ABSTRACT. We study the differential and metric structures of the set of real
square roots of a non-singular real matrix, under the assumption that the
matrix and its square roots are semi-simple, or symmetric, or orthogonal.

INTRODUCTION

A square root of an \( n \times n \) matrix \( M \) is any matrix \( Y \) such that \( Y^2 = M \).

As remarked in \cite{Higham2020}, matrix square roots arise in many applications, of-
ten in connection with other matrix problems such as polar decomposition, matrix
geometric means, Markov chains, quadratic matrix equations, generalized eigen-
value problems and recently in connection with machine learning. For more infor-
mation we refer to \cite{Horn-Johnson1991, Higham2008, Horn-Johnson2013} and
\cite{Higham2020}.

This research was partially supported by GNSAGA-INdAM (Italy).
As suggested in [Higham 2020], if $M$ satisfies certain given properties, it is natural to ask if there exist square roots, having the same or analogous properties. Moreover, if the set of such square roots of $M$ is not empty, it seems also natural to us to ask what sort of algebraic, topological, differential or metric structures can be induced by $M$ on this set.

In this paper we work with semi-simple matrices in $GL_n$ (the set of real $n \times n$ non-singular matrices). It is well-known that such matrices admit real square roots if and only if their (possible) negative eigenvalues have even multiplicity: for this reason in this paper we work also under this further assumption.

Let $M \in GL_n$ be semi-simple, whose (possible) negative eigenvalues have even multiplicity; our aim is to study the following sets:

- $SR(M)$, the set of all real square roots of $M$ (see §2);
- $SSR(M)$, the set of all real symmetric square roots of $M$, when $M$ is supposed to be symmetric positive definite (see §3);
- $OSR(M)$, the set of all orthogonal square roots of $M$, when $M$ is supposed to be special orthogonal (see §4).

Preliminary material is in §1, where, in particular, we recall the so-called trace metric, $g$, and its properties on the manifold of real non-singular matrices and on its submanifolds of symmetric matrices with fixed signature and of orthogonal matrices (Recall 1.5). We have already considered such metric in [Dolcetti-Pertici 2015], [Dolcetti-Pertici 2018a], [Dolcetti-Pertici 2019], [Dolcetti-Pertici 2020] and now we adapt our previous techniques and results to the study of square roots.

The trace metric (called also affine-invariant metric or Fisher-Rao metric) is widely considered in the setting of positive definite real matrices (together with some other metrics) in order to deal with many applications. For more information we refer, for instance and among many others, to [Bridson-Haefliger 1999], [Bhatia-Holbrook 2009], [Bhatia 2007], [Monkher-Zérali 2011], [Bhatia 2013], [Amari 2016], [Terras 2016], [Barbaresco-Nielsen 2017], [Nielsen-Barbaresco 2019]).

In general the sets $SR(M)$, $SSR(M)$ and $OSR(M)$ have not a structure of manifold, but each of them is disjoint union of suitable subsets, consisting in matrices having the same eigenvalues with the same multiplicities (Remarks-Definitions 2.2, 3.2 and 4.1). All these subsets are manifolds of various dimensions; we describe them explicitly and investigate their differential and metric properties (§2, §3 and §4 respectively).
In §2 we prove that each of these suitable subsets of $\mathcal{SR}(M)$ is a closed embedded totally geodesic homogeneous semi-Riemannian submanifold of $(GL_n, g)$ (Proposition 2.3 and Theorem 2.5).

In §3 we prove that the above suitable subsets of $\mathcal{SSR}(M)$ agree with its connected components and that they are compact totally geodesic homogeneous semi-Riemannian submanifolds of $(GL_n, g)$, always diffeomorphic to the product of real Grassmannians (Proposition 3.3 and Theorem 3.4).

Finally, in §4 we prove that each of the previous suitable subsets of $\mathcal{OSR}(M)$ is a compact totally geodesic homogeneous Riemannian submanifold of the Riemannian manifold of orthogonal matrices endowed with the metric induced by the Frobenius metric (Proposition 4.2 and Theorem 4.3). Indeed this last metric agrees on $O_n$ with the opposite of the trace metric.

1. Preliminary facts

1.1. Notations.

$M_n$ (and $\text{Sym}_n$): the $\mathbb{R}$-vector space of the real square matrices of order $n$ (which are symmetric);

$GL_n$: the multiplicative group of the non-singular real matrices of order $n$;

$GL_{\text{Sym}}(q)$: the matrices of $GL_n \cap \text{Sym}_n$ having $q$ positive eigenvalues and $n-q$ negative eigenvalues (i.e. having signature $(q, n-q)$);

$O_n$ (and $SO_n$ or $O_n^-$): the multiplicative group of real orthogonal matrices of order $n$ (with determinant 1 or $-1$);

$\mathfrak{s}\mathfrak{o}_n$: the Lie algebra of skew-symmetric real matrices of order $n$;

$M_n(\mathbb{C})$: the $\mathbb{C}$-vector space of the complex square matrices of order $n$;

$GL_n(\mathbb{C})$: the multiplicative group of the non-singular complex matrices of order $n$;

$\text{Herm}_n$: the vector space of the complex hermitian matrices of order $n$;

$\text{Herm}_n(\mu)$: the matrices of $GL_n(\mathbb{C}) \cap \text{Herm}_n$ having $\mu$ positive eigenvalues and $n-\mu$ negative eigenvalues (i.e. having signature $(\mu, n-\mu)$);

$U_n$: the multiplicative group of complex unitary matrices of order $n$;

$I_n$: the identity matrix of order $n$;

$i$: the imaginary unit.

We write $\bigcup_j X_j$ to emphasize the union of mutually disjoint sets.

For every $A \in M_n(\mathbb{C})$, $\text{tr}(A)$ is its trace, $A^T$ is its transpose, $A^* := A^T$ is its transpose conjugate, $\text{det}(A)$ is its determinant and, provided that $\text{det}(A) \neq 0$, $A^{-1}$ is its inverse.
For every $\theta \in \mathbb{R}$, we denote $E_\theta := \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}$; hence $E_\theta = (\cos \theta)I_2 + (\sin \theta)E_{\pi/2}$.

If $B_1, \cdots, B_m$ are square matrices (of various orders), $B_1 \oplus \cdots \oplus B_m$ is the block diagonal square matrix with $B_1, \cdots, B_m$ on its diagonal and, for every square matrix $B$, $B^{\oplus m}$ denotes $B \oplus \cdots \oplus B$ ($m$ times). The notations $(\pm I_0) \oplus B$ and $B \oplus (\pm I_0)$ simply indicate the matrix $B$.

If $S_1, \ldots, S_m$ are sets of square matrices, then $S_1 \oplus \cdots \oplus S_m$ denotes the set of all matrices $B_1 \oplus \cdots \oplus B_m$ with $B_j \in S_j$ for every $j$.

For every matrix $B \in GL_n$ we denote $C_B := \{ X \in GL_n : [B, X] = 0 \}$, where $[B, X] := BX - XB$ is the usual commutator of $B$ and $X$.

It is easy to prove that $C_B$ is a closed Lie subgroup of $GL_n$.

