We introduce a non-perturbative two scale Kirchhoff theory, in the context of light scattering by a rough surface. This is a two scale theory which considers the roughness both in the wavelength scale (small scale) and in the scales much larger than the wavelength of the incident light (large scale). The theory can precisely explain the small peaks which appear at certain scattering angles. These peaks can not be explained by one scale theories. The theory was assessed by calculating the light scattering profiles using the Atomic Force Microscope (AFM) images, as well as surface profilometer scans of a rough surface, and comparing the results with experiments. The theory is in good agreement with the experimental results.

PACS: 42.25.Fx, 68.37.-d

I. INTRODUCTION

Wave scattering by rough surfaces has been extensively studied both analytically and experimentally. For analytical approaches two methods have been generally considered: rigorous electromagnetic theory and approximate methods. The Kirchhoff theory is among the electromagnetic theories and is known as a “tangent plane theory”. This theory is most widely used to calculate the distribution of the specular and diffuse parts of the reflected light. The Kirchhoff theory treats any point on a scattering surface as a part of an infinite plane, parallel to the local surface tangent. The theory is therefore exact for an infinite, smooth and planar scatterer, but is approximate for scatterers that are finite sized, non-planar or for rough surfaces [1]. Due to the computational limitations, most studies have been done for one dimensional data of the surfaces. There are only few cases of the analysis of two dimensional surface data. One and two dimensional exact approaches have been successfully applied to dielectric, metallic or perfectly conducting surfaces [2,3], deterministic surfaces [4,5], dielectric films on a glass substrate [6] and dielectric films [7,8]. Such exact calculations have been compared with experimental results and approximate models [6,9]. Also some authors studied wave scattering from random layers with rough interfaces [10,11].

The joint probability density functions (PDF) of surface slopes and heights $P(\partial h, h)$, is a key function in the estimation of the main parameters of wave scattering by a rough surface [12–16]. This is more obvious in a geometrical optics approach, when the angular distribution of the scattered power is proportional to the specular reflecting slope PDF. The slope PDF has also been introduced in references [12,15,16] in the context of Bragg scattering. They have shown that, the Bragg scattering results must be averaged by the proper slope PDF of the rough surface. This is also true for the estimation of the thermal emission from rough surfaces at small grazing angles [15,16].

In the present paper, we introduce a non-perturbative two scale Kirchhoff theory. The theory is applied to explain the small peaks observed in the scattering profile of a rough surface, at certain scattering angles. The theory employs the data obtained from the rough surface in two different scales. To check the theory we have measured the scattered light intensity as a function of the scattering angle, $I(\theta)$, using a setup consisting of a He-Ne laser (632.8nm), a photo-multiplier tube (PMT) detector and a computer controlled micro-stepper rotation stage. The resolution of the micro-stepper was 0.5 minutes. Alumina sheets were used as the rough samples. The surface topography of the alumina samples in small scale $(< 5\mu m)$ was obtained using an atomic force microscope (AFM) (Park Scientific Instruments). The images in small scale were collected in a constant force mode and digitized into $256 \times 256$ pixels. A commercial standard pyramidal $Si_3N_4$ tip was used. A variety of scans, each with size $L$, where recorded at random locations on the surface. The large scale $(< 5\mu m)$ morphology line scans of the alumina samples were recorded using a surface profilometer (Taylor Hobson). Figures (1) and (2) show typical AFM image and surface profile data with resolutions of about $20nm$ and $0.25\mu m$, respectively.
II. NON-PERTURBATIVE TWO SCALE KIRCHHOFF THEORY

The Kirchhoff theory is based on three major assumptions [1]:

a) The surface is observed from far field.

b) The surface is regarded as flat, and the optical behavior is locally identical at any given point on the surface. Therefore the Fresnel laws can be locally applied.

c) The amplitude of the reflection coefficient, $R_0$, is independent of the position on the rough surface.

