Abstract: Rare actinomycetes are prolific in the marine environment; however, knowledge about their diversity, distribution and biochemistry is limited. Marine rare actinomycetes represent a rather untapped source of chemically diverse secondary metabolites and novel bioactive compounds. In this review, we aim to summarize the present knowledge on the isolation, diversity, distribution and natural product discovery of marine rare actinomycetes reported from mid-2013 to 2017. A total of 97 new species, representing 9 novel genera and belonging to 27 families of marine rare actinomycetes have been reported, with the highest numbers of novel isolates from the families Pseudonocardiaceae, Demequinaceae, Micromonosporaceae and Nocardioidaceae. Additionally, this study reviewed 167 new bioactive compounds produced by 58 different rare actinomycete species representing 24 genera. Most of the compounds produced by the marine rare actinomycetes present antibacterial, antifungal, antiparasitic, anticancer or antimalarial activities. The highest numbers of natural products were derived from the genera Nocardiopsis, Micromonospora, Salinispora and Pseudonocardia. Members of the genus Micromonospora were revealed to be the richest source of chemically diverse and unique bioactive natural products.

Keywords: rare actinomycetes; marine actinobacteria; cultivation; natural products; bioactive compounds

1. Introduction

Emerging infectious diseases and multidrug-resistant human pathogens are becoming a major threat to global health [1]. Therefore, there is an urgent need for new antibiotics to fight evolving bacterial infections. Despite the use of large synthetic combinatorial libraries of molecules to develop novel drugs, natural products and microbial metabolites, in particular, are a predominant source of bioactive scaffolds that represent the foundation for the development of life-saving antibiotics [2]. Nature encompasses millions of prokaryotes and eukaryotes with particularly high diversity in oceans and rainforests. However, so far only a small fraction (approximately 250,000–300,000 living species) of at least 1.5 million fungi, 0.5 million plant species and $10^{11}–10^{12}$ microbial species on Earth have been documented [3,4]. Moreover, even the known species have only been explored for bioactivity or for natural product discovery up to a limited extent. Therefore, natural resources are virtually unlimited for natural product discovery. The phylum Actinobacteria represents one of the largest phyla among the 30 major phyla currently recognized within the domain Bacteria. There are 6 classes, 18 orders, 14 suborders, 63 families and 374 genera recorded in this phylum until October 2016 (http://www.bacterio.net/-classifphyla.html#actinobacteria). In this review paper the term
“actinomycetes” (http://www.bacterio.net/-classifphyla.html#actinobacteria) will be used to refer the members of the order Actinomycetales of the phylum Actinobacteria. The members of actinomycetes have been characterized as the most important group of microorganisms in the field of biotechnology, as producers of bioactive secondary metabolites with medical, industrial and agricultural applications [5]. However, until now, only less than 1% of the actinomycetes have been identified, investigated and documented [3]. Out of 500,000 natural compounds reported worldwide from biological sources, approximately 70,000 are microbially-derived compounds (both from bacteria and fungi), of which 29% is derived from actinomycetes. Approximately 60% of antibiotics applied, were isolated from actinomycetes between 1950 and 1970, exclusively from the genus *Streptomyces* [3]. However, in more recent history, high replication of discovery of compounds has been reported from *Streptomyces* species, which diverted the attention to non-*Streptomyces* actinomycetes and a noteworthy renaissance in antibiotics development from microorganisms has come with the exploration of previously poorly assessed microorganisms from underexplored environments. The unexplored and underexplored environments including marine ecosystems are promising sources of rare actinomycetes that are believed to be rich sources of interestingly new compounds [6,7]. ‘Rare actinomycetes’ are defined as the actinomycete strains less frequently isolated than that of the ‘commonly’ isolated *Streptomyces* spp., even though they may not actually be rare in the environment.

Oceans occupy 71% of the Earth’s surface holding 97% of the planet’s water and nearly 87% of life with essentially untouched fauna and flora [3] and are a great source for undiscovered organisms including microorganisms and novel natural products. Marine-derived rare actinomycetes are reported to be a potentially rich source of diverse chemicals, structurally unique secondary metabolites and novel therapeutic compounds [2,6]. Only 11 rare actinomycetes genera had been reported by 1970, followed by 100 genera by 2005 and 220 genera by 2010 [7]. High-throughput metagenome sequencing methods have expanded our knowledge and revealed the presence of many novel actinomycetes that were not previously detected in cultivation studies [5,8,9]. The retrieval of rare actinomycetes in conventional cultivation experiments is generally lower than that of the streptomyces strains [5]. However, recent understanding of marine actinomycetes’ physiological, chemical, and structural features has enabled the design of selective isolation media [5]. A total of 13,700 bioactive metabolites were reported from actinomycetes up to 2010, of which 10,400 were derived from streptomycetes and 3300 from rare actinomycete strains [3]. In 1974, only 125 active metabolites had been isolated from rare actinomycetes, increasing to 361, 745, 1276, 2250, 2500 bioactive metabolites by 1980, 1984, 1988, 2005 and 2010, respectively [7]. In our previous review, we summarized the novel families, novel genera, and new species of rare actinomycetes from marine habitats including bioactive compounds reported from 2007 to mid-2013 [7]. The goal of this present review is to summarize new species of marine rare actinomycetes, and the bioactive compounds discovered between mid-2013 and 2017 and discuss their chemical diversity and biotechnological potential.

2. Isolation Methods for Marine Rare Actinomycetes

Members of the phylum Actinobacteria adapt well to and successfully colonize different extreme environments including the deep sea [10] and genera of this phylum exhibit huge diversity in terms of their morphology, physiology, and metabolic capabilities [5]. Marine rare actinomycetes generally require special growth conditions compared to terrestrial actinomycete species [11–14]. Notably, it has been observed that a large number of bacterial cells in under/unexplored environments are viable but not culturable (VBNC), as approximately 1% of bacterial cells can form colonies on isolation media by conventional methods [15]. Therefore, high throughput molecular techniques, including metagenomics, are increasingly favored to investigate microbial communities in the environment [16] for which culture-based approaches have been rather unsuccessful up to now. Concurrently, knowledge of functional characteristics of actinomycetes based on cultivation-independent studies, has led to improved strategies with respect to growth conditions and cultivation media to recover previously unculturable actinomycetes [5,17–21].
2.1. Basic Approaches for Isolation Media for Marine Rare Actinomycetes

Targeting unknown rare actinomycetes for isolation requires knowledge and experience of actinomycetes taxonomy, physiology and environmental factors, such as pH, cultivation temperature, oxygen, nutrient requirements etc. [22]. Sodium, is one of the most important medium components for growth of marine microorganisms including marine actinomycetes such as *Salinispora* spp. and therefore growth media should generally have osmotic values similar to seawater [13]. Besides, different carbon (soluble starch, glucose, dextrose, maltose, trehalose, mannitol, raffinose, fucose, chitin, glycerol and oatmeal) and combined carbon-nitrogen sources (peptone, yeast extract, casein, malt extract, meat extract, beef extract and tryptone) have been supplemented in isolation media for successful isolation of marine rare actinomycete taxa [23–27]. In addition, researchers have added sediment extracts, sponge extracts and natural seawater alone or as a supplement to mimic natural environmental conditions [12,28–34]. In general, low-nutrient media are more efficient than nutrient-rich media for isolation of marine rare actinomycetes [13,28,35]. Generally, some basic approaches may be followed for isolation of marine rare actinomycetes: 1, Three to five different isolation media with various components should be employed for any target genus of actinomycetes [9,11,28]; 2, The isolation media must meet the requirements of the target actinomycetes and at the same time should limit the growth of unwanted microbes [22,28]; 3, Growth inhibitors, in the form of antibiotics or chemicals, should be added into isolation media to inhibit or restrict the growth of Gram-negative bacteria and fungi [11,28]; 4, The medium should be so designed that it mimicks the microbe’s natural environmental conditions [12,28,29]; 5, The medium should also suppress the growth of fast-growing and common streptomycete strains [22].

