_A \) that monotonously flows from the initial, full contraction function \( \bar{\gamma}_A |_{\Lambda=\infty} = \bar{\gamma} \) given by Eq. (64) to the trivial final function \( \bar{\gamma}_A |_{\Lambda=0} = 0 \) where all occupations are suppressed. During this flow, we demand that the effective Liouvillian remains invariant: for every value of the cutoff parameter \( \Lambda \),

\[
L(z) = \bar{L} + \bar{\Sigma} \left( \{ \bar{\gamma}, \bar{L}, \bar{G} \} \right) = \bar{L}_A + \Sigma \left( \{ \bar{\gamma}_A, \bar{L}_A, \bar{G}_A \} \right) = \bar{L}_A |_{\Lambda=0}. \tag{192}
\]

Thus, \( L(z) \) has the same functional dependence on the contractions \( \bar{\gamma}_A \), the Liouvillian \( \bar{L}_A \), and vertices \( \bar{G}_A \). The latter two now acquire a \( \Lambda \) dependence to maintain invariance. The same diagram rules are thus valid for any value of \( \Lambda \). As a result, at the end of the flow where \( \bar{\gamma}_A |_{\Lambda=0} = 0 \), the effective Liouvillian is given simply by \( \bar{L}_A |_{\Lambda=0} \). The information about the reservoir degrees of freedom, previously incorporated into the self-energy \( \Sigma \), has now been incorporated fully into the dot Liouvillian (cf. Eq. (192)).

The RG flow is generated by making an infinitesimal change \( d\Lambda \) of the cutoff, resulting in an infinitesimal change \( d\bar{\gamma}_A \approx (d\bar{\gamma}_A/d\Lambda)d\Lambda \) of the Keldysh contraction function. In the perturbation series at scale \( \Lambda \), one splits up the contraction function as \( \bar{\gamma}_A = \bar{\gamma}_{A-d\Lambda} + d\bar{\gamma}_A \) and collects all terms in a perturbation series of the same form but containing only \( \bar{\gamma}_{A-d\Lambda} \) contractions. In this process, the terms containing one infinitesimal contraction \( d\bar{\gamma}_A \) can be identified with renormalizations \( dL \) of the Liouvillian, \( dG \) of the vertices, and newly generated higher-order vertices with more than one leg. The process is illustrated in Fig. 3: The Liouvillian \( \bar{L}_A - d\Lambda = \bar{L}_A - \bar{G}_A \), and vertices \( \bar{G}_A - d\Lambda = \bar{G}_A - d\bar{G}_A \) of the new perturbation series are then all defined for the new, lower cutoff scale \( \Lambda - d\Lambda \). We obtain differential equations for these quantities describing their renormalization as one continuously reduces the cutoff \( \Lambda \). These are the real-time renormalization group (RT-RG) equations.

A key requirement in setting up this continuous RG is that for any \( \Lambda \) the zero-eigen vector of \( \bar{L}^\Lambda \) does not appear in the resolvents \( (z + X - \bar{L}^\Lambda)^{-1} \), to avoid divergences as function of the frequencies. The RG thus has to be formulated such that the property (85) of the vertices in the causal representation is preserved. This can be shown to be the case [see Eq. (212) below].

The final key point is the choice of a cutoff-dependent distribution function in the contraction \( \bar{\gamma} \). The numerical integration of the RG equations is more stable when we introduce a contraction function with a cutoff on the imaginary frequency axis,

\[
\bar{\gamma}_{12,\Lambda}(\eta \omega) = \delta_{12} \frac{\Gamma}{\pi} T \sum_{l=0}^{\infty} \frac{\Theta_T(\Lambda - |\omega'|)}{\eta \omega' - \mu_r - i\omega'}, \tag{193}
\]

through the function

\[
\Theta_T(\omega) = \begin{cases}
\Theta(\omega) & |\omega| > \pi T \\
\frac{1}{2} + \frac{\omega}{\pi T} & |\omega| < \pi T,
\end{cases}
\tag{194}
\]

where \( \Theta(\omega) \) is the step-function and

\[
\omega' = (2l + 1)\pi T \tag{195}
\]

is the \( l \)-th Matsubara frequency \( (l = 0, 1, 2, \ldots) \). In the limit \( \Lambda \rightarrow +\infty \) we recover the partial fraction expansion of the meromorphic function \( (\Gamma/2\pi) \tan(\omega/2T) \) as required. Imposing this cutoff in Matsubara space leads to a suppression of the tails of \( \bar{\gamma}^\Lambda(\eta \omega) \) on the real frequency
(z - L_{\Lambda} - \Sigma_{\Lambda})^{-1} = \sum_{\gamma_\Lambda} + \gamma_{\Lambda-d\Lambda} + \cdots \quad \Rightarrow \quad (z - L_{\Lambda})^{-1} = \sum_{\gamma_{\Lambda}} + \gamma_{\Lambda-d\Lambda} + \cdots \quad \Rightarrow \quad G_{\Lambda-d\Lambda} = \sum_{\gamma_{\Lambda}} + \gamma_{\Lambda-d\Lambda} + \cdots \quad \Rightarrow \quad (z - \tilde{L}_{\Lambda-d\Lambda} - \tilde{\Sigma}_{\Lambda-d\Lambda})^{-1}

\[ \delta_{\tilde{L}_{\Lambda-d\Lambda}}(\eta\omega) = \frac{\Gamma}{\pi} \int_{-\Lambda}^{\Lambda} d\omega' \frac{1}{\eta\omega - \mu_r - i\omega'}. \]  

See Ref. [25] for a detailed discussion.

### B. RG in frequency space

#### 1. Non-equilibrium Matsubara representation and frequency dependence

To formulate the RG equations, we need a more compact notation for the various frequencies. Since the contraction functions \( \gamma_{\Lambda} \) depend on \( \eta\omega = x - \eta\mu \), we re-express the reservoir energies in the resolvents in \( \Sigma \) [Eq. (199)] in explicit calculations as

\[ E - X_i = E - x_{1...n} = E_{1...n} - \tilde{\omega}_{1...n}. \]  

(197)

Here, \( 1...n \) are the multiindices of the contractions going over diagram segment \( i \). The frequencies are now taken relative to the electrochemical potentials and we write their sums as repeated multiindices: for \( k = \eta k, \sigma k, r k, \omega k, \)

\[ x_k = \tilde{\omega}_k + \tilde{\mu}_k, \quad x_{1...n} = x_1 + \ldots + x_n, \]  

(198)

\[ \tilde{\omega}_k = \eta k \omega k, \quad \tilde{\omega}_{1...n} = \tilde{\omega}_1 + \ldots + \tilde{\omega}_n, \]  

(199)

\[ \tilde{\mu}_k = \eta k \mu_k, \quad \tilde{\mu}_{1...n} = \tilde{\mu}_1 + \ldots + \tilde{\mu}_n. \]  

(200)

Similarly, we express the dot energies relative to these chemical potentials as

\[ E_{1...n} = E - \sum_{i=1}^{n} \tilde{\mu}_i. \]  

(201)

A key advantage of the cutoff parametrization is that it allows us to analytically perform all the integrations over the reservoir frequencies \( \tilde{\omega} \) in Eq. (180) by closing each integration contour in the complex lower half-plane and by using the residual theorem. As a result, we can replace all integrations over real frequencies in the resolvents by summations over Matsubara frequencies lying in the lower half-plane: Eq. (197) becomes

\[ E_{1...n} + i\omega_{1...n}. \]  

(202)
For finite \( T \) the \( \omega_k \)-sum runs over the positive discrete frequency values \((2l_k + 1)\pi T, l_k = 0, 1, 2, \ldots\), which turns into an integral over positive \( \omega_k \) for \( T = 0 \). As always, we do not explicitly indicate this integral.

2. RG equations

During the RG flow, the Liouvillian develops a non-trivial dependence on both the real energy \( E \) of the QD and on \( \omega_r \), the sum of the imaginary frequencies of all the reservoir-contractions that pass over the propagator in a diagram. This is illustrated in Fig. 5(a). We separately keep track of these frequency dependencies by writing

\[
\bar{L}_\Lambda(E, \omega) := \bar{L}_\Lambda(E + i \omega), \quad \Pi_\Lambda(E, \omega) := \frac{1}{E + i \omega - L_\Lambda(E, \omega)}. \tag{203}
\]

This approximation requires that one also accounts for the renormalization of vertices to one-loop order:

\[
\frac{d\bar{G}_1(E, \omega, \omega_1)}{d\Lambda} = -\frac{\Gamma}{\pi} \bar{G}_2(E, \omega, \Lambda) \Pi(E_1, \omega + \Lambda) \bar{G}_1(E_1, \omega + \Lambda, -\Lambda) \bar{G}_1(E_1, \omega + \Lambda, -\Lambda). \tag{204}
\]

The frequency dependence in the RG equations Eq. (203)-(207) in the one and two-loop approximation needs to be carefully discussed. Before we turn to this in Sec. (III C)-(III D), we discuss some important general properties of the RG-equations in Sec. (III B 3) and their implications for the fermionic eigenvalues in Sec. (III B 4).

The formally exact, infinite hierarchy of RT-RG equations was derived in general form in Ref. [26]. Here, we restrict ourselves to the one- and two-loop order approximation for the Liouvillian and the limit of \( T \rightarrow 0 \):

\[
\bar{G}_1,\Lambda(E, \omega, \omega_1) := \bar{G}_1,\Lambda(E + i \omega, i \omega_1). \tag{205}
\]

The renormalization of the vertex \( \bar{G}_1 \) introduces similar dependencies and an additional dependence on the reservoir frequency \( \omega_r \) of the vertex "leg", i.e., the contraction connecting it to another vertex, see Fig. 5(b):

The exact properties derived in Sec. (III C 5 a) follow from the causal structure of the perturbation series (79). Since the RG equations (206) and (207) represent nothing but a reorganization of the terms in that expansion (as explicitly shown in Ref. [26]), we expect that they preserve these causal structure properties. We now show that this is indeed the case. Indeed, an exact left and right eigen-
supervector of the renormalized \( \vec{L} \) is given by

\[
(Z_L|\vec{L}(E, \omega), \omega_1) = 0, \quad (Z_L|\vec{L}(E, \omega)|Z_R) = -i4\Gamma|Z_R), \quad (Z_L, \vec{L}(E, \omega)|Z_R) = -i4\Gamma|Z_R),
\]

respectively. Since at \( \Lambda = \infty \) we have the initial condition \( \langle Z_L|\vec{L}|0 = 0 \) and \( \vec{L}|Z_R\rangle = -i4\Gamma|Z_R\rangle \), we only need to show that \( \langle Z_L|d\vec{L} = d\vec{L}|Z_R\rangle = 0 \), respectively, to prove Eqs. (210) and (211). We note that since Eq. (209) is an exact relation, Eqs. (210) and (211) must hold for the exact, infinite hierarchy of RT-RG equations (i.e., including all higher vertices generated during the RG flow that we neglect here). In our two-loop approximation this relation directly follows by letting Eq. (206) act on these vectors and using

\[
(Z_L|\vec{G}(E, \omega, \omega_1) = 0, \quad (Z_L|\vec{G}(E, \omega, \omega_1)|Z_R) = 0. \quad (Z_L|\vec{G}(E, \omega, \omega_1)|Z_R) = 0. \quad (Z_L|\vec{G}(E, \omega, \omega_1)|Z_R) = 0. \quad (Z_L|\vec{G}(E, \omega, \omega_1)|Z_R) = 0.
\]

Equations (212) and (213) follow by assuming that they hold for a given \( \Lambda \), and by \( Z_L|\vec{G} = Z_L|\vec{G}|Z_R \), obtained acting with Eq. (207) on these vectors. Since Eqs. (212) and (213) hold initially for \( \Lambda = \infty \) the result follows for any \( \Lambda, E, \omega, \omega_1 \).

Similarly, we now that for any \( \Lambda, E, \omega, \omega_1 \):

\[
(\alpha^{-}_\eta \sigma|d\vec{L}(E, \omega)) = 0, \quad (\alpha^{-}_\eta \sigma|d\vec{L}(E, \omega)) = 0, \quad (\alpha^{-}_\eta \sigma|d\vec{L}(E, \omega)) = 0, \quad (\alpha^{-}_\eta \sigma|d\vec{L}(E, \omega)) = 0.
\]

In our two-loop approximation for \( d\vec{L}/d\Lambda \), this follows from the property of the renormalized 1-leg vertices

\[
\vec{G}(E, \omega, \omega_1)|\alpha^{-}_\eta \sigma) \propto |Z_R\rangle \text{ or } 0, \quad (\alpha^{-}_\eta \sigma|\vec{G}(E, \omega, \omega_1) \propto |Z_L\rangle \text{ or } 0.
\]

The proof of Eq. (122)-(124) can be extended to the renormalized vertices as follows. We start by observing that the right-hand sides of the RG equations (206)-(207) have the same structure as \( \Sigma(z) \) (cf. Eq. (79)). Assuming that Eq. (210) holds for a given scale \( \Lambda \), the RG equation (207) implies that it is preserved under the flow: \( (\alpha^{-}_\eta \sigma²|\vec{G} = \frac{d\vec{G}}{d\Lambda}|\alpha^{-}_\eta \sigma)² \). Here, we used that by Eq. (210), (211) both \( |Z_R\rangle \) and \( |Z_L\rangle \) are eigen-supervectors of the renormalized \( \vec{L} \) for all \( \Lambda, E, \omega, \omega_1 \). Since Eq. (210), (217) hold initially for \( \Lambda = \infty \), this then implies it holds for all \( \Lambda \). From this, Eq. (214)-(215) follow directly. The above proofs are readily extended to the infinite hierarchy of exact RT-RG equations for vertices with multiple legs, confirming that Eq. (210), (211), (215) and (216) hold exactly (and not just in our two-loop approximation).

