Minimum degree conditions for monochromatic cycle partitioning

Dániel Korándi*  Richard Lang†  Shoham Letzter‡  Alexey Pokrovskiy§

Abstract

A classical result of Erdős, Gyárfás and Pyber states that any $r$-edge-coloured complete graph has a partition into $O(r^2 \log r)$ monochromatic cycles. Here we determine the minimum degree threshold for this property. More precisely, we show that there exists a constant $c$ such that any $r$-edge-coloured graph on $n$ vertices with minimum degree at least $n/2 + c \cdot r \log n$ has a partition into $O(r^2)$ monochromatic cycles. We also provide constructions showing that the minimum degree condition and the number of cycles are essentially tight.

1 Introduction

Monochromatic cycle partitioning is a combination of Ramsey-type and covering problems. Given an edge-coloured host graph $G$, one seeks to partition the vertex set of $G$ into as few monochromatic cycles as possible. The case where the number of used cycles $f$ can be upper-bounded by a function of the number of colours $r$ is of particular interest. A classical result in this area is due to Erdős, Gyárfás and Pyber [12], who showed that any $r$-edge-coloured complete graph $G = K_n$ admits a partition into $\lceil 25r^2 \log r \rceil$ monochromatic cycles. The same authors conjectured that their result could in fact be improved to $r$ cycles. For $r = 2$, this had been suggested about 20 years earlier by Lehel in a stronger sense, i.e. with the cycles having distinct colours. Lehel’s conjecture was first proved for large $n$ by Łuczak, Rödl and Szemerédi [31] and then for all $n$ by Bessy and Thomassé [3], after preliminary work by Gyárfás [14]. For $r \geq 3$, the conjecture of Erdős, Gyárfás and Pyber turned out to be false. Pokrovskiy [32] provided colourings of the complete graph that require $r$ cycles and a single additional vertex for a partition. He conjectured, however, that a partition into $r$ cycles and a constant number of vertices $c(r)$ should nevertheless be sufficient. In support of his conjecture, Pokrovskiy showed the case of $r = 3$ with $c(3) = 43000$. This was independently confirmed by Letzter [27] with $c(r) = 60$. The best known general upper bound for the number of monochromatic cycles required to partition any $r$-coloured complete graph is $100r \log r$, established by Gyárfás, Ruszinkó, Sárközy and Szemerédi [16].

1To avoid some trivial cases, we consider the empty set, vertices and edges to be cycles.
In the past decades monochromatic partitions of the complete graph have been researched in many ways, such as partitioning into graphs other than cycles [13, 36], more general colourings [8] and partitions of hypergraphs [7, 17]. For a broader overview, we refer the reader to the recent survey of Gyárfás [15]. Another natural problem arises when we consider host graphs that need not be complete. In particular, for which families of graphs can we still partition the vertex set into few monochromatic cycles? This question has been investigated for complete bipartite graphs [19], graphs with fixed independence number [35], infinite graphs [11, 34] and random graphs [24, 26] among others. Here we are interested in families of graphs characterized by a large minimum degree.

The study of minimum degree conditions for spanning substructures has a long tradition in extremal graph theory, Dirac’s theorem being a classical example. Recent milestones of this area include the resolution of the Pósa-Seymour conjecture by Komlós, Sárközy and Szemerédi [22], the Bandwidth theorem by Böttcher, Schacht and Taraz [5], and the Hamilton decomposition theorem by Csaba, Kühn, Lo, Osthus and Treglown [9]. Many other results in this line of research are covered in the survey of Kühn and Osthus [25].

For monochromatic cycle partitions, the research of minimum degree conditions was initiated by Balogh, Barát, Gerbner, Gyárfás and Sárközy [2] with a strengthening of Lehel’s conjecture. They showed that every 2-edge-coloured graph $G$ on $n$ vertices of minimum degree $(3/4 + \varepsilon)n$ admits a partition of all but $o(n)$ vertices into two monochromatic cycles of distinct colours. They also conjectured that this can be improved to a proper partition even without the term of $\varepsilon n$. (An easy construction shows that this is best possible.) The extension to a proper partition was verified by DeBiasio and Nelsen [10] and the full conjecture was subsequently proved by Letzter [28]. Given these advances, Pokrovskiy [33] conjectured that for a 2-edge-coloured graph $G$ with $\delta(G) \geq 2n/3$ and $\delta(G) \geq n/2$ a partition into 3 and 4, respectively, cycles is possible. (Again, constructions show that this is essentially best possible.) Allen, Böttcher, Lang, Skokan and Stein [1] confirmed the first part of this conjecture approximately, i.e. for $\delta(G) \geq (2/3 + \varepsilon)n$. Thus the problem for two colours is increasingly well understood.

The goal of this research was to determine the minimum degree threshold for partitioning an $r$-edge-coloured graph into $f(r)$ monochromatic cycles for general $r$, for any function $f(r)$ that depends only on $r$. A lower bound of $n/2 + O(\log n/\log \log n)$ already requires $\Omega(\log n/\log \log n)$ monochromatic cycles for a partition.

**Theorem 1.1.** Let $n$ be sufficiently large. Then there is a 2-edge-coloured graph $G$ on $n$ vertices with $\delta(G) \geq n/2 + \log n/(16\log \log n)$ whose vertices cannot be partitioned into fewer than $\log n/(16\log \log n)$ monochromatic cycles.

Our main contribution states that a minimum degree slightly larger than this is in turn sufficient for a partition into a $O(r^2)$ cycles.

**Theorem 1.2.** Let $n$ be sufficiently large. Then any $r$-edge-coloured graph $G$ on $n$ vertices with $\delta(G) \geq n/2 + 600r \log n$ admits a partition into $10^7r^2$ monochromatic cycles.
We also provide a construction that shows that the number of cycles of Theorem 1.2 is essentially best possible.

**Theorem 1.3.** Let \( \varepsilon > 0 \) and \( r \) be sufficiently. Then there is an \( r \)-edge-coloured graph \( G \) on \( n \) vertices with \( \delta(G) \geq (1 - 4\varepsilon)n \), whose vertices cannot be covered by fewer than \( \varepsilon^2(r - 1)^2/4 \) monochromatic trees.

It is worth mentioning here a recent paper of Bucić, Korándi and Sudakov [6], who were interested in covering \( r \)-coloured random graphs \( G(n, p) \) by monochromatic trees. Similarly to our results, they proved that the minimum number of monochromatic trees needed is \( \Theta(r^2) \) when \( p \) is just above the threshold for the existence of a covering with a bounded number of trees.

Our results imply in particular, that we can determine the smallest number of cycles necessary for a partition of bounded degree graphs up to a constant factor. This stands in contrast to the situation for complete graphs, where the gap between upper and lower bound remains a factor of \( \log r \).

## 2 Overview

A brief overview of the proof of Theorem 1.2 is as follows. Using Szemerédi’s regularity lemma, we obtain a regular partition \( \{V_0, V_1, \ldots, V_m\} \) of the vertices of \( G \), and define the corresponding reduced graph \( G' \). We then select \( O(r^2) \) monochromatic components of \( G' \) in such a way that their union, denoted by \( H \), robustly contains a perfect matching. The robustness roughly translates into \( H \) having a perfect matching even after removing any small set of vertices. So, in particular, \( H \) has a perfect matching \( M \). We can turn \( M \) into \( O(r^2) \) disjoint monochromatic cycles \( C_H \) covering almost all of \( G \) using a method of Luczak [30].

The plan is now to add the remaining vertices \( V(G) \setminus C_H \) into the cycles of \( C_H \). More precisely, we intend to use the blow-up lemma to find monochromatic spanning paths in the regular pairs corresponding to \( M \). There are two obstacles to this. First, there might be a small number of “bad” vertices blocking the use of the blow-up lemma. Second, the clusters \( V_i \setminus C_b \) might be slightly different in size, which prevents us from even allocating spanning paths in the pairs.

We deal with the irregular vertices by covering them with \( O(r^2) \) additional cycles \( C_b \), exploiting their large degrees. We then balance the clusters by carefully extending the cycles of \( C_H \) at the right location. At this point, the robustness under which \( H \) has a perfect matching is crucial. Having overcome these two issues, we can finish by applying the blow-up lemma to add the remaining vertices onto \( C_H \). Thus \( C_H \cup C_b \) presents the desired cycle partition.

This method works as long as \( G \) admits a spanning subgraph \( H \), which robustly contains a perfect matching, but unfortunately, we cannot always guarantee this. However, if such subgraph \( H \) does not exist, then we can show that \( G \) must be balanced bipartite after the removal of \( O(r) \) monochromatic cycles \( C \). (At this point, we use the additional \( 600r \log n \) in the minimum degree.)

Thus we can apply a bipartite analogue of the above detailed approach to cover the rest with cycles \( C_H \cup C_b \). In this case the cycle partition consists of \( C_H \cup C_b \cup C \).
3 Preliminaries

In this section we introduce some notations and tools needed for the proof of Theorem 1.2.

3.1 Notation

Let $G = (V, E)$ be a graph. The order of $G$ is $|V(G)|$ and the size of $G$ is $|E(G)|$. We denote the neighborhood of a vertex $v$ by $N_G(v)$ and write $N_G(v, W) = N_G(v) \cap W$ for a set of vertices $W \subseteq V(G)$. We denote the degree of $v$ by $\deg_G(v) = |N_G(v)|$ and $\deg_G(v, W) = |N_G(v, W)|$. For a set of vertices $S \subseteq G$ we write $N_G(S) = \left( \bigcup_{s \in S} N(s) \right) \setminus S$. When the underlying graph $G$ is clear from the context, we often omit the subscript $G$. For another graph $H$, the union $G \cup H$ is the graph on vertex set $V(G) \cup V(H)$ and edge set $E(G) \cup E(H)$. The independence number of $G$ is denoted by $\alpha(G)$. For disjoint set $X, Y \subseteq V(G)$, we denote by $G[X, Y]$ the induced bipartite subgraph of $G$ with bipartition $\{X, Y\}$.

An $r$-edge-colouring of $G$ assigns one colour from the set $[r] = \{1, 2, \ldots, r\}$ to each edge of $G$. For $i \in [r]$, we use $G_i$ to denote the subgraph on $V(G)$ whose edges are those that have colour $i$. A component of colour $i$ of $G$ is a component of $G_i$. When the context is clear, we will simplify our notation by using $i$ instead of $G_i$ in the subscript of $N$ and $\deg$. For example, a vertex $v$ with $\deg_2(v) = 0$ is in an $i$-coloured component of order 1.