2.2. Pretreatment of Marine Samples

Marine samples, particularly sediments used for the isolation of rare actinomycetes, may be treated prior to isolation to remove common terrestrial actinomycetes and unwanted microorganisms to reduce replication of isolation. Commonly used pre-treatment methods for the isolation of rare actinomycetes from marine samples generally include dilution and mixing with sterile natural seawater [25,36,37], artificial seawater [38–40], deionized/distilled water supplemented with NaCl [41,42], multi-salts [24,26,40], vitamin B mixtures [43], one-quarter Ringer’s solution [44] and saline solution [45] before transferring the inoculum to Petri dishes [44]. A variety of pre-treatment methods for selectively isolating actinomycetes has been applied (Table 1). However, the drying of the environmental sample using laminar air flow, dilution with seawater or saline prior to sample heating are most frequently employed pre-treatments (Table 1). Actinomycetes spores are generally resistant to desiccation and heating and can thus be used to select against other Gram positive bacteria [46]. Further, actinomycetes spores are resistant to a wide range of chemicals, such as benzethonium chloride, chlorhexidine gluconate, phenol, sodium dodecyl sulfate, and different antibiotics. These chemicals have been used to selectively isolate actinomycete taxa. Treatment with these chemicals for 30 min. can kill or inhibit aerobic Gram negative bacteria, endospore-forming bacilli and pseudomonads, thus increasing the chance of selectively isolating actinomycetes, and reduce other types of bacteria [22]. Additionally, ultrasonic waves can release actinomycetes propagules from sediment particles into suspension, thus also increasing the number of Actinobacterial strains and reducing unwanted bacteria [47].

3. Marine Habitats: The Largest Reservoir for Rare Actinomycetes

The world’s oceans constitute more than 90% of the inhabitable space on the planet and it is the largest reservoir of life on Earth. Approximately 80% of all life on Earth lives in the ocean and the oceans harbour 32 out of 33 known animal phyla, of which 15 are exclusively marine [48].
Table 1. Pre-treatment methods for the selective isolation of marine rare actinomycetes.

| Pre-treatment | Marine Source | Isolation Medium | Incubation Temperature/Time | Target Rare Genera | Ref. |
|---------------|---------------|------------------|----------------------------|--------------------|------|
| Incubation in water bath at 50 °C for 60 min | WS | Starch-casein agar + 10 µg nalidixic acid, 25 µg nystatin and 10 µg cycloheximide | 24 °C for 28 days | Micromonospora | [45] |
| | WS | M1 agar + 75 µg cycloheximide | 20-24 °C for 14-28 days | Micromonospora | [49] |
| 50 °C for 15 min | WS | Starch-casein agar + 10 µg nystatin and 25 µg cycloheximide | 28 °C for 7 days | Monashia, Microbacterium and Sinomonas | [23,50,51] |
| 55 °C for 20 min | WS | Glucose peptone tryptone agar + 50 mg nystatin, 50 mg cycloheximide, 25 mg novobiocin and 20 mg nalidixic acid | 28 °C for 21 days | Micromonospora | [52] |
| Incubation in water bath at 55 °C for 6 min | DS | M1-M5 agar + 100 µg cycloheximide and 5 µg rifampin | 25-28 °C for 2-6 weeks | Micromonospora and Salinispora | [11,53] |
| Incubation in water bath at 60 °C for 10 min | DS | M1-M12 agar + 100 µg cycloheximide and 50 µg nystatin | 28 °C for 3 months | Micromonospora and Salinispora | [28] |
| Speedvac 30 °C, 16 h; 120 °C, 60 min | DS | Different selective media + cycloheximide (50 µg/mL), nystatin (75 µg/mL) and nalidixic acid (30 µg/mL) | 20 °C for 2-6 weeks | Rare actinomycetes | [54] |
| 41 °C for 10, 30 and 60 days | DS | Different selective media | 28 °C for 2-3 weeks | Streptomyces, Catellatospora, Nocardiia and Actinopolyspora | [55] |
| 70 °C for 15 min | WS | Different selective media | 25 °C for 4 weeks | Micromonospora, Microbacterium, Actinoplanes and Actinomadura | [56] |
| 55 °C for 15 min | DS | Asparagine-glucose agar medium + nalidixic acid (25 µg/mL) and secnidazole (25 µg/mL) | 25 °C for 2 weeks | Pseudonocardia | [57] |
| 45, 55 or 65 °C for 30 min | WS | ISP-3 and ISP-4 + cycloheximide (50 µg/mL), nystatin (50 µg/mL), and nalidixic acid (20 µg/mL) | 27 °C for 3 weeks | Micromonospora | [58] |
| 60 °C for 6 min | WS | M1 medium and Glucose-yeast extract medium + nystatin (50 µg/mL), and nalidixic acid (10 µg/mL) | 25 °C for 6 weeks | Nocardia, Nonomuraea, Rhodococcus, Saccharopolyspora and Gordonia | [59] |
| Dry in laminar air flow hood, Stamping | WS/DS | M1-M12 agar + 100 µg cycloheximide and 50 µg nystatin | 28 °C for 3 months | Micromonospora and Salinispora | [28,53] |
| Shake with glass beads for 30 s and settled for 5 min | WS | Different selective media + cycloheximide (50 µg/mL), nystatin (75 µg/mL) and nalidixic acid (30 µg/mL) | 20 °C for 6 weeks | Rare actinomycetes | [54] |
| 1.5% phenol + 30 min at 30 °C | DS | Different selective media + cycloheximide (50 µg/mL), nystatin (75 µg/mL) and nalidixic acid (30 µg/mL) | 20 °C for 2-6 weeks | Micromonospora | [4] |
| 0.02% benzethonium chloride + 30 min at 30 °C | DS | Different selective media + cycloheximide (50 µg/mL), nystatin (75 µg/mL) and nalidixic acid (30 µg/mL) | 20 °C for 2-6 weeks | Rare actinomycetes | [54] |
| 0.05% SDS and 6% yeast extract (40 °C, 200 rpm, 30 min) | DS | Different selective media + cycloheximide (25-100 µg/mL) and nystatin (25-90 µg/mL) | 28 °C for 1-12 weeks | Actinomadura, Micromonospora, Nocardiia, Nonomuraea, Rhodococcus and Verrucosispora | [60] |

| Differential centrifugation | WS | Selective media | 28°C for 12 weeks | Micromonospora, Rhodococcus and Streptomyces | [30]|
| Freeze (−20°C, 24 h), thawed, dilution | WS | M1-M12 agar + 100 µg cycloheximide and 50 µg nystatin | 28°C for 3 months | Micromonospora and Salinispora | [28]|
| Freeze at −18°C | WS | Different selective media + nystatin (50 µg/mL) and nalidixic acid (10 µg/mL) | 28°C for 2–3 weeks | Nocardiopsis, Nocardia and Streptosporangium | [61]|
| UV irradiation for 30 s (distance 20 cm, 254 nm, 15 W) | WS | Different selective media + nystatin (50 µg/mL) and nalidixic acid (10 µg/mL) | 28°C for 2–3 weeks | Nocardiopsis, Nocardia and Pseudonocardia | [61]|
| Superhigh frequency radiation in microwave oven for 45 s (2460 MHz, 80 W) | WS | Different selective media + nystatin (50 µg/mL) and nalidixic acid (10 µg/mL) | 28°C for 2–3 weeks | Streptosporangium and Rhodococcus | [61]|
| Extremely high frequency radiation (1 kHz within wavelength band of 8–11.5 mm) | WS | Different selective media + nystatin (50 µg/mL) and nalidixic acid (10 µg/mL) | 28°C for 2–3 weeks | Nocardiopsis, Nocardia and Streptosporangium | [61]|

WS: Wet Sediment; DS: Dried Sediment.

