Abstract. Expression levels and clinical significance of 5-HT and 5-HT₃R in the intestinal mucosa tissue of patients with diarrhea-type irritable bowel syndrome (D-IBS) were investigated. A retrospective analysis was performed on 46 tissue specimens (observation group) of the intestinal mucosa of patients with D-IBS, who were diagnosed in the Tongde Hospital of Zhejiang Province and received colonoscopy from March 2016 to December 2017, and 18 tissue specimens (control group) of the intestinal mucosa of healthy subjects who received physical examinations. The expression levels of 5-HT and 5-HT₃R in the intestinal mucosa tissue of patients in the observation and control group were detected by ELISA, and the relationship between 5-HT, 5-HT₃R and the clinicopathological parameters of patients with D-IBS was analyzed. Pearson's correlation analysis was used to analyze the correlation between 5-HT and 5-HT₃R and the morbidity of IBS in the world is 5-20%, and the morbidity in Asia is 6.5-10.1% (4,5). The morbidity of IBS which conforms to Manning criteria in China is 22.8% and the morbidity is related to the stress of life and the pace of work (6). The patients with IBS are mainly young women (7).

Although IBS does not threaten patients’ life, it still greatly affects their quality of life, its pathogenesis is inexplicable and patients cannot be treated in a specific manner (8).

At present, it is held by most medical researchers that the abnormality of gastrointestinal motility, the high sensitivity of viscus and the disorder of the brain-intestine axis function are involved in the pathogenesis of IBS. In addition, endocrine dysfunction, the stress response of mentality and immunoreaction are also considered to be involved in the pathogenesis of IBS (9,10).

5-HT, also known as serotonin, is an immunoregulatory factor and neurotransmitter. A great deal of 5-HT is intensively distributed in the gastrointestinal tract but only a small amount of 5-HT is distributed in the central nervous system (11). It has certain specificity and is of great significance in the physiological and pathological processes of the human body, such as the thermoregulation, the regulation of blood pressure, the production of algiesia, as well as nausea and vomiting (12).

5-HT plays an important role in the brain-intestine axis which is between the intestinal tract and the central nervous system, and is also an important signal for maintaining intestinal balance; it regulates the intestinal motility, sensation and secretion of intestinal glands (13).

5-HT and 5-HT₃R may be involved in the pathogenesis of D-IBS, and potentially used for clinical treatment.

Introduction

Irritable bowel syndrome (IBS) is a chronic intestinal disease. The main clinical signs are abdominal pain accompanied by the intermittent or persistent irregularity of defecation and the abnormal texture and shape of feces (1,2). Since this disease does not show obvious abnormalities of biochemical indicators, it is a functional disease (3). According to the statistics, the morbidity of IBS in the world is 5-20%, and the morbidity in Asia is 6.5-10.1% (4,5). The morbidity of IBS which conforms to Manning criteria in China is 22.8% and the morbidity is related to the stress of life and the pace of work (6). The patients with IBS are mainly young women (7).

Although IBS does not threaten patients’ life, it still greatly affects their quality of life, its pathogenesis is inexplicable and patients cannot be treated in a specific manner (8).

Key words: diarrhea-type irritable bowel syndrome, intestinal mucosa, 5-HT, 5-HT₃R, clinical significance
receptor (5-HT₃,R) is an ion channel receptor found in the central and peripheral nervous systems. 5-HT₃,R is of great significance for the transmission of the information of digestive tract activity, regulation of intestinal peristalsis and secretion of intestinal glands. There are different clinical manifestations when 5-HT combines with different receptors. 5-HT mainly combines with 5-HT₃,R in patients with D-IBS, which leads to some intestinal dysfunctions, such as visceral hypersensitivity and abdominal discomfort. Most of 5-HT in the gastrointestinal tract is synthesized and stored by the chromaffin cells of the intestinal mucosa. When the intestinal tract is stimulated, it causes an increase of 5-HT in the chromaffin cells, and the combination of 5-HT and 5-HT₃,R which is in the nerve endings of exogenous primary afferent neurons, so that the visceral afferent nerve and the intestinal nervous system are in a hypersensitive state, which results in symptoms, such as diarrhea, abdominal pain and discomfort.

**Patients and methods**

**General data.** The tissue specimens of the intestinal mucosa of patients with D-IBS, who were diagnosed in the Tongde Hospital of Zhejiang Province (Hangzhou, China) and received colonoscopy from March 2016 to December 2017, were retrospectively analyzed (observation group). The tissue specimens of the intestinal mucosa of healthy subjects who received physical examinations or volunteers were also retrospectively analyzed (control group). There were 46 patients in the observation group, including 19 males and 27 females, with an average age of 40.35±5.68 years. Eighteen patients in the control group included 5 males and 13 females, with an average age of 39.85±6.12 years. Inclusion criteria: all patients conformed to the Rome III diagnostic criteria of IBS (19); and the intestinal cleanliness of all selected patients reached the standard, and patients with diarrhea-type irritable bowel syndrome (D-IBS) and provide some references for the research and development of new drugs for the treatment of D-IBS.

