Featured Application: This paper describes the thermal analyses of a piezoelectric micro actuator in an endoscopic biopsy to solve the overheating problem in the narrow space. The proposed method can be used for the operation of the piezoelectric micro actuator at a safe level, in order to achieve drive control and drug permeation promotion of precise dosing devices in the endoscopic biopsy channel.

Abstract: Micro actuators have been used to realize the arrival of digestive tract lesions for the local targeted application of drugs in endoscopes. However, there still exists a key safety issue that casts a shadow over the practical and safe implementation of actuators in the human body, namely an overheated environment caused by actuators’ operation. Herein, with the aim of solving the temperature rising problem of a piezoelectric micro actuator operating in an endoscopic biopsy channel (OLYMPUS, Tokyo, Japan), a thermal finite element method (FEM) based on COMSOL Multiphysics software is proposed. The temperature distribution and its rising curves are obtained by the FEM method. Both the simulated and experimental maximum temperatures are larger than the safety value (e.g., 42 °C for human tissues) when the driving voltage of the actuator is 200 Vpp, which proves that the overheating problem really exists in the actuator. Furthermore, the results show that the calculated temperature rising curves correspond to the experimental results, proving the effectiveness of this FEM method. Therefore, we introduce a temperature control method through optimizing the duty ratio of the actuator. In comparison with a 100% duty ratio operation condition, it is found that a 60% duty ratio with a driving voltage of 200 Vpp can more effectively prevent the temperature rising issue in the first 3 min, as revealed by the corresponding temperatures of 44.4 and 41.4 °C, respectively. When the duty ratio is adjusted to 30% or less, the temperature rise of the actuator can be significantly reduced to only 36.6 °C, which is close to the initial temperature (36.4 °C). Meanwhile, the speed of the actuator can be well-maintained at a certain level, demonstrating its great applicability for safe operation in the human body.

Keywords: piezoelectric micro actuator; endoscopic biopsy channel; thermal analyses; temperature rise control methods; finite element method (FEM)

1. Introduction

Over the past decades, the development of micro actuators and motors for providing an efficient approach to realizing the arrival of digestive tract lesions has triggered enormous interest from both academia and industry [1–4]. This is because even making use of modern advanced minimally invasive surgery, such as Endoscopic Submucosal Dissection (ESD), negative consequences, including perforation [5] and postoperative bleeding, may be induced [6,7], thus posing a threat to the patient’s life. It has been found that employing endoscopic hemostatic forceps or other surgical methods can...
temporarily stop bleeding; however, over 30% of patients still suffer from postoperative bleeding [8–10]. In addition, it should be noted here that ESD treatment is strictly prohibited for patients with blood clotting disorders and blood diseases [11–13]. On the other hand, chemotherapy-targeted drugs have been demonstrated to be effective for curing major gastrointestinal diseases [14,15]. However, the traditional oral approach for taking chemotherapy-targeted drugs is prone to causing systemic allergic reactions and serious side effects [16,17]. Therefore, there is an urgent need to develop a new and efficient approach to realizing the arrival of digestive tract lesions for local targeted applications of drugs in endoscopes.

Currently, for the practical and safe operation of micro actuators inside the human body, two main issues still exist, including the lack of linear motion and the temperature increase when operating in the endoscopic biopsy channel [18]. In particular, the temperature rising issue induced by the thermal effect of actuators can cause overheating, giving rise to histologic damage [19–21], i.e., burns and tissue necrosis, thus making it difficult to realize long-term safe operation inside the human body. Due to their distinguished features of a high precision [22,23], quick response [24,25], simple structure [26,27], and miniature size [28,29], piezoelectric actuators have emerged as one of the promising candidates. Our recent work demonstrated the capability of a small-sized piezoelectric actuator (diameter 3 mm) being operated in an endoscopic biopsy channel (OLYMPUS, Tokyo, Japan) for releasing targeted drugs [30]. However, the operation of a piezoelectric actuator in the endoscopic biopsy channel can also yield an elevated temperature of over 42 °C, which has been suggested to be the safe temperature limit, resulting in a temperature rising problem, as mentioned above. Therefore, exploring an effective approach to address this issue still remains a challenge for their practical and commercial application.