Marine habitats are also a rich source of diverse and largely uncharacterized microbial communities including actinomycetes [62]. This habitat shows extreme variations in ecological pressure, including competition for space, predation, available nutrients, light, oxygen concentration and pressure. Marine organisms including actinomycetes have developed a diverse range of secondary metabolites with unique structural elements to ensure their survival in these habitats [63]. Diverse new rare species including novel genera and novel families of actinomycetes have been isolated from marine habitats, such as coastal, tidal and deep-sea sediments, marine organisms (sponges, corals and ascidians), seawater and also mangrove forests [7]. Approximately 220 genera of rare actinomycetes were reported from marine sources until 2010 [64] and in the following sections we summarize new rare actinomycete isolates from these habitats since then [7]. For this review we’ve applied a conservative threshold on labelling a species as “novel” when sharing less than 97% similarity of the 16S rRNA gene to known species [65–70]. For the labelling of genera and families as “novel” we followed Silva taxonomy [71].

3.1. Rare Actinomycetes from Marine Sediments, Seawater, Eukaryotic Hosts and Mangroves

Approximately 83% of marine sediments are more than 1000 m below sea level, so most marine sediments are located in a cold, lightless, high pressure habitat where food is supplied from distant surface waters [72]. Deep-sea environments are divided into three zones: the bathyal (depth range between 200 and 2000 m), the abyssal (depth from 2000 to 6000 m) and the hadal (depth below 6000 m) [73]. Especially the abyssal and hadal zones are largely unexplored. Highest biodiversity has been recorded at a depth of 3000 m and the heterogeneity of biomass is expanding to 5000 m [74,75]. Cold deep-sea muds have an astounding species richness and diversity compared to tropical rain forests [76]. The majority of these species has not been isolated in the laboratory and an estimated 95% of these species are unidentified and mostly considered as new species [74].
Actinomycetes, including rare actinomycetes, are abundant in diverse marine sediments. A total of 48 new rare actinomycete species belonging to 16 different actinomycete families were isolated from marine sediments in the period from mid 2013 to 2017 (Table 2). Among them, 5 novel genera: *Flaviflexus*, *Halopolyspora*, *Mariniluteicoccus*, *Sediminivirga* and *Haloactinomyces* were described. The actinomycete families reported from marine sediments to which the novel species belong are *Pseudonocardiaceae* (8 new species), *Nocardioidaceae* (5 new species), *Nocardiopsaceae* (4 new species), *Microbacteriaceae* (4 new species), *Micrococcaceae* (4 new species), *Propionibacteriaceae* (4 new species), *Micromonosporaceae* (3 new species), *Nocardiaceae* (2 new species), *Demequinaceae* (2 new species), *Intrasporangiaceae* (2 new species), *Bogoriellaceae* (2 new species), *Acidimicrobiaceae* (2 new species), *Brevibacteriaceae* (2 new species), *Actinopolysporaceae* (2 new species), *Actinomycetaceae* (1 new species) and *Cellulomonadaceae* (1 new species).

Although earlier culture-dependent studies have described microbial population size to be only a few hundred cells per mL of seawater, the staining of cells using fluorescence microscopy studies demonstrated nominal cell densities of $>10^5$ cells per mL of seawater [77,78], which anticipates that the ocean harbors $3.6 \times 10^{29}$ microbial cells [79]. The microorganisms in the seawater play an important role in marine biogeochemical processes involved in cycling and decomposition of organic matter [80]. A total of 8 new rare actinomycete species were reported from seawater for the period mid-2013 to 2017 (Table 3), among which 2 novel genera, *Pontimonas* and *Tamlicoccus*. They belong to six actinomycete families: *Nocardioidaceae* (3 new species), *Cellulomonadaceae* (1 new species), *Micrococcaceae* (1 new species), *Microbacteriaceae* (1 new species), *Dermacoccaceae* (1 new species) and *Dermabacteraceae* (1 new species). From these studies, it is apparent that lower numbers of rare actinomycetes are isolated from seawater than from sediments. However, novel genera have been reported from seawater, which contribute to the extension of phylogenetic diversity of rare actinomycetes (Table 3) [7].

A substantial number of rare actinomycetes were reported to be associated to various members of marine benthic communities, such as sponges, corals, ascidians, sea anemones, sea cucumbers, sea urchins and seaweeds [7,62,81]. Five novel genera, 17 new rare actinomycete species belonging to 11 different actinomycete families were reported from marine plants and animals between 2007 and mid-2013 [7]. A total of 14 new species of rare actinomycetes belonging to 12 different families have been reported from various sponges, corals, algae, sea urchin, jelly fish and fish between mid-2013 and 2017 (Table 4). The families of novel (potentially symbiotic) actinomycete species reported from mid-2013 to 2017 are *Micromonosporaceae* (2 new species), *Pseudonocardiaceae* (2 new species), *Microbacteriaceae* (1 new species), *Erythrobacteriaceae* (1 new species), *Nocardioidaceae* (1 new species), *Micrococcaceae* (1 new species), *Intrasporangiaceae* (1 new species), *Nocardiaceae* (1 new species), *Rubrobacteraceae* (1 new species), *Actinosynnemataceae* (1 new species), *Gordoniaceae* (1 new species) and *Promicromonosporaceae* (1 new species). Thus, marine organisms remain a rich source of novel rare actinomycetes (Table 4) and a substantial number of host-associated rare actinomycete genera have not been reported from other marine habitats (*Labedella*, *Phycicola*, *Iamia*, *Euzebya* and *Koreibacter*) [7]. Interestingly, *Microbacterium aureliae* was reported for the first time from *Aurelia aurita*, the moon jellyfish.
Table 2. New species of rare actinomycetes from marine sediments reported during the period of mid 2013–2017.