For any other notation and for information on the matrices, not explicitly recalled here, we refer to [Horn-Johnson 2013] and to [Higham 2008].

1.2. Definition. Let $M \in M_n$ any matrix. A real square root of $M$ is every matrix of $M_n$, solving the matrix equation $X^2 = M$.

1.3. Remark. When $M$ is non-singular, the following fact is well-known (see for instance [Higham 2008], Thm. 1.23): $M \in GL_n$ has a real square root if and only if it has an even number of Jordan blocks of each size, for every negative eigenvalue.

Note that, if the matrix $M \in GL_n$ is semi-simple too, then it has a real square root if and only if each of its negative eigenvalues has even multiplicity; hence no matrix in $O_n^-$ has real square roots.

1.4. Notations. Assume that $M \in GL_n$ is semi-simple and that its (possible) negative eigenvalues have even multiplicity.

We want to study the following sets:

- $\mathcal{SR}(M)$, the set of all real square roots of $M$ (see §2);
- $\mathcal{SSR}(M) := \mathcal{SR}(M) \cap Sym_n$, the set of all real symmetric square roots of $M$, when $M$ is supposed to be symmetric positive definite (see §3);
- $\mathcal{OSR}(M) := \mathcal{SR}(M) \cap O_n$, the set of all orthogonal square roots of $M$, when $M$ is supposed to be an element of $SO_n$ (see §4).
1.5. Recall. We can consider the so-called trace metric on $GL_n$, given by

$$g_A(V, W) = tr(A^{-1}VA^{-1}W)$$

for every $A \in GL_n$ and every $V, W \in T_A(GL_n) = M_n$.

The trace metric, $g$, induces a semi-Riemannian structure on $GL_n$ and its restrictions (denoted always with the same symbol $g$) induce a semi-Riemannian structure on $GL_{sym}(q)$, for every $q$, a Riemannian structure on the manifold, $GL_{sym}(n)$, of real symmetric positive definite matrices, while, on $O_n$, the opposite metric, $-g$, agrees with the Riemannian metric induced by the usual (flat) Frobenius metric of $M_n$. Moreover $(O_n, g)$ and all $GL_{sym}(q)$ are totally geodesic semi-Riemannian submanifolds of $(GL_n, g)$.

As recalled in Introduction, we have studied all these metrics and their properties in [Dolcetti-Pertici 2015], [Dolcetti-Pertici 2018a], [Dolcetti-Pertici 2019], [Dolcetti-Pertici 2020], to which we refer for more information.

1.6. Remarks-Definitions. a) In this paper we consider the following maps, defined on $GL_n$:

- $j(X) := X^{-1}$ (inversion);
- $L_M(X) := MX$ (left-translation by a fixed matrix $M \in GL_n$);
- $R_M(X) := XM$ (right-translation by a fixed matrix $M \in GL_n$);
- $\hat{\Gamma}_M(X) := MXM^{-1}$ (conjugation by a fixed matrix $M \in GL_n$);
- $\Gamma_M(X) := MXMT$ (congruence by a fixed matrix $M \in GL_n$).

The above maps are isometries of $(GL_n, g)$, for any $M \in GL_n$, while they are isometries also of $(O_n, \pm g)$, for any $M \in O_n$. Finally the maps $j$ and $\Gamma_M$ are isometries of $(GL_{sym}(q), g)$, for any $M \in GL_n$ (see again [Dolcetti-Pertici 2015]), [Dolcetti-Pertici 2018a], [Dolcetti-Pertici 2019], [Dolcetti-Pertici 2020] for more information).

b) For every bijection $F$ of $GL_n$ (or of $O_n$) the set of fixed points of $F$ in $GL_n$ (or in $O_n$) is denoted by $Fix(F)$.

For any matrix $M \in GL_n$, the set $Fix(L_M \circ j)$ agrees with the sets of square roots of $M$: indeed $Y \in Fix(L_M \circ j)$ if and only if $Y = MY^{-1}$ if and only if $Y^2 = M$.

If $M \in SO_n$, $L_M \circ j$ defines also a map from $O_n$ onto itself and, so, $Fix(L_M \circ j) = OSR(M)$. 

1.7. Remark. Let $G$ be a real Lie group acting smoothly on a differentiable manifold $X$. The orbit of every $x \in X$ is an immersed submanifold of $X$, diffeomorphic to the homogeneous space $G/G_x$, where $G_x$ is the isotropy subgroup of $G$ at $x$.

This submanifold is not necessarily embedded in $X$, but, if $G$ is compact, then all orbits are embedded submanifolds (see [Popov 1991, p. 1]).

1.8. Remark-Definition. The mapping $\rho_1 : \mathbb{C} \to M_2$, $\rho_1(z) = \Re(z)I_2 + \Im(z)E_{\pi/2}$, is clearly a monomorphism of $\mathbb{R}$-algebras.

Note that $\rho_1(\overline{z}) = \rho_1(z)^T$ and that $\rho_1(z) \in GL_2$ as soon as $z \neq 0$.

More generally, for any $h \geq 1$, we define the mapping $\rho_h : M_h(\mathbb{C}) \to M_{2h}$, which maps the $h \times h$ complex matrix $Z = (z_{ij})$ to the $(2h) \times (2h)$ block real matrix $(\rho_1(z_{ij}))$, having $h^2$ blocks of order $2 \times 2$.

We have already considered the mappings $\rho_h$ in [Dolcetti-Pertici 2020, Rem. 2.8]; in particular we recall that $\text{tr}(\rho_h(Z)) = 2\Re(\text{tr}(Z))$, $\det(\rho_h(Z)) = |\det(Z)|^2$ and that $\rho_h$ is a monomorphism of $\mathbb{R}$-algebras, whose restriction to $GL_h(\mathbb{C})$ has image into $GL_{2h}$ and it is a monomorphism of Lie groups.

Furthermore we have: $\rho_h(Z^*) = \rho_h(Z)^T$, so the restriction of $\rho_h$ to $U_h$ is a monomorphism of Lie groups and $\rho_h(U_h) = \rho_h(\text{GL}_h(\mathbb{C})) \cap SO_{2h} = \rho_h(\text{GL}_h(\mathbb{C})) \cap \text{O}_{2h}$; analogously the restriction of $\rho_h$ to $\text{Herm}_h$ has image into $\text{Sym}_{2h}$ and it is a monomorphism of $\mathbb{R}$-vector spaces.

To simplify the notations and in absence of ambiguity, we will omit to write the symbol $\rho_h$, so, for instance, we can consider $M_h(\mathbb{C})$ as an $\mathbb{R}$-subalgebra of $M_{2h}$, $GL_h(\mathbb{C})$ as a Lie subgroup of $GL_{2h}$, $U_h$ as a Lie subgroup of $SO_{2h}$ and $\text{Herm}_h$ as an $\mathbb{R}$-vector subspace of $\text{Sym}_{2h}$.

2. Semi-simple case

Aim of this section is to study $\mathcal{SR}(M)$: the set of all real square roots of a non-singular semi-simple matrix $M$, whose (possible) negative eigenvalues have even multiplicity (Notations 1.4).

2.1. Remark. Let $A \in GL_n$. Then $A$ is semisimple if and only if $A^2$ is semisimple.

One implication is trivial.

