(Received on May 15, 2020; Revised on February 3, 2021; Accepted on March 2, 2021)

The genus *Streptomyces* demonstrates enormous promise in promoting plant growth and protecting plants against various pathogens. Single and consortium treatments of two selected *Streptomyces* strains (*Streptomyces shenzhenesis* TKSC3 and *Streptomyces* sp. SS8) were evaluated for their growth-promoting potential on rice, and biocontrol efficiency through induced systemic resistance (ISR) mediation against *Xanthomonas oryzae* pv. *oryzicola* (*Xoc*), the causal agent of rice bacterial leaf streak (BLS) disease. Seed bacterization by *Streptomyces* strains improved seed germination and vigor, relative to the untreated seed. Under greenhouse conditions, seed bacterization with consortium treatment TKSC3 + SS8 increased seed germination, root length, and dry weight by 20%, 23%, and 33%, respectively. Single and consortium *Streptomyces* treatments also successfully suppressed *Xoc* infection. The result was consistent with defense-related enzyme quantification wherein single and consortium *Streptomyces* treatments increased peroxidase (POX), polyphenol oxidase, phenylalanine ammonia-lyase, and β,1-3 glucanase (GLU) accumulation compared to untreated plant. Within all *Streptomyces* treatments, consortium treatment TKSC3 + SS8 showed the highest disease suppression efficiency (81.02%) and the lowest area under the disease progress curve value (95.79), making it the best to control BLS disease. Consortium treatment TKSC3 + SS8 induced the highest POX and GLU enzyme activities at 114.32 µmol/min/mg protein and 260.32 abs/min/mg protein, respectively, with both enzymes responsible for plant cell wall reinforcement and resistant interaction. Our results revealed that in addition to promoting plant growth, these *Streptomyces* strains also mediated ISR in rice plants, thereby, ensuring protection from BLS disease.

**Keywords**: biocontrol agent, plant growth-promoting agent, *Streptomyces*, *Xanthomonas oryzae* pv. *oryzicola*

**Handling Editor**: Yong Hoon Lee

Rice (*Oryza sativa* L.) is the most widely grown crop in the world. It is a staple food for most Asian countries, and more than 80% of the world’s rice is consumed by people from this region (Che Omar et al., 2019). Malaysia is a minor rice producer in Asia, accounting for only 0.4% (2.7 million tonnes) of Asia’s total rice production (Herman et al., 2015). Diseases are a major constraint to rice production and bacterial leaf streak (BLS) disease, caused by *Xanthomonas oryzae* pv. *oryzicola* (*Xoc*) is among the most devastating bacterial pathogen of this crop (Poulin et al., 2014). This disease is widely distributed in tropical and subtropical Asian countries, including China, Thailand,
Malaysia, India, Vietnam, the Philippines, and Indonesia (Niño-Liu et al., 2006) where yield losses range from 8-32% (Liu et al., 2014).

To date, there have been no studies explicitly conducted on BLS disease control, although many similar measures used for other bacterial rice diseases are expected to be effective against BLS (Niño-Liu et al., 2006). Cultivation of resistant varieties is one of the main strategies to control BLS disease (Khan et al., 2014), but these new varieties develop susceptibility to the disease after consecutive years of application (Ouhdouch et al., 2001). The loss of resistance among resistant varieties is due to the evolution of plant pathogens and the emergence of new pathogenic races (Xu et al., 2010). The application of either copper or chemical formulations as an alternative for bacterial disease control, however, has raised environmental concerns (Yang, 2010).

Microorganism communities that populate the rhizosphere are well known as plant growth and plant yield promoters (Akhami et al., 2017). Several types of plant growth-promoting rhizobacteria (PGPR) have also been reported to trigger a salicylic acid-dependent type of induced systemic resistance (ISR) that resembles pathogen-induced systemic acquired resistance (Pieterse et al., 2014). Although ISR is triggered by PGPR colonized in the root system, the defense signal spreads systemically throughout the plant and enhances the defensive capacity of distant tissues against subsequent infections from pathogens that are active on the foliage, flower or fruit (Van Loon and Bakker, 2006).