A $v$-$w$-path is a path that starts at $v$ and ends at $w$. As said above, we allow the empty set, single vertices and edges in our cycle partitions. We occasionally use the term “proper cycle” to emphasize that a cycle is not an empty set, a vertex or an edge.

In some of our statements, we will make assumptions of the form $x \ll y$ for certain parameters $x$ and $y$. This should be understood as equivalent to the condition $x \leq f(y)$ for some unspecified increasing function $f$. In our usage, this is always a strengthening of $x \leq y$.

3.2 Regularity

Given a graph $G$ and disjoint vertex sets $V, W \subseteq V(G)$ we denote the number of edges between $V$ and $W$ by $e(V, W)$ and the density of $(V, W)$ by $d(V, W) = e(V, W)/(|V||W|)$. The pair $(V, W)$ is called $\varepsilon$-regular, if all subsets $X \subseteq V, Y \subseteq W$ with $|X| \geq \varepsilon |V|$ and $|Y| \geq \varepsilon |W|$ satisfy $|d(V, W) - d(X, Y)| \leq \varepsilon$. We say that a vertex $v \in V$ has typical degree in $(V, W)$, if $\deg(v, W) \geq (d(V, W) - \varepsilon)|W|$. It follows directly from the definition of $\varepsilon$-regularity that

$$\text{all but at most } \varepsilon|V| \text{ vertices in } V \text{ have typical degree in } (V, W).$$ (3.1)

The next lemma allows us to find (spanning) paths in regular pairs. It is a corollary of the mighty blow-up lemma [21], but can also be proved independently with not too much effort.

**Lemma 3.1** (Long paths in regular pairs). Let $n$ be an integer and let $\varepsilon, d$ be numbers with $0 < 1/n \ll \varepsilon \ll d < 1$. Suppose that $(V_1, V_2)$ is an $\varepsilon$-regular pair of density $d = d(V_1, V_2)$ and
with $|V_1|, |V_2| \geq n$ in a graph $G$. For $i \in \{1, 2\}$, let $v_i \in V_i$ and let $U_i \subseteq V_i$ be a set of size at least $n/6$ which contains at least $\varepsilon |V_1|$ neighbours of $v_{3-i}$.

Then for every $2 \leq k \leq (1 - \sqrt{\varepsilon}) \cdot \min\{|U_1|, |U_2|\}$, there is a $v_1$-$v_2$-path of order $2k$ in $G[U_1 \cup \{v_1\}, U_2 \cup \{v_2\}]$.

If, additionally, $\delta(G[U_1, U_2]) \geq 3\varepsilon \cdot \max\{|V_1|, |V_2|\}$, then $G[U_1 \cup \{v_1\}, U_2 \cup \{v_2\}]$ contains a $v_1$-$v_2$-path of order $2k$ for every $2 \leq k \leq \min\{|U_1 \cup \{v_1\}|, |U_2 \cup \{v_2\}|\}$.

Szemerédi’s Regularity Lemma [38] allows one to partition the vertex set of a graph into clusters of vertices, in a way that most pairs of clusters are regular. We will use the regularity lemma in its degree form (see [23]), with $r$ colours and a prepartition.

**Lemma 3.2 (Regularity Lemma).** For every $\varepsilon > 0$ and integers $r, \ell$ there is an $M = M(\varepsilon, r, \ell)$ such that the following holds. Let $G$ be a graph on $n \geq 1/\varepsilon$ vertices whose edges are coloured with $r$ colours, let $\{W_1, \ldots, W_\ell\}$ be an equipartition of $V(G)$ for some $1 \leq \ell' \leq \ell$, and let $d > 0$. Then there is a partition $\{V_0, \ldots, V_m\}$ of $V(G)$ and a subgraph $G'$ of $G$ with vertex set $V(G) \setminus V_0$ such that the following conditions hold.

(a) $1/\varepsilon \leq m \leq M$,
(b) $|V_0| \leq \varepsilon n$ and $|V_1| = \cdots = |V_m| \leq \varepsilon n$,
(c) for every $i \in [m]$, there is $j \in [\ell']$ with $V_i \subseteq W_j$,
(d) for every $j \in [\ell']$, there are equally many $i \in [m]$ with $V_i \subseteq W_j$,
(e) $\deg_{G'}(v) \geq \deg_G(v) - (rd + \varepsilon)n$ for each $v \in V(G) \setminus V_0$,
(f) $G'[V_i]$ contains no edges for $i \in [m]$, and
(g) all pairs $(V_i, V_j)$ are $\varepsilon$-regular in $G'$ with density either 0 or at least $d$ in each colour.

Let $G$ be an $r$-edge-coloured graph with a partition $\{V_0, \ldots, V_m\}$ obtained from Lemma 3.2 with parameters $\varepsilon$ and $d$. We define the $(\varepsilon, d)$-reduced graph $\mathcal{G}$ to be a graph with vertex set $V(\mathcal{G}) = \{x_1, \ldots, x_m\}$ where two vertices $x_i$ and $x_j$ are connected by an edge of colour $c$, if $(V_i, V_j)$ is an $\varepsilon$-regular pair of density at least $d$ in colour $c$ (if this holds for multiple colours, we choose one of them arbitrarily). Note that if $G$ was balanced $\ell$-partite with partition $\{W_1, \ldots, W_\ell\}$, then $\mathcal{G}$ is a balanced $\ell$-partite graph, as well. It is often convenient to refer to a cluster $V_i$ via its corresponding vertex in the reduced graph, i.e. $V_i = V(x_i)$.

The following properties of the reduced graph are easy to check.

**Claim 3.3.**  
(a) If $\deg_G(v) \geq cn$ for some $v \in V_i$, $i \in [m]$, then $\deg_{\mathcal{G}}(x_i) \geq (c - rd - \varepsilon)m$.

(b) If $\deg_G(v) \geq cn$ for all but $\eta n$ vertices $v \in V(G)$, then $\deg_{\mathcal{G}}(x) \geq (c - rd - \varepsilon)m$ for all but $(\eta + \varepsilon)m$ vertices $x \in V(\mathcal{G})$.

(c) If $\bigcup_{x_i \in X} V_i$ induces at least $cn^2$ edges in $G$ for some $X \subseteq V(\mathcal{G})$, then $X$ induces at least $(c - rd - \varepsilon)m^2$ edges.
Proof. (a) Note that \( \deg_{G'}(v) \geq (c - rd - \varepsilon)n \), so \( v \) is adjacent to vertices from at least \( (c - rd - \varepsilon)n / |V_i| \geq (c - rd - \varepsilon)m \) clusters in \( G' \). By the definition of \( G' \), this means that \( x_i \) is adjacent to the corresponding vertices in \( G \).

(b) We may assume \( \eta + \varepsilon < 1 \), as otherwise there is nothing to prove. Let \( X \) be the set of vertices \( x \) in \( G \) with \( \deg_{G}(x) < (c - rd - \varepsilon)m \). By (a), we know that every vertex \( v \) in the clusters corresponding to \( X \) must have \( \deg_{G}(v) < cn \). So if \( |X| > (\eta + \varepsilon)n \), then at least \( |X||V_i| > (\eta + \varepsilon)(1 - \varepsilon)n = (\eta + \varepsilon(1 - \eta - \varepsilon))n > \eta m \) vertices \( v \in V(G) \) have \( \deg_{G}(v) < cn \), contradicting our assumption.

(c) As \( G' \) is obtained by deleting at most \((rd + \varepsilon)n^2\) edges from \( G \backslash V_0 \), we know that \( \bigcup_{x_i \in X} V_i \) induces at least \((c - rd - \varepsilon)n^2\) edges in \( G' \). But then there are at least \((c - rd - \varepsilon)n^2 / |V_i|^2 \geq (c - rd - \varepsilon)m^2 \) pairs \( \{x_i, x_j\} \) in \( X \) with an edge between the corresponding clusters \( V_i \) and \( V_j \) in \( G' \). By the definition of \( G' \), this means that \( X \) induces at least \((c - rd - \varepsilon)m^2\) edges in \( G \).

The next lemma of Luczak allows us to connect clusters by short paths, if the corresponding vertices in the reduced graph lie in the same connected component.

**Lemma 3.4** (Connecting Paths, [30]). Let \( n \) be an integer and let \( \varepsilon, d \) be numbers with \( 0 < 1/n \ll \varepsilon \ll d \leq 1 \). Let \( G = (V, E) \) be a graph on \( n \) vertices and with an \((\varepsilon, d)\)-reduced graph \( G \) obtained from Lemma 3.2. Suppose that \( W \subseteq V \) is a vertex set such that \( |W \cap V_i| \leq (d/2) \cdot |V_i| \) for every \( i \in [m] \). Let \( x_1y_1, x_2y_2 \in E(G) \) be two edges in a connected component of colour \( c \).

Then for any two vertices \( v_1 \in V(x_1) \) and \( v_2 \in V(x_2) \) of typical degree in \((V(x_1), V(y_1))\) and \((V(x_2), V(y_2))\), \( G \) contains a \( c \)-coloured \( v_1-v_2 \)-path \( P \) of order at most \( 2m \) that avoids all vertices of \( W \).

### 3.3 \( b \)-matchings

We will adapt Luczak’s connected matchings method for our proof, which is by now a standard way of constructing long paths and cycles in dense graphs. The usual procedure is to apply the regularity lemma, and find large matchings in the connected components of the reduced graph (a matching whose edges belong to the same component is called a connected matching). The point is that a connected matching in the reduced graph can easily be converted into a cycle in the original graph.

In our case, it will be more convenient to work with \( 2 \)-matchings, i.e. subgraphs, where each vertex can touch at most two edges. These convert to cycles the same way as matchings.

**Definition 3.5** (Perfect \( b \)-matching). Let \( b : V(G) \to \mathbb{Z}^{\geq 0} \) be a function on the vertices of a graph \( G \). A **perfect \( b \)-matching** of \( G \) is a non-negative function \( \omega : E(G) \to \mathbb{Z}^{\geq 0} \) on the edges, such that \( \sum_{w \in N(v)} \omega(vw) = b(v) \) for every vertex \( v \). When \( b \) is the constant 2 function, we call \( \omega \) a **perfect 2-matching**.
It is easy to see that perfect 2-matchings correspond to vertex-disjoint cycles and edges that cover all the vertices. For example, a perfect matching with weight 2 on each edge is a perfect 2-matching. The following analogue of Tutte’s theorem is a convenient characterization of graphs that admit a perfect 2-matching (see [37, Corollary 30.1a]).