For the other, assume that $A^2$ is semisimple. The multiplicative Jordan-Chevalley decomposition implies that there is a semisimple matrix $S$ and a nilpotent matrix $N$ such that $A = S(I + N) = (I + N)S$ (see for instance [Humphreys 1975, § 4.2] and also [Dolcetti-Pertici 2017], [Dolcetti-Pertici 2018b]).
Now $A^2 = S^2(I + 2N + N^2)$ with $S^2$ semisimple and $2N + N^2$ nilpotent, so from the uniqueness of the multiplicative Jordan-Chevalley decomposition we get $A^2 = S^2$ and $N^2 + 2N = 0$. Hence the minimal polynomial, $x^k$, of $N$ is a divisor of $x^2 + 2x$, hence $k = 1$, $N = 0$ and $A$ is semisimple.

2.2. Remarks-Definitions. a) Let $M \in GL_n$ be a semisimple matrix, whose every (possible) negative eigenvalue has even multiplicity, and denote its eigenvalues in the following way:

- the distinct positive eigenvalues are: $\lambda_1 < \lambda_2 < \cdots < \lambda_p$ ($p \geq 0$) with multiplicity $h_1, h_2, \cdots, h_p$ respectively (if $p \geq 1$);

- the distinct non-real eigenvalues are: $\rho_1, \rho_2, \cdots, \rho_s$, up to $\rho_1, \rho_2, \cdots, \rho_s$, where both $\rho_i \in \mathbb{C}$ have multiplicity $m_i$ for every admissible $i$ and $t$ ($r \geq 0$) and where $0 < \theta_1 < \theta_2 < \cdots < \theta_r < \pi$ and $0 < \rho_{i_1} < \rho_{i_2} < \cdots < \rho_{i_q}$ for every $i = 1, \cdots, r$ (if $r \geq 1$); 

- the distinct negative eigenvalues are: $-\zeta_1 > -\zeta_2 > \cdots > -\zeta_q$ ($q \geq 0$) with multiplicity $2k_1, 2k_2, \cdots, 2k_q$ respectively (if $q \geq 1$).

Note that $\sum_{i=1}^ph_i + 2\sum_{t=1}^r \sum_{i=1}^{s_i} m_{it} + 2\sum_{i=1}^q k_i = n$.

We denote by $J_M$ the matrix

$$J_M := \left( \bigoplus_{i=1}^p \lambda_i I_{h_i} \right) \oplus \left( \bigoplus_{t=1}^r \bigoplus_{i=1}^{s_i} \rho_{it} E_{\theta_i}^{m_{it}} \right) \oplus \left( \bigoplus_{i=1}^q (-\zeta_i) J_{2k_i} \right).$$

Then there is a matrix $C \in GL_n$ such that

$$M = C J_M C^{-1}$$

(see for instance [Horn-Johnson 2013, Cor. 3.4.1.10 p. 203]).

Following [Dolcetti-Pertici 2020, Remark-Definition 1.7], we call such matrix $J_M$ the real Jordan standard form (shortly: RJS form) of $M$.

b) Let $M$ be as in (a) and denote by $Y \in GL_n$ a square root of $M$. By Remark 2.1 $Y$ is semisimple and its eigenvalues are (complex) square roots of the eigenvalues of $M$. Hence the eigenvalues of $Y$ are

- $\sqrt{\lambda_i}$ with multiplicity $u_i \geq 0$ and $-\sqrt{\lambda_i}$ with multiplicity $v_i \geq 0$ where $u_i + v_i = h_i$ ($i = 1, \cdots, p$, if $p \geq 1$);

- $\sqrt{\rho_{it}} \exp(\pm i \theta_i/2)$ both with multiplicity $\mu_{it}$ and $\sqrt{\rho_{it}} \exp(\pm i(\theta_i/2 - \pi))$ both with multiplicity $\nu_{it}$, where $\mu_{it} + \nu_{it} = m_{it}$ (for every admissible $i$ and $t$);

- $\pm \sqrt{\zeta_i}$ both with multiplicity $k_i$ ($i = 1, \cdots, q$, if $q \geq 1$).
We denote by $\tilde{J}_Y$ the matrix

$$\tilde{J}_Y := \left[\Theta_{i=1}^q \left(\sqrt{\lambda_i} \oplus (-I_{v_i})\right)\right] \left[\bigoplus_{i=1}^p \bigoplus_{j=1}^s \sqrt{\mu_{ij} \mu_{ij}^{\prime} \oplus \mu_{ij}^{\prime} \mu_{ij}}\right] \left[\Theta_{i=1}^q \sqrt{\zeta_i^{\prime} E_{\pi/2}}\right].$$

Then there exists a matrix $K \in GL_n$ such that

$$Y = K \tilde{J}_Y K^{-1}. $$

Note that

$$E_{\phi - \pi} = -E_\phi, \forall \phi, \text{ and } (\tilde{J}_Y)^2 = J_M. $$

Remark that the last equality implies that $\mathcal{C}_{\tilde{J}_Y} \subseteq \mathcal{C}_{J_M}$. Analogously to [Dolcetti-Pertici 2020, Remark-Definition 1.8], we can call the matrix $\tilde{J}_Y$ the real Jordan auxiliary form (shortly: RJA form) of $Y$.

c) We denote by $\text{SR}(M)_{(u_1, \cdots, u_p)}$ the subset of $\text{SR}(M)$ of all real square roots of $M$ whose eigenvalues have the same multiplicities of the eigenvalues of $Y$ as in (b).

Note that any two matrices in $\text{SR}(M)_{(u_1, \cdots, u_p)}$ have the same RJA form; indeed the matrix $M$ and the two families of indices $(u_1, \cdots, u_p)$ and $(\mu_{11}, \cdots, \mu_{1s_1}; \cdots; \mu_{r1}, \cdots, \mu_{rs_r})$ determine also the $v_i$'s, the $\nu_l$'s and the $k_j$'s.

One or both families of indices $(u_1, \cdots, u_p)$ and $(\mu_{11}, \cdots, \mu_{1s_1}; \cdots; \mu_{r1}, \cdots, \mu_{rs_r})$ can be empty (indeed $p$ and $r$ can vanish). In this case we can use the same notations, by omitting the family or both families of indices.

Note that, if $p = r = 0$ (and so $q \geq 1$), then the RJA form of every square root of $M$ is $\bigoplus_{i=1}^q \sqrt{\zeta_i^{\prime} E_{\pi/2}}$ and that $\text{SR}(M)$ (without any lower and upper index) agrees with the set of all real square roots of $M$.

Note also that, if at least one between $p$ and $r$ is non-zero, then $\text{SR}(M) = \sqcup_{(u_1, \cdots, u_p)} \text{SR}(M)_{(u_1, \cdots, u_p)}$, where the disjoint union is taken on all indices $0 \leq u_i \leq h_i$ for every $1 \leq i \leq p$ (if $p \geq 1$) and $0 \leq \nu_l \leq m_l$ for every $1 \leq l \leq r$ and for every $1 \leq t \leq s_l$ (if $r \geq 1$).

In the following statements of this section it is understood that one or both families of the above indices can be empty.