4. Fermionic excitations

a. Fermionic eigenvalues  We can now pick up the discussion of Sec. (11D). Since the supermatrix structure of \( d\vec{L}_\Lambda/d\Lambda \) in the fermionic sector is preserved under the RG flow and is the same as that of \( \vec{\Sigma}(z) \), we can now directly relate the coefficient \( \Delta F^{-}_{q\sigma} \) introduced in Sec. (11D) using Eq. (208):

\[
\Delta F^{-}_{q\sigma}(E + i\omega) = \int_{0}^{\infty} d\Lambda \frac{dF^{-}_{q\sigma\Lambda}(E + i\omega)}{d\Lambda}
\]

This coefficient determines the fermionic excitations at arbitrary complex frequency as given by Eq. (163) for the exact \( \Sigma(z) \) when the infinite hierarchy of RG-equations is used to compute the right-hand side. We see that the \( \Lambda \)-dependent coefficient \( F^{-}_{q\sigma\Lambda} \) of \( \vec{L}_\Lambda \) interpolates between the infinite temperature limit, where \( \Delta F^{-}_{q\sigma} = 0 \), and the exact value \( \Delta F^{-}_{q\sigma} \) of \( \Sigma(z) \) through Eq. (218) as was anticipated in Sec. (11D). All renormalization effects enter into the fermionic excitations through the renormalization of the four complex coefficient \( F^{-}_{q\sigma\Lambda} \) of \( \vec{L}_\Lambda \). During this flow, the qualitative features of these excitations, discussed in Fig. 3, may change. During the continuous RG, the complex parameters \( \Delta F^{-}_{q\sigma\ Lambda} \) will grow from zero and modify both real and imaginary parts in Eq. (163). This happens only for the interacting Anderson model, \( U \neq 0 \) since \( U \) multiplies these coefficients in Eq. (163). This flow may include bifurcations as function of the flow parameter \( \Lambda \), but for large enough \( U \gg 2T \) the excitations energies (real parts) remain non-degenerate. However, the general result (163) shows that during this non-trivial flow the average of the complex eigenvalues stays fixed for all frequencies. We conclude generally that the fermionic excitation energies and decay rates are renormalized symmetrically with respect to the average values \( \epsilon_0 \pm \sigma \lambda \) and \( 2T \), respectively, for any complex frequency \( E + i\omega \) with \( \omega > 0 \).

Finally, we note that the stability constraint discussed in Sec. (11D) imposes a constraint on the RG flow: since at any stage of the RG flow the effective Liouvillian \( L(z) \) (191) can be calculated from the perturbative expansion (79), the imaginary parts of all non-zero eigenvalues of the renormalized \( \vec{L}_\Lambda \) must be negative to avoid unphysical divergence of the time-dependent density operator. Such behavior would not go unnoticed in the RG since zero denominators would appear in the resolvents in Eq. (227), leading to an instability in the RG-flow. This provides a simple criterion for the stability of the RG flow for the Anderson model that can be checked easily in numerical approximations. Although in previous applications of the RT-RG no instabilities have been reported, and in the present study none were encountered either, the general conditions for stability are currently not known.

b. Fermionic supermatrix elements  The properties

\[
\text{Eq. (208)-(217) strongly restrict the fermionic matrix elements of the resolvents } \Pi \text{ that can appear in the RG equations.}
\]

We will see that implies that quite generally the RG equations decouple into smaller sets of equations (see Sec. (11C)) and that important simplifications arise in the \( U = 0 \) limit (see Sec. (11C)). These simplifications arise since in general on the right-hand side of RG
equations such as Eq. (207) the resolvent $\Pi$ always appears sandwiched between pairs of $G$ vertices (all are renormalized quantities but $\Lambda$ is not written). We list the different cases:

- In matrix elements of terms with only one resolvent, $(X|\Pi G Y)$, there are no restrictions only if $X = Z_R, Y = Z_L$. Indeed, upon inserting the completeness relation $1 = \sum_{\eta, \sigma, \nu} \langle \alpha_{\eta \sigma}\rangle \langle \alpha_{\nu \sigma}\rangle + (\text{bosonic terms})$ left and right of $\Pi$, we see that according to Eq. (219) all intermediate fermionic supermatrix elements contribute. However, when the basis supervectors $X, Y$ involve one of the supervectors $Z_L, Z_R$, then only certain matrix elements contribute: for $\nu = \pm$ these are

\[(\alpha_{\eta \sigma}^\dagger \Pi \alpha_{\eta \sigma}^\dagger), \quad X = Z_R, Y \neq Z_L, \quad (219)\]

\[(\alpha_{\eta \sigma}^\dagger \Pi \alpha_{\eta \sigma}^\dagger), \quad X \neq Z_R, Y = Z_L, \quad (220)\]

whereas, if the supervectors $Z_L, Z_R$ are not involved, only one factor is possible:

\[(\alpha_{\eta \sigma}^\dagger \Pi \alpha_{\eta \sigma}^\dagger), \quad X \neq Z_R, Y \neq Z_L. \quad (221)\]

- In terms with $n \geq 3$ resolvents $(X | G_1 G_2 G_3 Y)$, Eq. (219) and (221) apply to the leftmost “boundary” resolvent. Otherwise, the expression vanishes for any $\Lambda$ since by Eq. (217) $(X|\Pi \alpha^+(\alpha^+|G_1 G_2 G_3 \cdots \alpha^+|G Y) = 0$. Here, we used that $(Z_L)$ an exact eigenvector of $L$, and thereby of $\Pi$ by Eq. (210), and a zero eigenvector of $G$ by Eq. (212).

Similarly, Eq. (220) and (221) also apply to the rightmost “boundary” resolvents since $\cdots G_1 \Pi \alpha^-(\alpha^-|G Y) = 0$ by Eq. (216), (211), (213).

- Finally, in terms with $n \geq 3$ resolvents, the resolvents that are not at the boundary can only contribute with fermionic matrix element $(\alpha_{\eta \sigma}^\dagger \Pi \alpha_{\eta \sigma}^\dagger)$, irrespective of $X$ and $Y$: this factor must always occur at least $n - 2 \geq 1$ times.

C. 1 loop RG equations

1. Frequency dependence

Since our goal is to calculate the stationary state from the effective Liouvillian $L(z) = \frac{d L}{d \Lambda}(E, \omega)|_{\Lambda = 0}$ at $z = E + i \omega = i 0$, we first consider the RG equation for this quantity in the one-loop approximation and at frequency $E = 0$

\[\frac{d \tilde{L}^0(0)}{d \Lambda} = \frac{\Gamma}{\pi} G_1^0 (\bar{\mu}_1, \Lambda) G_1^0. \quad (222)\]

Here, the superscript 0 indicates that we also evaluate the Liouvillian at zero reservoir frequency, $\omega = 0$: $\tilde{L}^0(E) := \tilde{L}(E, 0)$. Similarly, in Eq. (222) we approximate the vertices by their initial values, as given by Eqs. (113) and (120), or by Eq. (61).

\[\tilde{G}_1(0, 0, \Lambda) \approx \tilde{G}_1(\bar{\mu}_1, \Lambda, -\Lambda) \approx G_1^0 \quad (223)\]

equating their dependence on the dot frequency ($E_1 = \bar{\mu}_1$), the reservoir frequency ($\omega = \Lambda$), and the vertex-leg frequency ($\omega_1 = \pm \Lambda$). Such frequency dependencies arises only when accounting for the renormalization of the vertices: for small frequencies we can approximate in Eq. (204)

\[\frac{d \tilde{G}}{d \Lambda} \sim \frac{\Gamma}{\Lambda^2} \tilde{G}^3 \quad (224)\]

on the right-hand side $\tilde{G} \sim \tilde{G}^0 \sim 1$, giving $\tilde{G} = G^0 + O(\Gamma/\Lambda)$. In 1-loop order for $\tilde{L}$ one must therefore consistently neglect the renormalization of $\tilde{G}$, Eq. (223), with respect to the log-corrections to the Liouvillian that arise from Eq. (222). This will be checked later on. The resolvent is likewise evaluated at $\omega = \Lambda$. Note that the $\omega$ dependence of the resolvent in first approximation,

\[\Pi^0(E, \omega) = \frac{1}{E + i \omega - \tilde{L}^0(E)}. \quad (225)\]

does not originate from the Liouvillian.

In contrast, Eq. (224) depends on QD frequency $E$ in an important way: Due to the finite bias voltage the renormalization of the zero $E$-frequency Liouvillian couples to the finite frequency Liouvillian $E \to E_1 = \bar{\mu}_1 = \eta_1 r_1 V/2$ appearing in the right-hand side. We therefore need to consider instead the following RG equations on a discrete grid of finite $E$-frequency Liouvillian $E = k_L \bar{\mu}_L + k_R \bar{\mu}_R = \eta (k_L - k_R) V/2$:

\[\frac{d \tilde{L}^0(E)}{d \Lambda} = \frac{\Gamma}{\pi} G_1^0 \Pi^0(E_1, \Lambda) G_1^0 \quad (226)\]

where $k_L, k_R = 0, 1, 2, \ldots$. In the numerical calculations, we keep as many equations as required to make the solution converge with respect to the $k_j$. This coupling of the RG flow of the Liouvillian at energies differing by multiples of the voltage arises because the Matsubara frequencies of the different reservoirs are shifted by different electrochemical potentials: this is typical feature of renormalization in a non-equilibrium system. We discuss the effect of neglecting the QD energy $E$-dependence in the RG equations in detail when we analyze the numerical results in Sec. [4-5].

2. Explicit 1-loop RG-equations for the Liouvillian

Inserting the spectral decomposition for $\tilde{L}(E)$, cf. Eq. (104), into Eq. (220),

\[\frac{d \tilde{L}^0(E)}{d \Lambda} = \frac{\Gamma}{\pi} \frac{1}{\Lambda - i \tilde{\Theta}_1^0} \tilde{G}_1^0 \tilde{G}_1^0 \tilde{G}_1^0 \tilde{G}_1^0 \tilde{G}_1^0 \quad (227)\]
we obtain, abbreviating $\Theta^k_i = E_i - \lambda^k(E_1)$,

$$
\frac{d}{d\Lambda}(\kappa_3|\tilde{L}^0(E)|\kappa_0) = \frac{\Gamma}{\pi}(\kappa_3|\mathcal{M}|\kappa_0),
$$

(228)

where $|\kappa_i\rangle$ are elements of the basis $|\eta\rangle$ and the super matrix elements are sums (or sums implicit) of factored contributions:

$$(\kappa_3|\mathcal{M}|\kappa_0) = i \sum_i (\kappa_3|\tilde{G}_i^0|\kappa_2)(\kappa_1|\tilde{G}_i^0|\kappa_0)(\kappa_2|\Pi_i^1|\kappa_1).$$

(229)

The product of $\tilde{G}^0$ matrix elements gives a simple numerical factor 0 or $\pm 1$ (see expansions (118), (120)), whereas the super matrix elements

$$i(\kappa_2|\Pi_i^1|\kappa_1) = \frac{1}{\Lambda - i\Theta^k_i}(\kappa_2|P_i^1|\kappa_1)$$

(230)

arise from the spectral decomposition of the resolvent, $\Pi^0(E_1, \Lambda) = \sum\Pi_i^1$. To explicitly sum over $\eta$ (contained in the multiindex $1 = \eta, \sigma, r$), which enters the resolvents only through $E_{\eta r} := E - \eta \mu_r$, we abbreviate $\lambda^k(E_1) := \lambda^k_{\eta r}$, $P^0(\eta r) := P^0_{\eta r}$ and

$$i\lambda_{\eta r}^k := \frac{P^0_{\eta r}}{\Lambda - iE_{\eta r} + i\lambda_{\eta r}^k}.$$  

(231)

Expanding Eq. (220) in the basis Eq. (211) - (220), we obtain:

$$
\frac{d\tilde{L}^0(E)}{d\Lambda} = \frac{i\Gamma}{\pi} \left[ - \left( \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle + \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle \right) |Z_{\eta r}\rangle |Z_0\rangle + \left( \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle + \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle \right) |\chi_{\eta r}\rangle |\chi_0\rangle \\
+ \left( \langle \alpha^{-\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{+\sigma}\rangle + \langle \alpha^{+\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{-\sigma}\rangle \right) |S_{\eta r}\rangle |S_0\rangle - \left( \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle + \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle \right) |T_{\eta r}\rangle |T_0\rangle - \left( \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle + \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle \right) |T_+\rangle |T_0\rangle - \left( \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle + \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle \right) |T_0\rangle |T_-\rangle - \left( \langle \alpha^{+\sigma}|\Pi^{\alpha^{+\sigma}}_{\eta r}\alpha^{-\sigma}\rangle + \langle \alpha^{-\sigma}|\Pi^{\alpha^{-\sigma}}_{\eta r}\alpha^{+\sigma}\rangle \right) |T_-\rangle |T_0\rangle \right].
$$

(232)

Here, we leave implicit the summation over $\sigma$ and $r$, as well as the summation over the two eigenvalues in the $\chi$ and $\alpha_{\eta r}$ subspaces [cf. Eq. (101)]. The first two terms in the equation do not contribute to the calculation of the remaining terms of the effective Liouvillian or the transport current, but they are written here for completeness. Due to $|Z_0\rangle \tilde{G} = 0$ [cf. discussion of Eq. (59)], the zero eigen projector $P^{\tilde{L}_0}$ does not appear in Eq. (232), ensuring that none of the resolvents can diverge during the RG-flow.

Using the relations $K(\Lambda - i(z - \tilde{L}(z)))^{-1} K = (\Lambda - i(-z^* - \tilde{L}(-z^*)))^{-1}$, [cf. Eq. (70), (117)], and by expanding resolvents into eigen-projectors using Eq. (231), we obtain the explicit RG equations for the Liouvillian expansion coefficients. We have a set of equations for 10 complex coefficients on an infinite, discrete grid of frequencies $E$
Importantly, the eigen projectors of the Liouvillian \( \hat{L}^0 \)
\[ P^0_{\eta} = P^0(E - \eta \mu_r) \]
with eigenvalues \( \lambda^0_r = \lambda^0(E - \eta \mu_r) \)
[cf. Eq. (143)]
depend on the frequency \( E - \eta \mu_r \). The explicit expressions for the project matrix elements on the right-hand side are given in Eqs. (150), (152), (153), (156), and (159) and involve only the 10 coefficients appearing on the left-hand side. Eq. (233)-(238) thus form a closed set of equations. This derives from the fact that the eigenprojectors of \( \hat{L}_A \) that involve the zero eigenvectors \( Z_L \) and \( Z_R \) drop out on the right-hand side by Eq. (161). Note that the fermionic matrix elements in the equations for the coefficients of bosonic terms that do not involve a \( Z_L \) or \( Z_R \) (\( \xi_{\sigma\sigma'}, E_{\sigma} \) and \( M_{\eta} \)) illustrate the simplification brought by Eq. (161).

