Abstract. Let $G$ be a compact group. For $1 \leq p \leq \infty$ we introduce a class of Banach function algebras $A^p(G)$ on $G$ which are the Fourier algebras in the case $p = 1$, and for $p = 2$ are certain algebras discovered in [21]. In the case $p \neq 2$ we find that $A^p(G) \cong A^p(H)$ if and only if $G$ and $H$ are isomorphic compact groups. These algebras admit natural operator space structures, and also weighted versions, which we call $p$-Beurling-Fourier algebras. We study various amenability and operator amenability properties, Arens regularity and representability as operator algebras. For a connected Lie $G$ and $p > 1$, our techniques of estimation of when certain $p$-Beurling-Fourier algebras are operator algebras rely more on the fine structure of $G$, than in the case $p = 1$. We also study restrictions to subgroups. In the case that $G = SU(2)$, restrict to a torus and obtain some exotic algebras of Laurent series. We study amenability properties of these new algebras, as well.

0.1. Introduction and plan. In [21], the problem of understanding various amenability properties of Fourier algebras of homogeneous spaces over compact groups, $A(G/K)$, was investigated. Of particular interest were the algebras $A^\Delta(G) = A((G \times G)/\Delta)$, where $\Delta$ is the diagonal subgroup. Certain problems of operator amenability of $A(G)$, and of spectral theory of $A(G \times G)$, were shown to be encoded in $A^\Delta(G)$. It was discovered that in terms the $d_\pi \times d_\pi$-matrix-valued Fourier coefficients, $\hat{u}(\pi)$, for irreducible representations $\pi$, i.e. elements of $\hat{G}$, that

$$u \in A^\Delta(G) \text{ if and only if } \sum_{\pi \in \hat{G}} d_{\pi}^{3/2} \|\hat{u}(\pi)\|_{S_{d_\pi}} < \infty$$

where each $\|\cdot\|_{S_{d_\pi}}$ denotes the Hilbert-Schmidt norm. This result was mysterious to the authors at the time, and there were questions about the underlying meaning of the formula. We remark that the space $A^\Delta(G)$ seems to have appeared before. It arises as a host space for sufficiently differentiable functions on compact Lie groups; see [53] or [15 12.2.2], for example. For comparison sake, we recall the well-known fact, which goes back to Krein (see [26 §34], for example), that

$$u \in A(G) \text{ if and only if } \sum_{\pi \in \hat{G}} d_\pi \|\hat{u}(\pi)\|_{S_{d_\pi}} < \infty$$

Key words and phrases. compact group, Fourier series, operator weak amenability, operator amenability, Arens regularity.

where each $\|\cdot\|_{S_1^d}$ denotes the trace-class norm.

We provide an answer to this question of understanding $A_{\Delta}(G)$ by developing a family of algebras $A^p(G)$, $1 \leq p \leq \infty$, which recovers the Fourier algebras when $p = 1$, and the algebras $A_{\Delta}(G)$ when $p = 2$. We may simply refer to each of these as the $p$-Fourier algebra of $G$. We immediately warn the reader that these algebras are distinct from, and not to be confused with, the Figà-Talamanca–Herz algebras $A_p(G)$, $1 < p < \infty$. For example, we observe for virtually abelian groups that $A^p(G) = A(G)$ isomorphically (Theorem 1.9), while this does not hold for $A_p(G)$, even for general compact abelian groups. In particular, our class of algebras is new only for sufficiently non-abelian compact groups.

Having constructed this class of algebras $A^p(G)$, we embark on a systematic program of understanding how its members behave as Banach algebras. It is helpful for us to consider weighted versions $A^p(G, \omega)$ in the sense of [35] or [36]. For certain natural weights we consider the Gelfand spectrum in Section 1.2. In Section 1.3 we show for $p \neq 2$, $A^p(G) \cong A^p(H)$ isometrically isomorphically if and only if $G \cong H$ as compact groups. We note that each $A^p(G)$ comes equipped with a natural operator space structure, though for $p = 2$ multiple operator space structures arise naturally.

