86 GHz VERY LONG BASELINE POLARIMETRY OF 3C 273 AND 3C 279
WITH THE COORDINATED MILLIMETER VLBI ARRAY

ABSTRACT

Very long baseline polarimetry at 86 GHz probes magnetic field structures within the cores of active galactic nuclei at higher angular resolutions and a spectral octave higher than previously achievable. Observations of 3C 273 and 3C 279 taken in 2000 April with the Coordinated Millimeter VLBI Array have resulted in the first total intensity (Stokes I) and linear polarization VLBI images reported of any source at 86 GHz. These results reveal the 86 GHz electric vector position angles within the jets of 3C 273 and 3C 279 to be orthogonal to each other and the core of 3C 273 to be unpolarized. If this lack of polarization is due to Faraday depolarization alone, the dispersion in rotation measure is $\gtrsim 90,000$ rad m$^{-2}$ for the core of 3C 273.

Subject headings: galaxies: active — galaxies: jets — galaxies: magnetic fields — polarization — quasars: individual (3C 273, 3C 279)

1. INTRODUCTION

Magnetic fields trace the flows of relativistic plasma ejected from the cores of active galactic nuclei (AGNs) in the form of powerful jets. Ordering of the jet magnetic fields by shocks (e.g., Hughes, Aller, & Aller 1985; Marscher & Gear 1985) or shear (Wardle et al. 1994) occurs within a fraction of a parsec from the jets’ points of origin. Although synchrotron theory predicts sources may exhibit up to 75% fractional linear polarization ($m$) in the optically thin regime, this level of polarization has never been observed in AGN cores. It is likely that the modest $m$ observed in AGN cores at centimeter wavelengths results from disordered magnetic fields, depolarization, and high optical depths. Very long baseline polarimetry (VLBP) at 86 GHz ($\lambda = 3.5$ mm) should be sensitive to intrinsic field order and may reveal the first instances of magnetic field ordering mechanisms, for the effects of Faraday rotation ($\propto \lambda^2$) and depolarization are reduced at high frequencies.

2. OBSERVATIONS AND CALIBRATION

Images of 3C 273 and 3C 279 were produced from data taken with four antennas (Fort Davis, Los Alamos, Pie Town, Kitt Peak 12 m) during the Coordinated Millimeter VLBI Array (CMVA)$^1$ program CA01 over ~7 hr on 2000 April 17 (epoch 2000.30). The data were recorded at 86 GHz with a total bandwidth of 64 MHz. This four-station subset of the complete CMVA run was correlated on the NRAO$^2$ correlator as a width of 64 MHz. This four-station subset of the complete 2000.30. The data were recorded at 86 GHz with a total band-

CMVA operations and correlation at Haystack are conducted under support from the National Science Foundation.

3. RESULTS

Naturally weighted images in $I$ and $P$ are presented in Figures 1 and 2. These images are the first 86 GHz VLBI Stokes $I$- and $P$-images presented for any source. Currently, there is no known calibrator by which to register absolute EVPAs at

$^3$ PCAL algorithms are restricted to very simple source structure and therefore could not be applied to the extended structure of 3C 273.
86 GHz; therefore, line segments in the $P$-images represent the orientation of the electric field vectors assigned an arbitrary instrumental position angle, rotated through an adopted 90° EVPA calibration constant as explained in § 4.2. Note that the EVPAs of the two sources relative to each other are correctly registered.

The $I$-images presented in Figures 1a and 2a have dynamic ranges of $\sim100 : 1$, and the Fourier transforms of the clean components represented by the images result in the best matches to the $(u, v)$-data among many trials of hybrid mapping and self-calibration, down to timescales of 30 s in phase and 2 minutes in amplitude. DIFMAP’s MODELFIT routine was used to fit individual components in $I$, $Q$, and $U$. Because $Q$- and $U$-positions were restricted to the locations of the $I$ peaks, resultant values of $m_{86}$ do not necessarily represent the true maximum $m_{86}$ of a component. Model fits for both 3C 273 and 3C 279 are presented in Table 1.