Streptomyces is a prominent genus of actinobacteria. It is considered one of the most beneficial genera among rhizosphere microbes as it plays various functions in soil nutrient cycling and plant growth promotion (Sreevidya et al., 2016). Numerous studies have proved Streptomyces potential as a promising biocontrol agent against plant diseases, via a direct antagonistic mechanism (by secondary metabolite production) and ISR mediation (Rais et al., 2017; Suárez-Moreno et al., 2019; Viaene et al., 2016). Streptomyces as a filamentous sporulating microorganism offers the advantage of survivability under stress in unfavorable environmental conditions, and thus is frequently used as a bioinoculant for biofertiliser, phytostimulation, and biocontrol (Vurukonda et al., 2018).

Streptomyces potential as plant growth promoter and plant resistance inducer has been reported in rice (Hastuti et al., 2012; Suárez-Moreno et al, 2019) and oak (Kurth et al., 2014). However, information on Streptomyces-ISR particularly against BLS disease, is unavailable. This study was conducted to evaluate the effectiveness of selected Streptomyces strains as growth promoters in rice as well as their potential to control BLS disease through the induction of defense-related enzymes.

Materials and Methods

Streptomyces strains inoculum preparation. Two Streptomyces strains, S. shenzhenensis TKSC3 (TKSC3) and Streptomyces sp. SS8 (SS8) were selected based on a previous study (Hata et al., 2015). TKSC3 and SS8 16S rDNA sequences have been deposited in the GenBank database with accession numbers KP792984 and KP792988, respectively. These strains were kept in yeast malt broth modified with 20% glycerol and stored at −70°C for long term preservation. Streptomyces strains were later revived in yeast malt broth and streaked onto International Streptomyces Project Medium-2 agar and incubated for 7 days at 30°C. Aerial mycelium were scraped off from the agar surface using a sterile loop, suspended in sterile distilled water and the suspension filtered through cheesecloth. The spore suspension was measured using a hemocytometer, and the concentration was adjusted to 10^6 spores/ml.

Phytopathogen inoculum preparation and plant material. Bacterial pathogen Xoc used in this study was provided by the Bacteriology Laboratory, Department of Plant Protection, Faculty of Agriculture, Universiti Putra Malaysia. The Xoc strain TKSC1 used in this study was previously characterized (Hata et al., 2019), and the GenBank accession number for the sequence is MH560793. Xoc culture was inoculated in peptone sucrose agar supplemented with cycloheximide (0.05 g/l), cephalaxin (0.04 g/l), and kasugamycin (0.02 g/l). Plates were incubated at 28°C for 3 days. The Xoc colonies were scraped off from the agar surface, and diluted in sterile distilled water. The concentration of the pathogen suspension was adjusted to approximately 10^7-10^8 colony forming units (cfu/ml using a spectrophotometer (Hach DR2800, Loveland, CO, USA) at a wavelength of 660 nm. The highly disease susceptible Malaysian rice cultivar MR219 (Zuki et al., 2020) was used throughout this study, the seeds of which were obtained from the Malaysian Agricultural Research and Development Institute (MARDI).

Influence of S. shenzhenensis TKSC3 and Streptomyces sp. SS8 treatment on seed germination and seedling vigor (in vitro). Fresh Streptomyces suspensions of single and consortium treatments were prepared, namely TKSC3 (S. shenzhenensis TKSC3), SS8 (Streptomyces sp. SS8), and TKSC3 + SS8 (consortium treatment of S. shenzhenensis TKSC3 and Streptomyces sp. SS8). The consortium treat-
ment was using a 1:1 ratio of *S. shenzhenensis* TKSC3 and *Streptomyces* sp. SS8 suspension. Untreated seeds were negative control seeds without any *Streptomyces* treatment.