Herein, in this work, with the aim of preventing the temperature issue of our piezoelectric actuator, we propose a thermal finite element method (FEM) based on COMSOL Multiphysics software to achieve thermal analyses. Additionally, systematic work is performed to study the effect of the duty ratio on the temperature and speed of the actuator because, when the actuator is installed in the endoscope, the permanent magnet orbit is ground to a thickness of 0.35 mm, and its magnetic induction intensity is 43 mT, making it difficult to decrease the temperature by decreasing the driving voltage amplitude (the minimum driving voltage is 200 V$_{pp}$). Therefore, only modulating the duty ratio of the actuator is applicable to control the temperature rises of the actuator. According to the theoretical analysis and experimental results, it is found that a 60% duty ratio with a driving voltage of 200 V$_{pp}$ can more effectively decrease the temperature rise from 44.4 °C to 41.4 °C in the first 3 min. Moreover, the temperature of the actuator is significantly reduced to around 36.6 °C when the duty ratio is modulated to less than 30%. Furthermore, the speed of the actuator can be well-held at a certain level, proving its safe usability for operation in the endoscopic biopsy channel.

2. Material and Methods

2.1. Micro Piezoelectric Actuator in the Endoscopic Biopsy Channel

To ensure actuator operation in the endoscopic biopsy channel, a light-weight surface milli-walker based on piezoelectric actuation was designed and reported in our recent research [30]. Although its overall size met the size limit of an endoscope, the actuator needs a pre-pressure track, which was provided by an electromagnet and corresponding power supply wire in actual installation, and the resultant overall size turned out to be too large to be integrated into the biopsy channel of an endoscope. Therefore, a permanent magnet orbit instead of an electromagnet is used to provide the magnetic field for the actuator in this paper. Despite the permanent magnet size, whose thickness is far smaller than that of an electromagnet, it still has a high magnetic induction intensity to provide enough pre-pressure, making it suitable for application in the endoscopic biopsy channel, as shown in Figure 1a. In addition, the overall size of the actuator is miniaturized to 4.5 mm × 1.5 mm × 1.5 mm (length × width × height) and its driving frequency is 10.4 kHz in this paper. The actuator weight is 0.063 g, in which the size of the thickness is 0.2 mm and the size of the piezoelectric ceramic is 1.5 mm × 0.2 mm × 3 mm, as seen in
Moreover, to enable the linear motion of the actuator in the endoscopic biopsy channel, the permanent magnet orbit is polished by sand paper to achieve a thickness of 0.35 mm and an effective working distance of 10 mm, and the object is shown in Figure 1c.

Generally, the biopsy forceps, needles, and other medical consumables of an endoscope that can move in the endoscopic biopsy channel during surgery are installed with the help of a cleaning brush. In this work, we also employed the cleaning brush to install the actuator and permanent magnets in the endoscopy and realize their combination. The schematic diagram is shown in Figure 1a. The cleaning brush was modified to remove the hair brush of its head and use it as a guide line. Then, the permanent magnet orbit was fixed at the end of the cleaning brush using adhesive tape and the actuator was absorbed on the orbit by the magnetic field. After that, two wires were also fixed on the...
cleaning brush to ensure that the driving voltage could be applied outside. As described above, the actuator system could be installed in the endoscope biopsy channel as a whole, as shown in Figure 1c.

The installation steps of the actuator and permanent magnet orbit in the endoscopic biopsy channel are as follows:

1. Put the actuator on the permanent magnet orbit and fix the actuator through the magnetic field, making it unable to fall off during the installation process;
2. Insert the guide line from the entrance of the biopsy channel. During the installation process, the cleaning brush and the actuator must be inserted under a smooth condition;
3. Ensure the bending angle of the endoscope is not too large to avoid damage to the actuator and permanent magnet orbit when the actuator passes through the bending part of the endoscope;
4. When removing the actuator after use, it should be pulled out from the entrance of the biopsy channel slowly and lightly to prevent the actuator from falling off the track and leaving the endoscope during the pulling process.

It should be noted here that due to the thickness of the permanent magnet orbit being only 0.35 mm, it is easy to break under collision, and thus, special attention should be paid to the installation process. Using the aforementioned steps, the actuator system and its supporting cleaning brush were successfully installed in the endoscopic biopsy channel, as shown in Figure 1d.