The following 5 complex coefficients do not appear in the eigenvalues and projector matrix elements on the right-hand side of Eq. (233)-(238). Their RG-equations
\[ \frac{d\psi_r(E)}{d\Lambda} = \frac{\Gamma}{\pi} \left( \frac{(\alpha^+_{-\sigma} | P^{\sigma-\sigma'}_{-\sigma-\sigma'} | \alpha^-_{-\sigma})}{\Lambda - i(E_{-\sigma} - \lambda^{\sigma-\sigma'}_{-\sigma-\sigma'})} - \frac{(\alpha^+_{-\sigma} | P^{\sigma+\sigma'}_{-\sigma+\sigma'} | \alpha^-_{-\sigma})}{\Lambda - i(E_{-\sigma} - \lambda^{\sigma+\sigma'}_{-\sigma+\sigma'})} \right), \]
(233)
\[ \frac{d\phi_r(E)}{d\Lambda} = \frac{\Gamma}{\pi} \left( \frac{(\alpha^-_{-\sigma} | P^{-\sigma-\sigma'}_{-\sigma-\sigma'} | \alpha^+_{-\sigma})}{\Lambda - i(E_{-\sigma} - \lambda^{\sigma-\sigma'}_{-\sigma-\sigma'})} - \frac{(\alpha^-_{-\sigma} | P^{-\sigma+\sigma'}_{-\sigma+\sigma'} | \alpha^+_{-\sigma})}{\Lambda - i(E_{-\sigma} - \lambda^{\sigma+\sigma'}_{-\sigma+\sigma'})} \right), \]
(234)
are therefore not required for the solution of Eq. (233)-(238), but these coefficients do renormalize and depend on this solution. For the calculation of the current only \( \psi_r \) is required. In contrast, the coefficients \( \zeta \) and \( \phi_r \) are only required if one wishes to calculate, e.g., the stationary density matrix (151).

The remaining coefficients do not flow under the one-loop RG, and remain at their initial values. For the two diagonal matrix elements of the coefficient matrix \( \xi \) in the bosonic sector we have
\[ \frac{d\xi_{-\sigma}}{d\Lambda}(E) = 0, \]
(242)
which is valid only within the present one-loop approximation. In contrast, for the remaining 16 fermionic coefficients, we have in general (e.g., also in two-loop order)
\[ \frac{dF_{\pm\sigma}}{d\Lambda}(E) = \frac{dF_{\pm\sigma}^0}{d\Lambda}(E) = 0, \]
(243)
due to the causal structure (cf. Sec. (11D.3) and Sec. (11E.1)). We furthermore note that Eq. (233)-(241) explicitly satisfy the Hermicity conditions Eq. (144) and (157). Moreover, the proper transformation under charge and spin-rotations is explicitly guaranteed by our use of irreducible tensor superoperators, cf. Sec. (11C.5.1).

Finally, for the calculation of the current at a specific electrode \( r = \pm \) (corresponding to \( L, R \)) we need the RG equations for the coefficients of the self-energy components \( \hat{L}^r \), cf. Eq. (209). These are simply obtained from the above equations by (i) giving all coefficients a superscript \( r \) and (ii) suppressing the summation over \( r \) contained in the multiindex 1 on the right-hand side, i.e., by setting \( 1 = \eta, \sigma, +, \omega \).

Before we proceed to calculate the two-loop corrections to Eq. (222), we first show that already in the above one-loop approximation we obtain the exact solution for the current in the limit \( U = 0 \). This is important since it demonstrates that for the current the two-loop corrections to \( \hat{L} \), the one-loop corrections to the vertex \( \hat{G} \), and the \( \omega \) frequency dependence that we neglected here, are
intimately connected with interaction effects. We note, however, that for \( U = 0 \) there are nonzero two-loop corrections which do not affect the current \( I \).

3. **Non-interacting case \( U = 0 \): Exact solution**

Without local interaction, \( U = 0 \), the Hamiltonian Eq. (11) is quadratic in the fermionic operators and the non-equilibrium Anderson model can be solved exactly in this limit. A solution using the real-time approach was reported in Ref. 52. We now show that (i) using the causal field superoperator algebra one can obtain this solution within RT-RG framework and (ii) within the 1-loop, frequency-independent approximation this result is recovered upon careful inspection.

a. **Exact current** In general, to calculate the current according to Eq. (189), we need the elements \( \xi \) and \( \psi_\sigma \) of the bosonic part of the effective Liouvillian \( \hat{L}_\Lambda \). From these we can then easily find the other required coefficients \( \xi^r \) and \( \psi_\sigma^r \) of \( \hat{L}_\Lambda^r \), which we do at the end. The coefficients \( \xi \) and \( \psi_\sigma \) in turn require the solution of Eq. (233)-(238), which we first discuss. Then we show that higher order correction as well as frequency corrections that we neglected in deriving Eq. (233)-(238) have no influence on the stationary current. We start by noting that on the right-hand side of the RG-Eq. (233)-(236) for the bosonic sector only fermionic intermediate states appear in the resolvent matrix elements. We therefore first calculate the eigenvalues of the fermionic projectors to which these coefficients couple. From Eq. (163) it follows that for \( U = 0 \)

\[
\lambda^{\alpha\eta,\pm} = \eta \epsilon + \sigma \frac{B}{2} \mp 2i\Gamma \pm i\Gamma, \quad (244)
\]

\[
P^{\alpha\eta,\pm} = \frac{1}{2} \left( \alpha^0_{\eta\sigma} \pm \eta \alpha^3_{\eta\sigma} \mp \eta \frac{\Delta F^{\alpha\eta,\pm}_{0,\sigma}}{\Gamma} \alpha_{\eta\sigma} \right) \quad (245)
\]

There are three important points. (i) Since \( U = 0 \) the eigenvalues are independent of \( \Delta F^{\alpha\eta,\pm}_{0,\sigma} \), i.e., they are not renormalized (cf. Sec. (11D3)) and therefore do not acquire a frequency dependence. (ii) The right-hand side of the RG equation for any bosonic superoperator that is relevant to the current, i.e., excluding \( \zeta, \phi \), but with the exception of \( \psi_\sigma \) contains the off-diagonal super matrix elements

\[
(\alpha^+_\eta \mid \Pi^{\alpha\eta,\pm}_{\sigma} | \alpha^-_{\eta\sigma} ) = 0 \quad (246)
\]

as a factor by the general property \( 220 \). This matrix-element vanishes for \( U = 0 \) by Eq. (245), implying that these coefficients do not renormalize in any higher loop order since such coefficients always contain this factor on the right-hand side of Eq. (206) at least once by Eq. (221). (iii) In contrast, the renormalization of the quantities \( \psi_\sigma \) at \( E = 0 \) involve fermionic virtual states with the simple factors

\[
i(\alpha^+_\eta \mid \Pi^{\alpha\eta,\pm}_{\sigma} | \alpha^+_\eta ) = \sum_r \frac{1}{\Delta - i\Gamma V/2 + i\lambda^{\alpha\eta,\pm}_{r,\sigma} (rV/2)} (\alpha^+_\eta )
\]

\[
= \sum_r \frac{1}{\Delta + \Gamma + i(\epsilon_\sigma - rV/2)}, \quad (247)
\]

where we defined \( \epsilon_\sigma := \epsilon + \sigma |B|/2 \). Importantly, for \( U = 0 \) these matrix elements do not vanish, but they become independent of \( \Delta F^{\alpha\eta,\pm}_{\sigma} \). Higher loop corrections for \( \psi_\sigma \) vanish since they contain the factor \( 246 \) at least once by Eq. (219). Therefore, Eq. (239) is the exact RG equation for \( \psi_\sigma \) at \( E = 0 \) and for \( U = 0 \):

\[
\frac{d\psi_\sigma (0)}{d\Lambda} = \sum_r \frac{2\Gamma_r}{\pi} \text{Im}(\epsilon_\sigma |\Pi^{\alpha\eta,\pm}_{\sigma} | \alpha^+_\eta ) \quad (249)
\]

\[
= \sum_r \frac{2\Gamma_r}{\pi} \frac{\epsilon_\sigma - rV/2}{(\Delta + \Gamma)^2 + (\epsilon_\sigma - rV/2)^2}, \quad (250)
\]

where we again used the \( K \)-conjugation properties Eq. (70), (117). With the initial value \( \psi_{\sigma,\Lambda=\infty} = 0 \) (cf. Eq. (134)) we obtain

\[
\psi_\sigma (0) = -\sum_r \frac{2\Gamma_r}{\pi} \text{arctan} \left( \frac{\epsilon_\sigma - rV/2}{\Gamma} \right). \quad (251)
\]

Leaving out the summation over the electrode \( r \) in the above calculation, we obtain the coefficients of the self-energy component \( \hat{L}^r_{\Lambda=0} = \Sigma^r(0) \), required for the current (cf. Eq. (189)),

\[
\langle I \rangle = \frac{1}{\sqrt{2}} \left[ \langle T_0 | \psi^r \rangle - \langle T_0 | \psi^r \sigma_1 \psi^{-1} \rangle \right] = \frac{1}{\sqrt{2}} \sum_\sigma \langle \psi^r - \psi^r \sigma \rangle, \quad (252)
\]

using \( \frac{1}{\sqrt{2}} \langle T_0 \rangle = \frac{1}{2} \sum_\sigma \langle \chi_\sigma \rangle \) and \( \xi^r = \xi / 2 \), giving the current

\[
\langle I \rangle = \sum_{r,\sigma=\pm} \frac{\Gamma}{2\pi} \text{arctan} \left( \frac{\epsilon_\sigma + rV/2}{\Gamma} \right) \quad (252)
\]

and the non-linear differential conductance:

\[
\frac{dI}{dV} = \frac{1}{4\pi} \frac{\Gamma^{2}}{\Gamma^{2} + (\epsilon_\sigma + rV/2)^2}, \quad (253)
\]

in our units \( e = 1, \ h = 1 \). Restoring Gaussian units, the current and conductance prefactors become \( \frac{\Gamma}{\pi} \rightarrow \frac{\Gamma^{2}}{\pi^{2}} \rightarrow \frac{\Gamma^{2}}{\pi^{2}} \) giving in linear response a conductance of \( e^2/h \) per spin channel. The importance of recovering this exact result for \( U = 0 \) is that already at this level of approximation our the RT-RG approach captures correctly the weak interaction limit \( U \ll \Gamma \) while treating the tunneling non-perturbatively in \( \Gamma \). Moreover, it shows that the 2-loop corrections to the Liouvillian and 1-loop corrections to the vertices that affect the stationary current are generated by the Coulomb interaction. In general, however, the non-interacting limit requires a 2-loop treatment.
D. 2 loop RG equations

1. Vertex frequency dependence

We concluded in Sec. III C 1 that in the 2-loop approximation for the Liouvillan one should consider the vertex renormalization and \( \omega \)-dependence of both \( G \) and \( \bar{L} \). Indeed, we find below that these effects are comparable and involve important cancellations. Systematically expanding about the frequency-independent bare vertex \( \bar{G}^0 \), we can incorporate the vertex corrections into a single effective equation for the 2-loop Liouvillan, Eq. (252) below. We proceed in three steps:

Step 1 The starting point is the 1-loop approximation defined by Eq. (226) for any \( E \). This we use to calculate a first approximation for the \( \omega \)-dependence of both the Liouvillan and the propagator. We expand

\[
\bar{L}(E, \omega) \approx \bar{L}^0(E) + \bar{L}^1(E, \omega),
\]

\[
\Pi(E, \omega) \approx \Pi^0(E, \omega) + \Pi^1(E, \omega).
\]

The 1-loop equation accounting for the leading frequency dependence is obtained by setting \( G \approx \bar{G}^0 \) and \( \Pi(E, \omega) \approx \Pi^0(E, \omega) \) in the 1-loop part of Eq. (206):

\[
\frac{d\bar{L}(E, \omega)}{d\Lambda} = i\frac{\Gamma}{\pi} \bar{G}_1^0 \Pi^0 \bar{G}_1^0 (E, \omega, \Lambda + \omega) \bar{G}_1^0.
\]

(256)

We stress that the argument under the integral depends on \( \Lambda' \) both through the explicit arguments as well as through the cutoff dependence of \( \bar{L}_N \) (\( \bar{G}^0 \) is the bare vertex). Restoring the latter explicitly,

\[
\Pi^0_N(E, \omega + \Lambda') = \frac{1}{\omega' + \Lambda' - i\bar{L}_N(E)}.
\]

(261)

Since this is only important at this point, we stick with the implicit notation.