**Theorem 3.6 (Tutte).** A graph $G$ has a perfect 2-matching if and only if every independent set $S \subseteq V(G)$ satisfies $|N(S)| \geq |S|$.

However, we will need stronger conditions so that our graph is guaranteed to have a perfect 2-matching even after slight modifications.

### 3.4 Robustly matchable graphs

**Definition 3.7 ($\mu,\nu$)-robustly 2-matchable graphs.** A graph $H$ on $n$ vertices is ($\mu,\nu$)-robustly 2-matchable if any of the following two conditions holds.

1. $\delta(H) \geq (1/2 - \mu)n$ and every set of $(1/2 - \nu)n$ vertices spans at least $\nu n^2$ edges.
2. $H$ is a balanced bipartite graph with parts $A, B$ (of size $n/2$) such that
   - $\delta(H) \geq (1/32 - \mu)n$, and
   - all but at most $(1/64 + \mu)n$ vertices in $H$ have degree at least $(1/3 - \mu)n$.

We will distinguish robustly 2-matchable graphs of the first and second type accordingly.

Note that every ($\mu',\nu'$)-robustly 2-matchable graph with $\mu' < \mu$ and $\nu' > \nu$ is automatically ($\mu,\nu$)-robustly 2-matchable, as well.

The following claim explains why we call these graphs “2-matchable”.

**Claim 3.8.** Every ($\mu,\nu$)-robustly 2-matchable graph $H$ with $\mu \leq \nu < 1/1000$ contains a perfect 2-matching.

**Proof.** If $H$ is a type 1 robustly 2-matchable graph, then for every non-empty independent set $S$, we have

$$|S| \leq (1/2 - \nu)n \leq (1/2 - \mu)n \leq \delta(H) \leq |N(S)|$$

(using the independence of $S$ in the first and last step), so $H$ satisfies the conditions of Theorem 3.6.

Now suppose $H$ is of the second type with bipartition $V(H) = A \cup B$. By König’s theorem, it is enough to check that every independent set has size at most $n/2$. Indeed, this would guarantee the existence of a perfect matching, and hence a perfect 2-matching. So let $S$ be an independent set in $H$, and let $S_A = S \cap A$ and $S_B = S \cap B$. We may assume that $|S_A| \leq |S_B|$, and note that $N(S_A) \subseteq B \setminus S_B$.

If $1 \leq |S_A| \leq (1/64 + \mu)n$, then $|N(S_A)| \geq \delta(H) \geq (1/32 - \mu)n \geq (1/64 + \mu)n \geq |S_A|$. (If $S_A$ is empty, then trivially $|N(S_A)| \geq |S_A|$.) So $|S| = |S_A| + |S_B| \leq |N(S_A)| + |S_B| \leq |B| = n/2$.

On the other hand, if $|S_A| > (1/64 + \mu)n$, then there is a vertex $v \in S_A$ of degree at least $(1/3 - \mu)n \geq n/4$, so $|N(S_A)| \geq n/4$. As $|S_B| \geq |S_A| > (1/64 + \mu)n$, we similarly get $|N(S_B)| \geq n/4$. But then $|S| = |S_A| + |S_B| \leq n - |N(S_A)| - |N(S_B)| \leq n/2$, as needed.

□
The next two statements illustrate the robustness of the above definition.

**Lemma 3.9.** Suppose $H$ is a $(\mu, \nu)$-robustly 2-matchable graph on $n$ vertices and let $\varepsilon > 0$. Suppose $H'$ is a spanning subgraph of $H$ such that $\deg_{H'}(v) \geq \deg_H(v) - \varepsilon n$ for every vertex $v$. Then $H'$ is $(\mu + \varepsilon, \nu - \varepsilon)$-robustly 2-matchable. Moreover, if $H$ is of type 1, then $H'$ is of type 1. And if $H$ is of type 2, then $H'$ is of type 2.

**Proof.** If $H$ is a type 1 robustly 2-matchable graph, then $\delta(H') \geq \delta(H) - \varepsilon n \geq (1/2 - (\mu + \varepsilon))n$, as needed. Also, $H'$ loses at most $\varepsilon \delta^2$ edges compared to $H$, so every set of $(1/2 - \nu)n$ vertices spans at least $(\nu - \varepsilon)n^2$ edges. In particular, the same holds for every set of $(1/2 - (\nu - \varepsilon))n$ vertices.

On the other hand, if $H$ is of the second type, then we similarly get $\delta(H') \geq (1/32 - (\mu + \varepsilon))n$, as well as $\deg_{H'}(v) \geq (1/3 - (\mu + \varepsilon))n$ for all but $(1/64 + \mu)n$ vertices $v$.

**Lemma 3.10.** Suppose $H$ is an $r$-edge-coloured $(\mu, \nu)$-robustly 2-matchable graph on $n$ vertices. Let $H'$ be the $(\varepsilon, d)$-reduced graph of $H$ for some $\varepsilon, d > 0$, obtained from Lemma 3.2 with parameters $\varepsilon, d$ and $\ell = 2$ (and the corresponding bipartition if $H$ is of type 2).

Then $H'$ is $(\mu + rd + 2\varepsilon, \nu - rd - 2\varepsilon)$-robustly 2-matchable. Moreover, if $H$ is of type 1, then $H'$ is of type 1, and if $H$ is of type 2, then $H'$ is of type 2.

**Proof.** Suppose that $H$ has $m$ vertices. If $H$ is a robustly 2-matchable graph of the first type, then Claim 3.3(a) guarantees that $\delta(H) \geq (1/2 - \mu - rd - \varepsilon)m$, and Claim 3.3(c) implies that every set of $(1/2 - \nu)n$ vertices spans at least $(\nu - rd - \varepsilon)m^2$ edges.

Now suppose that $H$ is of type 2 with bipartition $\{A, B\}$. Then $H'$ is balanced bipartite, as well. By Claim 3.3(a), we have $\delta(H) \geq (1/32 - \mu - rd - \varepsilon)m$. By Claim 3.3(b), we have $\deg_H(x) \geq (1/3 - \mu - rd - \varepsilon)m$ for all but at most $(1/64 + \mu + \varepsilon)m$ vertices $x \in V(H)$.

We will also need the following lemma, which provides sufficient conditions for the existence of $b$-matchings in a graph.

**Lemma 3.11.** Let $t, \gamma$ be constants, and let $H$ be a $(\mu, \nu)$-robustly 2-matchable graph on $m$ vertices such that $m/t \leq \gamma \leq \mu \leq \nu/4 \leq 1/5000$. Then $H$ has a perfect $b$-matching for every function $b : V(H) \to \mathbb{Z}^{\geq 0}$ such that

(a) $(1 - \gamma)t \leq b(x) \leq t$ for every $x \in V(H)$,

(b) $\sum_{x \in \Psi} b(x)$ is even for every component $\Psi$ of $H$, and

(c) if $H$ is of type 2 with bipartition $\{X, Y\}$, then $\sum_{x \in X} b(x) = \sum_{y \in Y} b(y)$.

**Proof.** As $\sum_{x \in \Psi} b(x)$ is even in every connected component $\Psi$, we can pair up the vertices with odd $b(x)$ within each component. Take a path in $H$ between each such pair, and let $\omega_0 : E(H) \to \mathbb{Z}^{\geq 0}$ be the function where $\omega_0(e)$ is the number of paths containing $e$. Then it is
Now suppose that \( H \) is of type 2, then we also have
\[
\sum_{x \in X} b_1(x) = \sum_{x \in X} b(x) - \sum_{e \in E(H)} \omega_0(e) = \sum_{y \in Y} b(y) - \sum_{e \in E(H)} \omega_0(e) = \sum_{y \in Y} b_1(y).
\]

Let \( H' \) denote the graph obtained by replacing each vertex \( x \) by a set \( W(x) \) of size \( b_1(x)/2 \) and replacing each edge \( xy \) by a complete bipartite graph with bipartition \( W(x) \cup W(y) \). Then \( H' \) has \( n = \sum_{x \in V(H)} b_1(x)/2 \) vertices, and \( (1 - 2\gamma)t_m/2 \leq n \leq t_m/2 \). We will show that \( H' \) has a perfect 2-matching \( \omega' \). Then \( \omega_1(xy) = \sum_{x \in W(x), y \in W(y)} \omega'(x'y') \) is a perfect \( b_1 \)-matching in \( H \), and hence \( \omega(xy) = \omega_0(xy) + \omega_1(xy) \) is a perfect \( b \)-matching in \( H \).

Let us first consider the case when \( H \) is a robustly 2-matchable graph of the first type. As \( \delta(H) \geq (1/2 - \mu)m \), we readily get \( \delta(H') \geq (1/2 - \mu)(1 - 2\gamma)t_m/2 \geq (1/2 - \mu - \gamma)n \). As in the proof of Claim 3.8, it is enough to show that every independent set in \( H' \) has size at most \( (1/2 - \mu - \gamma)n \), because then \( |N_{H'}(S)| \geq |S| \) holds for every independent \( S \), and we can apply Theorem 3.6 to get a perfect 2-matching.

So take any independent set \( S \) in \( H' \), and observe that if \( u \in S \cap W(x) \) and \( v \in S \cap W(y) \) for some \( x, y \) in \( H \), then \( xy \) is not an edge of \( H \) (otherwise \( v \) and \( w \) are adjacent in \( H' \)). So \( S \subseteq \bigcup_{x \in U} W(x) \) for some independent set \( U \) in \( H \). Since \( H \) is of first type, we have \( |U| \leq (1/2 - \nu)m \). Thus
\[
|S| \leq (1/2 - \nu)m/2 \leq \frac{1/2 - \nu}{1 - 2\gamma} n \leq (1/2 - \nu + 2\gamma)n \leq (1/2 - \mu - \gamma)n,
\]
as needed.

Now suppose that \( H \) is of the second type. In this case, \( \sum_{x \in X} b_1(x) = \sum_{y \in Y} b_1(y) \) guarantees that \( H' \) is also balanced bipartite. Also, \( \delta(H) \geq (1/32 - \mu)m \) implies \( \delta(H') \geq (1/32 - \mu - \gamma)n \) as before. Moreover, for every vertex \( x \) of degree at least \( (1/3 - \mu)m \) in \( H \), we get that every vertex in \( V(x) \) has degree at least \( (1/3 - \mu - \gamma)n \) in \( H' \). As there are at most \( (1/64 + \mu)t_m/2 < (1/64 + \mu + \gamma)n \) exceptions, we see that \( H' \) is \( (\mu + \gamma, \nu) \)-robustly 2-matchable. In particular, by Claim 3.8, it has a perfect 2-matching.