3.1. 3C 273

The source 3C 273 (J1229+0203) is a low optical polarization quasar with $z = 0.158$ (Strauss et al. 1992), corresponding to $2.63 \, h^{-1} \, \text{pc mas}^{-1}$. A typical core-jet source, 3C 273 contains a bright component to the east, which is resolved in the north-south direction, and a jet extending to the west-southwest. The $P$-image shown in Figure 1b displays linear polarization only in the jet component (C2) adjacent to the core (D); the core itself is unpolarized to a limit of 1%. Model fits to the data (Table 1) show that C2 has $m_{86} \sim 11\%$.

Historically, at frequencies lower than 86 GHz 3C 273 displays very low levels of fractional core polarization with increasing levels further down the jet. The variable nature of 3C 273 and the differing resolutions provided by images at other frequencies make temporal and spatial comparisons of all but the core quite difficult. The most recent, published VLBI values of $m$ for 3C 273 are presented by Taylor (1998) and Lister & Smith (2000, hereafter L&S). At 15 GHz (epoch 1997.07), 3C 273 displayed $m_{15} \sim 0.2\%$ in the core (Taylor 1998). At 22 GHz (epoch 1999.03), L&S found a maximum core polarization of $m_{22} < 0.1\%$; 43 GHz results, also at epoch 1999.03, reveal a maximum core polarization of $m_{43} < 0.6\%$.

3.2. 3C 279

The object 3C 279 (J1256−0547) is a compact source with a jet extending to the west-southwest. It is a high optical polarization quasar with $z = 0.536$ (Marziani et al. 1996), corresponding to $5.89 \, h^{-1} \, \text{pc mas}^{-1}$. In the $P$-image of Figure 2b, both the core (D) and the jet component (C1) are linearly polarized. In fact, C1 is highly polarized, displaying $m_{86} \sim 20\%$, while the core displays $m_{86} \sim 5\%$ (Table 1).

The 3C 279 results presented here are consistent with past high-frequency VLBI observations of the source. Taylor (1998, 2000) found 15 GHz fractional polarization of $m_{15} = 4.0\%$ in the core of 3C 279 at epoch 1997.07, and $m_{43} = 7.6\%$ at epoch 1998.59—an increase of 90%. L&S found upper limits on the core polarizations to be 3.9% at 22 GHz and 6.6% at 43 GHz, both at epoch 1999.03. Epoch 1997.58 Very Long Baseline Array observations at 43 GHz show $m_{43} = 4.5\%$ in the core of 3C 279 (A. P. Marshner et al. 2001, in preparation).

4. DISCUSSION
4.1. Proper Motion Extrapolation

Using an average proper motion of 1 mas yr$^{-1}$ for 3C 273 as derived from six epochs of dual-frequency data by Homan et al. (2001), extrapolation of jet components from epoch...
Fig. 2.—Naturally weighted images of 3C 279, epoch 2000.30, made with the CMVA at 86 GHz. (a) Total intensity distribution, with contours of $I$ at $-60.00, 60.00, 84.85, \ldots$ (factors of $\sqrt{2}$), $5431$, and $7680$ mJy beam$^{-1}$; the peak is $9885$ mJy beam$^{-1}$, and the restoring beam shown in the lower left is $0.99$ mas $\times 0.52$ mas at $\phi = 2\degree.55$. (b) Linear polarization distribution, with contours of $p$ at $70.00, 98.99, \ldots$ (factors of $\sqrt{2}$), $280.0$, and $396.0$ mJy beam$^{-1}$; the peak is $456.2$ mJy beam$^{-1}$. The line segments show the orientation $\chi$ of the electric field in the source rotated through an estimated $90\degree$ calibration constant (see § 4.2). The restoring beam is the same as for $I$.