The field scattered by the rough surface, $\psi^{sc}(r)$, is obtained by an integration over the mean reference plane $S_M$ [1], (the geometry is displayed in figure (3))

$$\psi^{sc}(r) = \frac{ik \exp(ikr)}{4\pi r} \int \int_{S_M} \left( a \frac{\partial h}{\partial x_0} + b \frac{\partial h}{\partial y_0} - c \right)$$

$$\exp \left( ik(Ax_0 + By_0 + Ch(x_0,y_0)) \right) dx_0 dy_0$$

(1)

where

$$A = \sin \theta_1 - \sin \theta_2 \cos \theta_3,$$

$$B = -\sin \theta_2 \sin \theta_1,$$

$$C = -(\cos \theta_1 + \cos \theta_2),$$

$$a = \sin \theta_1(1 - R_0) + \sin \theta_2 \cos \theta_3(1 + R_0),$$

$$b = \sin \theta_2 \sin \theta_3(1 + R_0),$$

$$c = \cos \theta_2(1 + R_0) - \cos \theta_1(1 - R_0)$$

In the derivation of the equation(1), it is assumed that the incident wave $\psi^{in}$ is a plane wave with a wave vector $k$ as $\psi^{in}(r) = \exp(ik \cdot r)$.

In most cases, the wave scattering models from rough surfaces implicitly assume that the surface is rough on a single scale. However, in practice all surfaces are rough on several scales, ranging from atomic scale to the scale determined by the length of the surface. Nevertheless, only a finite range of scales are important in scattering of waves from a surface, i.e. the range covering the wavelength of the incident radiation. Models have been developed for describing surfaces that consist of high frequency fluctuations superimposed on a slowly varying roughness [1]. These models use perturbation theories to describe the scattering from the high frequency roughness and this is modified in some manner by the low frequency component [17]. All of the perturbative methods deal with the effect of the large scale fluctuations as perturbation to the small scale height fluctuations. Here, we intend to observe the surface in two scales with resolutions of nanometer and micrometer. The figure (4), shows schematically the modulation of small scale height fluctuations by large scale variations. Various statistical parameters like the joint height and height gradient PDF, surface roughness $\sigma$, correlation function $C(R)$, correlation length $\tau$ etc., were measured in two scale.

In what follows, we are going to describe the non-perturbative two scale Kirchhoff theory. We first calculate the contributions of the coherent and the diffuse fields by the Kirchhoff theory in small scale. The coherent field with a gaussian height distribution will be [1]:

$$\langle \psi^{sc} \rangle^* = I_0 \exp(-g)$$

(2)

where $g = k^2 \sigma^2 C^2$. Also $k$, $\sigma$ and $I_0$ are the norm of wave vector, surface roughness in small scale and the scattered reflected intensity of the corresponding smooth surface. For isotropic surface and for samples with the sizes much larger than the correlation length $L \gg \tau$, (and for a slightly rough surface i.e. $g \ll 1$) the diffuse field
In the small scale, we denote the height field in positions which depend on the positions of the small mesh. Therefore for each mesh we have a similar expression for coherent field as equation (2), but with different parameters, $h_s'$, here is the $h_s$ rotated such that it coincide on the vertical time In the three dimensional case, $h_s'$ is rotated to $h_s$ by Euler matrices.

$$y = y_l + y_s'$$ (5)

The indices $l$ and $s$ denote the large and small scales, respectively. The vector $(x_s', y_s')$ is the position of the $h_s'$ on the small scale coordinates. In figure (5) we have shown the $(h_s', x_s', y_s')$ and $(h_l, x_s, y_s)$, schematically. We note that the AFM images will gives us the $h_s(x_s, y_s)$ and via the large scale topography we will find the $h_l(x_l, y_l)$. The vectors $(h_l', x_l', y_l')$ and $(h_s, x_s, y_s)$ can be related to each other, via rotational Euler matrix, with three rotational angles $\alpha, \beta, \gamma$ i.e. $A(\alpha, \beta, \gamma) = R_h(\gamma)R_y(\beta)R_x(\alpha)$.

The Local angles $(\theta_1, \theta_2, \theta_3)$ are defined by the average plane in the small scale. Therefore, all $a, b, c, A, B, C$ are constant for all points within the small piece. In each small scale element $h_l$ is fixed so that $\frac{\partial h}{\partial z} = 0$. Hence, the total scattered field has the following expression:

$$\psi^{sc}(r) = \sum_{x_l, y_l} \left[ \frac{ik \exp(ikr)}{4\pi r} \right] \int \int_{s,M} (a_s \frac{\partial h_l'}{\partial x_s'} + b_s \frac{\partial h_l'}{\partial y_s'})$$