**Statistical methods.** The analysis was carried out using SPSS 20.0 statistical software (Shanghai Kabei Information Technology Co., Ltd., Shanghai, China). Enumeration data were expressed as n (%), and the Chi-square test was used for the comparison between groups. Mean ± SD was used to express the measurement data. The independent sample t-test was used for the comparison between two groups, while the paired t-test for the comparison within the group. Pearson’s correlation analysis was applied to analyze the correlation of 5-HT and 5-HT₃,R in the D-IBS group; P<0.05 was considered to indicate a statistically significant difference.

**Results**

**Comparison of general data.** There was no significant difference in age, sex, body mass index (BMI), smoking, drinking, and place of residence between the observation and control group (P>0.05), which suggested that the groups were comparable. The difference in the history of gastrointestinal infection (history of acute gastrointestinal infection at least 1 day before the onset of D-IBS symptoms, cured with treatment for <5 days, with no recurrence) was statistically significant (P<0.05) (Table 1).

**Expression levels of 5-HT and 5-HT₃,R in the intestinal mucosa tissue of the observation and control group.** The expression levels of 5-HT and 5-HT₃,R in the intestinal mucosa tissue of patients in the observation group (476.59±75.23 ng/ml and 28.69±15.62 pg/ml, respectively) were both significantly higher than those in the control group (344.86±67.52 ng/ml and 20.54±10.23 pg/ml, respectively) but were not statistically significant (P>0.05) (Table 2).
Correlation analysis of 5-HT and 5-HT₃R in the intestinal mucosa tissue of patients with D-IBS. The expression levels of 5-HT and 5-HT₃R in the intestinal mucosa tissue of patients with D-IBS were positively correlated (r=0.725, P<0.001) (Fig. 2).

Relationship between 5-HT, 5-HT₃R and clinicopathological parameters of D-IBS. The expression levels of 5-HT and 5-HT₃R in patients with D-IBS were not significantly associated with the course of disease, smoking, drinking, and place of residence (P>0.05), but were associated with age, sex, and the history of gastrointestinal infection, and the differences were statistically significant (P<0.05). The expression levels of 5-HT and 5-HT₃R in patients with D-IBS who were aged ≥40 years were significantly higher than those in patients who were >40 years of age, and the expression levels of 5-HT and 5-HT₃R in female patients with D-IBS were significantly higher than those in male patients. The expression levels of 5-HT and 5-HT₃R in patients with D-IBS who had history of

and 13.04±8.34 pg/ml, respectively), and the differences were statistically significant (P<0.001) (Fig. 1 and Table II).

The morbidity of irritable bowel syndrome (IBS), a common global disease, is correlated with the level of economic development, and is higher in cities with developed economy and a heavy pressure of work and life (20). The course of IBS is generally long and repetitive, and it requires patients to take a large number of oral medicines chronically, which increases patients' economic and mental stress, and also greatly consumes the medical resources (21). According to Choung et al (22), D-IBS is affected by psychological and environmental factors, so clinical trials are more practical than animal experiments.

It is known that the complex 5-HT receptors are divided into 7 families, namely 5-HT1-7R, and 14 subtypes, including two major classes: ligand-gated ion channel receptors and G protein-coupled receptors (23). 5-HT binds to the 5-HT receptor to regulate complex functions, such as secretion, absorption, gastrointestinal motility and sensation, which lead to a series of typical symptoms of IBS, such as bowel movement abnormalities (24). According to a previous study (25), 5-HT in animal models and isolated tissues can promote the secretion of intestinal water and electrolytes, so it is considered that the symptoms of D-IBS patients, such as increased intestinal gland secretion, diarrhea and the improvement of digestive tract transport capacity may be related to the increase of intestinal motility and intestinal gland secretion by 5-HT. 5-HT3R is widely distributed in the digestive tract and is expressed in the submucosal plexus and intestinal myenteric plexus. The activation of 5-HT3R can lead to depolarization of the cell membrane, calcium influx, and thus excite the central and peripheral neurons, promoting the release of neurotransmitters, such as acetylcholine from parasympathetic nerve endings, which leads to the development of high sensitivity of the viscera and regulates contraction and relaxation of smooth muscle (26). Andresen and Hollerbach (27) found that 5-HT3

*P<0.05, compared within the group. D-IBS, diarrhea-type irritable bowel syndrome.

### Figure 2. Correlation analysis of 5-HT and 5-HT3R in the intestinal mucosa tissue of the patients in the observation group. Pearson's correlation analysis showed that the expression levels of 5-HT and 5-HT3R in the intestinal mucosa tissue of patients with D-IBS were positively correlated (r=0.725, P<0.001). D-IBS, diarrhea-type irritable bowel syndrome.
receptor antagonists can effectively treat D-IBS, but its clinical use is limited due to its adverse reactions.