The delivery mode selected in this study was the seed bacterization method, as described by Chithrashree et al. (2011). Seeds were surface sterilized with 1% sodium hypochlorite (NaOCl) prior to seed bacterization. Sterilized seeds were soaked in a fresh single (TKSC3 and SS8) and consortium (TKSC3 + SS8) *Streptomyces* suspensions with $10^6$ spores/ml concentration (0.2 g/ml). Untreated seeds were only soaked in sterile distilled water. After 6 and 12 h room temperature incubation, seeds were drained and dried under laminar flow.

The germination test was conducted based on the paper towel assay developed by Singh and Rao (1977). Seeds (100 seeds/treatment) were arranged and covered in paper towels (45 cm × 28 cm), previously moistened with 25 ml sterile distilled water. Paper towels containing the seeds were rolled up and the ends were tied with a rubber band. After 10 days of incubation at 30°C, paper towels were unrolled and seed germination, root length, shoot length, and weight were measured. The experiment was conducted in three replicates, with each replicate containing 100 seeds. Based on these parameters, the vigor index was calculated by multiplying germination (%) and seedling length (mm) (Abdul Baki and Anderson, 1973).

**Greenhouse trial for rice growth promotion studies.** An *in vivo* experiment was conducted in Greenhouse Field 2, Universiti Putra Malaysia. Experimental soil was obtained from the Tanjung Karang rice cultivation area in Selangor, Malaysia. The soil was sterilized using soil sterilizer (Thermoforce Ltd.) at 240 V for 1 h, and 5.0 kg was added to each plastic pot (40 cm in diameter). The experiment was conducted in four treatments as described previously: TKSC3, SS8, TKSC3 + SS8, and untreated plants. For this experiment, treatments were delivered by two different modes: seed bacterization of 12 h (method as described in the previous subsection) and root-dip method (Gopalakrishnan et al., 2013). Germinated seedlings (10 days) were uprooted and the roots were dipped in the respective single and consortium *Streptomyces* fresh suspension (containing $10^6$ spores/ml) for 45 min and transplanted to the sterilized soil.

Randomized complete block design (RCBD) were used with five replications per treatment and 4 seedlings per replication Thirty days after transplantation, seedlings were uprooted and parameters associated with plant growth development such as seedling emergence, root length, plant height, total plant weight, and the number of tillers were measured.

**Greenhouse evaluation on BLS disease control by *Streptomyces* treatment.** Seed bacterization and the root-dip method were used as delivery methods in this experiment. A RCBD was used with three replications per treatment and four seedlings per replication. The rice plants were fertilized with NPK fertilizer on days 15 and 40 after sowing. The soil was maintained in a flooded condition until the end of the experiment.

The following treatments were included in this experiment: (1) untreated plants were infected plants without *Streptomyces* treatment, (2) infected plants with copper-based fungicide treatment, (3) infected plants with *S. shenzhenensis* TKSC3 treatment (TKSC3), (4) infected plants with *Streptomyces* sp. SS8 treatment (SS8), and (5) infected plants with *S. shenzhenensis* TKSC3 and *Streptomyces* sp. SS8 treatment (TKSC3 + SS8). Leaves of 40-day-old plants were spray-inoculated with *Xoc* pathogen suspension and covered with plastic for 24 h.

Disease severity was recorded at 5, 10, 15, and 20 days post inoculation (DPI). Disease severity was recorded based on the Standard Evaluation System by the International Rice Research Institute (1996). Disease severity (%), area under the disease progress curve (AUDPC) value and disease suppression efficiency were calculated based on Ji et al. (2008), Adhikari and Mew (1994), and Chithrashree et al. (2011), respectively.

**Assay of defense-related enzymes (peroxidase, polyphenol oxidase, phenylalanine ammonia-lyase, and β,1-3 glucanase).** Leaves were collected at 0, 2, 6, and 12 DPI and immediately homogenized with liquid nitrogen. Enzyme extraction from tissue samples were performed according to Lee et al. (2005). All enzyme assays and quantification were repeated three times. Enzyme production was quantified via absorbance reading at respective wavelengths for each of the enzymes using the Multiskan Go Spectrophotometer (Thermo Fisher Scientific, Waltham, MA, USA).