2.3. Proposition. Let $M \in GL_n$ be a semisimple matrix, whose every (possible) negative eigenvalue has even multiplicity and let $C \in GL_n$ be such that $M = C J_M C^{-1}$ as in Remarks-Definitions 22 (a).

Fix any set $\text{SR}(M)_{(u_1, \cdots, u_p)}$ as in Remarks-Definitions 22 (c) and denote by $\tilde{J}$ the RJA form of every $Y \in \text{SR}(M)_{(u_1, \cdots, u_p)}$. Then
diffeomorphic to the homogeneous space $\mathbb{C}$
Moreover $\mathcal{S}\mathcal{R}(M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)$ is a closed embedded submanifold of $GL_n$,
diffeomorphic to the homogeneous space $\mathbb{C}\mathcal{J}_M\mathcal{J}_C$.

Proof. If $Y \in \mathcal{S}\mathcal{R}(M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)$, then $Y = K\tilde{J}\tilde{Y}K^{-1}$ for some $K \in GL_n$ and $Y^2 = K(\tilde{J}\tilde{Y})^2K^{-1} = KJMK^{-1} = C\mathcal{J}_MC^{-1} = M$. Hence $C^{-1}K \in C\mathcal{J}_M$ and, so, $K = CX$ for some $X \in C\mathcal{J}_M$. This gives one inclusion of the first equality.
The reverse inclusion is a simple computation. The second equality follows directly from the definition of $\tilde{G}_C$.

Now $\tilde{G}_C$ is a diffeomorphism of $GL_n$, so it suffices to prove that the set
\[
\{X\tilde{J}X^{-1} : X \in C\mathcal{J}_M\} = \mathcal{S}\mathcal{R}(J_M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)
\]
has the requested properties. Let us consider the left action by conjugation of $C\mathcal{J}_M$ on $GL_n$.
The set $\{X\tilde{J}X^{-1} : X \in C\mathcal{J}_M\}$ is the orbit of $\tilde{J}$. By Remark 12.7, this set is an immersed submanifold of $GL_n$, diffeomorphic to the homogeneous space $\mathbb{C}\mathcal{J}_M\mathcal{J}_C$, being $\mathbb{C}\mathcal{J}_M \subseteq C\mathcal{J}_M$, and being $\mathbb{C}\mathcal{J}_C$ the isotropy subgroup of the action.

Finally $\mathcal{S}\mathcal{R}(J_M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)$ is closed in $GL_n$. Indeed if $\{Y_m\}$ is a sequence in $\mathcal{S}\mathcal{R}(J_M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)$, converging to $Y \in GL_n$, then $Y^2 = J_M$ too and the characteristic polynomial of $Y$ is the same characteristic polynomial of all $Y_m$’s (constant with respect to $m$).

Hence $Y \in \mathcal{S}\mathcal{R}(J_M)\left(\mu_{11}, \cdots, \mu_{1r} ; \cdots ; \mu_{r1}, \cdots, \mu_{rr}\right)$ and this last is closed and, therefore, it is an embedded submanifold of $GL_n$ (see for instance [Montgomery-Zippin 1955 § 2.13 Theorem, p. 65]). \hfill \Box

2.4. Lemma. a) Let $J$ be the matrix
\[
J = (\bigoplus_{l=1}^r \lambda_l I_{h_l}) \oplus (\bigoplus_{l=1}^s \rho_l E_{\theta_0}^{\oplus m_l}) \oplus (\bigoplus_{i=1}^q (-\zeta_i)I_{2k_i}),
\]
where all indices satisfy the numerical conditions of Remarks-Definitions 2.2 (a).
Then the Lie group of non-singular matrices, commuting with $J$, is
\[
\mathcal{C}_J = (\bigoplus_{l=1}^r GL_{h_l}) \oplus (\bigoplus_{l=1}^s GL_{m_l}(\mathbb{C})) \oplus (\bigoplus_{i=1}^q GL_{2k_i}).
\]
b) Let $\tilde{J}$ be the matrix $\tilde{J} :=$
\[
[\bigoplus_{l=1}^r (\sqrt{\lambda}(I_{h_l} \oplus (-\zeta_l))) \oplus \bigoplus_{l=1}^s \sqrt{\lambda} \bigoplus_{l=1}^q \sqrt{\lambda} E_{\theta_0/2}^{\oplus m_l} \oplus \bigoplus_{i=1}^q \sqrt{\lambda} E_{\theta_0/2}^{\oplus k_i}],
\]
where all indices satisfy the numerical conditions of Remarks-Definitions 2.2 (b).
Then the Lie group of non-singular matrices, commuting with $\tilde{J}$, is
\[
\mathcal{C}_{\tilde{J}} = \bigoplus_{l=1}^r (GL_{h_l} \oplus GL_{v_l}) \oplus \bigoplus_{l=1}^s \bigoplus_{i=1}^q (GL_{m_l}(\mathbb{C}) \oplus GL_{v_l}(\mathbb{C})) \oplus \bigoplus_{i=1}^q GL_{2k_i}(\mathbb{C}).
\]
2.5. Theorem. Let $M \in GL_n$ be a semisimple matrix, whose every (possible) negative eigenvalue has even multiplicity. Then

a) every connected component of $\mathcal{SR}(M)$ is a closed totally geodesic homogeneous semi-Riemannian submanifold of $(GL_n, g)$;

b) every manifold $\mathcal{SR}(M)_{(\mu_1, \ldots, \mu_p)}$ is diffeomorphic to the following product of homogeneous spaces:

\[
\left( \prod_{i=1}^{p} \frac{GL_{\mu_i}}{GL_{\mu_i} \oplus GL_{\mu_i}} \right) \times \left( \prod_{i=1}^{n} \frac{GL_{\pi(i)}}{GL_{\pi(i)} \oplus GL_{\pi(i)}} \right) \times \left( \prod_{i=1}^{q} \frac{GL_{lt}}{GL_{lt} \oplus GL_{lt}} \right),
\]

where $\nu_i = \mu_i - \pi(i)$ and $v_{lt} = m_{lt} - \mu_{lt}$.

Proof. Since $\mathcal{SR}(M) = \hat{\Gamma}_C(\mathcal{SR}(M))$ (with $C$ as in Proposition 2.3) and $\hat{\Gamma}_C$ is an isometry of $(GL_n, g)$, it suffices to prove (a) for the matrix $\mathcal{J}M$ instead of $M$. Every connected component of $\mathcal{SR}(\mathcal{J}M)$ is contained in some $\mathcal{SR}(\mathcal{J}M)_{(\mu_1, \ldots, \mu_p)} = \{X, \mathcal{J}X^{-1} : X \in C_{\mathcal{J}M}\}$ (remember the notations of Proposition 2.3) and this last is the orbit of $\mathcal{J}$ under the action of $C_{\mathcal{J}M}$ on $GL_n$. Since all conjugation maps are isometries of $(GL_n, g)$, every connected component of $\mathcal{SR}(\mathcal{J}M)_{(\mu_1, \ldots, \mu_p)}$ is a semi-Riemannian submanifold of $(GL_n, g)$.