Step 2 In a similar way, we now calculate the \( \omega \) correction in the leading 1-loop order for the vertices:

\[
\bar{G}_1(E, \omega, \omega_1) = \bar{G}_1^0 + \bar{G}_1^1(E, \omega, \omega_1).
\]

(259)

Keeping only the leading term on the right-hand side of Eq. (207), we obtain with the same approximations as above

\[
\bar{G}_1^1(E, \omega, \omega_1) = -i\frac{\Gamma}{\pi} \int d\omega' \bar{G}_2^0 \Pi^0 (E_2, \omega + \omega') \bar{G}_1^0 \Pi^0 (E_1, \omega_1 + \omega) \bar{G}_1^0.
\]

(260)

are the terms appearing from the expansion of the 1-loop diagram in \( \Pi^1 \),

\[
\frac{d\bar{L}^{(2\text{loop})}}{d\Lambda} = \frac{\Gamma^2}{\pi^2} \bar{G}_1^0 \Pi^0 (E_1, \Lambda) \bar{G}_2^0 \times \Pi^0 (E_2, \Lambda + \omega) \bar{G}_2^0 \Pi^0 (E_1, \Lambda) \bar{G}_1^0
\]

(264)

is 2-loop term with bare vertices, and

\[
\frac{d\bar{L}^{(\text{vertex})}}{d\Lambda} = i\frac{\Gamma}{\pi} \bar{G}_1^0 (E, 0, \Lambda) \Pi^0 (E_1, \Lambda) \bar{G}_1^0
\]

(265)

\[
+ i\frac{\Gamma}{\pi} \bar{G}_1^0 \Pi^0 (E_1, \Lambda) \bar{G}_1^1 (E_1, \Lambda, -\Lambda)
\]

(266)

are the terms appearing from the expansion of \( \bar{G} \) in \( \Pi^1 \) in the 1-loop diagram. Inserting Eq. (257) into the 1-loop Liouvillan frequency correction [last term in Eq. (263)], we see that it exactly cancels the 2-loop term (264). Neither term therefore needs to be calculated, simplifying the approach to a great extent.

The above holds for any \( E \) and \( \omega \): integrating the Eq. (262) at \( \omega = 0 \) using the above calculated right-hand
side we obtain a new approximation for $\tilde{L}(E)$, improving over our initial approximation based on the one-loop equation Eq. (220). In principle, steps 1 and 2 should be repeated, resulting in corrections of higher orders, which we neglect. We thus equate $d\bar{L}/d\Lambda \approx \tilde{L}(E)$ on the left-hand side of Eq. (262). We obtain a central result of this section: a single effective two-loop RG equation for the Liouvillian at $\omega = 0$:

$$
\frac{d\tilde{L}(E)}{d\Lambda} = i\Gamma \bar{G}\Pi (E_1, \Lambda) \bar{G}^0_1 + i\Gamma_1 \bar{G}^0_1 (E, 0, \Lambda) \Pi (E_1, \Lambda) \bar{G}_1^0 + i\Gamma_0 \bar{G}_0^0 (E_1, \Lambda) \bar{G}^1_1 (E_1, \Lambda, -\Lambda). \tag{267}
$$

Notably, due to the cancellation the entire leading reservoir $\omega$ frequency dependence comes from the vertex corrections (260). This single equation yields a significant simplification over the coupled integro-differential equations Eq. (260) and Eq. (261). The equation (267) for $\tilde{L}$ can be converted into a differential RG equation by analytically performing the integral in Eq. (260), see Sec. IIID. Furthermore, since we can work with the bare vertex superoperators, we can make use of their simple anticommutation relations (55), which are not preserved under the RG (in contrast to other useful properties of the vertex, see App. C). The QD frequency ($E$) dependence in Eq. (267) is of the same type as for the 1-loop equations Eq. (222); the RG equation for $L(0)$ depends on $L(\mu_1) = L(\eta_1 \Gamma_1 V/2)$, etc. It therefore has to be solved in the same way by including multiple Matsubara axes and converging the energy-hierarchy of equations, see Sec. IIIC and Sec. IV. Finally, we also note that one can indeed neglect the frequency dependence generated by vertex renormalization since it is indeed small, as we assumed in our derivation of the 1-loop equations. This can be seen if one substitutes the calculated correction Eq. (260) into Eq. (267). Here, we anticipate the projector expansion of $\bar{G}$, Eq. (271): it is seen that $\bar{G}$ is a well behaved function of the cutoff and frequency, decaying at small $\Lambda$. It generates only small corrections in agreement with our approximation Eq. (224).

2. Explicit 2-loop RG equations for the Liouvillian

To obtain a differential RG equation from Eq. (267), the integration in Eq. (260) needs to be performed. This is complicated by the implicit $\Lambda'$ dependence of the propagators that we pointed out with Eq. (261). We now make an adiabatic approximation by expanding only this dependence about $\Lambda' = \Lambda$, i.e., we substitute

$$
\tilde{L}_{\Lambda'} \approx \tilde{L}_\Lambda \tag{268}
$$

in Eq. (261) and neglect corrections $\sim d\tilde{L}_{\Lambda'}/d\Lambda$, which, by the RG equation (267), are of higher order and should therefore be neglected. To preserve the compact form of the equations we define

$$
\Theta_{1...n} = E_{1...n} - \lambda'(E_{1...n}), \tag{269}
P_{1...n} = \lambda'(E_{1...n}), \tag{270}
$$

where $P(E)$ and $\lambda'(E)$ are eigenprojectors and eigenvalues of $\tilde{L}$ at cutoff $\Lambda$ (not $\Lambda'$) and we will implicitly sum over all appearing eigenvalue labels $i, j, k$ below. To perform the integral we insert the projector expansion Eq. (268) of $\tilde{L}$ evaluated at $\Lambda$ under the integral and obtain the explicit $\omega$-dependent vertex correction:

$$
\bar{G}_1^0 (E, \omega, \omega_1) = \int_D d\Lambda' \frac{\bar{G}_1^0 P_1^0 \bar{G}_1^0 (\Lambda') \bar{G}_1^0 (\Lambda') \bar{G}_1^1 (\Lambda')}{(\Lambda' + \omega - i\Theta_1) (\Lambda' + \omega + \omega_1 - i\Theta_{12})} \tag{271}
$$

Combining the rest of Eq. (263) with Eq. (260) we obtain:

$$
\frac{d\tilde{L}(E)}{d\Lambda} = \frac{\Gamma}{\pi} \left( \frac{1}{\Lambda - i\Theta_1} \right) \bar{G}_1^0 P_1^0 \bar{G}_1^0 - i\frac{\Gamma^2}{\pi^2} \left( \frac{1}{\Lambda - i\Theta_1} \right) \ln \left( \frac{2\Lambda - i\Theta_{12}}{-\Theta_{12}} \right) \tag{272}
$$

This central result of the paper. The explicit evaluation of Eq. (272) for the Anderson model is required for our numerical implementation, but also allows us to draw some general conclusions about the 2-loop (and higher) corrections. The 1-loop part is given by Eq. (220) and we proceed analogously for the 2-loop part:

$$
\left. \frac{d\tilde{L}(E)}{d\Lambda} \right|_{2\text{loop}} = -i\frac{\Gamma^2}{\pi^2} (\kappa_\beta |\mathcal{M}| \kappa_\alpha)(\kappa_\alpha), \tag{273}
$$

where the super matrix elements are factored as follows:

$$
(\kappa_\beta |\mathcal{M}| \kappa_\alpha) = \sum_{\kappa_0,..\kappa_1} (\kappa_\beta |\bar{G}_1^0 |\kappa_6)(\kappa_5 |\bar{G}_2^0 |\kappa_4)(\kappa_3 |\bar{G}_1^1 |\kappa_2)(\kappa_1 |\bar{G}_2^1 |\kappa_0) \times \mathcal{N} \left( (\kappa_6 |P_1^k |\kappa_5), (\kappa_4 |P_{12}^k |\kappa_3), (\kappa_2 |P_2^k |\kappa_1) \right). \tag{274}
$$

The product of $\bar{G}_1^0$ matrix elements gives a simple numerical factor, whereas the remaining part,

$$
\mathcal{N} \left( (\kappa_6 |P_1^k |\kappa_5), (\kappa_4 |P_{12}^k |\kappa_3), (\kappa_2 |P_2^k |\kappa_1) \right) = \mathcal{S}(\Theta_1, \Theta_{12}, \Theta_{12}) \left( (\kappa_6 |P_1^k |\kappa_5)(\kappa_4 |P_{12}^k |\kappa_3)(\kappa_2 |P_2^k |\kappa_1) \right), \tag{275}
$$
contains the product of the non-trivial projector matrix elements and the propagator factors

\[
S(\Theta^k_1, \Theta^j_2, \Theta^j_{12}) = \frac{\ln \left( \frac{2\Lambda - i\Theta^j_{12}}{\Lambda - i\Theta^j_2} \right)}{(\Lambda - i\Theta^j_1) \left( \Lambda - i\left(\Theta^j_{12} - \Theta^j_2\right)\right)} + (\Theta^k_1 \leftrightarrow \Theta^j_2).
\]  

(276)

The argument of this function is constructed by formally putting the variables containing the eigenvalues of the three projectors in the argument of \( \mathcal{N} \) into the corresponding arguments of the scalar function \( \Theta \). With this we can give explicit expressions for Eq. (273). It is shown in App. C how the conservation of Hermiticity by the self-energy can be used to minimize the number of terms to be calculated. For the right-hand side of Eq. (273), we now explicitly list half of the terms:

- \( |\chi_\sigma)(\chi_\sigma| \times \)

\[
\mathcal{N} \left( (\alpha^+_{\sigma}\chi^+_1|P^\Delta_1|\alpha^-_\bar{\sigma}) \right), (T_+|P^\Delta_1|T_+) \left( (\alpha^+_{\bar{\sigma}}|P^\Delta_2|\alpha^-_{\sigma}) \right) + \mathcal{N} \left( (\alpha^+_{\sigma}|P^\Delta_1|\alpha^-_{\bar{\sigma}}) \right), (S_\sigma|P^\Delta_2|S_\bar{\sigma}) \left( (\alpha^+_{\bar{\sigma}}|P^{\Delta_2-}\alpha^-_{\sigma}) \right) + |\chi_\sigma)(Z_L| \times \)

\[
\mathcal{N} \left( (\alpha^+_{\bar{\sigma}}|P^\Delta_1|\alpha^-_{\sigma}) \right), (T_+|P^\Delta_1|T_+) \left( (\alpha^+_{\sigma}|P^\Delta_2|\alpha^-_{\bar{\sigma}}) \right) - \mathcal{N} \left( (\alpha^+_{\sigma}|P^\Delta_1|\alpha^-_{\bar{\sigma}}) \right), (S_\sigma|P^\Delta_1|S_\bar{\sigma}) \left( (\alpha^+_{\bar{\sigma}}|P^{\Delta_2-}\alpha^-_{\sigma}) \right) + |\chi_\sigma)(S_\sigma| \times \)

\[
\mathcal{N} \left( (\alpha^+_{\bar{\sigma}}|P^\Delta_1|\alpha^-_{\sigma}) \right), (S_\bar{\sigma}|P^\Delta_2|S_\sigma) \left( (\alpha^+_{\sigma}|P^{\Delta_2-}\alpha^-_{\bar{\sigma}}) \right) + |\alpha^-_{\bar{\sigma}})(\alpha^+_{\sigma}| \times \)

\[
\mathcal{N} \left( (T_+|P^\Delta_1|T_+) \left( (\alpha^+_{\sigma}|P^\Delta_1|\alpha^-_{\bar{\sigma}}) \right), (S_\sigma|P^\Delta_2|S_\bar{\sigma}) \right) + \mathcal{N} \left( (T_+|P^\Delta_1|T_+) \left( (\alpha^+_{\bar{\sigma}}|P^\Delta_2|\alpha^-_{\sigma}) \right), (\chi_\sigma|P^\Delta_2|\chi_\bar{\sigma}) \right) + |\alpha^-_{\bar{\sigma}})(\alpha^+_{\sigma}| \times \)

\[
\mathcal{N} \left( (\alpha^+_{\sigma}|P^\Delta_2|\alpha^-_{\bar{\sigma}}) \right), (S_\sigma|P^\Delta_2|S_\bar{\sigma}) \left( (\alpha^+_{\bar{\sigma}}|P^{\Delta_2-}\alpha^-_{\sigma}) \right) + |\alpha^-_{\sigma})(\alpha^+_{\bar{\sigma}}| \times \)

\[
\mathcal{N} \left( (\chi_\sigma|P^\Delta_1|\chi_\bar{\sigma}) \right), (\alpha^+_{\sigma}|P^\Delta_2|\alpha^-_{\bar{\sigma}}) \left( (\alpha^+_{\bar{\sigma}}|P^{\Delta_2-}\alpha^-_{\sigma}) \right) - |\chi_\sigma)(\chi_\bar{\sigma}| \times \)

Here we use the notation

\[
P^k_i = P^k(\eta_i \mu_i), \quad P^k_{ij} = P^k(\eta_i \mu_i - \eta_j \mu_j).
\]  

(284)

FIG. 6: Zero-temperature non-linear conductance, \( dI/dV \), vs bias \( V \) and gate voltage \( V_g = - \epsilon \) for strong interaction \( U = 30 \Gamma \) and (a) zero magnetic field \( B = 0 \) and (b) finite field \( B = 9 \Gamma \). Both figures are calculated in 2-loop RG [Eqs. (226) and (273)] and are converged with respect to the number of non-equilibrium Matsubara axes (cf. Sect. III B 1) using a sufficiently large bandwidth \( D = 10^3 \Gamma \). The linear conductance in (b) shows good agreement with the Friedel sum rule (cf. Fig. 4).

We fixed the particle-hole index \( \eta_i \) in the multiindices as

\[
\eta_i = \begin{cases} +, & i = 1, 2 \\ -, & i = 1, 2 \end{cases}
\]  

(285)

All other indices in Eqs. (273-284) are implicitly summed over. The other half of the terms of Eq. (273) can be constructed in the same way by taking into account the opposite sign of \( \eta_i \) using the recipe of App. C.

For the calculation of the current only the left-most reservoir index \( r_1 \) should not be summed over.

We presented Eqs. (273-284) in order to show a number of important general properties. First, in the fermionic sector (282, 283), the structure is the same as for the one-loop equation, i.e., only terms \( |\alpha^+_{\eta_1})(\alpha^-_{\eta_2}| \)
appear as discussed (Sec. III B 3). This property holds in any order of RG and is manifestation of the general properties Eq. (192) - (193).