The activities of each enzyme (peroxidase [POX], polyphenol oxidase [PPO], phenylalanine ammonia-lyase [PAL], and β,1-3 glucanase [GLU]) were calculated based on the concentration of total protein in each sample. The total protein of all leaf extracts was determined by using bovine serum albumin as a standard. The variation in activity of defense-related enzymes, POX, PPO, PAL, and GLU were determined by enzyme assays described in Furumo and Furutani (2008), Ferraz et al. (2015), Chandrasekaran and Chun (2016), and Lever (1972), respectively.
Statistical analysis. All statistical analyses were conducted in SAS version 9.4 (SAS Institute Inc., Cary, NC, USA). In vitro experiments were conducted in a completely randomized design. Two-way analysis of variance (ANOVA) was used to determine the effect of Streptomyces treatments and seed bacterization period and its interactions on plant growth parameters. A one-way ANOVA was conducted for the analysis of plant growth parameters (seedling emergence, radicle length, coleoptile length, dry weight roots, and vigor index) with different Streptomyces seed treatments. Means were compared using the Tukey’s test, and significance was assigned at $P < 0.05$.

Greenhouse experiments (plant growth promotion, disease assessment, and enzyme quantification) were performed based on RCBD. Data collected on the plant growth promotion, disease severity, AUDPC, disease suppression efficiency, and enzyme activity were subjected to one-way ANOVA, and the means were compared using the Tukey’s test and significance was assigned at $P < 0.05$.

Results and Discussion

*In vitro seed germination and seedling vigor studies (paper towel assay).* In this experiment, none of the Streptomyces strains had any phytotoxic effect on rice seeds, and all treatments resulted in a germination rate above 80%. Single and consortium treatments of *Streptomyces* (TKSC3, SS8, and TKSC3 + SS8) demonstrated significantly higher growth responses among all parameters evaluated (seed germination, radicle length, coleoptile length, and vigor index) compared to untreated seeds.

*Streptomyces* treatment, seed soaking times and their interaction significantly ($P < 0.05$) affected seed germination and coleoptiles length. Indeed, higher mean values recorded by 12 h seed bacterization compared to 6 h for all the growth parameters observed in this study. Among all treatments, TKSC3 showed the highest value in seedling emergence, radicle length, and vigor index for both 6 and 12 h seed bacterization soaking times. Seedlings with *Streptomyces* treatment produced longer primary roots and formed an abundance of root hairs produced from the lateral roots (Fig. 1). *S. shenzhenensis* TKSC3 and *Streptomyces* sp. SS8 have been previously characterized as indole-3-acetic acid (IAA) producers, 15.10 µg/ml, and 8.91 µg/ml, respectively in a previous study (Hata et al., 2015). IAA is a key hormone for plant growth and this study proved that *Streptomyces* producing IAA were capable of enhancing seedling growth by promoting primary and lateral roots as well as root hair development (Rahman et al., 2002; Viaene et al., 2016). Sharma et al. (2014) reported that *Streptomyces* could enhance root formation and density, thus facilitating an efficient nutrient absorption from the soil.

**Fig. 1.** Seedling growth observation from *in vitro* paper towel assessment (A, C) and root images captured under a compound light microscope at 4× magnification (B, D). (A, B) Untreated seeds. (C, D) Seeds treated with *Streptomyces shenzhenensis* TKSC3 and *Streptomyces* sp. SS8 (TKSC3 + SS8). Arrows indicate the primary root, lateral root, and root hair.
Biocontrol and Plant Growth Promotion by *Streptomyces* spp.