2.2. Measurement Methods

To enable the safe movement of the actuator in the endoscopic biopsy channel, heat should be controlled to a certain extent (≤42 °C). A FOTRIC thermal imaging camera (226 s) was used here to witness the temperature rise of the actuator in the endoscopic biopsy channel with a measurement accuracy of 2 °C, which was obtained from ZXF Laboratories (Dallas, TX, USA). Additionally, a thermostat (DHG 303-0) was used to mimic a body temperature of 37 ± 1 °C (the errors come from thermal convection in the air) on the surface of the endoscopic channel, which was obtained from Huyue Co., Ltd. (Yiwu, Zhejiang province, China). In the experiments, the actuator with the endoscopic biopsy channel was installed in the thermostat by adhesive tape, as shown in Figure 2. The maximum temperature of the front end of the actuator in the endoscopic biopsy channel was measured by the thermal imaging camera with the minimum infrared resolution (384 × 288 pixels), which may cause heat damage to the human body.

![Figure 2](image-url)  
Figure 2. Experimental method of measuring temperature rises of the actuator in the biopsy channel.

3. Temperature Field Model

3.1. Assumptions

In this section, we use the FEM model built in COMSOL Multiphysics software to analyze the temperature field. The following assumptions are made for the temperature field model of the device:

(1) The voltage applied to the actuator is constant, and the environmental temperature and heat-transfer coefficients are invariable;
(2) Heat energy generated by the friction loss is ignored because the actuator’s movement time is short and it vibrates in the same position at the rest time. Therefore, the mechanical loss and dielectric loss are considered the main sources of heat energy;

(3) Heat energy generated by the mechanical loss or dielectric loss is uniformly distributed in the actuator and piezoelectric wafer.

3.2. Piezoelectric Coupling

For the actuator shown in Figure 1a, the driving voltage is applied in the piezoelectric ceramics, and the converse piezoelectric effect can be calculated by classical piezoelectric equations [31] by considering the mechanical loss and dielectric loss factors, which can be represented as follows (in a linear elastic range):

\[
\begin{align*}
S_i &= s_{ij}^E T_j + d_{im} E_m, \quad i, j = 1, 2, 3, 4, 5, 6; \quad m, n = 1, 2, 3, \\
D_m &= d_{mj} T_j + \varepsilon_{mn}^T E_n
\end{align*}
\]

where \( S_i \) is the strain component; \( D_m \) is the electric displacement; \( s_{ij}^E \) is the flexibility coefficient; \( T_j \) is the stress component; \( E_m \) is the electric field; \( d_{im} \) and \( d_{mj} \) are the piezoelectric constants; \( \varepsilon_{mn}^T \) is the free dielectric constant; and \( i, j, m, \) and \( n \) are shortened subscripts representing different tensor orientations (more details can be seen in ref. [31]). In this paper, \( s_{ij}^E \) would be a complex expression by including the loss factor \( \eta_i \) in COMSOL. The boundary condition assumes that the outside area of the actuator is free.

3.3. Initial and Boundary Conditions

When the actuator operates in the endoscopic biopsy channel, because the contact area of the actuator and the permanent magnet orbit is very small, the main part of the heat on its surface is transferred to the atmosphere by convection. The equation of thermal convection can be expressed as [31]

\[-k \frac{\partial T}{\partial n} = h_p(T^4 - T_c^4), \tag{2}\]

where \( T_c \) is the ambient temperature, \( h_p \) is the thermal convection dissipation coefficient (determined by the heat dissipation environment), \( k \) is the heat conductivity, \( n \) is the spatial vector, and \( \frac{\partial T}{\partial n} \) represents the temperature gradient along the \( n \) direction.

Given that part of the heat is transmitted in the form of radiation, the effect of thermal radiation should also be taken into account. The expression is [32]

\[-k \frac{\partial T}{\partial n} = \sigma A(T^4 - T_r^4), \tag{3}\]

where \( \sigma \) is the Stefan–Boltzmann constant, \( T_r \) is the environmental temperature, and \( A \) is the radiant surface shape factor.

In order to calculate the temperature field distribution of the actuator, the initial temperature field state needs to be defined. The overall initial temperature is constant:

\[ T_{t=0} = T_0, \tag{4}\]

where \( t \) is the working time and \( T_0 \) is the initial environmental temperature.