The present study showed that the expression levels of 5-HT and 5-HT\textsubscript{3}R in the intestinal mucosa tissue of patients in the observation group are significantly higher than those of patients in the control group, and the differences were found to be statistically significant (P<0.001). In accordance to these results, Sun et al (28), have revealed that the positive cells of 5-HT and the expression of 5-HT\textsubscript{3}R are both significantly higher than those in the normal control group. Another study has speculated that there is a direct relationship between the increase in colonic mucosal expression of 5-HT, R and the onset of D-IBS (29). Combined with the results of this study, 5-HT and 5-HT3R may be involved in the occurrence of D-IBS. After electroacupuncture and medicine treatment, the abnormal expression of 5-HT and 5-HT3R in D-IBS colonic mucosa has been shown to significantly decrease, and the levels of 5-HT and 5-HT3R in the electroacupuncture group are significantly lower than those in the medicine group, suggesting that the therapeutic effect is better than medicine (30). It is suggested that the expression changes of 5-HT and 5-HT3R may reflect the severity of D-IBS and the evaluation of curative effect. However, more research is needed to prove the specific conclusions. The interaction between 5-HT and 5-HT3R may regulate intestinal secretion, motor function, and pain level through the regulation information of central nervous system (31). It is speculated that 5-HT is associated with 5-HT3R. In the present study, after the correlation coefficient analysis, the results showed that the expression levels of 5-HT and 5-HT3R in the intestinal mucosa tissue of patients with D-IBS are positively correlated (r=0.725, P<0.001). Spiller (32) has found that in the colonic mucosa of D-IBS patients, the synthesis and secretion of 5-HT increases, and the expression of 5-HT3 receptor is upregulated, suggesting that 5-HT and 5-HT3 receptors may be correlated. However, there are few related studies at present, and further research is needed to prove this.

The results of the present study also showed that the expression levels of 5-HT and 5-HT3R in the patients with D-IBS were not significantly correlated with the course of disease, smoking, drinking and place of residence (P>0.05), but were correlated with age, sex and the history of gastrointestinal infection, and the differences were statistically significant (P<0.05). Among the patients, the expression levels of 5-HT and 5-HT3R in patients with D-IBS who were aged ≥40 years were significantly higher than those in patients who were >40 years of age, and the expression levels of 5-HT and 5-HT3R in female patients with D-IBS were significantly higher than those in male patients. The expression levels of 5-HT and 5-HT3R in patients with D-IBS who had history of gastrointestinal infection were significantly higher than those of patients who did not have history of gastrointestinal infection. We speculate that the expression levels of 5-HT and 5-HT3R in D-IBS patients may be affected by hormone levels, resulting in a higher expression in females than males. The study of Thompson et al (33) has shown that the morbidity of female patients with IBS is higher than that of male patients, which may be related to the menstrual cycle and the hormone level changes of females, similar to the results of this study. Since both 5-HT and 5-HT3R exist in the central nervous system of the human body and the occurrence of IBS could also be affected by psychological factors (34,35), there are many reasons that may have caused the expression levels of 5-HT and 5-HT3R in the young subjects and patients with D-IBS who had history of gastrointestinal infection to be significantly higher than those in patients who were aged >40 years and did not have the history of gastrointestinal infection. These reasons include heavy pressure of work and life, psychological anxiety, the irregularity of diet, food hygiene, and the belated diagnosis caused by the personal negligent care (36,37).

In this study, the expression levels of 5-HT and 5-HT3R in D-IBS patients were studied in many aspects, which provided a reference for clinical research. However, there are limitations in this retrospective analysis, such as possible bias in design. The exact mechanism of 5-HT and 5-HT3R in the development of D-IBS remains to be further studied.

In summary, the expression levels of 5-HT and 5-HT3R in the intestinal mucosa tissue of patients with D-IBS are both significantly higher than those of healthy subjects, and the expression levels of 5-HT and 5-HT3R in patients with D-IBS are not significantly correlated with the course of disease, smoking, drinking, and place of residence, but are correlated with age, sex and the history of gastrointestinal infection. 5-HT and 5-HT3R may be involved in the pathogenesis of D-IBS, and potentially be used for clinical treatment.

Funding

The present study was supported by the National Natural Science Foundation of China Young Scientist Program (no. 81302957); the Zhejiang Provincial Natural Science Foundation of China (nos. LY17H270003 and LQ19H270051); the Zhejiang Province Institute of Science and Technology of Special Foundation (no. 2017F30044); the Zhejiang Province Key Research Project of Traditional Chinese Medicine (no. 2018ZZ005); the Zhejiang Medical and Health Science and Technology Plan Project (no. 2018KY326); and the Zhejiang Province Project of Traditional Chinese Medicine (no. 2018ZB030).

Availability of data and materials

The datasets used and/or analyzed during the present study are available from the corresponding author on reasonable request.

Authors’ contributions

RF and MC designed the study and drafted the manuscript. YC acquired the data. GM and SL analyzed the data and revised the manuscript. All authors read and approved the final manuscript.

Ethics approval and consent to participate

The study was approved by the Ethics Committee of Tongde Hospital of Zhejiang Province (Hangzhou, China). Patients...
who participated in this research had complete clinical data. Signed informed consents were obtained from the patients and/or guardians.

**Patient consent for publication**

Not applicable.

**Competing interests**

The authors declare that they have no competing interests.