Second, the terms (277) - (284) are only those on the right-hand side of the two-loop RG equations that are relevant to the current. They are all proportional to the matrix elements $\langle \alpha^+_{\nu\sigma}|P_{\alpha\sigma}|\alpha^-_{\nu\sigma}\rangle$ as was anticipated in Sec. III C 3. This is also a general property that holds in any loop order of the RG. In the non-interacting limit, $U = 0$, this implies that all two-loop (and higher loops) corrections relevant to the current vanish exactly [cf. Eq. (214)]. We emphasize that there are additional terms not listed in Eqs. (277) - (284) that are irrelevant to the current. These describe the 2-loop renormalization of the $\zeta$ coefficient and involve factors $\langle \alpha^+_{\nu\sigma}|P_{\alpha\sigma}|\alpha^-_{\nu\sigma}\rangle$ and therefore do not vanish, even for $U = 0$. However, the corrections to this coefficient beyond the two-loop order do contain the factors (216) and again vanish for $U = 0$. See for more details Ref. [47].

IV. RESULTS

In this section we perform a detailed numerical investigation of the zero-temperature two-loop RT-RG equations $dL^0(E)/d\Lambda = dL^0(E)/d\Lambda|_{\text{loop}} + dL^0(E)/d\Lambda|_{\text{2 loop}}$, where the right-hand sides are given by Eq. (224) and (228). We calculate the current as explained after Eq. (209). We focus on the dependence on the interaction $U$ and the magnetic field $B$ as a function of both the bias $V$ and the gate voltage $V_g = -\epsilon$. To clearly structure the discussion we first summarize the central features of the calculated conductance as exemplified in Fig. 6(a) and (b) for zero and finite magnetic field $B$, respectively, and assess the limits of applicability.

A. Overview and limits of applicability

At zero magnetic field the dominant features in Fig. 6(a) are the Coulomb blockade diamonds defined by lines along which a single-electron tunneling resonance appears. In our calculated results, these $dI/dV$ peaks are broadened on the scale $\Gamma$ due to non-perturbative tunneling processes and have a peak height $e^2/h$, i.e., the quantum conductance. Going into either of the Coulomb blockade regimes, where the charge is quantized to $N = 0, 1$ and 2, the current decays non-exponentially due to higher order tunneling (cotunneling and higher order processes). At very small bias, however, the conductance shows a pronounced anomaly, but only in the $N = 1$ regime, where the dot has an unpaired spin. We stress from the start that this should not be naively identified with the Kondo anomaly of the Anderson model: the correct description of the Kondo peak requires three-loop RT-RG corrections, which are beyond the scope of this work [27,34]. To clarify in which regimes of voltages our results apply, we first discuss the linear conductance through the spin channel $\sigma$: $g_{\sigma} = \langle dI_{\sigma}/dV \rangle_{V=0}$, in particular the consistency with the Friedel sum rule,

$$g_{\sigma} = \frac{e^2}{h} \sin^2(\pi\langle n_{\sigma}\rangle).$$

In Fig. 7 it is clearly seen that at zero field $B = 0$ the conductance increasingly violates the Friedel sum rule between the two SET peaks for larger $U$. The violation becomes maximal at the particle-hole symmetry point: our result reaches $4e^2/h$ instead of $2e^2/h$. At best, in this regime our two-loop approach can be a starting point for further three-loop corrections containing the log-divergent Kondo corrections: However, it should be noted that the violation is finite, even at zero $T$. The key observation in Fig. 4 is that beyond a magnetic field $B \sim \Gamma$, only a renormalized elastic cotunneling background remains and our results rapidly become consistent with the Friedel sum rule. Clearly, at voltages above $B \sim \Gamma$, the three-loop Kondo renormalization is expected to be negligible compared to the one- and two-loop corrections that we accounted for here. In all further analyses, the low-bias regime $V < \Gamma$ will thus be ignored for magnetic fields $B \lesssim \Gamma$. We do, however, show our results in this bias regime for two reasons: (i) knowing the behavior of the two-loop scheme is of interest as it presents a starting point for future three-loop calculations, and (ii) the behavior of the two-loop approach can be compared with that for other methods in this regime. We note, e.g., that for $U = 2.5\Gamma$, the violation of the Friedel sum rule is still rather modest, even at zero field.
FIG. 8: Peak positions of $dI/dV$: shown is $dI^2/dV^2$ in a zoom of Fig. 6, making the zeros of $dI/dV$ stand out as curves separating red (positive) and blue (negative) regions. The yellow lines are guides to the eye obtained by accurate extrapolation of the linear parts of the resonance lines (including data points outside the figure). These emphasize the change of the slope of the linear parts of the resonance positions, in addition to the non-linear renormalizations close to the kinks. In (a) kinks occur at $V \approx 0$ and $V \approx \pm U$, whereas in (b) they occur at $V \approx \pm \frac{U}{2}$ and $V = \pm U + B$. Note that in (b) there is no discernible kink at $V = \pm (U - B)$: at this energy there is a SET resonance “hitting” the Coulomb blockade diamond edge but there is no onset of inelastic cotunneling, in contrast to $V = \pm B$, where there is such an excitation. This signals the importance of inelastic cotunneling for the appearance of such kinks.

Our two-loop RG thus accounts non-perturbatively for the strong tunneling effects at zero temperature, covering the complete finite-bias stability diagram, where previous perturbative generalized master / kinetic equation approaches break down.

Based on the above, we expect that for a finite magnetic field $B \gtrsim \Gamma$, the two-loop RT-RG calculations reliably address transport features, illustrated in Fig. 6(b), at all applied voltages. Clearly, the SET resonance peaks have been split due the Zeeman effect. The zero-bias anomaly splits into two inelastic cotunneling resonances at finite bias $V \approx B$ (Zeeman excitations). A much smaller zero-bias anomaly remains, which should be ignored, as mentioned above. The above-mentioned features are of course known from previous studies and have been observed in many experiments. Our approach, however, includes renormalization effects of these basic transport signatures, which are non-perturbative in $\Gamma$ far from equilibrium. The following more detailed analysis, bearing the above restrictions in mind, indeed reveals several low-temperature renormalization effects that may be of experimental relevance.

B. Single electron resonance: Level renormalization and broadening

1. Kinks

Careful inspection reveals that the SET resonance lines, in fact, change their slope when crossing $V = 0$ and $U$. This can already be seen for small $\Gamma$ in Fig. 6(a), where we plot the $V$-derivative of Fig. 6(a) to follow the peak positions, adding a linear extrapolation. The SET resonance lines of the inner diamond change in such a way that the charge gap hardly renormalizes for $U \gg \Gamma$,
although diamond distortions are visible by kinks in the linear extrapolations. The charge gap can both be determined from the height of the diamond (non-linear response) or from the width of the diamond (linear response) and no significant deviation is found in this limit.

A related effect arises in a magnetic field: the SET slope below (above) the ICT threshold is smaller (larger) than the slope of the bare resonance line. As a result, the SET lines now show a kink at finite $V = \pm B$. We note that no such kink is seen at $V = U - B$: this indicates that indeed the ICT is responsible for this effect since at $V = U - B$, in contrast to $V = B$, there is no ICT excitation. In (a) at $V = 0$ there is some non-linearity around $V = \Gamma$ (small $V$ should be ignored, see above), which persists in (b) around $V = B$ in a magnetic field.

Upon increasing $\Gamma$ relative to $U$, these effects are enhanced as shown in Fig. 9(a). The edges of the $N = 1$ Coulomb-blockade regime tend to bend inwards, towards the diamond center. Notably, above the onset of ICT the slope is slightly larger than that of the bare resonance line. We furthermore observe that this also leads to the suppression of the excitation $| \downarrow \rangle \rightarrow | 2 \rangle$ at $\mu_L - \mu_R = \epsilon_f + U$ in Fig. 9 (see arrow), which is still clearly visible in Fig. 6, see arrows in Fig. 9(a) and (b).

2. Analysis

It seems not possible to analytically extract a simple physical picture explaining the above non-linearities. The following analysis aims to indicate why this is the case: we trace back at which stage of the 2-loop RG scheme the various effects are generated taking the parameter set of Fig. 9(b) as a starting point. In Fig. 10 we show the conductance calculated both in 1- and 2-loop RG, both with and without introducing the calculations with respect to the non-equilibrium Matsubara axes.

Clearly, the different slopes and non-linearities already arise in the one-loop RG: this is visible from Fig. 11(b) and (f). Their strength correlates with that of the signatures of ICT appearing in the stability map in the various approximations. However, this effect only arises when the Matsubara axes are accounted for: this is seen by directly comparing Fig. 11(a) and (b) and is confirmed by Fig. 12 where we explicitly plot the difference of former two figures.

Overall, the two-loop corrections are most pronounced along the SET-regime boundaries and the ICT threshold as comparison of Fig. 10(b) and Fig. 10(d) and the plot of their difference in Fig. 12 shows. Also, in 2-loop order, the kinks are most pronounced in the Matsubara-converged result. We conclude that the 2-loop fluctuation effects result in a non-trivial energy dependence of the vertices and Liouvillian, which shows up in anomalous features of the measurable stability diagram, even for such a simple Anderson model of a quantum dot. We emphasize that these features are not related to renormalization processes that generate the Kondo effect (3-loop, not included here) and have an effect at $V \sim B \gtrsim \Gamma$.

3. Experimental implications

Having traced the origin of the change of the slopes and the non-linearities of the SET resonances, we now
FIG. 11: Effect of Matsubara axes convergence, i.e., the converged result minus the result neglecting all Matsubara axes: (a) 1-loop RG, Fig. 10(b)−(a) and (b) 2-loop RG, Fig. 10(d)−(c). Adjacent red and dark blue regions indicate that the correction is an S-shaped curve, which, when added to a peaked curve, results in a shift the peak position. Clearly, the Matsubara frequency dependence has an impact on the positions of all resonances and should be fully accounted for.

FIG. 12: Effect of 2-loop corrections, i.e., the 2-loop result minus the 1-loop result (a) without Matsubara frequency dependence, Fig. 10(c)−(a); (b) with converged Matsubara frequency dependence, Fig. 10(d)−(b). Note the positive corrections to the magnitude of the inelastic cotunneling in (b).

discuss their relevance to experiments. In fact, kinks in SET resonances are often observed in various type of quantum dot systems. Our calculations indicate that tunnel-induced renormalization is a possible mechanism for their occurrence, but other (e.g., electrostatic) mechanisms should not be ruled out in an experimental situation. However, for strong coupling, it is physically not unexpected that when ICT sets on, the level renormalization significantly changes, resulting in such a kink.

A direct test of this assumption would be to track the Coulomb diamond as a function of the coupling strength $\Gamma$. In Fig. 13(b) and (c) we show predictions for the evolution of the SET resonance point for two fixed gate voltages, one below and one above the ICT threshold, respectively. The main observation from such a plot is that the peaks evolve along curves that are not simply offset by a constant bias. This indicates that the renormalization of SET resonance becomes increasingly nonlinear and a kink must develop. (Note that experimentally $\Gamma$ may change non-linearly with control voltages but this does not spoil the argument.) It is important to properly choose the point above the ICT threshold: depending on the gate voltage position the peak may renormalize stronger or weaker than the peak below the threshold. We are aware that experimentally such tuning of $\Gamma$ with gate voltages may lead to other side effects that may be hard to distinguish from the effect. Here the different renormalization of the ICT resonance can be of use, which is discussed next.

C. Cotunneling resonance: Gap renormalization and reduced broadening

Having discussed the effect of the ICT on the SET resonances, we now study the ICT features themselves in more detail. Fig. 14 shows how the inelastic cotunneling resonance exhibits a Zeeman splitting with increasing magnetic field. Despite the zero temperature, the width of the inelastic cotunneling feature is finite and...
FIG. 14: (a) Zeeman splitting of the cotunneling resonance (change in blue color) and shift of the SET peaks (red peak) for $U = 30\Gamma$ and $V_g = -\epsilon = U/6 = 5\Gamma$. (b) Zoom in of the bias-derivative of (a), i.e., $dI/dV^2$ showing the resonance position. The sharp peak in $dI/dV$ in (a), starting from the lower left corner, closely follows the diagonal line $V = B$. The step in $dI/dV$ in (a), starting from the upper right corner, instead follows a line that is parallel to the diagonal $V = B$ but offset by a constant, negative magnetic field (in this case $\approx 0.45\Gamma$). (c) $dI/dV$ traces of (a) for $B/\Gamma = 2.0, 3.0, 4.0, 6.0, 8.0, 10.0$.

This enhancement is not related to Kondo-exchange tunneling, which is known to lead to additional logarithmic enhancements: their renormalization is not included in our 2-loop calculations and is expected to be of limited importance at this large magnetic fields (several times $\Gamma$). The qualitative change of the inelastic conductance feature from a step to a peak in Fig. 14(b) implies some ambiguity in the extraction of the excitation energy, either from the inflection point of the step (upper right corner) or from the peak position (lower left corner).

Finally, close inspection Fig. 13(a) shows that the ICT bias peak position has a weak gate voltage dependence. In contrast, in the high-temperature limit this resonance lies at the unrenormalized cotunneling excitation $V = B$. Strong tunneling thus leads to an apparent renormalization in the cotunneling peak position, even for this simple model, cf.\textsuperscript{65}. Although our effective Liouvillian contains parameters $E_\sigma$ and $F_{\eta\sigma}$ that relate to the magnetic field (compare Eq. 135 and Eq. 136), these parameters depend on energy and our full result requires their values at several different energy scales since many non-equilibrium Matsubara frequency axes must be accounted for.

V. OVERVIEW AND OUTLOOK

We have studied the standard model of an interacting quantum dot, an Anderson impurity, in the low-temperature, non-equilibrium limit. We have calculated...
the effective time-evolution kernel \( L(z) = L + \Sigma(z) \) for the kinetic equation of the reduced density operator, where \( \Sigma \) is the non-trivial self-energy superoperator. In contrast to many previous studies using such a generalized / quantum master equation approach, we have calculated the time-evolution kernel using the real-time renormalization group (RG). The equations for the effective kernel are integrated as a function of a cutoff parameter \( \Lambda \): as \( \Lambda \) is reduced, the renormalized Liouvillian \( \hat{L}_\Lambda \) in principle flows to the exact result, \( \hat{L}_\Lambda|_{\Lambda=0} = \hat{L}(z) \). This RG calculation of the effective kernel involves a number of key elements:

- Transitions between all Liouville space superoperators need to be accounted for. This includes those elements of \( \hat{L}_\Lambda \) and \( \hat{L}(z) \), which in a perturbative calculation of the kernel drop out due to conservation laws (charge, spin, and possibly particle-hole symmetry). The reason for this is that as one integrates out energy scales, effectively higher-order diagrams are included into a renormalization of the kernel that describe virtual intermediate states, which are less restricted by conservation laws.