| Strain/Family | Nature of Sample | Isolation Medium | Ref. |
|---------------|------------------|------------------|------|
| Saccharomonospora amidosensis/Pseudonocardiaceae | Deep marine sediment at a depth of 60 m | SM3 medium (yeast nitrogen base 67.0 g, casamino acids 100 mg were added to a litre of distilled water and the solution sterilised using cellulose filters (0.20 mm) prior to the addition of sterilised di-potassium hydrogen phosphate (200 mL; 10%, w/v); 100 mL of this basal medium was added to 900 mL of sterilised molten agar (1.5%, w/v) followed by filter sterilised solutions of D(+)-melezitose (1%, w/v), cycloheximide (50 µg mL\(^{-1}\)), neomycin sulphate (4 µg mL\(^{-1}\)) and nystatin (50 µg mL\(^{-1}\)) | [82] |
| Saccharomonospora oceani/Pseudonocardiaceae | Marine sediment | Trypticase soy broth agar (DSMZ Medium 535) | [83] |
| Actinophytocola sediminis/Pseudonocardiaceae | Marine sediment at a depth of 2439 m | Starch casein nitrate agar medium (10.0 g soluble starch, 0.3 g casein, 2 g KNO\(_3\), 0.05 g MgSO\(_4\)-7H\(_2\)O, 35 g NaCl, 2 g K\(_2\)HPO\(_4\), 0.02 g CaCO\(_3\), 10 mg FeSO\(_4\), 20 g agar, distilled water 1 L) | [84] |
| Pseudonocardia sediminis/Pseudonocardiaceae | Sea sediment at a depth of 652 m | DSMZ 621 medium (250 mg each of Bacto peptone (Difco), Bacto yeast extract and glucose, as well as 20 mL Hutner’s basal salts medium, 10 mL vitamin solution no. 6, 35 g NaCl and 1000 mL distilled water) | [85] |
| Amycolatopsis flavus/Pseudonocardiaceae | Marine sediment | CMKA medium ([L\(^{-1}\)] 0.5 g casein hydrolysate, 1.5 g mannitol, 1 g KNO\(_3\), 2 g (NH\(_4\))\(_2\)SO\(_4\), 0.5 g K\(_2\)HPO\(_4\), 0.5 g CaCO\(_3\), 20 g agar). The multi-salts comprised of 49% (w/w) MgCl\(_2\).6H\(_2\)O, 32% (w/w) NaCl, 14% (w/w) CaCl\(_2\) and 5% (w/w) KCl | [86] |
| Saccharopolyspora griseoalba/Pseudonocardiaceae | Marine sediment | CMKA medium ([L\(^{-1}\)] 0.5 g casein hydrolysate, 1.5 g mannitol, 1 g KNO\(_3\), 2 g (NH\(_4\))\(_2\)SO\(_4\), 0.5 g K\(_2\)HPO\(_4\), 0.5 g CaCO\(_3\), 20 g agar). The multi-salts comprised of 49% (w/w) MgCl\(_2\).6H\(_2\)O, 32% (w/w) NaCl, 14% (w/w) CaCl\(_2\) and 5% (w/w) KCl | [87] |
| Amycolatopsis albispora/Pseudonocardiaceae | Deep-sea sediment at a depth of −2945 m | Modified Zobell 2216E agar (1.0 g yeast extract, 5.0 g tryptone, 34 g NaCl, 15 g agar and 1 L distilled water) | [88] |
| Pseudonocardia profundimaris/Pseudonocardiaceae | Marine sediment at a depth of −7118 m | Modified ZoBell 2216E agar plates (0.5% tryptone, 0.1% yeast extract, 3.4% sodium chloride and 1.8% agar) | [89] |
| Nocardoides pacificus/Nocardoidaceae | Deep sub-seafloor sediment at a depth of 107.3–107.4 m | Marine agar 2216 (Difco) | [90] |
| Strain/Family                          | Nature of Sample                  | Isolation Medium                                                                 | Ref.   |
|---------------------------------------|-----------------------------------|----------------------------------------------------------------------------------|--------|
| *Nocardioides nanhaiensis*/*Nocardioidaceae* | Sea sediment at a depth of 880 m | DSMZ 621 medium (250 mg each of Bacto peptone (Difco), Bacto yeast extract and glucose, as well as 20 mL Hutner's basal salts medium, 10 mL vitamin solution no. 6, 35 g NaCl and 1000 mL distilled water) | [91]   |
| *Nocardioides antarcticus*/*Nocardioidaceae* | Marine sediment                  | Marine agar 2216 (Becton Dickinson)                                             | [92]   |
| *Nocardioides litoris*/*Nocardioidaceae* | Marine beach sediment             | Starch casein agar (1% soluble starch, 0.03% casein, 0.2% KNO₃, 0.2% NaCl, 0.005% MgSO₄·7H₂O, 0.2% K₂HPO₄, 0.02% CaCO₃, 0.001% FeSO₄·7H₂O, 1.8% agar) | [93]   |

| Brachybacterium aquaticum/Dermabacteraceae   | Seawater                  | Tryptic soy agar medium (HiMedia)                                                | [127]      |

Mangrove forests are highly dynamic ecosystems that cover and protect approximately 75% of the world’s tropical and subtropical coastal areas [128] and harbor a rich diversity of marine, freshwater and terrestrial flora and fauna. The diversity of the microbial community in mangrove environments is still rather unexplored [60]. The large fluctuation of salinity and tidal gradients make the mangrove forests unique environments that favors the production of unusual metabolites among the residing microorganisms [60]. Novel actinomycetes reported from different mangrove habitats including sediments, mangrove plant rhizosphere soil and mangrove endophytes are classified into 25 genera, 11 families and 8 suborders [7,129]. A total of 27 new species of rare actinomycetes belonging to 13 different families have been reported from mangrove habitats for the period mid-2013–2017 (Table 5). Among them, two novel genera, Mamia and Monashia, were reported to be isolated from the 20 cm top-layer of mangrove soil. The families reported in mangrove sediments between mid-2013 and 2017 are Demequinaceae (9 new species), Micromonosporaceae (5 new species), Nocardiopsaceae (2 new species), Micrococcaceae (2 new species), Nocardioidaceae (1 new species), Intrasporangiaceae (1 new species), Pseudonocardiaceae (1 new species), Microbacteriaceae (1 new species), Thermomonosporaceae (1 new species), Jiangellaceae (1 new species), Beutenbergiaceae (1 new species), Streptosporangiaceae (1 new species) and Kineosporiaceae (1 new species).
Table 4. New species of symbiotic rare actinomycetes from eukaryotic hosts reported during the period of mid 2013–2017.

| Strain/Family                        | Nature of Sample | Isolation Medium                                                                 | Reference |
|--------------------------------------|------------------|----------------------------------------------------------------------------------|-----------|
| *Verrucosispora andamanensis*        | Marine sponge Xestospongia sp. | Starch-casein nitrate seawater agar (10 g soluble starch, 1 g sodium caseinate, 0.5 g KH$_2$PO$_4$, 0.5 g MgSO$_4$ and 18 g agar in 1 L of seawater) | [130]     |
| *Micromonospora spongicola*          | Marine sponge at a depth of 5 m | Starch-casein nitrate agar (10 g soluble starch, 1 g sodium caseinate, 2 g KNO$_3$, 0.5 g KH$_2$PO$_4$, 0.5 g MgSO$_4$ and 18 g agar in 1 L seawater) | [131]     |
| *Prauserella coralliicola*           | Marine coral Galaxea fascicularis at a depth of 5 m | Isolation medium (yeast extract 0.25 g, K$_2$HPO$_4$ 0.5 g, agar 12 g, 500 mL seawater and 500 mL distilled water) | [132]     |
| *Saccharopolyspora spongiae*         | Marine sponge Scopalina ruetzleri at depths between 20 and 30 m | M1 medium [1% starch, 0.4% yeast extract, 0.2% peptone, 2% agar containing artificial seawater (33 g red sea salt L$^{-1}$) amended with cycloheximide and nystatin (each at 25 µg mL$^{-1}$)] | [40]      |
| *Microbacterium aureliae*            | Moon jellyfish Aurelia aurita | Zobell marine agar (HiMedia) and Tryptic soy agar (HiMedia) | [133]     |
| *Mycobacterium stephanolepidis*      | Marine teleost fish Stephanolepis cirrhifer | Middlebrook 7H11 agar with oleic albumin dextrose catalase (OADC) enrichment (Becton Dickinson) | [134]     |
| *Marmoricola aquaticus*              | Marine sponge Glodia corticostylifera | M1 agar (soluble starch 10 g L$^{-1}$, yeast extract 4 g L$^{-1}$, peptone 2 g L$^{-1}$, agar 15 g L$^{-1}$, 80% artificial seawater) | [38]      |
| *Arthrobacter echini*                | Purple sea urchin Heliocidaris crassispina | Marine agar 2216 (Difco) | [135]     |