### 3.5 Cycle covers in unbalanced bipartite graphs

Another tool we need is the following variant of a lemma of Erdős, Gyárfás and Pyber [12]. It finds a monochromatic cycle cover of the smaller part of an unbalanced bipartite graph if this part has large minimum degree.

**Lemma 3.12** (Erdős–Gyárfás–Pyber [12]). Let \( H \) be an \( r \)-coloured bipartite graph with bipartition \( \{A, B\} \). Suppose that \( |A| \geq 5000r^3|B| \) and that every vertex in \( B \) has at least \( |A|/20 \) neighbours in \( A \). Then there are \( 20r^2 \) monochromatic pairwise vertex-disjoint proper cycles and edges that together cover all vertices of \( B \).
We give a short proof of this lemma for completeness, although our argument is nearly identical to the original proof. An important ingredient is the following classic result of Pósa (see [29]).

**Theorem 3.13** (Pósa). The vertices of any graph $G$ can be covered with at most $\alpha(G)$ vertex-disjoint cycles.

**Proof of Lemma 3.12.** For $x \in B$ let $N_i(x)$ denote the set of vertices in $A$ adjacent to $x$ in colour $i$. Let $\{B_1, B_2, \ldots, B_r\}$ be a partition of $B$ such that for any $1 \leq i \leq r$ and $x \in B_i$, we have $|N_i(x)| \geq |A|/(20r)$ (clearly, such a partition exists). Define a graph $G_i$ on vertex set $B_i$ for every $i \in \{r\}$ as follows. For $x, y \in B_i$, let $xy$ be an edge of $G_i$ if and only if $|N_i(x) \cap N_i(y)| \geq |A|/5000r^3$. We claim that the independence number of $G_i$ is at most $20r$ for $i \in \{r\}$.

Indeed, suppose otherwise, and let $x_1, \ldots, x_{20r+1} \in B_i$ be pairwise non-adjacent. Then

$$|A| \geq \left| \bigcup_{1 \leq j \leq 20r+1} N_i(x_j) \right| \geq \sum_{1 \leq j \leq 20r+1} |N_i(x_j)| - \sum_{1 \leq j < k \leq 20r+1} |N_i(x_j) \cap N_i(x_k)| \geq |A| \left( 20r + 1 \right) \left( \frac{20r+1}{20r} - \frac{\binom{20r+1}{2} - \binom{20r}{2}}{5000r^3} \right) = |A| \left( \frac{5000r^3 + 250r^2 - 200r^2 - 10r}{5000r^3} \right) > |A|,$$ 

a contradiction.

So $\alpha(G_i) \leq 20r$, and thus by Theorem 3.13, $G_i$ can be partitioned into a family $C_i$ of at most $20r$ vertex-disjoint cycles. Using the definition of $G_i$ and the fact that $|N_i(x) \cap N_i(y)| \geq |A|/5000r^3 \geq |B|$, we can then greedily replace the edges $xy$ in each $C_i$ with $i$-coloured paths $xwy$ (where $w \in N_i(x) \cap N_i(y) \subseteq A$), where each edge uses a distinct vertex $w$, to find at most $20r^2$ monochromatic vertex-disjoint proper cycles and edges in $G$ that cover $B$.  

### 3.6 Random sampling

The following lemma is a well-known Chernoff-type bound on the tail of the binomial distribution (see e.g. [20, Theorem 2.1]).

**Lemma 3.14** (Chernoff bound). Let $X \sim \text{Bin}(n, p)$ be a binomial random variable. Then the following bounds hold for every $0 \leq a \leq 1$.

- $\Pr[X < (1-a)np] \leq e^{-a^2np^2/2}$, and
- $\Pr[X > (1+a)np] \leq e^{-a^2np/3}$.

In our proof, we will need a small set of vertices that contains many neighbours of every large-degree vertex. As shown by the next result, a randomly chosen set satisfies these properties.

**Proposition 3.15.** Let $G$ be a graph on $n$ vertices with $(\varepsilon, d)$-regular partition $\{V_0, \ldots, V_m\}$ as provided by Lemma 3.2. Also, let $p$ be a positive parameter, and let $B \subseteq V = V(G)$ be a vertex set satisfying $|B \cap V_i| \leq 10p|V_i|$ for every $i \in [m]$. If $m \log n/\sqrt{n} < p < 1/100$ and $\varepsilon < 1/10$, then there is a set $A \subseteq V \setminus B$ with the following properties.
(a) $|A| \geq (p/2)n$.

(b) $|A \cap V_i| \leq 2p|V_i|$ for every $i \in [m]$.

(c) $\deg(v, A \cap V_i) \geq (p/2)\deg(v, V_i)$ for every $v \in V$ and $i \in [m]$ with $\deg(v, V_i) > 30p|V_i|$.

(d) $\deg(v, A) \geq |A|/12$ for every vertex $v \in V$ with $\deg(v, V \setminus B) > n/3$.

Proof. Let $A$ be a random subset of $V \setminus B$ where every vertex is included in $A$ independently with probability $p$. We will show that the event that $A$ satisfies all of the properties has positive probability.

(a) Note that $|A| \sim \text{Bin}(|V \setminus B|, p)$, and by assumption, $|B| < 10pn + \varepsilon n < n/3$. Hence, by Lemma 3.14,

$$\Pr[|A| < \frac{p}{2}n] \leq \Pr\left[|A| < \frac{3}{4}|V \setminus B|p\right] < e^{-|V \setminus B|p/32} \leq e^{-np/48}.$$

(b) Again, $|A \cap V_i| \sim \text{Bin}(V_i \setminus B, p)$ so by Lemma 3.14 and $|V_i \setminus B| \geq (9/10)|V_i| > n/(2m)$,

$$\Pr[|A \cap V_i| > 2p|V_i|] < \Pr[|A \cap V_i| > 2p|V_i \setminus B|] < e^{-|V \setminus B|p/3} < e^{-np/(10m)}.$$

(c) Here $\deg(v, A \cap V_i) \sim \text{Bin}(\deg(v, V_i \setminus B), p)$, and as $\deg(v, V_i \setminus B) \geq \deg(v, V_i) - |B \cap V_i| > (2/3)\deg(v, V_i)$, we can apply Lemma 3.14 to get

$$\Pr[\deg(v, A \cap V_i) < \frac{p}{2}\deg(v, V_i)] < e^{-\deg(v, V_i)p/48} < e^{-|V_i|p^2/2} < e^{-np^2/(4m)}.$$

(d) Like in the previous argument, $\deg(v, A) \sim \text{Bin}(\deg(v, V \setminus B), p)$, so by Lemma 3.14 and $\deg(v, V \setminus B) > n/3$,

$$\Pr[\deg(v, A) < \frac{p^2n}{6}] \leq \Pr[\deg(v, A) < \frac{p}{2}\deg(v, V \setminus B)] < e^{-\deg(v, V \setminus B)p/8} \leq e^{-np/24}.$$

But the argument for Property (b) shows that $\Pr[|A| < 2pn] < ne^{-np/(10m)}$, so

$$\Pr[\deg(v, A) < \frac{|A|}{12}] < e^{-np/24} + ne^{-np/(10m)}.$$

Now taking a union bound over all choices of $v$ and $i$, we get that $A$ satisfies all properties with probability at least $1 - n^2e^{-np^2/(4m)} > 0$ (using $p > m \log n/\sqrt{n}$). In particular, there is such a set $A$. \qed

4 Main proof

The proof of Theorem 1.2 comes as a combination of the following two results.
Theorem 4.1. Let $1/n \ll \mu \ll 1$, and let $G$ be an $r$-edge-coloured graph on $n$ vertices with minimum degree $\delta(G) \geq n/2 + 600r \log n$. Then $G$ is the vertex-disjoint union of at most $400r + 2$ monochromatic cycles and a $(\mu, 20\mu)$-robustly 2-matchable graph $H$ on at least $n/2$ vertices.

Theorem 4.2. Let $1/n \ll \mu \ll \nu/20 \ll 1$. Every $r$-edge-coloured $(\mu, \nu)$-robustly 2-matchable graph on $n$ vertices can be partitioned into $2(1/\mu + 20)^3$ monochromatic cycles.

Let us first elaborate on the conditions that are implicit in our $\ll$ notation. We will need to select the five parameters $\nu, \mu, d, \varepsilon$ and $n$, in this order. As a point of reference, we describe here the exact constraints that come from the proofs of Theorems 4.1 and 4.2:

$$
\nu < \frac{1}{1000}, \\
\mu < \min \left\{ \frac{1}{700000}, \frac{\nu}{20} \right\}, \\
d \leq \frac{\mu}{r}, \\
\varepsilon < \min \left\{ \frac{1}{100000}, \frac{\mu^4}{4000}, \frac{d^2}{400}, \varepsilon_{3.1}(d), \varepsilon_{3.4}(d) \right\}, \\
n > \max \left\{ 4 \varepsilon (M_{3.2}(\varepsilon, r, 2))^4, n_{3.1}(\varepsilon), n_{3.4}(\varepsilon) \right\},
$$

where $M_{3.2}, \varepsilon_{3.1}, \varepsilon_{3.4}, n_{3.1}$ and $n_{3.4}$ are the appropriate constants coming from Lemmas 3.1, 3.2 and 3.4. Let us emphasize that $1/n < \varepsilon < d < \mu < \nu < 1$.

Now the proof of Theorem 4.1 is a somewhat technical argument that shows that either $G$ is already robustly 2-matchable of the first type, or it can be turned into a type 2 graph by deleting few monochromatic cycles. We defer its proof to Section 5, and proceed with the proof of Theorem 4.2.

Proof of Theorem 4.2. Let $G = (V, E)$ be an $r$-edge-coloured $(\mu, \nu)$-robustly 2-matchable graph with $20\mu \leq \nu$. If $G$ is of type 2, then it is a balanced bipartite graph, and we denote its bipartition by $\{A, B\}$. By $\ll$, we are guaranteed a partition $V_0, V_1, \ldots, V_m$ of $V(G)$ as detailed in Lemma 3.2. Let $\mathcal{G}$ be the corresponding $(\varepsilon, d)$-reduced graph with $\varepsilon \leq \mu/2$ and $d \leq \mu/r$. If $G$ is of type 2, then $\mathcal{G}$ is also balanced bipartite, and we denote its bipartition by $\{A, B\}$. Note that $\mathcal{G}$ has $m \leq M_{3.2}(\varepsilon, r, 2)$ vertices.