Now the map $L_M \circ j : (GL_n, g) \to (GL_n, g)$, $L_M \circ j(X) = MX^{-1}$ is an isometry of $(GL_n, g)$, whose set of fixed points is $\mathcal{SR}(M)$. Hence we can conclude (a) by [Kobayashi-Nomizu 1969] Ex. 8.1 p. 61, Prop. 8.3 p. 56], remembering again Proposition 2.3 too.

Part (b) follows from Proposition 2.3 and from Lemma 2.4. \qed

2.6. Definition. Let $M \in GL_n$ be a semisimple matrix, whose every (possible) negative eigenvalue has even multiplicity. We say that a matrix $X$ is a generalized principal square root of $M$, if $X^2 = M$ and every eigenvalue of $X$ has principal argument in $[-\pi/2, \pi/2]$.

This definition is more general than the usual one of principal square root (see for instance [Higham 2008] Thm. 1.29 p. 20]).

We denote by $\mathcal{PSR}(M)$ the set of all generalized principal square roots of $M$.

2.7. Remarks. Let $M \in GL_n$ be a semisimple matrix, whose every (possible) negative eigenvalue has even multiplicity.

a) We have $\mathcal{PSR}(M) = \mathcal{SR}(M)_{(\mu_1, \ldots, \mu_p)}$ and so, by Theorem 2.5 it is a single point if $M$ has no negative eigenvalue, according to the usual
definition (see [Higham 2008, Thm. 1.29 p. 20]), otherwise it is diffeomorphic to
the product of homogeneous spaces: \[ \prod_{i=1}^{p} \frac{GL_{2k_i}}{GL_{k_i}(\mathbb{C})} \] (\( q \) is the number of distinct
negative eigenvalues and \( 2k_1, \ldots, 2k_q \) are their multiplicities).

In any case \( \mathcal{PSR}(M) \) has \( 2^q \) connected components, since every factor has 2
connected components.

b) Every \( \mathcal{SR}(M)\{[\mu_1, \cdots, \mu_{1,\cdots}, \mu_{r,\cdots}, \cdots] \} \) has dimension
\[ 2[\sum_{i=1}^{p} u_i(h_i - u_i) + 2\sum_{t=1}^{r} \sum_{i=1}^{q_t} m_t(\mu_t - \mu_i) + \sum_{i=1}^{q} k^2_i] \]
From this, we get that \( \mathcal{SR}(M) \) if finite if and only if the eigenvalues of \( M \) have
multiplicity 1 and no eigenvalue of \( M \) is negative. In this case \( M \) has exactly
\[ 2^q 2^{(n-p)/2} = 2^{(p+n)/2} \] distinct real square roots, where \( p \) is the number of positive
eigenvalues of \( M \).

3. Symmetric case

Aim of this section is to study \( \mathcal{SSR}(M) \): the set of all real symmetric square roots
of \( M \), with \( M \) symmetric positive definite (Notations \([\text{1.4}]\).

3.1. Remark. If \( X \in GL_n \) is symmetric, then \( X^2 \) is symmetric positive definite.
Hence, to have real symmetric square roots of a real symmetric matrix \( M \), we must
assume that \( M \) is positive definite too.

3.2. Remarks-Definitions. Let \( M \in GL_n \) be a symmetric positive definite matrix
with distinct (real positive) eigenvalues \( \lambda_1 < \lambda_2, \cdots < \lambda_p \) with multiplicity
\( h_1, h_2, \cdots, h_p \), respectively, so the RJS form of \( M \) is \( J_M = \bigoplus_{i=1}^{p} \lambda_i I_{h_i} \); in this case
there exists \( Q \in O_n \) such that \( M = QJ_M Q^T \).

We denote by \( \mathcal{SSR}(M)\{u_1, \cdots, u_p\} = \mathcal{SR}(M)\{u_1, \cdots, u_p\} \cap Sym_n \) (with \( 0 \leq u_i \leq h_i \) for
every \( 1 \leq i \leq p \)): the set of all \( Y \in \mathcal{SSR}(M) \), having
\( \tilde{J} = \bigoplus_{i=1}^{p} [\sqrt{\lambda_i} (I_{u_i} \oplus (-I_{(h_i-u_i)}))] \) as its RJA form.

We have \( \mathcal{SSR}(M)\{u_1, \cdots, u_p\} \subseteq GLSym_n(u) \) (with \( u := \sum_{i=1}^{p} u_i \)) and, if
\( Y \in \mathcal{SSR}(M)\{u_1, \cdots, u_p\} \), then there exists \( R \in O_n \) such that \( Y = R\tilde{J} R^T \).

Note also that \( \mathcal{SSR}(M) = \sqcup \mathcal{SSR}(M)\{u_1, \cdots, u_p\} \), where the disjoint union is taken
on all indices \( u_1, \cdots, u_p \) as above.

3.3. Proposition. Let \( M \) be a symmetric positive definite real matrix with
distinct (real positive) eigenvalues \( \lambda_1 < \lambda_2, \cdots < \lambda_p \) with multiplicity \( h_1, h_2, \cdots, h_p \)
respectively and let \( Q \in O_n \) be such that \( M = QJ_M Q^T \).

Fix any set \( \mathcal{SSR}(M)\{u_1, \cdots, u_p\} \) as above and denote by \( \tilde{J} \) the RJA form of any
\( Y \in \mathcal{SSR}(M)\{u_1, \cdots, u_p\} \). Then
\(\text{SSR}(M)_{(u_1, \ldots, u_p)} = \{ QX\tilde{J}X^TQ^T : X \in C_{\tilde{J}M} \cap O_n \} = \Gamma_Q(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)})\),
where \(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)} = \bigoplus_{i=1}^p \sqrt{\lambda_i(\mathcal{O}_{h_i} \cap \text{GLSym}_n(u_i))}\).

Moreover \(\text{SSR}(M)_{(u_1, \ldots, u_p)}\) is a compact submanifold of \(\text{GLSym}_n(u)\) (with \(u := \sum_{i=1}^p u_i\)), diffeomorphic to the homogeneous space \(\mathcal{C}_{\tilde{J}M} \cap O_n\).

**Proof.** As in Propositions 2.3 we can proof that \(\text{SSR}(M)_{(u_1, \ldots, u_p)} = \{ QX\tilde{J}X^TQ^T : X \in C_{\tilde{J}M} \cap O_n \} = \Gamma_Q(\{ X\tilde{J}X^T : X \in C_{\tilde{J}M} \cap O_n \})\) and \(\{ X\tilde{J}X^T : X \in C_{\tilde{J}M} \cap O_n \}\) is clearly equal to \(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)}\).

By Lemma 2.3 (a) we have \(C_{\tilde{J}M} \cap O_n = (\bigoplus_{i=1}^p GL_{h_i}) \cap O_n = \bigoplus_{i=1}^p \mathcal{O}_{h_i}\).

Hence, if \(X = \bigoplus_{i=1}^p V_i \in \bigoplus_{i=1}^p \mathcal{O}_{h_i} = C_{\tilde{J}M} \cap O_n\), then we obtain:

\[X\tilde{J}X^T = \bigoplus_{i=1}^p \sqrt{\lambda_i}V_i(I_{u_i} \oplus (-I_{(h_i-u_{i})}))V_i^T.\]

In the last expression the \(i\)-th summand is clearly a generic element of \(\sqrt{\lambda_i}(\mathcal{O}_{h_i} \cap \text{GLSym}_n(u_i))\); this concludes the first part.