3.2. Marine Rare Actinomycetes Diversity: A Decade of Experience (2007–2017)

In summary, a total of 97 new species belonging to 27 different rare actinomycete genera, of which 9 represent novel genera, were reported, from the marine environment between mid-2013 and 2017 (Tables 2–6; Figure 1). Furthermore, the families Pseudonocardiaceae, Demequinaceae, Micromonosporaceae and Nocardioidaceae were most frequently isolated from the marine environment. For the period 2007-mid 2013, 80 new species belonging to 23 families of marine rare actinomycetes were reported (Table 6). These data show that the discovery rate of new rare actinomycetes from marine habitats is steady. Interestingly, isolates from 10 actinomycete families, such as Actinomycetaceae, Actinopolysporaceae, Brevibacteriaceae, Rubrobacteraceae, Actinosynnemataceae, Gordoniaceae, Jiangellaceae, Kineosporiaceae, Dermacoccaceae and Dermabacteraceae were reported for the period between mid-2013 and 2017 that were not reported for the period 2007 to mid-2013. Cumulatively this means that a total of of 177 new species of rare actinomycetes representing 33 families including 3 novel families and 29 novel genera were reported from marine habitats in the last 10 years (Table 6).

| Actinomycete families | 2007 to mid-2013 | Mid-2013 to 2017 | Total (2007–2017) |
|------------------------|------------------|------------------|-------------------|
| Micromonosporaceae     | 13               | 10               | 23                |
| Nocardioidaceae        | 10               | 9                | 19                |
| Pseudonocardiaceae     | 6                | 11               | 17                |

4. Actinomycetes as Sources of Antibiotics

Actinomycetes has been one of the most fertile sources for the discovery of new antibiotics since they were first discovered and a number of the antibiotics currently in use are natural products or analogs of natural products from actinomycetes [153]. Actinomycin was the first antibiotic discovered from actinomycetes in 1940 from a culture of *Streptomyces antibioticus* [154], followed by streptothricin from *Streptomyces lavendulae* in 1942 [155], and streptomycin from *Streptomyces griseus* in 1944 [156]. *Streptomyces* species have been the key source of clinical antibiotics, and more than 80% of all antibiotics of actinomycetes origin have been derived from this single genus [3,157]. Out of all microbiobly-derived antibiotic classes, 10 classes are exclusively produced by actinomycetes. These are polyprene macrolides, oligomycin-type large-membered macrolides, daunomycin-type anthracyclines, nigericin-type polyether antibiotics, nonactin-type cyclopolylactones, aminoglycosides, anthracyclines, streptothricins, actinomycins and quinoxaline-peptides [3]. The antibiotics production of different actinomycete strains can vary enormously as some actinomycete species produce a single antibiotic, whereas some produce a wide-range of different compounds and compound classes [5]. A total of 30 new antibiotics have been launched worldwide since 2000. Of the 30 new antibiotics, 2 were natural products (NP), 12 were NP-derived and 16 were synthetic antibiotics [158]. Out of these 30 new antibiotics, 12 were reported from members of actinomycetes, either as natural product or natural product-derivatives representing 7 different antibiotic classes (Table 7). Due to the decline in the number of new chemical scaffolds and rediscovery of known molecules, the innovation in antibiotic development has slowed down. The exploration of alternative taxa, which have not been previously cultivated, could alleviate urgent needs related to resistance against currently used antibiotics.

4.1. Rare Actinomycetes: A Target for Future Drugs

As a result, rare actinomycetes are becoming an increasingly important focus of investigation in the search for novel natural products because (1) they occupy a poorly explored taxonomic and environmental space, which reduces the likelihood of replication of discovery, and (2) the phylum Actinobacteria is a rich source of bioactive secondary metabolites [46] that can be expected to yield novel chemical scaffolds for the development of new antibiotics.

4.2. Marine Rare Actinomycetes Is a Source of Antibiotics

Approximately 100 new bioactive compounds were reported from 38 rare actinomycete strains belonging to 15 genera described between 2007 and mid-2013. Out of these 15 different genera, *Salinispora* (20 new compounds), *Verrucospora* (18 new compounds), *Nocardiopsis* (12 new compounds), *Actinoalloteichus* (11 new compounds), *Marinicipirulus* (10 new compounds) and *Micromonospora* (9 new compounds) were predominant for discovery of novel secondary metabolites from 2007 to mid-2013 [7]. A total of 4 compounds derived from marine actinomycetes are currently in clinical trials (Table 7) of which 3 were obtained from marine *Salinispora* spp., indicating that *Streptomyces* spp. are no longer the most important biological resource for new antibiotics.
Table 7. Antibiotics of therapeutic natural products derived from actinomycetes.

| Drug Name/Compound | Natural Product (NP) or Derivative | Source Organism        | Chemical Class       | Therapeutic Activity       | Clinical Status (Year) | Reference |
|--------------------|-----------------------------------|------------------------|----------------------|----------------------------|------------------------|-----------|
| Telithromycin      | Erythromycin (NP-derivative)      | Saccharopolyspora erythraea | Macrolide            | Antibacterial (G+ve/G−ve)  | Approved (2001)        | [158]     |
| Biapenem           | Thienamycin (NP-derivative)       | Streptomyces cattleya   | Carbapenem           | Antibacterial (G+ve/G−ve)  | Approved (2002)        | [158]     |
| Eraptamen          | Thienamycin (NP-derivative)       | Streptomyces cattleya   | Carbapenem           | Antibacterial (G+ve/G−ve)  | Approved (2002)        | [158]     |
| Daptomycin         | Natural product                    | Streptomyces roseosporus| Lipopeptide          | Antibacterial (G+ve)       | Approved (2003)        | [158]     |
| Doripenem          | Thienamycin (NP-derivative)       | Streptomyces sp.        | Carbapenem           | Antibacterial (G+ve/G−ve)  | Approved (2005)        | [158]     |
| Tigecycline        | Tetracycline (NP-derivative)      | Streptomyces aureofaciens| Tetracycline         | Antibacterial (G+ve/G−ve)  | Approved (2005)        | [158]     |
| Tebipenem pivoxil  | Thienamycin (NP-derivative)       | Streptomyces sp.        | Carbapenem           | Antibacterial (G+ve/G−ve)  | Approved (2009)        | [158]     |
| Telavancin         | Vancomycin (NP-derivative)        | Actinoplanes orientalis| Glycopeptide         | Antibacterial (G+ve)       | Approved (2009)        | [158]     |
| Fidaxomicin        | Natural product                    | Dactylolopangium aurantiacum | Tiacumicin         | Antibacterial (G+ve)       | Approved (2011)        | [158]     |
| Dalbavancin        | Teicoplanin (NP-derivative)       | Nonomurania sp.         | Glycopeptide         | Antibacterial (G+ve)       | Approved (2014)        | [158]     |
| Oritavancin        | Chloroeremomycin (NP-derivative)  | Actinoplanes orientalis| Glycopeptide         | Antibacterial (G+ve)       | Approved (2014)        | [158]     |
| Tazobactam         | NP-derivative                      | Actinomycete strain     | Penicillanic acid sulfone derivative and β-lactamase inhibitor| Antibacterial (G−ve)     | Approved (2014)        | [158]     |