- The dependence of the renormalized kernel on the real QD frequency (\( E \)) (Laplace variable conjugate to time) is important even in the stationary state. During the RG flow the renormalized Liouvillian at frequency \( E \) self-consistently couples to its action on virtual intermediate states at frequencies differing from \( E \) by multiples of the bias voltage \( \mu_L - \mu_R \). We have shown that this non-equilibrium effect leads to significant quantitative corrections and may require tens of bias-multiples to achieve convergence.

- The reservoir-frequency (\( i\omega \)) dependence of both the kernel and the vertices becomes important when going beyond the leading, 1-loop approximation, in addition to the QD frequency \( E \). This dependence is generated on the imaginary frequency axis when the reservoirs are integrated out and it may cancel 2-loop corrections calculated without frequency dependence.

We have systematically accounted for the leading frequency correction within a one-plus-two-loop approximation to the exact RT-RG equations and derived an effective RG equation for the time-evolution kernel only. This includes the relevant vertex renormalization corrections. Importantly, the leading frequency correction of the one-loop renormalization of the Liouvillian \( \hat{L}_\Lambda \) was found to exactly cancel the two-loop zero frequency term.

For the non-interacting Anderson problem \( (U = 0) \), we found that the current is exactly captured already in the one-loop approximation without any frequency dependence even though the complete solution (i.e., including the density operator) is contained only within the one-plus-two-loop approximation. For the strongly interacting case of interest the non-linear transport spectrum \( (dI/dV \) stability diagram) was calculated for a wide range of parameters. The different, intrinsic broadening of the single-electron tunneling and cotunneling resonances was captured, as well as the zero-temperature renormalization of their positions. As emphasized throughout, due to the restriction to one- and two-loop diagrams, the small Kondo regime cannot be addressed. This regime has been recently studied in detail using the RT-RG approach based on the mapping to a Kondo model. This allowed the entire crossover from weak to strong coupling to be described. Our study thus provides a starting point for a three-loop analysis of the non-equilibrium Anderson model in which the interplay of Kondo spin fluctuations and charge fluctuations can be described.

The RT-RG study benefited a lot from an extensive reformulation of the underlying real-time perturbation theory in terms of vertex superoperators \( G \) and \( \tilde{G} \). Although originally introduced in the context of the RT-RG\textsuperscript{26}, we have revealed their full significance as fermionic field superoperators that directly generate the Liouville Fock space in complete analogy to closed quantum many-body systems:

- Field superoperators obey definite anticommutation relations, and a simple fluctuation-dissipation relation similar to that of the underlying usual field operators. The Wick theorem in Liouville space at finite temperature can be obtained algebraically using relation \( [23] \) in the usual way\textsuperscript{66}, avoiding the necessary careful explicit accounting of fermion-parity signs in other proofs.\textsuperscript{26} This difficult aspect of Liouville-space fields was noted earlier\textsuperscript{34,42}.

- The causal structure of the theory is reflected by the vanishing of 2 out of 4 reservoir correlation functions (rather than 1 out of 4, as in the Keldysh Green-function technique). This results in an exponential reduction of the number of terms contributing to the time-evolution kernel (additional to the reduction in the wide-band limit). The remaining contributing diagrams are easily identified by their topology.

We have extended the use of these fermionic field superoperators to the perturbation theory underlying the RT-RG. This resulting causal representation of the perturbation theory has many advantages:

- Probability conservation of the kernel is manifest term-by-term, allowing non-conserving approximations to be easily spotted. In addition, other exact eigenvectors and eigenvalues of the kernel were found, which limit the form of the exact effective Liouvillian \( L(z) \) as expressed in our central result Eq. \[ 139 \].

- Term-by-term diagrammatic evaluation of the wide-band limit. Diagrams that vanish in this limit can be identified by their topology and the remaining diagrams can be shown to be independent of
the cutoff using the fundamental fermionic algebra of the field superoperators. This results in a further strong reduction in the number of contributing terms as function of the perturbation order. Moreover, the advantage of working with the complete space of the QD states becomes explicit.

- Finally, the fundamental importance of the infinite temperature limit becomes explicit. It defines the Liouville Fock-space vacuum and the perturbation theory can be explicitly decomposed into infinite temperature renormalization effects and the nontrivial finite-temperature contributions. This provides a natural starting point for the RT-RG, which readily suggests itself.

Aside from their application to the RT-RG, we have already found useful application of some of these points in perturbative studies, as discussed here in connection with Ref. 39 and in forthcoming works on time-dependence\textsuperscript{32} and adiabatic driving\textsuperscript{38}.

Acknowledgments

This work was initiated by intense discussions with H. Schoeller, which are gratefully acknowledged. We thank D. DiVincenzo, T. Costi and J. Splettstoesser for valuable comments and A. Flesch, E. Gorelov and F. Reckermann for suggestions regarding the numerical calculations. We are grateful to D. Kosov for pointing out Prosen’s work and his kind help in establishing the relations between our and other existing superfermion approaches. This work has also benefited from a preliminary study undertaken together with M. Kurz.

Appendix A: Wick theorem for causal field superoperators of the reservoirs $J^q$

Here, we show how the algebraic proof of the Wick theorem\textsuperscript{66} for standard field operators directly applies to the field superoperators $J$ in the causal representation. In this proof, one considers the average of $J_q^n$ taken together with $M$. Kurz. This work has also benefited from a preliminary study undertaken together with M. Kurz.

\begin{equation}
X = \langle J_1^{q_1} \cdots J_n^{q_n} \rho \rangle^R,
\end{equation}
which can be nonzero only for even $n$. One then commutes $J_n^{q_n}$ to the left-hand side, using that the field superoperators obey the anticommutation relations\textsuperscript{61}. We first consider the case $q_n = -\gamma$ and make use of the zero-trace property of $\rho$ of the causal representation. This reduces the average to expressions of the same form,

\begin{equation}
X = \sum_{k \neq n} (-1)^{N_{k,n}} \tilde{\gamma}_{k,n} X_{k,n},
\end{equation}
but with averages over $n - 2$ operators

\begin{equation}
X_{n,k} = \text{Tr}_R \left( J_1^{q_1} \cdots J_{k-1}^{q_{k-1}} \ast J_{k+1}^{q_{k+1}} \cdots J_{n-1}^{q_{n-1}} \rho_{\text{res}} \right),
\end{equation}
weighted with the contraction function

\begin{equation}
\tilde{\gamma}_{k,n} = \frac{\Gamma_0}{2\pi} \delta_{k,n} \delta_{+q_k}.
\end{equation}
Here, $N_{k,n} = n - k - 1$ is the number of permutations to bring $J_k^{q_k}$ and $J_n^{q_n}$ together.

For $q_n = +\gamma$ we proceed in the same way, except that before permuting $J_n^{q_n}$ to the far left we apply the fluctuation-dissipation superoperator identity\textsuperscript{65}. This transforms the expression into that for $q_n = -\gamma$ case multiplied with the Keldysh distribution function: Eq. (A2) applies again but with $\tilde{\gamma}_{k,n}$ replaced by

\begin{equation}
\tilde{\gamma}_{k,n} = \tanh(\eta_n \omega_n/2T_{\text{res}}) \tilde{\gamma}_{k,n},
\end{equation}
where the multiindex $n$ of $J_n^{q_n}$ reads $n = (\eta_n, \sigma_n, r_n, \omega_n, \gamma_n)$.

We thus find the standard Wick recursion relation

\begin{equation}
X = \sum_{k \neq n} (-1)^{N_{k,n}} \tilde{\gamma}_{k,n} X_{k,n}
\end{equation}
with $\gamma_{k,n} = \tilde{\gamma}_{k,n} \delta_{+q_n} + \tilde{\gamma}_{k,n} \delta_{-q_n}$, which by iteration gives the Wick theorem\textsuperscript{60} with the contractions\textsuperscript{63-65}.

Appendix B: Main properties of the causal vertex superoperators $G^q$

a. “Bare” vertices In Sec. (II B 2) the main properties\textsuperscript{53} and\textsuperscript{57} of the causal superoperators $\bar{G}$ and $\bar{G}$, respectively, were introduced, namely, their anticommutation relations \textsuperscript{53} and their relation by Hermitian conjugation in Liouville space, Eq. (57). We now give the proof of the latter relation. We note that both relations are fundamental as they imply a formal correspondence of causal $G^\pm = \bar{G}, \bar{G}$ operators with the usual fermionic field operators and allow us to develop the “second quantization” technique for fermionic Liouville Fock-space.

Super-Hermitian conjugation is defined relative to the scalar product in Liouville space, $(A|B) = \text{Tr} A^\dagger B$, where $A$ and $B$ are dot operators. To prove Eq. (57) we first notice that the “naive” field superoperators\textsuperscript{40} obey

\begin{equation}
(g^I_1)^\dagger = g^I_1,
\end{equation}
where $1 = \eta \sigma$ and $I = \bar{\eta} \bar{\sigma}$. Superoperators with the same Keldysh index $p$ are thus conjugated to each other in the usual way: Hermitian conjugation is equivalent to inverting the particle-hole index $\eta$. This follows from the cyclic property of the trace:

\begin{align}
(A|g^I_1^+|B) &= \text{Tr}_D A^\dagger d_{\eta,\sigma} B = (\text{Tr}_D B^\dagger d_{\bar{\eta},\bar{\sigma}} A)^* \\
&= (B|g^I_1^+|A)^* = (B|g^I_1^+|A)^*, \quad (B2) \\
(A|g^I_1^-|B) &= \text{Tr}_D A^\dagger B d_{\eta,\sigma} = (\text{Tr}_D d_{\bar{\eta},\bar{\sigma}} B^\dagger A)^* = (\text{Tr}_D B^\dagger A d_{\bar{\eta},\bar{\sigma}})^* \\
&= (B|g^I_1^-|A)^* = (B|g^I_1^-|A)^*, \quad (B3)
\end{align}
where $\ast$ denotes complex-conjugation and $\dagger$ denotes either usual Hermitian-conjugation or super-Hermitian-conjugation depending on whether it acts on an operator or superoperator, respectively. These superoperators, however, have the disadvantage that they satisfy no definite fermionic or bosonic commutation relations [cf. Eq. (43)].

The transformed field superoperators \[\mathcal{G}_{\eta,\sigma}\] which include the fermion-parity sign, obey the definite anticommutation relations \[\{\mathcal{G}_{\eta,\sigma}, \mathcal{G}_{\eta',\sigma'}\}\] and hole fields \([\mathcal{G}_{\eta,\sigma}]^\dagger = \mathcal{G}_{\eta',\sigma'}\). However, they are not related by super-Hermitian conjugation in the usual way:

\[(\mathcal{G}_{\eta,\sigma}^p)^\dagger = p \mathcal{G}_{\eta,\sigma}^p, \quad \text{(B4)}\]

which follows from Eq. (31) and the properties \((L^n)^\dagger = L^n\) and \([L^n, \mathcal{G}_{\eta,\sigma}^p]_\ast = \eta \mathcal{G}_{\eta,\sigma}^p\) of \(L^n = [n, \cdot]_\ast\):

\[(\mathcal{G}_{\eta,\sigma}^p)^\dagger = (pL^n \mathcal{G}_{\eta,\sigma}^p)^\dagger = (\mathcal{G}_{\eta,\sigma}^p)^\dagger pL^n = pL^{n+1} \mathcal{G}_{\eta,\sigma}^p = p \mathcal{G}_{\eta,\sigma}^p. \quad \text{(B5)}\]

Finally, the causal field superoperators \[\mathcal{G}_{\eta,\sigma}\] obtained from \(\mathcal{G}_{\eta,\sigma}^p\) by a Keldysh-rotation obey both definite commutation relations \[\mathcal{L}\] and standard Hermitian-superconjugation relations \[\mathcal{L}\]: using \(p^2 = 1\) we obtain

\[(\mathcal{G}_{\eta,\sigma}^p)^\dagger = \frac{1}{\sqrt{2}} \sum_p p^{(1-q)/2} (\mathcal{G}_{\eta,\sigma}^p)^\dagger = \frac{1}{\sqrt{2}} \sum_p p^{(3-q)/2} \mathcal{G}_{\eta,\sigma}^p = \mathcal{G}_{\eta,\sigma}^q. \quad \text{(B6)}\]

This clearly demonstrates the fundamental advantage of the causal representation over the other ones.

Note that due to the \(p\)-dependence of the superoperators entering into the definition \[\mathcal{G}\] of our superoperator \(\mathcal{G}_{\eta,\sigma}\), the latter is either a commutator or an anticommutator with the fermionic operator \(d_{\eta,\sigma}\), depending on the argument on which it acts. For example \(\mathcal{G}_{\eta,\sigma} A = [d_{\eta,\sigma}, A]_\ast\) if \(A\) is a fermionic dot operator (odd in charge, see Eq. (49)) and \(\mathcal{G}_{\eta,\sigma} A = [d_{\eta,\sigma}, A]_+\) if \(A\) is bosonic (even in charge, see Eqs. (41)–(53)). For the \(\mathcal{G}_{\eta,\sigma}\) the opposite holds. The crucial relation \[\mathcal{L}\], namely \(\mathcal{L}\mathcal{G}_{\eta,\sigma} = 0\) nevertheless always holds: one obtains zero in the first case as the trace of a commutator and in the second case as the trace of an operator which is off-diagonal in charge.