As has been amply demonstrated in the case of Fourier algebras the use of operator space structure makes analysis on non-abelian groups more tractable: compare the results of [31] and [18] with those of [47] and [51, 50]. We examine operator weak amenability and operator amenability in Sections 2.1 and 3.1. Special attention is paid to the $2 \times 2$ special unitary group, SU(2), since its representation theory allows more direct computations. Banach algebra amenability properties are noted in Section 2.2. We study the problem of restriction to subgroups. In the case of factors of direct products, and related, we obtain a full restriction theorem, mimicking the well-known fact for Fourier algebras themselves. However, we illustrate by example of a torus in SU(2) in Section 3.2, that restriction can produce more difficulties.

In particular we gain an exotic class of Banach algebras of Laurent series. We characterize operator weak amenability, and operator amenability of these algebras. In Section 4.1 we conduct a study of Arens regularity of these algebras, and in Section 4.2 we study, in the case of connected Lie groups, some conditions which allow our algebras to be represented as operator algebras. In [23] our estimates for the latter relied only on the dimension $d(G)$ of the connected Lie group $G$. In the present work, we gain advantage by refining a critical estimate from Lie theory, and we have more data to sharpen our estimates.

Since this paper features a wide variety of different results, many of them quantitative, we include two tables in the last section which summarize most of the results of this paper in the context of known results. We also point out some questions which arise naturally form the present investigation.

0.2. Fourier series on compact groups. For a compact group $G$, we let $\hat{G}$ denote its dual object, the set of unitary equivalence classes of all irreducible unitary representations. By standard abuse of notation, we shall identify elements of $\hat{G}$ with representatives of the equivalence classes. Each $\pi$ in $\hat{G}$ acts on a space $H_{\pi}$ of dimension $d_{\pi}$. Let $M_d$ denote the space of $d \times d$ complex matrices. Given $\pi$ in $\hat{G}$ we let $\text{Trig}_\pi = \{\text{Tr}(A\pi(\cdot)) : A \in M_{d_{\pi}}\}$ and $\text{Trig}(G) = \bigoplus_{\pi \in \hat{G}} \text{Trig}_\pi$, where the sum may be regarded as an internal direct sum in the space of continuous functions.
on $G$. Given $u = \sum_{\pi \in \hat{G}} d_{\pi} \Tr(A_{\pi}(\cdot))$ (finite sum) in $\Trig(G)$, Schur's orthogonality formula provides that $A_{\pi} = \int_{G} u(s) \pi(s^{-1}) \, ds$ (normalized Haar integration). We denote this matricial coefficient $A_{\pi} = \hat{u}(\pi)$. The linear space $\Trig(G)$ admits algebraic dual space $\Trig(G)^{\dagger} = \prod_{\pi \in \hat{G}} M_{d_{\pi}}$ via the duality

\[ \langle u, (T_{\pi})_{\pi \in \hat{G}} \rangle = \sum_{\pi \in \hat{G}} d_{\pi} \Tr(\hat{u}(\pi) T_{\pi}). \]  

This duality is constructed specifically to recognize the functionals of evaluation at points: for $s$ in $G$, let $(\pi(s))_{\pi \in \hat{G}}$, and we have $u(s) = \langle u, \lambda(s) \rangle$ for each $u$ in $\Trig(G)$. Furthermore, a consequence of Schur’s lemma is that span $\lambda(G)$ is weak$^{\ast}$ dense in $\Trig(G)^{\dagger}$, i.e. dense with respect to the initial topology $\sigma(\Trig(G)^{\dagger}, \Trig(G))$ with respect to the dual pairing (0.1). We let $m : \Trig(G) \otimes \Trig(G) \cong \Trig(G \times G) \rightarrow \Trig(G)$ denote the pointwise product, and define the coproduct $M : \Trig(G)^{\dagger} \rightarrow \Trig(G \times G)^{\dagger}$ to be the adjoint of $m$. Hence $M$ is defined by the relation

\[ M\lambda(s) = \lambda(s) \otimes \lambda(s) \text{ for } s \text{ in } G \]