Now \(\text{SSR}(M)_{(u_1, \ldots, u_p)}\) and \(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)}\) are diffeomorphic, since \(\Gamma_Q\) is a diffeomorphism of \(\text{GLSym}_n(u)\).

By considering the action by congruence of \(C_{\tilde{J}M} \cap O_n\) on \(\text{GLSym}_n(u)\), \(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)}\) is the orbit of \(\tilde{J}\), while the isotropy subgroup at \(\tilde{J}\) is \(C_{\tilde{J}} \cap O_n \subseteq C_{\tilde{J}M} \cap O_n\).

Hence \(\text{SSR}(\mathcal{M})_{(u_1, \ldots, u_p)}\) (and also \(\text{SSR}(M)_{(u_1, \ldots, u_p)}\)) is a compact submanifold of \(\text{GLSym}_n(u)\) diffeomorphic to \(\mathcal{C}_{\tilde{J}M} \cap O_n\) (see Remark 1.7). This concludes the proof. \(\square\)

### 3.4. **Theorem.** Let \(M\) be a symmetric positive definite real matrix with distinct (real positive) eigenvalues \(\lambda_1 < \lambda_2 \cdots < \lambda_p\) with multiplicity \(h_1, h_2, \ldots, h_p\) respectively. Then

a) every manifold \(\text{SSR}(M)_{(u_1, \ldots, u_p)}\), as above, is diffeomorphic to the following product of homogeneous spaces:

\[\prod_{i=1}^p \frac{\mathcal{O}_{h_i}}{\mathcal{O}_{u_i} \oplus \mathcal{O}_{v_i}},\]

where \(v_i = h_i - u_i\) (note that \(\frac{\mathcal{O}_{h_i}}{\mathcal{O}_{u_i} \oplus \mathcal{O}_{v_i}}\) is diffeomorphic to the real Grassmannian \(\mathcal{G}_{u_i}(\mathbb{R}^{h_i})\));

b) the connected components of \(\text{SSR}(M)\) are the manifolds \(\text{SSR}(M)_{(u_1, \ldots, u_p)}\) and each of them is a compact totally geodesic homogeneous semi-Riemannian submanifold of \((\text{GL}_n, g)\).
Proof. From Proposition 3.3, $SSR(M)(u_1, \ldots, u_p)$ is diffeomorphic to the homogeneous space $\frac{C_{J_M} \cap O_n}{C_{\tilde{J}} \cap O_n}$. By Lemma 2.4, $C_{J_M} \cap O_n = \bigoplus_{i=1}^{p} O_{h_i}$ and $C_{\tilde{J}} \cap O_n = \bigoplus_{i=1}^{p} (O_{u_i} \oplus O_{v_i})$. This allows to conclude (a).

Every manifold $O_{h_i}$ is diffeomorphic to a real Grassmannian and, so, it is compact and connected. This implies that $SSR(M)(u_1, \ldots, u_p)$ is compact and connected too. Since $SSR(M)$ is disjoint union of such manifolds, these last are its connected components.

As in the proof of Theorem 2.5, it is possible to prove that $SSR(M)(u_1, \ldots, u_p)$ is a semi-Riemannian submanifold of $(GL_n, g)$.

Now every connected component of $SR(M)$ is a totally geodesic semi-Riemannian submanifold of $(GL_n, g)$ again by Theorem 2.5 and, for every $0 \leq q \leq n$, $GLSym_n(q)$ is a totally geodesic semi-Riemannian submanifold of $(GL_n, g)$ by [Dolcetti-Pertici 2019, Prop. 2.3].

We can conclude part (b), since $SSR(M)(u_1, \ldots, u_p) = SR(M)(u_1, \ldots, u_p) \cap GLSym_n(u)$ (with $u := \sum_{i=1}^{p} u_i$): intersection of two totally geodesic submanifolds. □

3.5. Remarks. Assume the same hypotheses and notations as in Theorem 3.4.

a) If $u_1 = h_1, \ldots, u_p = h_p$ or if $u_1 = \cdots = u_p = 0$, then the manifold $SSR(M)(u_1, \ldots, u_p)$ is a single point. In the first case this point is a symmetric positive definite matrix: the usual (positive definite) square root of $M$, denoted by $\sqrt{M} = M^{1/2}$; in the second case it is a symmetric negative definite matrix and precisely $-\sqrt{M} = -M^{1/2}$.

b) $SSR(M)$ is a finite set if and only if all eigenvalues of $M$ have multiplicity 1; in this case $SSR(M)$ has cardinality $2^n$ and $SR(M) = SSR(M)$.

4. Orthogonal case

Aim of this section is to study $OSSR(M)$, the set of all orthogonal square roots of $M$, where $M$ is in $SO_n$ (Notations 1.4). We have already remarked that $Fix(L_M \circ j) = OSSR(M)$ (remember Remarks-Definitions 1.6 (b)).

4.1. Remarks-Definitions. a) Remembering 2.2 the RJS form of $M \in SO_n$ is

\[ J_M = I_h \oplus E_{\theta_1}^{\oplus m_1} \oplus \cdots \oplus E_{\theta_r}^{\oplus m_r} \oplus (-I_{2k}) \]

with $h, r, k \geq 0$, $h + 2m_1 + \cdots + 2m_r + 2k = n$ and $0 < \theta_1 < \theta_2 < \cdots < \theta_r < \pi$; the eigenvalues of $M$ are: 1 with multiplicity $h \geq 0$, exp($\pm i \theta_1$) both with multiplicity $m_1$, \cdots, up to exp($\pm i \theta_r$) both with multiplicity $m_r$ ($m_j > 0 \ \forall j$, if $r > 0$) and $-1$ with multiplicity $2k \geq 0$. 
The eigenvalues of any (orthogonal) square root \( Y \) of \( M \) are necessarily: 1 with multiplicity \( u \), -1 with multiplicity \( h-u \) (where \( 0 \leq u \leq h \)), \( \exp(\pm \frac{1}{2} i \theta_j) \) both with multiplicity \( \mu_j \) and \( \exp(\pm i (\frac{1}{2} \theta_j - \pi)) \) both with multiplicity \( m_j - \mu_j \) (\( 0 \leq \mu_j \leq m_j \)), for every \( 1 \leq j \leq r \), if \( r > 0 \), and finally \( \pm i \) both with multiplicity \( k \), so that the RJA form of \( Y \) is the following:

\[
\tilde{\mathcal{J}} := I_u \oplus (-I_{(h-u)}) \oplus E_{\frac{1}{2} \theta_1} \oplus E_{(\frac{1}{2} \theta_1 - \pi)} \oplus \cdots \oplus E_{\frac{1}{2} \theta_1} \oplus E_{(\frac{1}{2} \theta_1 - \pi)} \oplus E_{\frac{1}{2} k}.
\]

\( \text{(**) \hspace{1cm} \tilde{\mathcal{J}} := I_u \oplus (-I_{(h-u)}) \oplus E_{\frac{1}{2} \theta_1} \oplus E_{(\frac{1}{2} \theta_1 - \pi)} \oplus \cdots \oplus E_{\frac{1}{2} \theta_1} \oplus E_{(\frac{1}{2} \theta_1 - \pi)} \oplus E_{\frac{1}{2} k}.} \)

b) We denote by \( \mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] \) the subset of \( \mathcal{OSR}(M) \) of matrices whose RJA form is of the type (**) above.