The analogy to the usual field operators extends also to the transformation behavior under spin-rotations. The usual field operators in Fock space, \(d_{\eta,\sigma}'\) and \(\sigma d_{\eta,\sigma}'\), transform as irreducible tensor operators (ITOs) of rank 1/2 and index \(\sigma/2\) (note the \(\sigma\)-signs). Similarly, superoperators corresponding to particle fields \((\eta = +, -)\), \(\sigma \mathcal{G}_{\eta,\sigma}'\), and hole fields \((\eta = -, -)\), \(\sigma \mathcal{G}_{\eta,\sigma}'\), are irreducible tensor superoperators (ITSOs) of rank 1/2 with index \(\sigma/2\). This applies to all the representations of the field superoperators that we used: the same holds for \(\mathcal{G}_{\eta,\sigma}'\), \(\sigma \mathcal{G}_{\eta,\sigma}'\), and \(\mathcal{G}_{\eta,\sigma}'\). To prove this, we note that for any two superoperators \(A^p\) and \(B^p\) generated in the same way as \(G_{\eta,\sigma}^1\) (cf. Eq. (40)) by two operators \(A\) and \(B\),

\[A^p\cdot = \begin{cases} A\cdot, & p = + \\ \sigma A, & p = - \end{cases} \quad \text{(B7)}\]

the commutator of superoperators can be expressed in the superoperator corresponding to the commutator: \([A^p, B^p]_- = p\mathcal{P}_{p,p'}([A, B])_-^p\). This directly shows that the field superoperators \(G_{\eta,\sigma}^p\) transform in the same way as the field operators \(d_1\) under spin-rotations: \([L^{\eta,\sigma}, \mathcal{G}_{\eta,\sigma}^p]_- = ([L, d_1]_-)^p\). The superoperators \[\mathcal{G}\] and \[\mathcal{G}\] simply inherit this property since spin and charge superoperators commute, \([L^{\eta,\sigma}, L^n]_- = 0\).

Appendix C: Prosen’s fermionic superoperators

For open systems described by a Lindblad equation that is quadratic in fermion operators, superoperators fields similar to ours (cf. Eq. (31)), were introduced by Prosen [31] with the aim of explicitly constructing the steady state in the Liouville Fock space. These fields obey the anticommutation relations \[\mathcal{L}\] and the Hermitian-conjugation relations \[\mathcal{L}\]. Moreover, the superoperators \(c_{j}^\dagger\) introduced in that work also satisfy Eq. (55) and thus possess the causal structure discussed here. The latter property is, however, not explicitly seen in the formulation of Ref. [31], and becomes clear only after setting up the correspondence \[\mathcal{L}\] between our, and Prosen’s, superoperators.

In Ref. [31], the opposite order of construction was used, i.e., first a Fock space was constructed (cf. our Eq. (91)), as an ordered product of the Majorana operators, which are linear combinations of usual fermion creation and annihilation operators. Then, fermionic superoperators were defined on this space (cf. our Eq. (51)). The fermion-parity superselection rule, which plays an explicit, key role in our construction, was implicitly taken into account by the ordering of the Majorana operators and by a specific definition of the creation and annihilation superoperators. Careful comparison of the Fock spaces shows that superoperators \(c_{j}^\dagger\) of Ref. [31] are related to our \(\mathcal{G}_{\eta,\sigma}\) by the following unitary transformation:

\[c_{j}^\dagger = \frac{1}{\sqrt{2}} \left( G_{j,m} + G_{j,m}^\dagger \right), \quad j = 2m - 1, \quad \text{(C1)}\]

\[c_{j}^\dagger = \frac{i}{\sqrt{2}} \left( G_{j,m}^\dagger - G_{j,m} \right), \quad j = 2m. \quad \text{(C2)}\]

Corresponding relations for the superoperators \(c_j\) can be obtained from Eq. (51) by super-Hermitian conjugation. Here, \(m = 1, 2, 3, \ldots\) enumerates the fermionic channels and \(\mathcal{G}_{\eta,\sigma}^\dagger\) are the \(\mathcal{G}_{\eta,\sigma}\) superoperators renumbered by the channel index. For our single level Anderson model we have only spin channels, giving

\[\mathcal{G}_{\eta,\sigma} = \begin{cases} \mathcal{G}_{\eta,\sigma}, & m = 1 \\ \mathcal{G}_{\eta,\sigma}^\dagger, & m = 2 \end{cases} \quad \text{(C2)}\]
For a multilevel model with several discrete channels numbered $k = 1, 2, 3, \ldots$:

$$
\hat{G}^k_{\eta, m} := \hat{G}^k_{\eta, \sigma}, \quad m = 2k + (\sigma - 1)/2. \quad (C3)
$$

It is not directly clear how the definitions in Ref. 31 can be applied to the case of an infinite and, especially, a continuous number of channels. In fact, the relation (C1) can be used as a definition of the $c^\dagger, c^\dagger_{\eta}$ superoperators in this case since the superoperators $\hat{G}_1, \hat{G}_1^\dagger$ have a proper definition also in this limit, see Eq. (53). In contrast to our case, the superoperators $c_j^\dagger$ are not irreducible tensor superoperators (ITSOs) with respect either spin- or charge-rotations. This fact would complicate the symmetry-classification similar that performed in Sec. II C 3. Moreover, the causal structure of the kernel, which in general plays a crucial role in the analysis and remains implicit in the representation. Finally, we emphasize the different scope of application of the microscopic derivation of the effective Liouvilleans, we here extend it to the reservoirs with continuous fields and use it to simplify the causal structure. Here, we discuss its additional properties to further clarify its physical meaning.

Appendix D: Schmutz’s fermionic superoperators

In Ref. 33, 34 alternative field superoperators denoted by $a_p, a_p^\dagger$ and $\bar{a}_\sigma, \bar{a}_\sigma^\dagger$ were discussed, which were first introduced by Schmutz. In our notation (15–17) and [39], (10), they read as:

$$
a^p_\eta = a^p_{\eta, \sigma} = \begin{cases} a_{\eta, \sigma}, & p = +1 \\
\bar{a}_{\eta, \sigma}, & p = -1. \end{cases} \quad (D1)
$$

They are related to our “intermediate” superoperators [17] as follows (the definition of Ref. 34, in fact, contains an additional $p$ sign that is not relevant here):

$$
a^p_{\eta, \sigma} = p^{1/2 \eta} G^p_{\eta, \sigma}. \quad (D2)
$$

The use of the additional $\eta$-dependent factor $p^{1/2 \eta}$ allows one to compensate the inconvenient signs $p$ in the anticommutation relations [17] and in the Hermitian-conjugation relation [34], thus restoring the usual fermionic algebra without performing the Keldysh-rotation [51]:

$$
[a^p_1, a^p_2]_+ = \delta_{1,2} \delta_{p_1, p_2}, \quad (a^p_0) = a^p_1. \quad (D3)
$$

The spin and particle-hole group transformations of these superoperators coincide with those introduced by us. However, they do not reveal the important property [35] which is crucial in our formulation of the causal structure. Also, the explicit $\eta$-dependence of the sign-prefix does not allow one to perform a simple Keldysh rotation of the $a^p_0$ superoperators to recover this property. Finally, we mention that during the preparation of this paper, a work appeared, in which Schmutz’s operators are modified by a complex phase factor.

Appendix E: Fermion-parity operator and superoperator

In Sec. II C 2 the operator $Z_R$ was constructed as the right eigen-supervector $|Z_R\rangle$ of causal field superoperator $\hat{G}_1$ (cf. Eq. (53)) and turned out to play an important role. Here, we discuss its additional properties to further clarify its physical meaning.

b. Fermion parity

The causal field superoperators [51], written out in terms of field operators, read

$$
G^*_1 \equiv \frac{1}{\sqrt{2}} \left\{ d_1 \bullet + q(-1)^n \bullet d_1(-1)^n \right\}, \quad (E1)
$$

where we used $(-1)^{L_+ \bullet \bullet} = (-1)^n \bullet (-1)^n$. Note that $n = \sum_\sigma n_\sigma$ is the occupation operator with $n_\sigma = d_\sigma^\dagger d_\sigma$. The definition of this representation is based on the fermion-parity superselection rule of quantum mechanics, cf. Sec. II B 2. The explicit form (E1) makes clear that $\hat{G}_1 = \hat{G}_1^\dagger$ has the operator

$$
Z_R = \frac{1}{2} (-1)^n \quad (E2)
$$
as its right zero eigen-supervector: upon substitution the two terms in Eq. (E1) simply cancel since $(-1)^{2n} = 1$. Noting that $(-1)^n = \prod_{\sigma} e^{i\pi n_\sigma} = \prod_{\sigma} (1 - 2n_\sigma)$ we recover the result [10] in the main text:

$$
Z_R = \frac{1}{2} (2n_\uparrow - 1)(2n_\downarrow - 1) = 2n_\uparrow n_\downarrow - n + \frac{1}{2}. \quad (E3)
$$

Clearly, from Eq. (E2) it follows that

$$
Z_R^2 = \frac{1}{4} \mathbb{1}, \quad (E4)
$$

which implies the normalization $(Z_R|Z_R) = 1$. The eigenvalue equation [55], $\hat{G}_1|Z_R\rangle = |d_1, Z_R\rangle_+ = 0$ requires $Z_R$ to anticommute with all the fermionic fields: $Z_R$ is therefore the unique operator (up to normalization and a phase) that (anti)commutes with all QD bosonic (fermionic) operators in the QD Liouville space, in close analogy to Grassmann numbers used in functional integral approaches. Eq. (E2) most clearly illustrates the physical meaning of the operator $Z_R$: we identify $Z_R$ as the fermion-parity operator (up to a constant),

$$
2Z_R|x\rangle = \pm |x\rangle. \quad (E5)
$$

when the state $|x\rangle$ has a well-defined, even / odd fermion number. Finally, it follows from $(-1)^n d_1(-1)^n = -d_1$ that $|Z_L\rangle = \frac{1}{2} \mathbb{1}$ is a zero eigen-supervector of $\hat{G}_1^\dagger$. The eigenvalue equation [55], $\hat{G}_1|Z_L\rangle = |d_1, Z_L\rangle_- = 0$, requires $Z_L$, considered as an operator, to commute with the QD field operators and therefore with all QD operators. This implies that indeed $Z_L$ is proportional to the unit operator.

c. Spin and charge rotations

By construction the two independent operators $Z_L$ and $Z_R$ transform as scalars under both spin and charge rotations (cf. Table 1). They must therefore be related to the two scalar
operators with respect to these groups, the Casimir operators of their Lie-algebras $S^2 = \sum_i S_i^2 = 3/4 \sum |\sigma\rangle\langle\sigma|$ and $T^2 = \sum_i T_i^2 = 3/4 (|0\rangle\langle 0| + |2\rangle\langle 2|)$:

$$Z_L = \frac{1}{2} \mathbb{1} = \frac{1}{2} (T^2 + S^2), \quad Z_R = \frac{1}{2} (T^2 - S^2). \quad (E6)$$

The first relation follows from the completeness relation and second one from Eq. (E5).

d. Fermion-parity superoperator We next consider the fermion-parity superoperator, defined naturally by the right action of the fermion-parity operator on an operator (identical results follow for the left action):

$$U \cdot := \mathcal{O}(2Z_R = \mathcal{O}(-1)^N. \quad (E7)$$

This unitary and Hermitian superoperator ($U^\dagger = U, U^2 = \mathbb{1}$) transforms the two types of causal field superoperators into each other,

$$UG_L^2 U = G_R^2. \quad (E8)$$

We can thus interchange the role of creation and annihilation superoperators in Liouville Fock-space by a linear transformation $U$. This is similar to the field operators $d_\sigma$ and $d_\sigma^\dagger$ that generate the standard Fock-space: the $\eta$ index distinguishing can be inverted by a unitary transformation

$$e^{i\pi(L_{\eta\sigma} - S_{\eta\sigma})}d_{\eta\sigma} e^{-i\pi(T_{\eta\sigma} - S_{\eta\sigma})} \quad (E9)$$

cf. Eq. (10) and Eq. (11). Note that $Kd_{\eta\sigma} = d_{\eta\sigma}$ as well, cf. Eq. (11), but this is an antiunitary transformation.

The result (E8) follows by considering an arbitrary fermionic operator $F$ for which $(-1)^L F = (-1)^N F(-1)^N = -F$. The superoperator $U$ transforms a commutator of $F$ with any operator to an anticommutator and vice versa: defining $L_\eta F = [F, \eta]_\pm = F \pm \mathcal{O}$:

$$UL_\eta F U \cdot = F (1 - 2n_{\eta\sigma}) + (1 - 2n_{\eta\sigma}) F (1 - n_{\eta\sigma}) \quad (E10)$$

Commutators with any bosonic operator $B$ remain unaffected. Since the superoperator $\tilde{G}_\sigma$ is a (anti-)commutator when acting on a fermionic (bosonic) operator and vice versa for $G$, the superoperator $U$ interchanges these two: $UG_{L} U = \tilde{G}_\sigma$ and $UG_{R} U = G_{\sigma}$.

e. Multiorbital Anderson models Finally, we indicate how the operators $|Z_L\rangle$ and $|Z_R\rangle$ can be constructed for more general multiorbital Anderson-type models. The super vacuum state is

$$|Z_L\rangle = \frac{1}{2^{N}} \mathbb{1},$$

where $N$ is the number of orbitals and the prefactor takes into account normalization ($\langle Z_L | Z_L \rangle = 1$. Equation (S7) is then simply extended to the maximally occupied state with respect to this vacuum

$$|Z_R\rangle = \prod_{k=1}^{N} \prod_{\sigma} \left( \prod_{\eta} \tilde{c}_{\eta\sigma} \right) |Z_L\rangle. \quad (E12)$$

Using Eq. (E12) and (S9), we can generalize Eq. (10) to

$$|Z_R\rangle = \frac{1}{2N} \prod_{k} \prod_{\sigma} (2n_{\eta_{k}} - 1) = \frac{1}{2N} e^{i\pi n_{k}}, \quad (E13)$$

implying $Z_{R}^{2} = \frac{1}{e^{i\pi}} \mathbb{1}$. Here, $n = \sum_{k,\sigma} n_{\eta_{k}}$ is the total dot particle-number operator. All properties of the single-orbital $Z_{R}$ operator, i.e. (anti)commutation relations with fermionic (bosonic) operators, transformation properties under charge and spin rotations, etc., also hold for the multiorbital case.