1999.03 (L&S) to the 86 GHz epoch of 2000.30 was performed. L&S’s component H evolves to a distance of $2.1$ mas from the core, coincident with 86 GHz component C1. Two intermediate components from L&S, i and j, are located at $1.4$ and $1.6$ mas, respectively, from the core. These two components lie between components C1 and C2 of the 86 GHz data.

Similarly, a proper motion of $0.2$ mas yr$^{-1}$, also from Homan et al. (2001), was used to extrapolate L&S’s epoch 1999.03 3C 279 jet components to epoch 2000.30. After extrapolation, L&S’s component F falls at a distance of $0.9$ mas from the core, consistent with 86 GHz component C1. Component F/C1 reveals high levels of polarization at $22$ GHz ($m_{22} = 18.3\%$), $43$ GHz ($m_{43} = 25.7\%$), and $86$ GHz ($m_{86} = 25\%$). High levels of fractional polarization ($\geq 20\%$) are not unique and have been seen in a number of sources, e.g., $32\%$ in OJ 287 (Gabuzda & Gomez 2001), $20\%$ in BL Lacertae (Denn, Mutel, & Marscher 2000), and $29\%$ in 3C 454.3 (Cawthorne & Gabuzda 1996). Note that the peak $m_{86} \sim 26\%$ in 3C 279 is located $0.85$ mas from the core, between the core and C1.

### 4.2. Electric Vector Position Angles

As previously stated, no absolute EVPA ($\chi$) calibration can yet be performed on the 86 GHz data. Nonetheless, the EVPAs of the two sources may be compared to each other and to values measured at other frequencies.

If $\Delta \chi = \chi_{3C273} - \chi_{3C279}$ then $\Delta \chi_{86} = 63\degree$ is the difference between the EVPAs of 3C 273 and 3C 279 at 86 GHz. Similarly, single-dish data from the James Clerk Maxwell Telescope results in $\Delta \chi_{270} = 87\degree$ at 270 GHz, epoch 1995.98 (Nartallo et al. 1998), and $\Delta \chi_{350} = 97\degree$ at 350 GHz, epoch 2000.26 (J. A. Stevens 2001, private communication). Epoch 1999.03 VLBI observations at 43 GHz show $\Delta \chi_{43} = 60\degree$ (L&S). The 86 GHz results are thus consistent with $\Delta \chi$-values at adjacent frequencies.

### TABLE 1

**EPOCH 2000.30 MODELFIT DATA FOR 3C 273 AND 3C 279 AT 86 GHz**

| Source | Component | $r$ (mas) | $\theta$ (deg) | $I$ (Jy) | $m$ (%) | $\chi$ (deg) | Major Axis (mas) | Minor Axis (mas) | $\phi$ (deg) |
|--------|-----------|-----------|----------------|----------|---------|--------------|----------------|----------------|-------------|
| 3C 273 | D         | 2.40      | $<1$           | 37 $\pm$ 8 | 0.19    | $<0.05$      | $-4.3$          |                |             |
|        | C2        | 1.06      | $-123.4$       | 1.51 $\pm$ 3 | 0.37    | 0.14         | 4.5             |                |             |
|        | C1        | 2.09      | $-130.8$       | 0.95 $\pm$ 1 | 0.87    | 0.39         | 17.5            |                |             |
| 3C 279 | D         | 10.23     | $5 \pm 1$      | $-27 \pm 5$ | 0.15    | 0.09         | 26.5            | $<0.05$         |             |
|        | C1        | 0.94      | $-122.6$       | 0.79 $\pm 7$ | 0.51    | 0.51         | 21.2            |                |             |

frequencies. Comparing the $\chi$-values of 3C 273 and 3C 279 at 86 GHz with those at 43 GHz suggests an offset between the two frequencies of $\sim 90^\circ$. This comparison is reasonable, as L&S's 43 GHz data are closest in resolution to and are only one spectral octave off from the 86 GHz data. It would therefore be reasonable to assume that the proper EVPA calibration constant at 86 GHz is $\sim 90^\circ$. This estimated 90$^\circ$ calibration constant has been applied to the $P$-images shown in Figures 1b and 2b.