By Lemma 3.10, $\mathcal{G}$ is $(3\mu, \nu - 2\mu)$-robustly 2-matchable. Let $\mathcal{H}$ denote the subgraph of $\mathcal{G}$ that consists of all edges contained in monochromatic components of order at least $(\mu/r)m$. Then $\mathcal{H}$ is the union of at most $(1/\mu)r^2$ monochromatic components, and $\deg_{\mathcal{H}}(x) \geq \deg_{\mathcal{G}}(x) - \mu m$ for every vertex $x$ in $\mathcal{G}$. By Lemma 3.10, $\mathcal{H}$ is $(4\mu, \nu - 3\mu)$-robustly 2-matchable. Moreover, if $G$ is of type 1, then $\mathcal{H}$ is of type 1. And if $G$ is of type 2, then $\mathcal{H}$ is of type 2. As $20\mu \leq \nu \leq 1/1000$ (by $\ll$), Claim 3.8 implies that $\mathcal{H}$ contains a perfect 2-matching $\mathcal{M}$.

Let us now call a vertex $v \in V_i$ ($i \in [m]$) *good* if $v$ has typical degree in each regular pair $(V_i, V_j)$ that corresponds to an edge of $\mathcal{M}$. In other words, $v$ is good if $\deg_{c}(v, V_j) \geq (d - \varepsilon)|V_j|$ for each edge $x_ix_j \in \mathcal{M}$ of colour $c$. We call all other vertices of $G$ *bad*. 

Claim 4.3. There is a collection $C^b$ of at most $20r^2$ vertex-disjoint monochromatic proper cycles and edges covering all bad vertices such that

$$|V_i \cap V(C^b)| \leq 5\sqrt{\varepsilon}|V_i| \quad \text{for every } i \in [m]. \quad (4.1)$$

Proof. Let $B$ be the set of bad vertices (note that $V_0 \subseteq B$). By (3.1), and because $M$ is a 2-matching, we know that $|B \cap V_i| \leq 2\varepsilon|V_i|$ for every $i \in [m]$. In particular, $|B| \leq 2\varepsilon|V_i| \cdot m + |V_0| \leq 2\varepsilon|V_i| \cdot m + \varepsilon n \leq 3\varepsilon n$.

This means that we can apply Proposition 3.15 with $p = 2\sqrt{\varepsilon}$ to obtain a set $A$ of size $|A| \geq \sqrt{\varepsilon n} \geq 15000r^3\varepsilon n \geq 5000r^3|B|$ such that $|A \cap V_i| \leq 4\sqrt{\varepsilon}|V_i|$ for every $i \in [m]$, and each vertex $v \in G$ with $\deg_G(v, V \setminus B) > n/3$ has at least $|A|/12$ neighbours in $A$. As $\delta(G) \geq n/2$ and $|B| < n/6$, this actually holds for every vertex of $G$. But then Lemma 3.12 provides a set $C^b$ of $20r^2$ disjoint monochromatic proper cycles and edges covering $B$. Note that the vertices of $C^b$ are contained in $A \cup B$, so (4.1) clearly holds.

Claim 4.4. There is a collection $C^h$ of at most $(1/\mu)r^2$ vertex-disjoint monochromatic proper cycles and edges, all disjoint from $C^b$, such that

(a) for every edge $e = x_ix_j$ of $H$, there is an edge $u_ev_e$ of colour $c(e)$ in $C^h$ between vertices $u_e \in V_i$ and $v_e \in V_j$ that have typical degree in the regular pair $(V_i, V_j)$, and

(b) $|V_i \cap V(C^h)| \leq \varepsilon|V_i|$ for every $i \in [m]$.

Proof. We will apply a simple algorithm to find one cycle for each monochromatic component of $H$. For this, take a component $\Phi$ of colour $c$, and let $e_1, \ldots, e_s \in E(H)$ be its edges. We will repeat each of the following two steps for $i = 1, \ldots, s$:

(1) Let $e_i = y_iz_i$, and pick $u_i \in V(y_i)$ and $v_i \in V(z_i)$ that are not yet used, but have typical degree in the regular pair $(V(y_i), V(z_i))$, and $u_iv_i$ is a $c$-coloured edge in $G$.

(2) Use Lemma 3.4 to find a $c$-coloured $v_i-u_{i+1}$ path $P_i$ in $G$ of order at most $2m$ that avoids all previously used vertices (except $v_i$ and $u_{i+1}$).

If these steps work, then $C^h = u_1v_1P_1u_2v_2P_2 \ldots u_sv_sP_su_1$ is a $c$-coloured cycle that takes care of all edges in $\Phi$. Repeating this gives us $(1/\mu)r^2$ disjoint monochromatic cycles satisfying Condition (a). Condition (b) is also satisfied because the edges and paths produced by these steps use at most $|E(H)| \cdot 2m \leq m^3 \leq \varepsilon|V_i|$ vertices in $G$ (using $n > 2m^4/\varepsilon$ and $|V_i| > n/(2m)$ in the second inequality). We just need to check that these steps can indeed be applied.

For Step (1), note that by (3.1), $V(y_i)$ and $V(z_i)$ each have at least $(1 - \varepsilon)|V(y_i)|$ typical vertices, of which at least $(1 - 2\varepsilon)|V(y_i)|$ are unused, as noted above. But then there is an edge between unused typical vertices in colour $c$ because $\varepsilon < 1/3$ and $(V(y_i), V(z_i))$ is $\varepsilon$-regular. For Step (2), we just need to apply Lemma 3.4 with the set $W$ of all previously used vertices except $v_i$ and $u_{i+1}$. This is possible because $|W| < \varepsilon|V_i|$.

Note that $C^b$ and $C^H$ together contain at most $(1/\mu + 20)\nu^2$ cycles. For parity reasons, we need another small collection $C^s$ of single vertices. For every component $\Psi$ of $\mathcal{H}$, add a single vertex of $\bigcup_{x \in \Psi} V(x) \setminus V(C^b \cup C^H)$ to $C^s$ if $|\bigcup_{x \in \Psi} V(x) \setminus V(C^b \cup C^H)|$ is odd. Since $\mathcal{H}$ is $(4\mu, \nu - 3\mu)$-robustly 2-matchable, $\mathcal{H}$ has at most two components. Thus we have $|C^s| \leq 2$. Write $C^0 = C^b \cup C^H \cup C^s$, and note that

$$|V_i \cap V(C^0)| \leq |V_i \cap V(C^b \cup C^H \cup C^s)| \leq (5\sqrt{\varepsilon} + \varepsilon)|V_i| + 2 \leq 6\sqrt{\varepsilon}|V_i| \quad (4.2)$$

for every $i \in [m]$. The rest of the proof will extend the cycles in $C^H$ so that they cover all the remaining vertices.

More precisely, $C^H$ will serve as the “skeleton” of our cycle cover in the sense that we will use Lemma 3.1 to replace each edge $u_\varepsilon v_\varepsilon$ (corresponding to some $e = x_i x_j$ in $\mathcal{H}$) with a $u_\varepsilon v_\varepsilon$ path $P_\varepsilon$ in $(V_i, V_j)$. But first we need to decide how long these paths should be. So for $C^0 = C^b \cup C^H \cup C^s$, fix an $\ell$ such that

$$(1 - \varepsilon^{1/4})|V_i| \leq \ell \leq (1 - \varepsilon^{1/4})|V_i| + 2 \text{ and } \ell \text{ is divisible by } 2. \quad (4.3)$$

Our plan is to cover at least $\ell$ vertices in each cluster by the paths corresponding to the edges of the 2-matching $\mathcal{M}$. By (4.2), this leaves

$$b(x_i) = |V_i \setminus V(C^0)| - \ell \geq \varepsilon^{1/4}|V_i| - |C^0| - 2 \geq 0 \quad (4.4)$$

vertices in each $V_i$. Note also that $b(x_i) = |V_i \setminus V(C^0)| - \ell \leq \varepsilon^{1/4}|V_i|$.

**Claim 4.5.** $\mathcal{H}$ has a perfect $b$-matching $\omega_0 : E(\mathcal{H}) \to \mathbb{Z}^{\geq 0}$.

**Proof.** By (4.4) and since $6\varepsilon^{1/4} < \mu$, we have

$$(1 - \mu)\varepsilon^{1/4}|V_i| \leq \varepsilon^{1/4}|V_i| - |C^0| - 2 \leq b(x_i) \leq \varepsilon^{1/4}|V_i|. $$

Moreover, the definition of $C^s$ implies that $\sum_{x \in \Psi} b(x)$ is even for every component $\Psi$ of $\mathcal{H}$. Recall that $\mathcal{H}$ is $(4\mu, \nu - 3\mu)$-robustly 2-matchable. If $G$ is of type 1, then $\mathcal{H}$ is of type 1 and we can finish by Lemma 3.11.

Suppose that $G$ is of type 2 and thus $\mathcal{H}$ is of type 2 as well. Recall that $G$ has bipartition $\{A, B\}$ and $\mathcal{H}$ has bipartition $\{A, B\}$. Moreover, $\bigcup_{x \in A} V(x) \subseteq A$ and $\bigcup_{y \in B} V(y) \subseteq B$. Since $G$ is balanced bipartite and $C^b \cup C^H$ consists of proper cycles and edges, it follows that $\sum_{x \in A} b(x) = \sum_{y \in B} b(y)$. Therefore, we can finish by Lemma 3.11. \qed

Let $\omega_0$ be the perfect $b$-matching guaranteed by Claim 4.5. Define $\omega : E(\mathcal{H}) \to \mathbb{Z}^{\geq 0}$ as

$$\omega(x_i x_j) = \begin{cases} 
\omega_0(x_i x_j) & \text{for } x_i x_j \notin \mathcal{M}, \\
\omega_0(x_i x_j) + \frac{\ell}{\deg_{\mathcal{M}}(x_i)} & \text{for } x_i x_j \in \mathcal{M}.
\end{cases}$$

Note that this is well-defined because $\deg_{\mathcal{M}}(x_i) = \deg_{\mathcal{M}}(x_j)$, and integral because $\ell$ is even and $\deg_{\mathcal{M}}(x_i) \in [2]$. Then for every vertex $x_i$ in $\mathcal{H}$, we have $\sum_{x \in \mathcal{H}} \omega(e) = |V_i \setminus V(C^0)|$ and
\[ \sum_{x_i \in V \setminus \mathcal{M}} \omega(e) \leq b(x_i) \leq \varepsilon^{1/4}|V_i|. \]

**Claim 4.6.** For every edge \( e = x_i x_j \) in \( E(H) \), there is a \( u_e-v_e \) path \( P_e \) of colour \( c(e) \) in \( G[V_i, V_j] \) that contains exactly \( \omega(e) + 1 \) vertices in both \( V_i \) and \( V_j \). Moreover, these paths can be chosen so that they are internally vertex-disjoint from each other and from \( C^0 \).