| Marine source       |                                    |                        |                      |                            |                        |          |
|---------------------|-----------------------------------|------------------------|----------------------|----------------------------|------------------------|-----------|
| Salinosporamide A   | Natural product                    | Salinispora tropica    | Beta-lactone-gamma lactam | Multiple cancer            | Phase I                | [159]     |
| (Marizomib)         |                                    |                        |                      |                            |                        |          |
| Arenamides A and B  | Natural product                    | Salinispora sp.        | Peptide              | Inflammation               | Pre-clinical           | [160]     |
| Anthracymycin       | Natural product                    | Streptomyces sp.       | Polykylide           | Anthrax                    | Pre-clinical           | [161]     |

G+ve: Gram positive; G−ve: Gram negative.
4.3. Novel/New Compounds from Marine Rare Actinomycetes between mid-2013 and 2017

A total of 167 different new bioactive compounds were reported from 58 rare actinomycete strains belonging to 24 genera from mid-2013 to 2017 (Table 8). Among them, genera such as *Nocardiopsis* (40 new compounds), *Micromonospora* (37 new compounds), *Salinispora* (21 new compounds) and *Pseudonocardia* (14 new compounds) are leading with respect to the number of novel secondary metabolites (Table 8). Among them, there are new/novel pyrones, structurally diverse natural products and unique chemical moieties (Figures 2–5).

**Table 8.** Numbers of new natural products/bioactive compounds produced by rare actinomycete genera from the marine environment between 2007 and 2017.

| Particular | 2007 to mid-2013 * | Mid-2013 to 2017 | Total (2007–2017) |
|------------|------------------|-----------------|-------------------|
| Novel/new compounds reported | 100 | 167 | 267 |
| Total number of rare actinomycetes | 38 | 58 | 96 |
| Total genera reported | 15 | 24 | 28 |

| No. of new compounds reported in each genus |
|--------------------------------------------|
| **Nocardiopsis** | 12 | 40 | 52 |
| **Micromonospora** | 9 | 37 | 46 |
| **Salinispora** | 20 | 21 | 41 |
| **Pseudonocardia** | 3 | 14 | 17 |
| **Verrucosispora** | 18 | 2 | 20 |
| **Amycolatopsis** | 1 | 3 | 4 |
| **Serinicoccus** | 1 | 1 | 2 |
| **Kocuria** | 1 | - | 1 |
| **Actinoalloteichus** | 11 | 5 | 16 |
| **Actinomadura** | 3 | 5 | 8 |
| **Dermacoccus** | 7 | 3 | 10 |
| **Kitasatospora** | 1 | - | 1 |
| **Nocardia** | 2 | - | 2 |
| **Saccharomonospora** | 1 | 5 | 6 |
| **Marinispora** | 10 | - | 10 |
| **Actinokineospora** | - | 2 | 2 |
| **Solvonaspora** | - | 2 | 2 |
| **Micrococcus** | - | 1 | 1 |
| **Microbacterium** | - | 3 | 3 |
| **Rubrobacter** | - | 2 | 2 |
| **Saccharothrix** | - | 4 | 4 |
| **Actinomycetespora** | - | 3 | 3 |
| **Williamsia** | - | 1 | 1 |
| **Streptomelanospora** | - | 4 | 4 |
| **Nesterenkonia** | - | 1 | 1 |
| **Kribella** | - | 4 | 4 |
| **Streptosporangium** | - | 3 | 3 |
| **Saccharopolyspora** | - | 1 | 1 |

* Adapted from Subramani and Aalbersberg [7].
A total of 7 different chemical classes of natural products were reported from marine Nocardiopsis spp. between mid-2013 and 2017 of which, α-pyrone (18 out of 40 compounds) were predominant (Table 9; Figure 2). These molecules have a wide range of biological activities, such as pro-inflammatory activity (enhancing and stimulating the inflammatory response), anti-inflammatory activity, antibacterial and cytotoxic activities (Table 9). In addition, the genera Streptomonospora and Saccharomonospora also produce a substantial number of α-pyrones. Besides, nocardimazole from Nocardiopsis sp. possess a 4-aminoimidazole ring rarely found in microbial secondary metabolites [162] and rare
prolinyl-macrolactam polyketides were isolated from *Nocardiopsis* sp. [163]. Sterol O-acyltransferase [SOAT, also known as acyl-CoA: cholesterol acyltransferase (ACAT)], an endoplasmic reticulum membrane protein, catalyzes the synthesis of cholesteryl ester from free cholesterol and long-chain fatty acyl-CoA. SOAT has been postulated as a target for modulation by a new type of antiatherosclerotic agent. Interestingly, a diketopiperazine derived from marine *Nocardiopsis* sp. was found to be an effective SOAT inhibitor [164].

**Figure 4.** Some of the unique chemical moieties in natural products produced by marine rare actinomycetes between mid-2013 and 2017.

Marine *Micromonospora* spp. produced 37 out of the 167 compounds reported from mid-2013–2017 and were chemically diverse (Table 9; Figure 3). In total, 13 chemical classes, including macrolides, polyene macrocyclic lactams, polycyclic tetramic acid macrolactams, aromatic tautomers, hydroxamates, diterpenoids, diterpenes, angucyclines, quinolone alkaloids, dioxanes, glycosylated paulomycins, glycosides and aglycone spirotetrorates were identified in *Micromonospora* spp. during this period. Polyene macrolactams are an underexplored group of natural products that have only been found in actinomycetes. Micromonolactam is a new polyene macrocyclic lactam isolated from a marine *Micromonospora* sp. (Figure 3). However, micromonolactam did not show antibacterial activities against test pathogens [165]. Another interesting group of natural products, paulomycins, are glycosylated molecules containing a pauloate residue that are of pharmacological interest due to their strong antibiotic properties [166]. Paulomycin G is structurally unique because it is the smallest bioactive paulomycin in the paulomycin family of antibiotics, lacking the paulomycose moiety (Figure 3). Furthermore, a number of novel chemical skeletal structures are reported from marine *Micromonospora* spp. For
example, polycyclic tetramic acid macrolactams of butremycin [167], halimane-type diterpenoids of micromonohalimanes [168] and a novel pimarane diterpene in isopimara-2-one-3-ol-8,15-diene [169] (Figure 3).