If \( Y \in \mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] \), then there is a matrix \( H \in \mathcal{O}_n \) such that \( Y = H \tilde{\mathcal{J}} H^T \).

Proof. As in Propositions 2.3 and 3.3, we have:

\[
\mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] = \{ X \tilde{\mathcal{J}} X^T : X \in \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n \} = \Gamma_{\mathcal{C}_{\mathcal{FM}}}(\mathcal{OSR}(\mathcal{FM})[\mu_1, \ldots, \mu_r]),
\]

where \( \mathcal{OSR}(\mathcal{FM})[\mu_1, \ldots, \mu_r] := [\mathcal{O}_n \cap \text{Sym}_n(u)] \oplus [\bigoplus_{j=1}^r \exp(\frac{1}{2} i \theta_j)(U_{m_j} \cap \text{Herm}_{m_j}(\mu_j))] \oplus [\mathcal{O}_{2k} \cap \mathfrak{s}\mathfrak{o}_{2k}]. \)

Moreover \( \mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] \) is a compact submanifold of \( \mathcal{O}_n \), diffeomorphic to the homogeneous space \( \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n / \mathcal{C}_{\tilde{\mathcal{J}} \cap \mathcal{O}_n}. \)

4.2. Proposition. Let \( M \in SO_n \) whose RJS form, \( \mathcal{J}_M \), is as in Remarks-Definitions 4.1 (*) and let \( C_0 \in \mathcal{O}_n \) such that \( M = C_0 \mathcal{J}_M C_0^T \). For every \( 0 \leq u \leq h \), \( 0 \leq \mu_j \leq m_j \), \( 1 \leq j \leq r \), let \( \tilde{\mathcal{J}} \) be the matrix of the form (**) as in Remarks-Definitions 4.1.

Then

\[
\mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] = \{ C_0 X \tilde{\mathcal{J}} X^T C_0^T : X \in \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n \} = \Gamma_{\mathcal{C}_{\mathcal{FM}}}(\mathcal{OSR}(\mathcal{FM})[\mu_1, \ldots, \mu_r]),
\]

where \( \mathcal{OSR}(\mathcal{FM})[\mu_1, \ldots, \mu_r] := [\mathcal{O}_n \cap \text{Sym}_n(u)] \oplus [\bigoplus_{j=1}^r \exp(\frac{1}{2} i \theta_j)(U_{m_j} \cap \text{Herm}_{m_j}(\mu_j))] \oplus [\mathcal{O}_{2k} \cap \mathfrak{s}\mathfrak{o}_{2k}]. \)

Moreover \( \mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] \) is a compact submanifold of \( \mathcal{O}_n \), diffeomorphic to the homogeneous space \( \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n / \mathcal{C}_{\tilde{\mathcal{J}} \cap \mathcal{O}_n}. \)

Proof. As in Propositions 2.3 and 3.3, we have:

\[
\mathcal{OSR}(M)[\mu_1, \ldots, \mu_r] = \{ X \tilde{\mathcal{J}} X^T : X \in \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n \} = \Gamma_{\mathcal{C}_{\mathcal{FM}}}(\{ X \tilde{\mathcal{J}} X^T : X \in \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n \}) \quad \text{and} \quad \{ X \tilde{\mathcal{J}} X^T : X \in \mathcal{C}_{\mathcal{FM}} \cap \mathcal{O}_n \} = \mathcal{OSR}(\mathcal{FM})[\mu_1, \ldots, \mu_r].
\]
Analogously to Proposition 3.3 by Lemma 2.3 (a), we get: \( C_{J_M} \cap O_n = (GL_u \oplus GL_{m_1}(\mathbb{C}) \oplus \cdots \oplus GL_{m_r}(\mathbb{C}) \oplus GL_{2k}) \cap O_n = O_h \oplus U_{m_1} \oplus \cdots \oplus U_{m_r} \oplus O_{2k} \).

Hence, if \( X = V \oplus Z_1 \oplus \cdots \oplus Z_r \oplus W \in O_h \oplus U_{m_1} \oplus \cdots \oplus U_{m_r} \oplus O_{2k} = C_{J_M} \cap O_n \), then, remembering Remark-Definition 1.8, we obtain: \( X \tilde{J} X^T = [V(I_u \oplus (-I(h-u)))W] \oplus \left( \bigoplus_{j=1}^r \right) \exp\left( \frac{1}{2} \right) Z_j \left( I_{\mu_j} \oplus (-I(m_j-\mu_j)) \right) Z_j^* \oplus [W(\mathbb{C}^k)W] \).

In the last expression the first and the last summand are clearly generic elements of \( O_h \cap \text{Sym}_{h}(u) \) and of \( O_{2k} \cap \mathfrak{s}\mathfrak{o}_{2k} \), respectively. Finally, for every \( j \), the matrix \( Z_j \left( I_{\mu_j} \oplus (-I(m_j-\mu_j)) \right) Z_j^* \) is a generic element of \( U_{m_j} \cap \text{Herm}_{m_j}(\mu_j) \); this concludes the first part.

Again \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) and \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) are diffeomorphic, since \( \Gamma_0 \) is a diffeomorphism of \( O_n \).

In the action by congruence of \( C_{J_M} \cap O_n \) on \( O_n \), \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) is the orbit of \( \tilde{J} \), while the isotropy subgroup at \( \tilde{J} \) is \( C_{J_M} \cap O_n \subseteq C_{J_M} \cap O_n \); so \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) and \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) are compact submanifolds of \( O_n \) diffeomorphic to \( C_{J_M} \cap O_n \) (again by Remark 1.8). This concludes the proof.

4.3. Theorem. Let \( M \in SO_n \) whose RJS form, \( J_M \), is as in Remarks-Definitions 4.2 (\( * \)) and let \( C_0 \in O_n \) such that \( M = C_0 J_M C_0^T \). For every \( 0 \leq u \leq h \), \( 0 \leq \mu_j \leq m_j \), \( 1 \leq j \leq r \), we have:

a) \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) is a compact homogeneous differentiable manifold diffeomorphic to the product

\[
\frac{O_h}{O_u \oplus O_{(h-u)}} \times \prod_{j=1}^r \frac{U_{m_j}}{U_{\mu_j} \oplus U_{(m_j-\mu_j)}} \times \frac{O_{2k}}{U_k}
\]

whose dimension is \( u(h-u) + 2 \sum_{j=1}^r \mu_j (m_j - \mu_j) + k(k-1) \).