which is the familiar co-commutative coproduct from the theory of (compact) quantum groups. We shall require a form of this which is more suitable for certain norm computations, however. If $\sigma$ is equivalent to a subrepresentation of $\pi \otimes \pi' \in \sigma$ in this case – we let $U_{\sigma, \pi \otimes \pi'}^{(i)} : \mathcal{H}_{\pi} \rightarrow \mathcal{H}_{\pi} \otimes \mathcal{H}_{\pi'}$, $i = 1, \ldots, m(\sigma, \pi \otimes \pi')$, denote a maximal family of isometric intertwiners with pairwise disjoint ranges. Then for suitably sized matrices $A_{\pi}$ and $A_{\pi'}$, we see that

\[ m(\Tr(A_{\pi}(\cdot)) \otimes \Tr(A_{\pi'}(\cdot))) = \sum_{\sigma \subset \pi \otimes \pi'} \sum_{i=1}^{m(\sigma, \pi \otimes \pi')} \Tr(A_{\pi} \otimes A_{\pi'} U_{\sigma, \pi \otimes \pi'}^{(i)}) \sigma(\cdot) U_{\sigma, \pi \otimes \pi'}^{(i)*}. \]

We note that there is a natural linear isomorphism $\Trig(G \times G) = \Trig(G) \otimes \Trig(G)$, and that $\Trig(G \times G)^{\dagger} = \prod_{\pi, \pi' \in \hat{G}} M_{d_{\pi}} \otimes M_{d_{\pi'}}$. Hence by the weak$^{\ast}$ density of span $\lambda(G)$ in $\Trig(G)^{\dagger}$, and the weak$^{\ast}$ density of $\bigoplus_{\pi, \pi' \in \hat{G}} M_{d_{\pi}} \otimes M_{d_{\pi'}}$ in $\Trig(G \times G)^{\dagger}$, we have that

\[ MW_{\pi, \pi'} = \bigoplus_{\sigma \subset \pi \otimes \pi'} U_{\sigma, \pi \otimes \pi'}^{*} W_{\sigma, \pi \otimes \pi'}, \]

where the sum now counts multiplicity, i.e. we absorb indices $i = 1, \ldots, m(\sigma, \pi \otimes \pi')$ so as to simplify the notation in our future computations. It is well-known, see, for example, [53], that $M(A(G)^{\ast}) \subset A(G)^{\ast} \otimes A(G)^{\ast}$ where $\otimes$ denotes the normal spatial, or von Neumann, tensor product.

We note that for any norm $\| \cdot \|_{4}$ on $\Trig(G)$, the completion $\mathcal{A}(G)$ of $\Trig(G)$ with respect to that norm may be understood to have its continuous dual space $\mathcal{A}(G)^{\ast}$ as a subspace of $\Trig(G)^{\dagger}$. For example, the Fourier algebra, mentioned earlier, satisfies

\[ \mathcal{A}(G) \cong \ell^{1} \bigoplus_{\pi \in \hat{G}} d_{\pi} S_{d_{\pi}} \quad \text{and} \quad \mathcal{A}(G)^{\ast} \cong \ell^{\infty} \bigoplus_{\pi \in \hat{G}} S_{d_{\pi}}^{\infty}, \]

i.e. Banach space direct sum of weighted trace-class matrix spaces and direct product of operators on $d_{\pi}$-dimensional Hilbert spaces, respectively.
0.3. **Operator spaces.** Our standard references for the theory of operator spaces are [12] and [44]. An operator space is a complex vector space $V$ admitting a family of norms $\|\cdot\|_{\mathcal{M}_n(V)}$, one on each of the spaces of $n \times n$ matrices with entries in $V$, satisfying certain compatibility conditions of Ruan (which we shall not explicitly use), and for which each $\mathcal{M}_n(V)$ is complete. For us, the space $S_\infty^d$ will always have the canonical operator space structure it admits by virtue of being a $C^*$-algebra. The space $S_1^d$ will come by its operator space structure as the dual space of $S_\infty^d$. We shall make use of direct products and direct sums (the latter of which is described nicely in [44]), denoted $\odot_\infty$ or $\ell_\infty^\odot$ and $\odot_1$ or $\ell_1^\odot$, respectively; as well as operator projective, operator injective (or spatial), and Haagerup tensor products, denoted $\hat{\otimes}$, $\check{\otimes}$ and $\otimes^h$, respectively. We shall also often use the normal spatial tensor product $\bar{\otimes}$ of operator dual spaces. In particular, there are distributive laws over infinite families of operator space sums and the operator projective tensor product, and over operator dual spaces of operator direct products and the normal spatial tensor product.