3.4. Thermal Sources

The transient thermal equilibrium equation can be represented as

\[ \rho C_p \frac{\partial T}{\partial t} + \rho C_p u \cdot \nabla T = \nabla (k \nabla T) + Q, \tag{5}\]
where $T$ is the temperature, $t$ is the time, $\rho$ is the material density, $C_p$ is the heat capacity, $k$ is the thermal conductivity, $u$ is the velocity field, and $Q$ is the heat source—more heat sources can be added separately. The velocity field $u$ is assumed to be null (ignoring acoustic fluid). For the heat source $Q$ in the experiment, it is made from the following parts: the mechanical and dielectric loss of the actuator and piezoelectric ceramic, represented as

$$
\begin{align*}
Q_m &= \eta_s (2\pi f \cdot W_h) \\
Q_d &= \eta_e (2\pi f \cdot E^2 \cdot \varepsilon_p)
\end{align*}
$$

where $Q_m$ is the mechanical loss of the actuator body or the piezoelectric ceramics, and $Q_d$ is the dielectric loss of the piezoelectric ceramics. $W_h$ is the mechanical energy density of the actuator in the vibration, $E$ is the electric field, and $\varepsilon_p$ is the relative dielectric constant. $\eta_s$ and $\eta_e$ are the mechanical loss factor and dielectric loss factor, respectively. $Q_m$ and $Q_d$ can be calculated in terms of Equation (1), and the thermal calculation can then be obtained from Equation (3) according to the initial and boundary conditions.

3.5. FEM Calculation

The dimension parameters of the actuator are shown in Figure 1b and the thickness of the glue layer (Epoxy resin), which is used for adhering the piezoelectric ceramics (PZT-8) and actuator body (Ferronickel), and conducting film (Polyimide) is set as 0.01 mm. The material parameters of the actuator are shown in Table 1. The heat sources shown in Equation (4) determined that the analyzed model should be 3-D and include all the main structural parts. For solving the transient temperature field, the full method in COMSOL software is selected and the calculation time is set to 3 min with a time step of 1 min. The mesh of the actuator is shown in Figure 3.

Figure 3. The mesh of the piezoelectric micro actuator.

4. Results and Discussion

With a driving voltage of 200 V_{pp} and a resonant frequency of 10.4 kHz, the actuator can move forward outside or inside the endoscopic channel (see Figure 4) and thus modulate the distance between the actuator and disease part, proving that the piezoelectric actuator and permanent magnet orbit can meet the size requirements of the endoscope and also be applicable for linear driving of the micro ultrasonic transducer or other dosing devices in the biopsy channel for drug penetration in an unresectable or non-abatable archenteric gastrointestinal tumor.

![Figure 4](image)

*Figure 4.* The motion process of the piezoelectric actuator: (a) outside the endoscopic biopsy channel (Video S2); (b) inside the endoscopic biopsy channel (Video S1).

To correlate the speed upon the application of driving voltage, duty ratio, and magnetic induction intensity, a performance test platform is established to obtain the motion performance of the piezoelectric actuator on the permanent magnet track. The permanent magnet orbit has an effective working distance of 10 mm and its motion process is given in Figure 5a. Shown in Figure 5b is the speed versus applied voltage performance of the actuator on the permanent magnet orbit, whose magnetic induction intensity is 145 mT. An upward trend in the speed with the increasing driving voltage is observed. A maximum speed of 168 mm/s is achieved with a driving voltage of 200 V_{pp} at 10.4 kHz. Meanwhile, a minimum speed of 25 mm/s is achieved with a driving voltage of 120 V_{pp}. In addition, the amplitude of the leg is too small and it is difficult for the actuator to work stably when the driving voltage is lower than 120 V_{pp}, and the piezoelectric ceramics can be easily broken down when the driving voltage is higher than 200 V_{pp}. To characterize the effect of the magnetic induction intensity on the speed of the actuator, we measured the speed under various magnetic induction intensities and the obtained data are given in Figure 5c. The magnetic induction intensity can be changed by alcohol lamp heating permanent magnets and the grinding of permanent magnets. As can be seen from Figure 5c, the speed of the actuator under different magnetic induction intensities basically presents a linear distribution, and the speed of the actuator increases with the increase of the magnetic induction intensity. When the magnetic induction intensity of the permanent magnet orbit is 43 and 145 mT, the corresponding actuator speed is 41 and 168 mm/s, respectively. In this paper, because the permanent magnet orbit is ground to a thickness of 0.35 mm when the actuator is installed in the endoscope, its magnetic induction intensity is 43 mT.