If \( k = 0 \) (i.e if \(-1\) is not an eigenvalue of \( M \)), the manifold \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) is connected, otherwise it has two connected components and both are diffeomorphic to

\[
\frac{O_h}{O_u \oplus O_{(h-u)}} \times \prod_{j=1}^r \frac{U_{m_j}}{U_{\mu_j} \oplus U_{(m_j-\mu_j)}} \times SO_{2k}
\]

b) \( O\text{SR}(M^u_{\{\mu_1,\cdots,\mu_r\}}) \) is also a totally geodesic homogeneous Riemannian submanifold of \( (O_n, -g) \).

Proof. In the proof of Proposition 4.2 we have seen that

\( C_{J_M} \cap O_n = O_h \oplus U_{m_1} \oplus \cdots \oplus U_{m_r} \oplus O_{2k} \).

By Lemma 2.3 (b), we get also: \( C_{\tilde{J}} \cap O_n = \)

\[
\{(GL_u \oplus GL_{(h-u)}) \oplus \left( \bigoplus_{j=1}^r GL_{\mu_j}(\mathbb{C}) \oplus GL_{(m_j-\mu_j)}(\mathbb{C}) \right) \oplus GL_k(\mathbb{C}) \} \cap O_n = O_u \oplus O_{(h-u)} \oplus U_{\mu_1} \oplus U_{(m_1-\mu_1)} \oplus \cdots \oplus U_{\mu_r} \oplus U_{(m_r-\mu_r)} \oplus U_k.
\]
Taking into account Proposition 4.2, we obtain the first part of (a), because it is easy to see that the corresponding quotient is naturally diffeomorphic to the product in the statement; the dimension is a trivial computation on the product of the quotients. Since every factor is compact, the product is compact too. The factor $\mathcal{O}_h/\mathcal{O}_{(h-u)}$ is diffeomorphic to the real Grassmannian $G_u(\mathbb{R}^k)$, every factor $U_{m_j}^{\mu_j} \mathcal{O}_j / U_{(m_j-\mu_j)}$ is diffeomorphic to the complex Grassmannian $G_{\mu_j}(\mathbb{C}^{m_j})$, while the last factor $\mathcal{O}_{2k} / U_k$ is diffeomorphic to the manifold of skew-symmetric orthogonal matrices of order $2k$. This allows to obtain the statement about the connectedness (and hence to conclude (a)), for instance, by means of the description of $\mathcal{O}_{2k} / U_k$, given in [Dolcetti-Pertici 2018a, Rem. 3.1 and Prop. 3.2]).

As in Theorem 2.5, the map $L_M \circ j : (\mathcal{O}_n, -g) \to (\mathcal{O}_n, -g)$, $L_M \circ j(X) = MX^{-1}$ is an isometry of $(\mathcal{O}_n, -g)$, whose set of fixed points is $\mathcal{OSR}(M)$; hence we can conclude (b) by [Kobayashi 1995, Thm. 5.1, pp. 59-60]. □

4.4. Remarks. a) We have: $\mathcal{OSR}(-I_{2m}) = \mathcal{O}_{2m} \cap \mathfrak{so}_{2m} = SO_{2m} \cap \mathfrak{so}_{2m}$ for every $m \geq 1$ and $(SO_{2m} \cap \mathfrak{so}_{2m}, -g)$ is a compact totally geodesic Riemannian submanifold of $(SO_{2m}, -g)$ with two connected components identified by the sign of the pfaffian of their matrices. Both components are simply connected and diffeomorphic to $SO_{2m} / U_m$. This follows from Proposition 4.2 and Theorem 4.3, taking into account the analysis developed in [Dolcetti-Pertici 2018a, § 3].

b) We have: $\mathcal{OSR}(I_n)_u = \mathcal{O}_n \cap GL_{Sym}(u)$ for every $0 \leq u \leq n$ and this is a compact totally geodesic Riemannian submanifold of $(\mathcal{O}_n, -g)$, diffeomorphic to the real Grassmannian $G_u(\mathbb{R}^n)$. This follows again from Proposition 4.2 and Theorem 4.3 (see also [Dolcetti-Pertici 2018a, § 4]).

4.5. Remark. Let $M \in SO_n$ and assume the same notations as in Remarks-Definitions 4.1. Then $\mathcal{OSR}(M)$ is the disjoint union of the sets $\mathcal{OSR}(M)^{(\mu_1, \cdots, \mu_r)}_u$ (on all admissible indices $u, \mu_1, \cdots, \mu_r$) and its connected components are homogeneous differentiable manifolds of various dimensions. The number of such components can be obtained from Theorem 4.3.

In particular there are finitely many orthogonal square roots of $M$ if and only if each possible $\mathcal{OSR}(M)^{(\mu_1, \cdots, \mu_r)}_u$ has dimension 0, i.e. if and only if
0 ≤ h, m_1, ⋅⋅⋅, m_r, k ≤ 1, i.e. if and only if M has the eigenvalues different from −1, all of multiplicity 1, and, if −1 is an eigenvalue, its multiplicity is 2. Hence, if there are finitely many orthogonal square roots of M, their number is precisely \( 2^{\lfloor (n+1)/2 \rfloor} \), where \( \lfloor (n+1)/2 \rfloor \) denotes the integer part of \( n/2 \).

4.6. Remark. Let \( M \in SO_n \) and assume the same notations as in Remarks-Definitions 4.1.

If 1 is not an eigenvalue of \( M \) (i.e. if \( h = 0 \)), then \( OSR(M) \subseteq SO_n \).

Otherwise (i.e. if \( h ≥ 1 \)) \( OSR(M) \cap SO_n \) and \( OSR(M) \cap O_n^- \) are both not empty with

\[
OSR(M) \cap SO_n = \bigcup_{0 ≤ i ≤ [h/2] ; 0 ≤ μ_j ≤ m_j ; 1 ≤ j ≤ r} OSR(M)^{(μ_1, ⋅⋅⋅, μ_r)}_{h-2i},
\]

\[
OSR(M) \cap O_n^- = \bigcup_{0 ≤ i ≤ [(h-1)/2] ; 0 ≤ μ_j ≤ m_j ; 1 ≤ j ≤ r} OSR(M)^{(μ_1, ⋅⋅⋅, μ_r)}_{h-2i-1}.
\]

Indeed, by Remarks-Definitions \( \lfloor h/2 \rfloor \) \( det(Y) = (-1)^{h-u} \), if \( Y \in OSR(M)^{(μ_1, ⋅⋅⋅, μ_r)}_u \).

4.7. Remark. Let \( M \in SO_n \) and, analogously to Definition 2.6 and to Remarks 2.7, we can define the set \( POSR(M) \) of generalized principal orthogonal square roots of \( M \) and, with the same notations as in Remarks-Definitions 4.1, we get:

\[
POSR(M) = OSR(M)^{(m_1, ⋅⋅⋅, m_r)}_{h}.
\]

By Theorem 4.3, \( POSR(M) \) is a single point if −1 is not an eigenvalue of \( M \), while it is diffeomorphic to \( O_{2k}/U_k \) if −1 has multiplicity \( 2k ≥ 2 \) as eigenvalue of \( M \).

In particular, if \( k = 1 \), \( POSR(M) \) consists of two distinct points.

We refer, for instance, to [Dolcetti-Pertici 2018a, § 3] for more properties of the homogeneous space \( O_{2k}/U_k \).