**Proof.** Let us first apply Proposition 3.15 with \( p = 2\sqrt{\varepsilon} \) and \( B = V(C^0) \) to get a set \( S^1 \), and then apply it again with the same \( p \) and \( B = V(C^0) \cup S^1 \) to get another such set \( S^2 \). This is possible because \( V(C^0) \cap V_i \leq 6\sqrt{\varepsilon}|V_i| \), and consequently, \( |S^1 \cap V_i| \leq 4\sqrt{\varepsilon}|V_i| \) for every \( i \in [m] \).

Let \( \sum_{x_i \in V \setminus \mathcal{M}} \omega(e) \leq b(x_i) \leq \varepsilon^{1/4}|V_i| \).

(a) \( |S^6_i| \leq 4\sqrt{\varepsilon}|V_i| \) for every \( i \in [m] \) and \( b \in [2] \), and

(b) for every edge \( x_i x_j \) in \( H \) of colour \( c \) and every vertex \( v \in V_j \) with typical degree in the regular pair \( (V_i, V_j) \), we have \( \deg_c(v, S^1_i) \geq 4\varepsilon|V_i| \) for \( b \in [2] \).

To see (b), note that every such vertex \( v \) of typical degree satisfies \( \deg_c(v, V_i) \geq (d - \varepsilon)|V_i| > 60\sqrt{\varepsilon}|V_i| \), so by Proposition 3.15, \( \deg_c(v, S^1_i) \geq \sqrt{d-\varepsilon}|V_i| > 60\varepsilon|V_i| \) (using \( d \leq 61\sqrt{\varepsilon} \)).

Let us first consider the edges \( e_1, \ldots, e_s \) of \( H \setminus \mathcal{M} \). We will find the \( u_{k-v_k} \) paths \( P_k \) (where \( u_{k-v_k} \) is the edge in \( C^H \) corresponding to \( e_k \), as obtained in Claim 4.4) one by one so that for every \( k \), the vertex set of \( P_k = \bigcup_{j = 1}^{k-1} P_j \) is disjoint from each \( S^2_i \), and intersects each \( S^1_i \) in at most \( k - 1 \) vertices. Suppose we have already found \( P_1, \ldots, P_{k-1} \). Let us also assume that \( u_k \in V_i \) and \( v_k \in V_j \) (so \( e_k = x_i x_j \)), and let \( c \) be the colour of \( e_k \).

If \( \omega(e_k) = 0 \), then there is nothing to do: we can take \( P_k = u_k v_k \). If \( \omega(e_k) = 1 \), then \( \deg_c(u_k, S^1_j \setminus V(P_k)) \geq 4\varepsilon|V_j| - k \geq \varepsilon|V_j| \) (using \( \varepsilon|V_i| > \varepsilon n/(2m) > m^2 \)) and similarly, \( \deg_c(v_k, S^1_i \setminus V(P_k)) \geq \varepsilon|V_i| \). Hence, by regularity, we can find adjacent vertices \( u \in S^1_i \setminus V(P_k) \) and \( v \in S^1_j \setminus V(P_k) \) where \( P_k = u_k v w u_k \) is a \( c \)-coloured path, as needed.

So suppose \( \omega(e_k) > 1 \). Let \( W = V(C^0) \cup S^1 \cup S^2 \cup V(P_k) \) be the set of “forbidden” vertices. We will again need neighbours \( u \in S^1_i \setminus V(P_k) \) and \( v \in S^1_j \setminus V(P_k) \) of \( v_k \) and \( u_k \), but this time we want to apply Lemma 3.1 to connect them with a \( u-v \) path of the right length that avoids \( W \).

We have seen above that \( \deg_c(u_k, S^1_i \setminus V(P_k)) \geq \varepsilon|V_j| \). Also,

\[ |V_i \setminus W| \geq |V_i| - |V_i \cap V(C^0)| - |S^1_i| - |S^2_i| - b(x_i) \geq (1 - 14\sqrt{\varepsilon} - \varepsilon^{1/4})|V_i| \geq |V_i|/2, \]

so by regularity, there is a neighbour \( v \in S^1_i \setminus V(P_k) \) of \( u_k \) such that \( \deg_c(v, V_i \setminus W) \geq (d - \varepsilon)|V_i|/2 \geq \varepsilon|V_i| \). Similarly, there is a neighbour \( u \in S^1_j \setminus V(P_k) \) of \( v_k \) such that \( \deg_c(u, V_j \setminus W) \geq \varepsilon|V_i| \). As \( \omega(e_k) \leq \varepsilon^{1/4}|V_i| \leq \sqrt{1 - \varepsilon^2})|V_i \setminus W| \), we can apply Lemma 3.1 to find a \( c \)-coloured \( v-u \) path \( P' \) of order \( \omega(e_k) \) that is internally vertex-disjoint from \( W \). But then \( P_k = u_k v P' w u_k \) is a path satisfying our requirements.

Finally, let \( e_{s+1}, \ldots, e_{s+t} \) be the edges of \( \mathcal{M} \). Note that each vertex of \( H \) touches exactly one or two of these edges. Using the same notation as before, we will find the \( u_{k-v_k} \) paths \( P_k \) so that
\( \mathcal{P}_k \) is disjoint from \( S_i^2 \) unless \( e_k = x_ix_j \) is the last edge at \( x_i \) (according to the ordering), and similarly for \( x_j \).

Fix \( k \), and let \( U_i = V_i \setminus (V(C^0) \cup V(\mathcal{P}_k)) \) if \( e_k \) is the last edge at \( x_i \), and let \( U_i = V_i \setminus (V(C^0) \cup V(\mathcal{P}_k) \cup S_i^2) \) otherwise. Using \( |S_i^2| \leq \ell/2 \) and the assumption that \( \varepsilon \) is small (see \((\ll))\), it is easy to check from the definitions that we have \( |U_i| \geq \omega(e_k) \geq \ell/2 \geq |V_i|/3 \). We similarly get \( |U_j| \geq \omega(e_k) \geq |V_i|/3 \) for the analogously defined \( U_j \).

We want to use Lemma 3.1 to find the required \( u_k-v_k \) path \( P_k \) of order \( 2(\omega(e_k) + 1) \). As \( \min\{|U_i \cup \{u_k\}|, |U_j \cup \{v_k\}|\} \geq \omega(e_k) + 1 \), we just need to check that \( \delta(G[U_i, U_j]) \geq 4\varepsilon|V_i| \). This follows from the properties of \( S_i^1 \) and \( S_i^2 \): If \( e_k \) is the last edge at \( x_i \), then \( S_i^2 \subseteq U_i \), and otherwise all but \( k \) vertices of \( S_i^1 \) are in \( U_i \). Either way, \( \deg_c(v, U_i) \geq 2\sqrt{\varepsilon}|V_i| - k \geq 4\varepsilon|V_i| \) for every \( v \in U_j \), and we similarly get \( \deg_c(u, U_j) \geq 4\varepsilon|V_j| \) for every \( u \in U_i \), as needed.

Now for every \( e \in E(\mathcal{H}) \), we replace the edge \( u_au_v \) with the path \( P_e \) in the appropriate cycle of \( C^0 \). This gives us \( 2(1/\mu + 20)r^2 \) monochromatic cycles that cover all vertices in \( V_0 \), and (by the definition of the function \( \omega \)) \( |V_i| \) vertices in each \( V_i \). In other words, we find a monochromatic cycle partition of \( G \), as needed.

## 5 The structural lemma

Let us now prove the main structural lemma from Section 4.

**Theorem 4.1.** Let \( 1/n \ll \mu \ll 1 \), and let \( G \) be an \( r \)-edge-coloured graph on \( n \) vertices with minimum degree \( \delta(G) \geq n/2 + 600r\log n \). Then \( G \) is the vertex-disjoint union of at most \( 400r + 2 \) monochromatic cycles and a \((\mu, 20\mu)\)-robustly \( 2 \)-matchable graph \( H \) on at least \( n/2 \) vertices.

Our proof makes use of a classic result of Bondy and Simonovits on the extremal number of even cycles.

**Theorem 5.1** (Bondy–Simonovits, [4]). Let \( G \) be a graph on \( n \) vertices with at least \( e \) edges, and let \( \ell \) be such that \( \ell \leq e/(100n) \) and \( \ell n^{1/\ell} \leq e/(10n) \). Then \( G \) contains a cycle of length exactly \( 2\ell \).

More precisely, we need the following immediate corollary:

**Corollary 5.2.** Let \( \ell \geq (2/\log 10)\log n \) be even. Then every graph on \( n \) vertices with average degree at least \( 100\ell \) contains a cycle of length \( \ell \).

The main idea of the proof of Theorem 4.1 is to show that if \( G \) is not robustly \( 2 \)-matchable of the first type, then it has a bipartition \( \{X, Y\} \) such that \( G[X, Y] \) is essentially robustly \( 2 \)-matchable of the second type, except it might be unbalanced. We use Corollary 5.2 to balance out this bipartite subgraph by covering some vertices of \( G \) with cycles induced by \( X \) and \( Y \).
Proof of Theorem 4.1. First of all, we may assume that $n$ is even, as otherwise, we can take any single vertex to be one of the cycles in $C$.

Let us now assume that $G$ is not $(\mu, 20\mu)$-robustly 2-matching of the first type. The following claim provides us with useful information regarding the structure of $G$. Its proof, while somewhat technical, is routine.

Claim 5.3. There is a partition $\{X, Y\}$ of the vertices with the following properties.

(a) $|X| \geq |Y| \geq \frac{n}{2} - 540\mu n$,

(b) $\delta(G[X, Y]) \geq \frac{n}{10} - 1080\mu n$,

(c) all but $10800\mu n$ vertices have degree at least $\frac{2n}{5} - 1080\mu n$ in $G[X, Y]$, and

(d) if $|X| > \frac{n}{2}$ we have $\Delta(G[X]) \leq \frac{n}{10}$.