According to the experimental measurement methods of Section 2, the maximum temperature of the front end of the actuator working in the endoscopic channel in the first 3 min is shown in Figure 6 for when the driving voltage is 200 V. From the figure, it is obvious that the endoscopic biopsy channel displayed the highest temperature because of the existence of the piezoelectric actuator being operated, while the temperature of the remaining regions was also affected by the operation of the piezoelectric actuator. Moreover, it shows that the temperature rises from 36.4 °C to 44.4 °C with an
increasing operation time, which is beyond the safe temperature of the human body. In particular, the temperature of the actuator is more than 42 °C just after 1 min. As shown in Figure 7a, the temperature field distribution of the actuator is obtained and the maximum temperature appears on the surface of the piezoelectric ceramics. Moreover, the results of Figure 7b show that the calculated maximum temperature of the front end of the actuator (it is same measurement area as the experimental measurement area) rising curves corresponds to the experimental results, proving the effectiveness of this FEM method. These results all prove that the overheating problem really exists in the actuator. According to the theoretical analysis presented in Section 3, the temperature rise can be controlled by the driving voltage and duty ratio. Therefore, a study was carried out to characterize the influence of voltages and the duty ratio on the temperature rises of the actuator.

Figure 5. Performance of the actuator on the permanent magnet orbit: (a) the motion process; (b) speed versus applied voltage; (c) speed versus magnetic induction intensity.

Figure 6. Temperature rise experimental results of the actuator working in the endoscopic channel when the driving voltage is 200 Vpp in the first 3 min.
When the duty ratio is adjusted to 30% or less, the temperature rises are greatly reduced to only 36.6 °C, which is close to the initial temperature (36.4 °C). Therefore, adjusting the driving voltage duty ratio has been proven to be a feasible method for preventing the temperature rising issue of the actuator in the biopsy channel with only a slight sacrifice of the actuator speed. It is noteworthy that the amplitude of the leg is too small and it is too difficult for the actuator to work stably when the duty ratio is adjusted to 10%, the actuator speed is greatly reduced to only 2.3 mm/s. With a further decreasing duty ratio, the actuator speed will continue to decrease to interrupt the working stability of the actuator.

Meanwhile, an upward trend in the temperature with an increasing duty ratio can be seen. As compared with a 100% duty ratio operation mode, a 60% duty ratio can more effectively decrease the temperature rise, as revealed by the corresponding temperatures of 44.4 to 41.4 °C, respectively. When the duty ratio is adjusted to 30% or less, the temperature rises are greatly reduced to only 36.6 °C, which is close to the initial temperature (36.4 °C). Therefore, adjusting the driving voltage duty ratio has been proven to be a feasible method for preventing the temperature rising issue of the actuator in the biopsy channel with only a slight sacrifice of the actuator speed. It is noteworthy that the amplitude of the leg is too small and it is too difficult for the actuator to work stably when the driving voltage is lower than 200 Vpp with a magnetic induction intensity of 43 mT, so the temperature rise control method that adjusts the driving voltage is not practical under this circumstance.
5. Conclusions

A temperature rise control method of a piezoelectric actuator operated in an endoscopic biopsy channel has been studied in this paper. FEM based on COMSOL Multiphysics software has been proposed to achieve thermal analyses. The temperature distribution and its rising curves have been obtained by the FEM method. Both the simulated and experimental maximum temperatures are larger than the safety value when the driving voltage is 200 V_{pp}, which proves that the overheating problem really exists in the actuator. Furthermore, the results show that the calculated temperature rising curves correspond to the experimental results, proving the effectiveness of this FEM method. The experimental results demonstrate that the actuator speed increases with the increasing driving voltage and magnetic induction intensity of the permanent magnet orbit. However, when the actuator is installed in the endoscope, the permanent magnet orbit is ground to a thickness of 0.35 mm, and its magnetic induction intensity is 43 mT, making it difficult to realize temperature control by adjusting the driving voltage. Therefore, only modulating the duty ratio of the actuator is applicable to control the temperature rises of the actuator. The experimental results illustrate that a 60% duty ratio can more effectively decrease the temperature rise than a continuous operation in the first 3 min. When the duty ratio is adjusted to less than 30%, the temperature rises are greatly reduced to only 36.6 °C, which is close to the initial temperature (36.4 °C). Consequently, this work demonstrates that optimizing the duty ratio of the actuator can effectively control the temperature rises and well-maintain the speed of the actuator.