It is well known that the EVPAs of AGN jets are closely related to their jet position angles, $\theta$ (e.g., Cawthorne et al. 1993). VLBI observations at many frequencies generally show the EVPAs of 3C 273 to be transverse ($E_\perp$) to the VLBI jet axis and the EVPAs of 3C 279 to be longitudinal ($E_\parallel$) to the VLBI jet axis (e.g., 15 GHz: Homan & Wardle 1999; 22 and 43 GHz: L&S; 43 GHz: A. P. Marscher et al. 2001, in preparation). Aligning the EVPAs measured in single-dish measurements at 270 GHz (Nartallo et al. 1998) and 350 GHz (J. A. Stevens 2001, private communication) with the VLBI jet position angle of a lower frequency produces the same results: 3C 273 displays $E_\perp$ and 3C 279 displays $E_\parallel$. The 86 GHz $P$-images presented in Figures 1b and 2b reveal 3C 273's EVPAs to be transverse to the jet direction and 3C 273's to be longitudinal to the jet direction, consistent with results at adjacent frequencies. This suggests that application of the estimated 90$^\circ$ EVPAs at 86 GHz is appropriate.

4.3. Rotation Measures and Faraday Screens

Taylor (1998, 2000) and L&S derive absolute Faraday rotation measures (RM$s$) in excess of 1000 rad m$^{-2}$ in the cores of many quasars, including 3C 273 and 3C 279. Beyond projected distances of $\sim 20$ pc from the core, RM$s$ in the jets of quasars drop to $|RM| < 100$ rad m$^{-2}$ (Taylor 1998). The presence of large RM$s$ suggests that parsec-sized Faraday screens with organized magnetic fields will be found near the cores of quasars (L&S).

As Faraday rotation is proportional to $\chi^2$, RM$s$ are expected to diminish at high frequencies. The observations presented here challenge this expectation by showing the cores of 3C 273 and 3C 279 to have low levels of polarization even at 86 GHz. The core of 3C 273 is unpolarized in VLBP observations up through 43 GHz, and the addition of the 86 GHz results ($m_{86} \leq 0.6\%$) show that this trend continues at higher frequencies. It is interesting to explore the case where depolarization of 3C 273's core is attributed to Faraday depolarization alone. Assuming that $\sigma_{RM}$ is the standard deviation of a Gaussian distribution of many RM$s$ over a finely spaced grid (Burn 1966), and that $m_{86} \sim 11\%$ of the jet represents a purely depolarized state, $\sigma_{RM}$ must be $\leq 90,000$ rad m$^{-2}$ for the core of 3C 273.

Alternatively, the magnetic field in the core of 3C 273 may be initially tangled, becoming ordered somewhere between the core (D) and the adjacent polarized jet component (C2). The degree of order of the magnetic field may be calculated assuming the magnetic field in the unshocked jet fluid contains a small-scale tangled component plus a uniform component aligned perpendicular to the line of sight. The resulting fraction of magnetic energy in the tangled component in 3C 273 is then $\sim 89\%$ (Burn 1966; Wardle et al. 1994).

5. Conclusions

The CMVA results presented here validate 86 GHz VLBP as a practical and potent new tool to probe magnetic field properties of AGN cores. With only 86 GHz observations, it is impossible to distinguish between the depolarizing effects of a Faraday screen and a tangled magnetic field. Future simultaneous, multifrequency VLBP observations, including ones at 86 GHz, are crucial in testing various depolarization mechanisms in the cores of 3C 273 and 3C 279. With the addition of new 86 GHz antennas, particularly those that provide long baselines, resolutions much higher than those currently attainable at 43 GHz should be achieved. High-resolution observations should set limits on the sizes of Faraday screens in both 3C 273 and 3C 279 by resolving the cores of these objects into smaller components, thereby testing the discussion of § 4.3.