$$\left( -c_s \right) \exp ik(A_s x_s' + B_s y_s' + C_s h_l'(x_s', y_s'))$$

$$dx_s'dy_s' \exp ik(A_l x_l + B_l y_l + C_l h_l)$$

$$= \sum_{x_l, y_l} \psi^{sc}_s(r) \exp ik(A_l x_l + B_l y_l + C_l h_l)$$ (6)

we note that $\frac{\partial h_l'}{\partial x_s'} = \frac{\partial h}{\partial x_s}$ and the summation is over the small scale samples modulated by the large scale fluctuations. We assume that the joint PDF of heights and its
slopes of two scales are independent, then the average of the field scattered in any direction will be given by:

\[ < \psi_{sc}^e(r) > = N \sum_{h_1, \partial_x h_1} \sum_{x_1, y_1} < \psi_s^e(r) > \exp(i k C R(h_1) \exp(i k (A x_1 + B y_1))) P(h_1, \partial_x h_1) \]

\[ = N \sum_{h_1, \partial_x h_1} < \psi_s^e(r) > \exp(i k C R(h_1)) P(h_1, \partial_x h_1) \sum_{x_1, y_1} \exp((i k (A x_1 + B y_1))) \]

\[ = N \frac{\sin(k L_x) \sin(k L_y)}{k L_x} A_M \]

\[ \sum_{h_1, \partial_x h_1} < \psi_s^e(r) > \exp(i k C R(h_1)) P(h_1, \partial_x h_1) \]  

(7)

The subscript \((-e)\) denotes scattering from the surface without the edge terms. The rough surface has been assumed to be rectangular with extent \(-X \leq x_0 \leq X, -Y \leq y_0 \leq Y\). Also \(L_x\) and \(L_y\) are length scales in the scattering area (the effective area of light incidence), and \(S_M = \frac{\sin(k L_x) \sin(k L_y)}{k L_x} A_M\) is the constant term in all observation angles. The quantity \(N P(h_1, \partial_x h_1)\) is the number of points with height \(h\) and slope \(\partial_x h_1\). It is noted that for a homogeneous surface \(p(h, x)\) is independent of position along the surface, \(x\). In order to do analytical calculation, it is necessary to assume that the edge effects are non-stochastic, i.e. \(< \psi_e > = \psi_e [1]\). Based on this assumption, the coherent part becomes:

\[ < I_{coh} > = \langle \psi_{sc} \rangle > \langle \psi_{sc} \rangle^* = \]

\[ N^2 \sum_{h_1, \partial_x h_1} \sum_{h_2, \partial_x h_2} < \psi_s^sc >^2 P(h_1, \partial_x h_1) P(h_2, \partial_x h_2) \]

\[ \exp((i k C(h_2 - h_1))) \]  

(8)

where \(\psi_{sc} = \psi_e + \psi_{-e}\). It is noted that the non-stochastic assumption of the edge effect leads to the cancelation of all terms containing edge effects. In cylindrical coordinates, for an isotropic surface, the substitutions \(x_2 - x_1 = R \cos \theta\) and \(y_2 - y_1 = R \sin \theta\) can be made. Since the heights PDF and the heights difference PDF are independent (we will confirm this assumption in the next section), i.e. \(P(h_1, \partial_x h_1) = P(h_1) P(\partial_x h_1)\).

Define,

\[ \sum_{h_1, h_2} d h_2 d h_2 \exp(i k C(h_2 - h_1)) P(h_1) P(h_2) \]

\[ = \chi(kC, -kC, R) \]

then one finds:

\[ < I_{coh} > = S_M^2 N \sum_{\partial_x h_1} N P(\partial_x h_1) < \psi_s^{sc} > \]  

(11)

\[ \chi(kC, -kC, R) \]

It is known that the total average scattered field in small scale is \(< \psi_{sc}^e > = \chi(kC)\psi_{sc}^e\).