Appendix F: Symmetry of the self-energy

In this Appendix we derive the symmetry for QD Eq. (101) in contact with the reservoirs from the global symmetries (25) and (26). Quite generally, a quantity with QD and reservoir contributions, $A_{\text{tot}} = A + \tilde{A}$, is globally conserved when $[A_{\text{tot}}, \tilde{A}_{\text{tot}}] = 0$. The corresponding Liouville superoperators $L_{\text{tot}} = [A_{\text{tot}}, \mathcal{O}]$ and $L_{\text{tot}} = [\tilde{A}_{\text{tot}}, \mathcal{O}]$, then also commute:

$$[L_{\text{tot}}^{A}, L_{\text{tot}}^{R}] = 0, \quad (F1)$$

The commutator of the local part $L_{\text{tot}}^{A} = [A, \mathcal{O}]$ with the Laplace transformed evolution superoperator $\Pi(x) = \text{Tr}_{Z} L_{\text{tot}}^{A} - 1 \rho^{R}$ of the reduced density operator (cf. Eq. (11)) must then vanish:

$$L_{\text{tot}}^{A} \Pi(x) = \text{Tr}_{x} L_{\text{tot}}^{A} \rho^{R} x = 0, \quad (F2)$$

using subsequently $\text{Tr}_{x} L_{\text{tot}}^{A} = \Pi(x) \Pi(x) = 0$, Eq. (22), and finally $L_{\text{tot}}^{A} \rho^{R} = 0$. We note that this last result follows from Eq. (22) under the assumption that $\rho^{R}$ conserves both the reservoir energy and the particle number. $[A, \bar{H}^{R}] = [A^{R}, \bar{n}^{R}] = 0$, which is the case in our applications of the result. Clearly, this proof applies also to the time-evolution superoperator $\Pi_{0}$ without any QD-reservoir interaction, i.e., for $L_{V} = 0$. Then, using $[L_{\text{tot}}^{A}, \Pi(x)] = [L_{\text{tot}}^{A}, \Pi(0)] = 0$ and taking the commutator of $L_{\text{tot}}^{A}$ with the Dyson equation that defines the self-energy $\Sigma(x)$, $\Pi(x) = \Pi_{0}(x) - i \Pi_{0}(x) \Sigma(x) \Pi(x)$, we find that $[L_{\text{tot}}^{A}, \Sigma(x)] = 0$. 

Appendix G: Hermiticity

f. Hermitian conjugation superoperator The density operator is restricted to be invariant under Hermitian conjugation in Hilbert space. When considering density operators as supervectors in Liouville space, this Hermitian conjugation of an operator then corresponds to a superoperator that we denote by $K$,

$$K|A\rangle := |A^\dagger\rangle.$$  

It is to be distinguished from the Hermitian conjugation of a superoperator. $K$ is antilinear and satisfies

$$K^2 = I.$$  

where $I$ is the unit superoperator. Changing the basis in Liouville space by the superoperator $K$, we effect an antilinear transformation of a superoperator, $S \rightarrow KS\overline{K}$, referred to as “c-transform” in Ref. [26]. In the time representation the density operator is invariant under this transformation: $K\rho(t) = \rho(t)$, implying for the Laplace-transformed density matrix [22]: $K\rho(z) = \rho(-z^*)$. Applying $K$ to the kinetic equation [55], we obtain a conjugation relation restricting the kernel $\Sigma(z)$:

$$K\Sigma(z)K = -\overline{\Sigma(-z^*)}.$$  

Of course, this property also holds for the initial Liouvillian: $K\Sigma(z) = \overline{\Sigma(-z^*)}$. The transformation of the fields $\mathcal{G}^{p}$ follows by applying $K$ to Eq. (10) and using $(d^\dagger\cdot)^\dagger = \cdot^\dagger d = (K\cdot)d$,

$$K\mathcal{G}^{p}_i K = \mathcal{G}^{p}_i,$$  

(giving with Eq. (31), (22) and $KL^n K = -L^n$:

$$K\mathcal{G}^{p}_i K = p^{-L^n}\mathcal{G}^{p}_i = (-1)^L\mathcal{G}^{p}_i.$$  

The transformation of the causal field superoperators $G^{a}$ [Eq. (119) in the main text] now follows by applying Eq. (61):

$$KG^{a}_i K = q(-1)^L\mathcal{G}^{a}_i.$$  

Here, we write the sum over 1 explicitly and let $\overline{\Sigma}_{11}(z) := 3(\sigma_1)G_1\Pi_1G_1 = -K\overline{\Sigma}_{11}(-z^*)K$ denote a term in which the multiindex 1 has a fixed value and $\Pi_1 = (z - \bar{L} - x_1)^{-1}$. Furthermore, noting that 1 is dummy multini- dex, we can restrict the summation to one fixed $\eta$ configuration, e.g., $\eta_1 = +$, while manifestly preserving the structure $KG(z)K = -\overline{\Sigma}(-z^*)$:

$$\overline{\Sigma}(z) = \sum_{1} \delta_{\eta_1^+} (\overline{\Sigma}_{11}(z) - K\overline{\Sigma}_{11}(-z^*)K)$$  

The calculation of the supermatrix elements is now simplified: using the notation of Sec. II and the antilinear- ity of $K$, $(A|KSK|B) = (KA|SB)^*$ we obtain:

$$(\kappa_3|\overline{\Sigma}(z)|\kappa_0) = \sum_{1} \delta_{\eta_1^+} [(\kappa_3|\overline{G}_1|\kappa_2)(\kappa_1|G_1^\dagger|\kappa_0)](\kappa_2|\Pi_1(z)|\kappa_1) - (K\kappa_3|G_1^\dagger|\kappa_2)^*(\kappa_1|G_1|\kappa_0)^* (\kappa_2|\Pi_1(-z^*)|\kappa_1)^*$$  

In our Liouville-Fock basis the matrices representing $G^{a}$ are real, just as those of the field operators $d_1$, cf. Eq. (51). When the basis supervectors $|\kappa_3\rangle, |\kappa_0\rangle$ correspond to diagonal operators $(Z_i, \chi_\sigma, S_\sigma, T_0)$, then the second term in Eq. (G9) simply relates to the first one since these supervectors are mapped onto themselves by $K$, cf. Eq. (110). Eq. (G9) simplifies to

$$(\kappa_3|\overline{\Sigma}(z)|\kappa_0) = \sum_{1} \delta_{\eta_1^+} [(\kappa_3|\overline{G}_1|\kappa_2)(\kappa_1|G_1^\dagger|\kappa_0)](\kappa_2|\Pi_1(z)|\kappa_1) - [(\kappa_2|\Pi_1(z)|\kappa_1)^*(\kappa_2|\Pi_1(-z^*)|\kappa_1)^*]$$  

which is explicitly imaginary at $z = 0$ as it should be. Supervectors corresponding to non-diagonal operators $(S_\sigma, T_\eta, \chi_\sigma)$ come in pairs related by inversion of both indices $\eta$ and $\sigma$. The superoperator $K$ maps these pairs onto each other (possibly with a sign change, see Eq. (117)). Noting also that $\overline{G}$ only has non-zero matrix elements for one superket of each pair, cf. Eq. (118-1128), we see that in (G8) either the first or second term contributes or neither when $\kappa_3$ and / or $\kappa_0$ is a non-diagonal operator. In this way we have effectively eliminat- ed the need to evaluate the terms for $\eta_1 = -$ using the conjugation relations. This consideration is ge- neralized to 2-loop expressions by adding to Eq. (G8)

$$\sum_{12} \delta_{\eta_1^+}\delta_{\eta_2^+} (\overline{\Sigma}_{122}(z) - K\overline{\Sigma}_{122}(-z^*)K)$$  

where $\overline{\Sigma}_{122}(z)$ collects all 2-loop terms with a fixed multi- nidiexes 1 and 2. The same analysis applies to terms in the RG equations Eq. (200), (222) and (267).

h. Conjugation properties under RG flow In con- trast to the charge and spin transformation properties, the conjugation property (G16) – associated with the fundamental Hermiticity of the density operator – is exactly preserved under the RG flow. We first note that the vertices $G_1 = G_1^\dagger$ only determine the initial value of the
Liouvillean $\bar{L}$ and therefore are not affected by the ensuing RG flow: they therefore simply obey Eq. (G6). However, the vertices $\bar{G}_1 = G_1$ flow together with the Liouvillean $\bar{L}$ and thereby acquire a dependence on the dot frequency $z$. These vertices obey the following generalization of Eq. (G6) to non-zero $z$:

$$KC_1^z(z)K = q(-1)^L G_1^z(-z^*) .$$  \hspace{1cm} (G12)

To prove Eq. (G12) we use that the bare vertices, providing the initial values of the RG flow, have the property (G12). It remains to show that for each scale $\Lambda$ the infinitesimal correction to the $\bar{G}$ generated by the RG flow also has this property. We therefore apply $K \cdot K$ to the RG Eq. (207) for the vertex $\bar{G}_\alpha$, insert Eq. (G2), use Eq. (G3) and assume that the property (G12) holds:

$$K \frac{d \bar{G}}{d \Lambda} = (-1)^{(k+1)\alpha^n+k(k+1)/2} \left( \frac{d \gamma}{d \Lambda} \prod_i \bar{\gamma}_i(\bar{\omega}_i) \right)_\text{irr} \times \bar{\gamma}_1 \bar{G}_2 \cdots \bar{G}_{k-1} \frac{1}{z_1^* + L(-z_1^*)} \bar{G}_k \hspace{1cm} (G13)$$

$$- (-1)^L \left( \frac{d \gamma}{d \Lambda} \prod_i \bar{\gamma}_i(\bar{\omega}_i) \right)_\text{irr} \times \bar{G}_1 \frac{1}{z_1^* - L(-z_1^*)} \bar{\gamma}_1 \bar{G}_2 \cdots \bar{G}_{k-1} \frac{\bar{\gamma}_1(\bar{\omega}_i)}{z_1^* - L(-z_1^*)} \bar{G}_k \hspace{1cm} (G14)$$

At the first equality a sign factor arises when commuting all $(-1)^L$ factors to the left, using the fermion-parity property $(-1)^L \bar{G}_1 = \bar{G}_1(-1)^{L^*+1}$ which is preserved under the RG as well (since both sides of Eq. (207) have an odd number of $G$’s). After the second equality we inverted additional multindices $i \rightarrow i$ and inverted the integration variable $\bar{\omega}_i \rightarrow -\bar{\omega}_i$, giving a sign $(-1)^{k^2}$ due to the $k/2$ antisymmetric contraction functions (counting $\bar{\gamma}$’s and $d\gamma/d\alpha$), where $k$ is the even number of vertices other than $G_\alpha$. Since for even $k$ the integers $k/2$ and $k(k+1)/2$ have opposite parity the result follows.

This gives the correct grand-canonical average over the reservoirs, see Appendix A in Ref. [26] for a proof.

Formulating the theory in real-time, one can directly identify the retarded and Keldysh Green functions with their usual definitions when setting $\gamma = \pi$ (cf. Eq. 15), $-i\langle \mathcal{T} J_1(t) J_2(t) \rangle_R = -i\theta(|b_1(t)|^2 + b_2(t)|^2) R$ and $-i\langle \mathcal{T} J_1(t) J_2(t) \rangle_K = -i\langle b_1(t) b_2(-t) \rangle K$ where $\mathcal{T}$ is the time-ordering superoperator. In Laplace space, their time-evolution frequencies $\chi$ are convoluted together with the dot Liouvillian into $1/(\omega - \chi - \lambda)$ in the diagram rules [38]. The retarded function $\langle \mathcal{T} J_1(t) J_2(t) \rangle_R$ thus contributes only spectral information through $\chi$ since Eq. 25 contains only $\langle J_1(t) J_2(t) \rangle_R \propto |b_1(t)|^2 + |b_2(t)|^2$, whereas the Keldysh function $-i\langle \mathcal{T} J_1(t) J_2(t) \rangle_K$ additionally includes statistical information through Eq. 25 containing $\langle J_1(t) J_2(t) \rangle_K \propto |b_1(t)|^2 |b_2(t)|^2$.

In the wide-band limit the energy-independent contractions $\gamma$ correspond to the $\delta$-functions in time, leaving no phase space for the $\omega$-integrals when enclosing vertices.

For models not of the Anderson-type (bilinear coupling), higher skeleton diagrams and vertex renormalizations arise, requiring a more general discrete renormalization [26].

This relies on the anticommutation relations [32] of the bare vertices, which break down under renormalization: $[z R, \Sigma]$ given by Eq. 57 is thus not an eigen-supervector of renormalized vertices.

We emphasize that charge off-diagonal dot operators must be taken into account since in a virtual intermediate state of an open system, where, e.g., $G$ has acted on an even fermion parity QD density operator, there is a corresponding fermion operator $J$ acting on the reservoir. Although the latter is no longer explicitly present in the reduced density operator description (the reservoirs are integrated out), there is no change of the fermion parity of the total system described by an elementary process in $\Sigma$, in full agreement with the discussion of Eq. 35.

Our definition of the contraction $\delta \Lambda$ differs from that in Ref. [26] by a factor $-2\Gamma$ due to our (i) our sign convention for the $\eta$ index [67], cf. Eq. 15 (factor $-1$), (ii) our normalization of the field superoperators [76] such that $[\tilde{G}_1, \tilde{G}_1]_+ = 1$ (factor 2), and (iii) our inclusion of the coupling into the reservoir fields (factor $\Gamma$).

The positive imaginary part (integration contour in the lower half-plane) contrasts with Ref. [26], but the final notation Eq. 202 agrees again with Ref. [26] due to compensating differences in the notation.

Eq. 202 and 207 differ from those in Ref. [26] by a factor 2 for each loop due to our different normalization of $G$ (reduced by factor $\sqrt{2}$). The sign difference in the definition of the cut-off function [74] is compensated by our closing of the integration-contour in the lower (instead of the upper) half-plane.

For the density operator time-evolution, we need the Liouvillian $L$, $L + \Sigma(z) = \mathcal{L} + \Sigma(z) = L_\Lambda + \Sigma_\Lambda(z)$, but for the current we do not: $\Sigma' = \Sigma + \Sigma' = L_\Lambda + \Sigma_\Lambda'(z)$.