Proof. As $\delta(G) \geq n/2$, the assumption that $G$ is not type 1 $(\mu, 20\mu)$-robustly 2-matchable implies the existence of a set $S_0$ of size at least $(1/2 - 20\mu)n$ that spans fewer than $20\mu n^2$ edges. This set $S_0$ cannot contain more than $480\mu n$ vertices $v$ satisfying $\deg_G(v, S_0) \geq n/12$, so there is a subset $S_1 \subseteq S_0$ of size exactly $(1/2 - 500\mu)n$ such that $\Delta(G[S_1]) \leq n/12$.

Now let $T$ be the set of vertices not in $S_1$ that send at least $2n/5$ edges into $S_1$, and let $S_2$ be the set of vertices not in $S_1 \cup T$. If $q$ denotes the size of $S_2$, then we have $|S_1| = n/2 - 500\mu n$ and $|T| = n/2 + 500\mu n - q$. We can bound $q$ by double-counting the edges of $G$ between $S_1$ and $T \cup S_2$. Indeed, counting from $S_1$, the number of such edges is at least $|S_1| \cdot n/2 - 40\mu n^2 = (n/2)^2 - 290\mu n^2$.

On the other hand, counting from $T \cup S_2$, there are at most

$$|T||S_1| + |S_2| \cdot \frac{2n}{5} \leq \left(\frac{n}{2} + 500\mu n - q\right) \frac{n}{2} + q \cdot \frac{2n}{5} = \left(\frac{n}{2}\right)^2 + 250\mu n^2 - q \cdot \frac{n}{10}$$

such edges. Putting these together, we get that $q \cdot n/10 \leq 540\mu n^2$, so $q \leq 5400\mu n$.

Setting $S = S_1 \cup S_2$, we obtain the following bounds on the degrees in $G[S, T]$.

- for every $v \in T$, $\deg(v, S) \geq \frac{2n}{5}$;
- for every $v \in S_1$, $\deg(v, T) \geq \frac{n}{2} - \Delta(G[S_1]) - |S_2| \geq \frac{2n}{5} - 540\mu n$;
- for every $v \in S_2$, $\deg(v, T) \geq \frac{n}{2} - \frac{2n}{5} - |S_2| > \frac{n}{16} - 540\mu n$.

Now let $X_0$ be the larger of the two sets $S$ and $T$, and let $Y_0$ the smaller one. We then have $|X_0| = n/2 + k$ and $|Y_0| = n/2 - k$, where $k = |500\mu n - q| \leq 5400\mu n$. Let $Z \subseteq X_0$ be the set of vertices in $X_0$ with at least $n/16$ neighbours in $X_0$.

If $|Z| \geq k$, then let $Z_0 \subseteq Z$ be a subset of size $k$. We claim that $X = X_0 \setminus Z_0$ and $Y = Y_0 \cup Z_0$ satisfy the conditions. Indeed, as $|Z_0| \leq 5400\mu n$, we get $\deg(v, X) \geq \deg(v, X_0) - 5400\mu n$ for every vertex $v$ in $Y$, and $\deg(v, Y) \geq \deg(v, Y_0)$ for every $v \in X$. Combining this with (5.1), we see that $\delta(G[X, Y]) \geq n/16 - 10800\mu n$, and every vertex not in $S_2 \cup Z$ has degree at least $2n/5 - 10800\mu n$, establishing (b) and (c). As $|X| = |Y| = n/2$, (a) and (d) are also satisfied.
If \(|Z| < k\), then we take \(Z_0 = Z\) instead. The same argument shows that (b) and (c) hold. The definition of \(Z\) implies \(\Delta(G[X]) < n/16\), establishing (d), while (a) holds because \(k \leq 5400 \mu n\).

\(\square\)

Let \(X\) and \(Y\) be as in the claim. If \(|X| = |Y|\), then set \(H = G[X,Y]\). As will see, this satisfies the conditions. In the meantime, we may assume that \(|X| = n/2 + k\) for some \(0 < k \leq 5400 \mu n\).

Let us first consider the case when \(k \geq 400r \log n\). We can write \(2k = \ell_1 + \cdots + \ell_t\) as the sum of \(t \leq 400r + 1\) even numbers such that \(k/(400r) \leq \ell_i \leq k/(200r)\) for every \(i\). We will find pairwise disjoint monochromatic cycles \(C_1, \ldots, C_t\) in \(X\), where each \(C_i\) has length \(\ell_i\).

Suppose we have already found \(C_1, \ldots, C_{i-1}\) with these properties. We want to apply Corollary 5.2 to find \(C_i\). As \(\delta(G) \geq n/2\), the minimum degree of \(G[X]\) is at least \(k\), therefore \(X\) induces at least \(k|X|/2 \geq kn/4\) edges. On the other hand, (d) implies that the vertices of \(C_1, \ldots, C_{i-1}\) touch at most \(2k \cdot n/16 = kn/8\) edges. That is, at least half of the edges in \(G[X]\) are not incident with any of the cycles \(C_1, \ldots, C_{i-1}\), and hence the average degree induced by \(X' = X \setminus V(C_1 \cup \cdots \cup C_{i-1})\) is at least \(k/2\). The average degree of \(G[X']\) in the most common colour (say blue) is then at least \(k/(2r) \geq 100\ell_i\), so Corollary 5.2 provides the blue cycle of length \(\ell_i\), as needed (using \(\ell_i \geq \log n \geq (2/\log 10) \log n\).

Let \(C\) be the set of cycles \(C_1, \ldots, C_t\), and the singleton cycle if the original graph had odd order. Then \(C\) contains at most \(400r + 2\) cycles, and \(A = X \setminus V(C)\) and \(B = Y \setminus V(C)\) satisfy \(|A| = |B| = n/2 - k \geq (1/2 - 5400 \mu n) n\). In this case, we choose \(H = G[A,B]\).

Finally, suppose \(0 < k < 400r \log n\), and let \(\log n \leq \ell < \log n + 2\) be even. We can write \(\ell + 2k = \ell_1 + \cdots + \ell_t\) as the sum of \(t \leq 200r + 1\) even numbers such that \(\log n \leq \ell_i \leq 2 \log n\) for every \(i\). We will again find a monochromatic cycle \(C_i\) of length \(\ell_i\) in \(G[X]\) for every \(i\), but this time we will also need an \(\ell\)-cycle \(C\) induced by \(Y\) to balance out the graph.

The minimum degree of \(G[Y]\) is at least \(n/2 + 600r \log n - (n/2 + k) \geq 100r \ell\), so the most common colour (say blue) has average degree at least \(100 \ell\). By Corollary 5.2, there is a blue cycle \(C\) of length \(\ell\) in \(Y\).

To find \(C_1, \ldots, C_t\), we use the same argument as before. Suppose we already have \(C_1, \ldots, C_{i-1}\). The minimum degree of \(G[X]\) is at least \(600r \log n\), so \(X\) induces at least \(300r \log n\) edges. Out of these, at most \(2k \cdot n/16 = kn/8 \leq 50rn \log n\) are incident with some of the cycles \(C_1, \ldots, C_{i-1}\). Hence, the average degree in \(G[X']\), where \(X' = X \setminus V(C_1 \cup \cdots \cup C_{i-1})\), is at least \(200r \log n\), and the average in the majority colour (say blue) is at least \(200 \log n \geq 100 \ell_i\). As \(\ell_i \geq \log n\), we can use Corollary 5.2 to find a blue cycle \(C_i\) of length \(\ell_i\) in \(X'\), as needed.

Again, let \(C\) be the set of cycles \(C, C_1, \ldots, C_t\) and possibly a singleton. Then \(C\) contains at most \(200r + 3\) cycles, and \(A = X \setminus V(C)\) and \(B = Y \setminus V(C)\) satisfy \(|A| = |B| = n/2 - k - \log n - 2\).

We set \(H = G[A,B]\).

In either of the cases, \(H\) is obtained from \(G[X,Y]\) by deleting at most \(2k + 2 \log n + 4\) vertices, so each of the degrees can decrease by at most this value compared to (b) and (c). Assuming \(\mu < 1/700000\) and \(n > 100000\), we have \(2k + 2 \log n + 4 \leq 10800 \mu n + 2 \log n + 4 \leq n/32\).
Then it is easy to check that $H$ is a balanced bipartite graph on at least $n/2$ vertices, such that $\delta(H) \geq n/32$, and all but $n/64$ vertices have degree at least $n/3$. This $H$ is indeed a $(\mu, 20\mu)$-robustly 2-matchable graph of the second type. \hfill $\square$

6 Sharpness for the minimum degree

In this section we prove Theorem 1.1, which shows that the minimum degree condition in Theorem 1.3 is almost best possible.

Proof of Theorem 1.1. Our construction is based on the following claim.

Claim 6.1. For every sufficiently large $n$, there is a graph on $n$ vertices with minimum degree at least $\log n$ that does not contain any proper cycle of length shorter than $\log n/(4\log \log n)$.

Proof. During this proof, all cycles will be proper. Our construction is probabilistic. We start with the Erdős–Rényi random graph $G(n, p)$ on $n$ vertices, where any two vertices are connected by an edge independently with probability $p = 8 \log n/n$. Next, we take a maximal collection $\mathcal{C}$ of edge-disjoint cycles of length less than $k = \log n/(4\log \log n)$. By maximality, $G' = G(n, p) \setminus E(\mathcal{C})$ has no cycles whose length is shorter than $k$. So it is enough to show that $\delta(G') \geq \ell = \log n$ with positive probability.

To see this, first note that $\deg_{G(n, p)}(v) \sim \text{Bin}(n - 1, p)$ for every vertex $v$, so we can use the Chernoff bounds to bound the probability that the degree is small. Let $\mathcal{A}$ be the event that some vertex of $G(n, p)$ has degree less than $3\log n$. By Lemma 3.14 (with $a = 5/8$) and a union bound over the vertices, we get $\Pr[\mathcal{A}] \leq n \cdot e^{-(25/16) \log n} < 1/3$ for large enough $n$.