Greenhouse trial for rice growth promotion studies. Under greenhouse conditions, both single and consortium treatments of *Streptomyces* resulted in significantly \((P < 0.05)\) higher mean growth parameters for seedling emergence, radical length, coleoptile length and vigor index relative to that of untreated seeds (Table 1). However, in this greenhouse experiment, TKSC3 + SS8 consortium treatment produced the highest mean value for seed germination (88.3%), root length (10.6 cm), and dry plant weight (164.7 mg/seedling). The consortium treatment enhanced seed germination by 20%, root length by 23% and dry weight by 33% in rice seedlings compared to the untreated seedlings.

Our *in vitro* growth assessment (paper towel assay) revealed that the TKSC3 treatment as the best promoter of rice seedlings growth. However, under *in vivo* conditions (greenhouse trial), the consortium treatment (TKSC3 + SS8) demonstrated significantly higher mean values of seed germination, root length, and dry plant weight. In the greenhouse study, under the influence of the natural environment, both *Streptomyces* strains demonstrated more convincingly their ability to support rice growth.

The consortium treatment induced significantly more growth than individual strain treatments. Jha and Saraf (2012) reported that the root and shoot biomass of *Jatropha curcas* L. were maximized with a microbial consortium compared to both control and individual microorganisms. The microbial consortium has been proposed as a feasible strategy to enhance plant growth and health in commercial applications (Oluwambe and Kofoworola, 2016).

Greenhouse evaluation on BLS disease control by *Streptomyces* treatment. Rice plants treated with *Streptomyces* (either single or consortium treatments) demonstrated lower \((P < 0.05)\) disease severity at all observation times (5, 10, 15, and 20 DPI) compared to untreated plants and copper-based fungicide treatment (Table 2). Untreated plants demonstrated the highest \((P < 0.05)\) disease sever-

### Table 1. Effect of *Streptomyces* seed bacterization on the growth of rice seedlings under greenhouse conditions 30 days after transplantation

| Treatment       | Seed germination (%) | Root length (cm) | Plant height (cm) | No. of tillers | Dry plant weight (mg/seedling) |
|-----------------|----------------------|------------------|-------------------|---------------|--------------------------------|
| Untreated seeds | 71.1 ± 4.2 c         | 8.1 ± 0.3 c      | 31.5 ± 1.4 c      | 4.0 ± 1.1 b   | 106.7 ± 5.4 b                  |

Values are presented as mean ± standard error of three replicates. Values followed by the same letters are not significantly different according to Tukey test at \(P < 0.05\).

DPI, days post inoculation; AUDPC, area under the disease progress curve; *Xoc*, *Xanthomonas oryzae* pv. *oryzicola*; TKSC3, *Streptomyces shenzhenensis* TKSC3; SS8, *Streptomyces* sp. SS8; TKSC3 + SS8, *Streptomyces shenzhenensis* and *Streptomyces* sp. SS8.
ity (59.18%) at 20 DPI, whereas the TKSC3 + SS8 treated plant showed the lowest disease severity (11.23%). The highest AUDPC (quantitative summary of disease intensity over repeated disease observations) was recorded by untreated plants) at 603.94, followed by copper-based fungicide treated plants with 530.75. Streptomyces treatments exhibited a lower AUDPC value compared to untreated and copper based fungicide treated plants, with the lowest AUDPC shown by the consortium treatment TKSC3 + SS8 (95.79), followed by SS8 (114.00) and TKSC3 (128.90). Copper-based fungicide treated plants demonstrated the lowest ($P < 0.05$) disease protection against $Xoc$ pathogen at 5.98%. The highest protection against BLS was provided by consortium Streptomyces treatment TKSC3 + SS8 (81.02%), followed by single treatment SS8 (77.02%) and TKSC3 (73.20%).

*S. shenzhenensis* TKSC3 and *Streptomyces* sp. SS8 were proven to be effective in controlling BLS disease infection. *Streptomyces* spp. have been widely recognized as potential biocontrol agents, and some have been successfully developed into commercial biocontrol agents to control plant diseases. *Streptomyces*-based biocontrol products in the market include Mycostop (*Streptomyces griseoviridis* strain K61), Actinovate (*Streptomyces lydicus* WYEC108) and YAN TEN S. saraceticus (*Streptomyces saraceticus* KH400) (Olanrewaju and Babalola, 2019). In this present study, both *Streptomyces* strains were isolated from the rice rhizospheres (Hata et al., 2015) and applied to the plant through seed and root dip treatment.