![Figure 5. Some unusual biologically active compounds produced by marine rare actinomycetes between mid-2013 and 2017.](image)

Additionally, other rare actinomycete genera have yielded a number of unique chemical moieties, which were not previously reported from microbially-derived natural products (Figure 4). For example, thiasporine A is the first natural product with a 5-hydroxy-4H-1,3-thiazin-4-one moiety, along with two new thiazole derivatives and were reported from Actinomycespora chlora [170] (Figure 4). Other unusual structures include a curvularin macrolide with a rare α-D-glucopyranosyl substituent from Pseudonocardia sp. [171]; a butrepyrazinone, from Verrucosiphora sp. that possesses an unusual methylation pattern on the pyrazinone ring [172], a novel indole microindolinone A from Microbacterium sp. [173], new dimeric indole derivatives with acetylcholinesterase (AchE) inhibitory activity from Rubrobacter radiotolerans [174] and a structurally new amycofuran bearing a rhamnose sugar from Amycolatopsis sp. [175].

Actinomadura sp. derived halomadurones (Figure 5) demonstrated potent nuclear factor E2-related factor antioxidant response element (Nrf2-ARE) activation, which is an important therapeutic approach for treatment of neurodegenerative diseases [176]. Cyanogramide obtained from Actinalloteichus cyanogriseus showed efficient anticancer activity by reversing the adriamycin-induced resistance of K562/A02 and MCF-7/Adr cells, and the vincristine-induced resistance of KB/VCR cells [177].
Table 9. Novel/new bioactive compounds produced by marine rare actinomycetes between mid 2013 and 2017.

| Compounds                  | Chemical Family/Class | Marine Source      | Biological Activity                                      | Reference |
|----------------------------|-----------------------|--------------------|----------------------------------------------------------|-----------|
| Halomadurones A–D          | Halogenated electrophilic pyrones | Actinomadura sp.   | Potent Nrf2-ARE activation                                | [176]     |
| Levantilide C              | 20-membered macrolide | Micromonospora sp. | Antiproliferative activity                               | [178]     |
| Nocapyrones H–J            | α-pyrones             | Nocardiopsis sp.   | Pro-inflammatory factor, stronger inhibitory effect on nitric oxide | [179]     |
| Nocardiopsins C and D      | Prolinyl-macrolactam polyketides | Nocardiopsis sp. | Not specified                                            | [163]     |
| Nocardipyrone A            | α-pyrone polyketide  | Nocardiopsis sp.   | Not specified                                            | [163]     |
| Nocardiamide A and B       | Cyclic hexapeptides  | Nocardiopsis sp.   | Antimicrobial activity                                   | [180]     |
| Cyanosporasides C–F        | Polyketides           | Salinispora pacifica | Not specified                                             | [181]     |
| Micromonolactam            | Polyene macrocyclic lactam | Micromonospora sp. | No antimicrobial activity                                | [165]     |
| Cyanogramide               | Spirocyclic alkaloid  | Actinoalloteichus cyano griseus | Multidrug-resistance (MDR) reversing activity          | [177]     |
| Actinosporins A and B      | O-glycosylated angucyclines | Actinoalloteichus cyano griseus | Moderate activity against Trypanosoma brucei         | [182]     |
| Solvaric acids A and B     | Trialkyl-substituted aromatic acids | Solvaraspora sp. | Antibacterial activity against MDR pathogens             | [183]     |
| Seriniquinone              | Quinones              | Serinicoccus sp.   | A selective anticancer agent                             | [184]     |
| Cyanogrisides E–H          | Acyclic bipyridine glycosides | Actinoalloteichus cyano griseus | Cytotoxicity                                         | [185]     |
| Forazolime A               | Polyketides           | Actinomadura sp.   | Anti-candida activity                                    | [186]     |
| Amycofuran                 | Benzofuran glycoside  | Amycolatopsis sp.  | Modest cytotoxicity                                      | [175]     |
| Amycolactam                | Indole alkaloids      | Amycolatopsis sp.  | Cytotoxicity                                             | [175]     |
| Amycocyclopiazonic acid    | Cyclopiazonic acid    | Amycolatopsis sp.  | Modest cytotoxicity                                      | [175]     |
| Dermacozines H–J           | Heteroaromatic phenazines | Dermacoccus abysssi | Radical scavenging activity                             | [187]     |
| Microluside A              | O-glycosylated xanthone | Micrococcus sp.  | Antibacterial activity                                   | [188]     |
| Nocapyrone R               | α-pyrones             | Nocardiopsis sp.   | No cytotoxicity                                          | [189]     |
| Butremycin                 | Polycyclic tetramic acid macrolactams | Micromonospora sp. | Weak antibacterial activity                             | [167]     |
| 5′-Methylthioinosine       | Protonated aromatic tautomer | Micromonospora sp. | No antibacterial activity                                | [167]     |
| Butrepyrazinone            | Pyrazinone            | Verrucospora sp.   | No antibacterial activity                                | [172]     |
| Compounds                      | Chemical Family/Class | Marine Source          | Biological Activity                  | Reference   |
|-------------------------------|-----------------------|------------------------|--------------------------------------|-------------|
| MBJ-0003                      | Hydroxamate           | *Micromonospora* sp.   | Moderate cytotoxicity                | [190]       |
| Microbacterins A and B        | Peptaibols            | *Microbacterium* sediminis | Potent cytotoxic activity             | [191]       |
| Salinipostins A–K             | Bicyclic Phosphotriesters | *Salinospora* sp.     | Antimalarial activity                | [192]       |
| Nocarimidazoles A and B       | 4-aminoimidazole alkaloids | *Nocardiosis* sp.    | Weak antibacterial activity          | [162]       |
| Dimeric indole derivatives 1 and 2 | Dimeric indoles              | *Rubrobacter* radiotolerans | Acetylcholinesterase (AchE) inhibitory activity | [174] |
| Saccharothrixones A–D         | Aromatic polyketides   | *Saccharothrix* sp.    | Cytotoxic activity                   | [193]       |
| Thiasporines A–C              | Thiazone and Thiazole Derivatives | *Actinomycetospora* cloria | Cytotoxicity                      | [170]       |
| Diketopiperazine 1            | Diketopiperazine       | *Nocardiosis* sp.     | Sterol O-acyltransferase inhibitor   | [164]       |
| Isopimara-2-one-3-ol-8,15-diene | Pimarane Diterpene    | *Micromonospora* sp.   | Weak cytotoxicity                    | [169]       |
| Lagumycin B, Dehydrorabelomycin, Phenanthroviridone, WS-5995 A | Angucyclines | *Micromonospora* sp.   | Cytotoxicity                       | [169]       |
| Micromonohalimane A and B     | Halimane-type diterpenoids | *Micromonospora* sp. | Modest antibacterial activity against MRSA, bacteriostatic | [168]       |
| Quinoline alkaloid            | Alkaloid               | *Micromonospora* sp.   | Antibacterial activity               | [194]       |
| 1,4-dioxane derivative        | Dioxane                | *Micromonospora* sp.   | Antibacterial activity               | [194]       |
| Pseudonocardides A–G          | γ-butyrolactones       | *Pseudonocardia* sp.   | Antibacterial and cytotoxic activities | [195]       |
| Curvularin macrodiles 1–5     | Macrolides             | *Pseudonocardia* sp.   | Antibacterial and cytotoxic activities | [171]       |
| α-pyrones 1–8                 | α-pyrones              | *Nocardiosis* sp.      | Moderate antibacterial activity      | [196]       |
| Compounds 1–12                | Benzamides, Indoles    | *Nocardiosis* sp.      | Antibacterial, antifungal and cytotoxic activities | [197]       |
| 3-benzyl-3α,4β-dihydroxypentan-2-one | Phenolics           | *Williamsia* sp.      | Not specified                        | [198]       |
| Marinopyrones A–D             | α-pyrones              | *Streptomonospora* sp. | Inhibition of NO production          | [199]       |
| Glycerol 1-hydroxy-2,5-dimethyl benzoate | Salicylic derivative | *Verrucosispora* sp.  | Anti-MRSA activity                   | [200]       |
| Isomethoxyneihumicin          | Lactam-lactim tautomers | *Nocardiosis* alba     | Strong cytotoxicity                  | [201]       |