Now for every vertex $v$ of $G(n, p)$, let $\mathcal{B}_v$ be the event that $v$ is incident with at least $\ell$ pairwise edge-disjoint cycles of length shorter than $k$. Note that there are at most $n^{(k_1 - 1) + \cdots + (k_\ell - 1)}$ potential sets of $\ell$ edge-disjoint cycles of lengths $k_1, \ldots, k_\ell$ touching $v$, and each of them is a subgraph of $G(n, p)$ with probability $p^{k_1 + \cdots + k_\ell}$. Hence

$$\Pr[\mathcal{B}_v] \leq \sum_{3 \leq k_1, \ldots, k_\ell < k} n^{k_1 + \cdots + k_\ell - \ell} p^{k_1 + \cdots + k_\ell} \leq \left(\frac{1}{n} \cdot \sum_{k' < k} (np)^{k'}\right)^\ell \leq \left(\frac{(np)^k}{n}\right)^\ell \leq \left(\frac{1}{\sqrt{n}}\right)^\log n$$

using $(np)^k = (8 \log n)^{\log n/4\log \log n} \leq \sqrt{n}$. This means that the probability that $\mathcal{B} = \bigcup \mathcal{B}_v$ holds is at most $n \cdot n^{-(\log n)/2} < 1/3$ for large enough $n$.

So with positive probability, neither $\mathcal{A}$, nor $\mathcal{B}$ occur. But then every vertex $v$ touches at least $3\log n$ edges in $G(n, p)$, and at most $2\log n$ of those can appear in $\mathcal{C}$. This implies $\delta(G') \geq \log n$, as needed. \hfill $\square$

Let $A$ and $B$ be disjoint sets, such that $|A| = n/2 + \log n/(16 \log \log n)$, and $|B| = n - |A|$. Let $G$ be a graph with vertex set $A \cup B$, where all $A$-$B$ edges are present and are red, and $G[B]$ is a blue graph provided by Claim 6.1. So $G[B]$ has minimum degree at least $\log |B| \geq \log n - 2 \geq \log n/(8 \log \log n)$, and it induces no proper cycle shorter than $\log n/(4 \log \log n)$. 

19
Note that $G$ has minimum degree at least $n/2 + \log n/(16 \log \log n)$. Also, every red cycle in $G$ is either a singleton, or it covers an equal number of vertices in $A$ and $B$. Moreover, every blue cycle is either a singleton, an edge, or has length at least $\log n/(4 \log \log n)$.

Let $C$ be a collection of vertex-disjoint monochromatic cycles covering all vertices of $G$. If $C$ contains a proper blue cycle (of length at least $\log n/(4 \log \log n)$), then the remaining cycles of $C$ must cover at least $\log n/(8 \log \log n)$ more vertices in $A$ than in $B$. But $A$ is independent, so this is only possible if $C$ contains at least $\log n/(8 \log \log n)$ singletons. So $C$ cannot contain any proper blue cycle. But then, as $C$ covers $\log n/(8 \log \log n)$ more vertices in $B$ than in $A$, it must contain at least $\log n/(16 \log \log n)$ singletons or blue edges. Hence, in any case, $C$ consists of at least $\log n/(16 \log \log n)$ cycles, as desired. □

7 Sharpness for the number of cycles

The goal of this section is to prove Theorem 1.3, which shows that the number of cycles we use to partition the vertices is best possible, up to a constant factor.

We start with some preliminary lemmas.

Lemma 7.1. Every $n$-vertex graph $G$ with $e(G) \geq (1 - \varepsilon^2)n^2/2$ has a subgraph $H$ with $\delta(H) \geq (1 - 2\varepsilon)n$.

Proof. Let $S$ be the set of vertices $v$ in $G$ with $\deg(v) \leq (1 - \varepsilon)n$. We have $2e(G) \leq (n - |S|)n + |S|(1 - \varepsilon)n = n^2 - \varepsilon|S|n$ which combined with $e(G) \geq (1 - \varepsilon^2)n^2/2$ gives $|S| \leq \varepsilon n$. Then $H = G \setminus S$ is a graph with $\delta(H) \geq (1 - \varepsilon)n - |S| \geq (1 - 2\varepsilon)n$. □

Our argument uses the following theorem.

Theorem 7.2 (Gyárfás–Székely [18]). Every properly edge-coloured graph $G$ on $n$ vertices with $\delta(G) \leq n/2$ has a rainbow matching of size $\delta(G) - 2\delta(G)^{2/3}$.

Corollary 7.3. For $\varepsilon > 0$ and large enough $n$, every properly edge-coloured $n$-vertex graph $G$ with $\delta(G) \geq n/2$ has a rainbow matching of size $(1 - \varepsilon)n/2$.

Proof. Delete edges from $G$ to get a spanning subgraph $H$ with $\delta(H) = n/2$, and apply Theorem 7.2 to $H$. We get a rainbow matching of size $n/2 - 2(n/2)^{2/3} \geq (1 - \varepsilon)n/2$ (for sufficiently large $n$). □

Lemma 7.4. For $\varepsilon > 0$ and large enough $n$, every properly edge-coloured $n$-vertex graph $G$ with $e(G) \geq (1 - \varepsilon^2)n^2/2$ has a rainbow matching of size $(1 - 3\varepsilon)n/2$.

Proof. Apply Lemma 7.1 to get a subgraph $H$ on $m$ vertices with $\delta(H) \geq (1 - 2\varepsilon)n$. Apply Corollary 7.3 to $H$ (using that $\delta(H) \geq m/2$) in order to get a rainbow matching that has size $(1 - \varepsilon)m/2 \geq (1 - \varepsilon)\delta(H)/2 \geq (1 - \varepsilon)(1 - 2\varepsilon)m/2 \geq (1 - 3\varepsilon)m/2$. □

The following lemma is a bipartite version of the theorem we are aiming for.
**Lemma 7.5.** For any $\varepsilon > 0$ and sufficiently large $r$, there is an $r$-edge-coloured bipartite graph $G$ with parts $X$ and $Y$ such that

(a) $\deg(x) \geq (1 - 3\varepsilon)|Y|$ for all $x \in X$, and

(b) $X$ cannot be covered by fewer than $\varepsilon^2 r^2/4$ monochromatic components in $G$.

**Proof.** Let $Y$ be a set of size $r$. Let $K_Y$ be an auxiliary properly $r$-edge-coloured complete graph on vertex set $Y$. Let $X$ be the set of rainbow matchings in $K_Y$ of size $(1 - 3\varepsilon)r/2$.

The graph $G$ is defined as follows: For any $x \in X$ and $y \in Y$, we add the edge $xy$ to $G$ in colour $i$ if the rainbow matching $x$ of $K_Y$ contains a colour-$i$ edge through $y$. If the rainbow matching $x$ does not contain any edge through $y$, then $xy$ is not present in $G$.

To see that (a) holds, notice that every $x \in X$ is connected to all the vertices of $Y$ that appear in the rainbow matching $x$ of $K_Y$. Since the rainbow matching $x$ has size $(1 - 3\varepsilon)r/2$, we get $\deg(x) \geq (1 - 3\varepsilon)|Y|$.

Let $uv$ be an $i$-coloured edge of $K_Y$, and let $X_{uv} \subseteq X$ be the set of rainbow matchings containing $uv$. We claim that $T_{uv} = \{u, v\} \cup X_{uv}$ is an $i$-coloured component of $G$. Indeed, $u$ and $v$ are only adjacent to $X_{uv}$ in colour $i$ because $K_Y$ is properly coloured. Also, the matchings in $X_{uv}$ contain no $i$-coloured edges other than $uv$ because they are rainbow. This shows that every monochromatic component of $G$ is either of the form $T_{uv}$ or is a singleton.

Let $T_1, \ldots, T_k$ be any family of $k \leq \varepsilon^2 r^2/4$ monochromatic components in $G$. We will find a vertex in $X$ that is not covered by these monochromatic components. Using the previous paragraph, we may assume that the component $T_i$ has form $T_{u_i v_i}$ for some edge $u_i v_i \in K_Y$. Consider $H = K_Y \setminus \{u_1 v_1, \ldots, u_k v_k\}$. Then $e(H) \geq (1 - \varepsilon^2)r^2/2$, so by Lemma 7.4, $H$ has a rainbow matching $M$ of size $(1 - 3\varepsilon)r/2$. This $M$ thus corresponds to a vertex $x_M \in X$. However, as $M$ does not contain the edge $u_i v_i$ for any $i$, the vertex $x_M$ does not belong to any $T_i$. In other words, $T_1, \ldots, T_k$ do not cover the vertex $x_M$, establishing (b). \hfill \Box

We are now ready to prove the main result of this section.

**Proof of Theorem 1.3.** Let us apply Lemma 7.5 with $r - 1$ colours to obtain an $(r - 1)$-edge-coloured bipartite graph with parts $X$ and $Y$ satisfying (a) and (b). To construct $G$ from $H$, we blow up all vertices in $Y$ by a lot, and add all the edges inside $Y$ in some previously unused colour. Formally, we introduce a set of vertices $V_y$ of size $|X|/\varepsilon$ for every $y \in Y$, and set $Y' = \bigcup_{y \in Y} V_y$. The vertices of $G$ are $V(G) = X \cup Y'$. For any $x \in X$ and $v \in V_y$, the edge $xv$ is present in $G$ in colour $i$ precisely when the edge $xy$ is present in $H$ in colour $i$. For $u, v \in Y'$, the edge $uv$ is present in $G$ in colour $r$.

Let $n$ denote the number of vertices in $G$. Then $n = |X|(1 + (r - 1)/\varepsilon)$, so in particular, $|X| \leq \varepsilon n$. This together with the definition of $G$ implies that for every vertex $y \in Y$, we have $\deg_G(y) \geq |Y'| \geq (1 - \varepsilon)n$. Using (a) we also get that for every $x \in X$,

$$\deg_G(x) = \deg_H(x)|V_y| \geq (1 - 3\varepsilon)|Y||V_y| = (1 - 3\varepsilon)|Y'| \geq (1 - 3\varepsilon)(1 - \varepsilon)n \geq (1 - 4\varepsilon)n.$$
As $G$ was constructed from $H$ by blowing up $Y$ and then adding some edges in it using a new colour, we see that every monochromatic component of $G$ touching $X$ is of the form $\{x \in T\} \cup \{v \in V_y : y \in T\}$ for some monochromatic component $T$ of $H$. But then any covering of $G$ by fewer than $\varepsilon^2 (r - 1)^2 / 4$ monochromatic components would give a covering of $X$ in $H$ by fewer than $\varepsilon^2 (r - 1)^2 / 4$ monochromatic components, contradicting (b).

Acknowledgements

We would like to thank Louis DeBiasio for helpful discussions and remarks.