Advantage of *Streptomyces* is the morphology of these Gram positive bacteria resembles that of fungi, wherein they can form hyphae, mycelia and spores. As a filamentous and sporulating bacterium, *Streptomyces* can survive during unfavorable and stressful soil conditions such as drought, nutrient deficiencies and soil toxicities (Vurukonda et al., 2018).

**Fig. 2.** Effect of *Streptomyces* treatments on defense-related enzymes in leaves under the stress of *Xanthomonas oryzae* pv. *oryzicola* pathogen at 0, 2, 6, and 12 days post inoculation (DPI): peroxidise (POX) (A), polyphenol oxidase (PPO) (B), phenylalanine ammonia-lyase (PAL) (C), and β,1-3 glucanase (GLU) (D). Bars are standard errors of the means. Bars with different letters are significantly different according to Tukey test at $P < 0.05$. ‘ns’ denotes no statistical significance.
Biocontrol and Plant Growth Promotion by Streptomyces spp. in tomato by

**Assay of defense-related enzymes (POX, PPO, PAL, and GLU).** In this study, the production of defense-related enzymes was examined to determine their role in resistance reactions to infection, induced by *Streptomyces* treatments. Our results revealed that all *Streptomyces* treatments significantly induced POX and PPO enzymes compared to the untreated and copper-based fungicide treated plants (Fig. 2). The POX activity increased upon pathogen inoculation and was at its highest at 2 DPI. The highest accumulation was 115.32 µmol/min of mg protein in the TKSC3 + SS8 consortium treatment, which was three-fold higher than that for untreated plants. The highest activity in the PPO was at 2 DPI detected in plants treated with SS8 (136.40 µmol/min/mg protein), followed by TKSC3 + SS8 (130.36 µmol/min/mg of protein), and TKSC3 (118.52 µmol/min/mg of protein). The highest PAL enzyme activity was also recorded at 2 DPI in the TKSC3 treatment (51.36 nmol/min/mg of protein), followed by SS8 (50.36 nmol/min/mg of protein), and TKSC3 + SS8 (47.99 nmol/min/mg of protein) treatments. GLU enzyme activity was the highest at 6 DPI with 275.14 abs/min/mg of protein accumulation induced by TKSC3 + SS8 consortium treatment. Similarly, rice plants inoculated with the pathogen alone and plants treated with copper-based fungicide showed a slight increase in defense enzyme activity upon the Xoc pathogen challenge. Thereafter, enzyme activity declined gradually to below that of *Streptomyces* treatments.

 ISR triggered in the plant by soil, and plant microorganisms functioning for biocontrol purposes, stimulate the synthesis of defense chemicals, thus enhancing resistance against pathogens (Pal and Gardener, 2006). Previous reports provide evidence that, ISR can be elicited in plant systems by various biocontrol microorganism, for example, in tomato by *Streptomyces setonii*, *Bacillus cereus* and *Serratia marcescens* (Ferraz et al., 2015), rice by *Serratia marcescens* *Bacillus* *subtilis* and *Serratia marcescens*. Our results clearly showed early and increased defense enzyme activities (POX, PPO, PAL, and GLU) in *Streptomyces* treated plants, leading to disease suppression in response to Xoc pathogen inoculation. Treatments triggered reactions in plant roots and signals spread systemically through the plant’s system, ultimately enhancing the defensive capacity of distant tissues to subsequent infection by the pathogen (Van Loon and Bakker, 2005).

Application of *Streptomyces* presents enormous potential as a growth promoter and inducer of systemic resistance in rice plants against BLS disease. *Streptomyces* application could offer safer and sustainable alternatives to hazardous chemicals and could be incorporated into BLS disease management.