A marine sponge-derived *Actinokineospora* sp. produces actinosporins with selective activity against the parasite *Trypanosoma brucei brucei*, the causative agent of sleeping sickness [182]. Fungal infections, particularly candidiasis, is one of the serious diseases worldwide. A novel antifungal polyketide, forazoline A isolated from *Actinomadura* sp. showing significant activity against *Candida albicans* works through a new mechanism of action by disrupting membrane integrity [186]. Another way of controlling candidiasis is by capping enzyme repressors. Inhibitors of the enzyme RNA 5′-triphosphatase in yeast may be used against pathogenic yeasts such as *Candida*. Interestingly, novel kribellolides from a marine *Kribbella* sp. inhibit activity of Cet1p (RNA 5′-triphosphatase) from *Saccharomyces cerevisiae in vitro* [208]. Another interesting biological activity is anti-allergic activity shown by nesterenkoniane, a novel cyclic ether isolated from the deep-sea-derived *Nesterenkonia flava*. Nesterenkoniane is the first report on secondary metabolites from the genus of *Nesterenkonia* [202]. Furthermore, discovery of anti-malarial drugs is one of the targets of research in pharma industries. Salinipostin A, isolated from the marine genus *Salinispora* shows potent antimalarial activity against *Plasmodium falciparum* growth (EC$_{50}$ = 50 nM) and a high selectivity index (SI > 10$^3$) [192] (Figure 5).

### 4.4. Genome Mining of Marine Rare Actinomycetes

The rapid development of genome and metagenome sequencing methods including identification of secondary metabolite gene clusters has lead to the discovery of the genetic machinery encoding for novel natural products from microorganisms that have not yet been chemically identified [211]. The majority of these gene clusters encode for polyketides (PK), non-ribosomally synthesized peptides (NRP), ribosomally and post-translationally modified peptides (RiPPs) and aminoglycosides [211]. The bioinformatic analysis of genomes can also reveal silent secondary metabolite gene clusters, which are not expressed under standard laboratory conditions [212]. More than 23,000 PK and NRP have been reported so far, many of them found in actinomycetes, and they are being widely tested for pharmaceutical applications [213,214]. This approach has also been used for the identification of new antibiotic scaffolds from rare genera of actinomycetes from marine sediments [16]. Recently, Schorn and colleagues [215] have shown that rare marine actinomycetes-derived genomes demonstrated a high degree of novelty and diversity, with *Corynebacterium*, *Gordonia*, *Nocardiopsis*, *Saccharomonospora* and *Pseudonocardia* as genera representing the highest biosynthetic gene cluster diversity. A total of 13 new bioactive compounds have been derived from marine rare actinomycetes, such as *Saccharomonospora* sp., *Salinispora* spp., *Micromonospora* spp. and *Streptosporangium* sp. using genome-based approaches between mid 2013 and 2017 (Table 10).

These numbers of new biosynthetic gene clusters and corresponding compounds will undoubtedly increase in the near future due to revolutionary developments in the genome- and metagenome-based approaches for drug discovery [215] and it likely that omics-based screening for novel bioactive compounds will prevail over microbial isolation as the most efficient method for first identification of bioactivity potential of strains and environmental samples [216].

### Table 10. New bioactive compounds discovered from marine rare actinomycetes using genome-based approaches between mid-2013 and 2017.

| Compounds | Chemical Class/Family | Marine Source | Biological Activity | Reference |
|-----------|-----------------------|---------------|---------------------|-----------|
| Taromycin A | Dichlorinated lipopeptide | *Saccharomonospora* sp. | Moderate bioactivity against MDR pathogens | [217] |
| Retimycin A | Quinomycin-like depsipeptide | *Salinispora* sp. | Cytotoxicity against HCT-116 | [218] |
| Stexarathin | Carotenoid | *Salinispora* sp. | Siderophore | [219] |
| Lobosamides A–C | Polyene macrolactams | *Micromonospora* sp. | Anti-protozoan parasite, *Trypanosoma brucei* | [220] |
| Hexaricins A–C | Pentangular polyphenols | *Streptosporangium* sp. | Not specified | [221] |
| Tetrocarcin N and O | Glycosidic spiroetrazales | *Micromonospora* sp. | Modest antibacterial activity | [222] |
| Rifsaliniketal | Saliniketal | *Salinispora* sp. | Not specified | [223] |
| Nenestatin A | Benzofluorene | *Micromonospora echinospora* | Antibacterial activity | [224] |
5. Conclusions

In the last decade (2007–2017), a great range of diverse, new and rare actinomycetes have been isolated from the marine environment. Employment of heat-treatment of marine sediment samples, the use of low-nutrient agar medium (seawater agar) or a growth medium with natural seawater along with the use of antifungal agents, favor the isolation of marine rare actinomycetes. At least 177 new species, which represent 29 novel genera and 3 novel families, were obtained as pure cultures. Micromonosporaceae, Nocardioidaceae, Pseudonocardiaceae, Microbacteriaceae, Micrococcaceae, Demequiniaceae, Nocardiopsaceae, Propionibacteriaceae and Intrasporangiaceae were the families most frequently isolated from the marine environment.

In total, 267 new natural products derived from 96 different marine rare actinomycete strains belonging to 28 genera have been reported from 2007 to 2017. Out of these 28 marine genera, Nocardiopsis, Micromonospora, Salinispora, Verrucosispora, Pseudonocardia and Actinoalloteichus are topmost producers of novel new secondary metabolites.

The rare actinomycetes isolated and biomolecules discovered represent most likely only the low-hanging fruits and the immense diversity of microorganisms in marine habitats as shown from large cultivation-independent studies [225,226] are the proof for the presence of an even larger diversity of currently uncultivable rare actinomycetes and putative secondary metabolites. This uncultured majority should be the target of future selective isolation strategies and procedures. In addition, genetic engineering of whole biosynthetic gene clusters is finally gaining ground [216] and may be the key to access hidden gene clusters from rare actinomycetes. A breakthrough in heterologous expression would herald ‘another golden age’ of novel bioactive natural product discovery, for which marine rare actinomycetes may be one of the important sources.

Author Contributions: R.S. conceived, designed the work and wrote the manuscript; D.S. conceived, critically analyzed the data, revised and corrected the manuscript.

Funding: D.S. acknowledges funding from the European Union’s Horizon 2020 research and innovation program under Grant Agreement No. 679849 (SponGES).

Acknowledgments: We are thankful to Steven Sutcliffe, the University of the South Pacific for English proofreading of the manuscript.

Conflicts of Interest: The authors declare no conflict of interest.