For a gaussian height distribution, the one and two-dimensional characteristic function is given by:

\[ \chi(kC) = \frac{1}{\sigma_s \sqrt{2\pi}} \int_{-\infty}^{+\infty} \exp(- \frac{h^2}{2\sigma_s^2}) \exp(i k C \sigma_s) dh_s \]

\[ = \exp(-k^2 C^2 \sigma_s^2 / 2) \]  

(10)

and

\[ \chi(kC, -kC, R) = \exp(-k^2 C^2 \sigma_s^2 (1 - C(R))) \]  

(11)

where \(C(R) = \frac{< h(r) \delta(r+R) >}{\sigma_s^2} \), is the surface correlation function in the large scale. Also the average of total intensity are given by:

\[ < I_{tot} > = < \psi_{sc}^e \psi_{sc}^* > \]

\[ = N \sum_{h_1, \partial_x h_1} \sum_{h_2, \partial_x h_2} \sum_{y_0, x_0} \sum_{y_1, x_1} P(h_1, \partial_x h_1) < \psi_s^sc \psi_s^{sc} > \]

\[ \exp(i k (A(x_2 - x_1) + B(y_2 - y_1))) \]  

(12)

Performing the summation we find \(\sum_{h_1} = N\), where \(N\) is the number of points on the surface. So, the average total intensity becomes:

\[ < I_{tot} > = S_M^2 N \sum_{\partial_x h_1} N(\partial_x h_1) < \psi_s^{sc} \psi_s^{sc} > \]  

(13)

Finally, the diffuse field intensity is obtained as:

\[ < I_d > = < I_{tot} > - < I_{coh} > \]  

(14)
Kirshhoff theory and experimental results for scattered field (bold symbols).

slope must be independent at small and large scales, two conditions. First, the PDF of the height and its derivative (slope) must be independent. The second condition is that the height and its gradient PDFs are independent. The joint PDF of height and its gradient is given by

\[ P(h, \partial_x h) = P(h, \partial_x h_l)P(h, \partial_x h_s). \]

The homogeneous rough surfaces possess this condition. Indeed statistical parameters in small scale (roughness, exponents, etc.) are similar at any point of the sample (large scale). This means that the two PDFs are independent. The second condition is that the height and height gradient fluctuation must be independent in the large scale. This means that the joint PDF of the height and height gradients can be decomposed as

\[ P(h_l, \partial_x h_l) = P(h_l)P(\partial_x h_l). \]

In figure (6), we plotted the joint PDF and the multiplication of single PDFs fits with a line with slope one. Considering its statistical error we observe that the height and height gradient PDFs are independent. For large values of \( h \) and \( \partial_x h \), our assumption becomes poor and thus uncertainty increases.

To compare the experimental observation with those of the theoretical prediction, we need estimate the several statistical quantities such as surface roughness \( \sigma \), correlation function \( C(R) \), correlation length \( \tau \) etc., in small and large scales. We evaluate the height-height correlation function \( h(x + R)h(x) \) vs radial distance \( R \) for large scale fluctuations. We find the following expressions for the Alumina surface as, \( C(R) = 2.14 \exp(-\frac{R^2}{0.08}) \) and \( 1.27 \exp(-0.58R) \) for small and large scales, respectively. Also the roughness exponent, variance and scaling length for the small (large) scale have been found as, 0.85 (0.85, 0.031), 0.31\( \mu m \) (1.33\( \mu m \)) and 1.5\( \mu m \) (19.4\( \mu m \)), respectively. It is found that the height PDF in the two scales are almost gaussian. The estimated statistical quantities enable us to predict the average total intensity. In figure (7), we have plotted the experimental observation and theoretical prediction of total intensity. It is evident that the theoretical prediction fits with those of experimental observation. We observe the theory is able to predict small peak in the angle \( \theta \) in the variation of the total intensity vs angle scale \( \theta \). We note that if one plots the PDF of height gradient, then finds that the PDF has also small peaks at angle scale \( \tan^{-1}(\partial_x h) \approx 9^0 \). This means that the gradient PDF is responsible to have a small peak in the variation of the total intensity in terms of angle scale (we note that the slope \( \alpha = \tan^{-1}(\partial_x h) \), we produces 2\( \alpha \) contribution in the reflection of the light from the surface). In figure (8), the behavior of the slope PDF \( \partial_x h_l \) in terms of \( \partial_x h_l \), has been given. Also as shown in figure (7), the two scale Kirshhoff theory is able to predict the small peak in the variation of the total intensity in terms of angle scale. As we observe, there are other peaks in the figure (7), where the theory can not predict the peaks for large angle scales. Indeed for these angle scales we should take into account the shadowing effect [15,16]. In ref.[12], the validity range of geometrical shadow functions has been investigated for a randomly rough surface for which the shadowed Kirchhoff approximation has been shown to give good results for the scattered intensity distribution. We will discuss the modification of the two scale Kirshhoff theory by the shadowing effect elsewhere.