The spaces $S_p^d$, with Schatten $p$-norms, will have their operator space structures realized through Pisier’s complex interpolation theory ([43]): $S_p^d = [S_\infty^d, S_1^d]_{1/p}$. Hence the Hilbert-Schmidt space $S_2^d$ will be understood with the operator Hilbert space structure. However, we will also have occasions to consider this space as a column Hilbert space, $S_2^d, C$ or a row Hilbert space, $S_2^d, R$. We shall do the same with all of the $d$-dimensional spaces $\ell_p^d$. In this case $\ell_\infty^d$, being a commutative $C^*$-algebra, is a minimal operator space, while $\ell_1^d$, being its dual, is maximal. In the case $p = 2$, we let $C_d = \ell_2^d, C$ and $R_d = \ell_2^d, R$ denote the $d$-dimensional column and row spaces. We shall use the bilinear identifications $C_d^* \cong R_d$ and $R_d^* \cong C_d$, given by $(\xi, \eta) \mapsto \eta \xi$, $\xi \eta$, respectively. Thus we obtain completely isometric identifications

$$S_\infty^d = C_d \otimes^h R_d \quad \text{and} \quad S_1^d = R_d \otimes^h C_d.$$

Then, keeping with standard notation of [44], we obtain interpolated Hilbertian operator spaces

$$C_d^p = [C_d, R_d]_{1/p} \quad \text{and} \quad R_d^p = [R_d, C_d]_{1/p}.$$

In this notation we have $C_2^\infty = C_d$ and $C_1^1 = R_d$, for example. This notation proves itself in the remarkable tensorial factorizations

$$S_2^d = C_d^\infty \otimes^h R_d^1$$

which hold thanks to the stability of Haagerup tensor product under complex interpolation ([43]).

It is well-known that the space of completely bounded maps $\mathcal{CB}(C_d, R_d)$ is isometrically isomorphic to $S_2^d$. Hence the identity $\text{id} : C_d \to R_d$ has completely bounded norm $d^{1/2}$. We abbreviate this by writing that $\text{id} : d^{1/2} C_d \to R_d$ is a complete contraction.

We realize $p$-direct sums through interpolation: $\mathcal{V} \oplus^p \mathcal{W} = [\mathcal{V} \oplus^\infty \mathcal{W}, \mathcal{V} \oplus^1 \mathcal{W}]_{1/p}$, completely isometrically.

### 1. The algebras $A^p(G)$

Let $G$ be a compact group.
1.1. Definition and elementary properties of $A^p(G)$. Let $1 \leq p \leq \infty$ and $p'$ denote the conjugate index so $\frac{1}{p} + \frac{1}{p'} = 1$. We consider on $\text{Trig}(G)$ the norm

\[ \|u\|_{A^p} = \sum_{\pi \in \hat{G}} d_\pi^{1 + \frac{1}{p'}} \|\hat{u}(\pi)\|_p. \]

Let $A^p(G)$ denote the completion of $\text{Trig}(G)$ with respect to this norm, hence we have isometric identification

\[ (1.1) \quad A^p(G) \cong \ell^1 \bigoplus_{\pi \in \hat{G}} d_\pi^{1 + \frac{1}{p'}} S_{d_\pi}^p. \]

We may further put the canonical operator space structures on the individual spaces $S_{d_\pi}^p$ and use operator space direct sum, thus making a completely isometric identification. We note that for any positive integer $d$, $(dS_d^\infty, S_1^d)$ forms a natural compatible couple of operator spaces with interpolated spaces $[dS_d^\infty, S_1^d]_{1/p} = d^{1/p'} S_{d'}^{p'}$. Thus since the formal identity $dS_d^\infty \cong d^{1/2} C_d \hat{\otimes} h d^{1/2} R_d \hookrightarrow R_d \hat{\otimes} h C_d \cong S_1^d$ is a complete contraction, it follows standard operator interpolation theory we get for $1 \leq p \leq q \leq \infty$ completely contractive identity maps $dS_d^\infty \hookrightarrow d^{1/q'} S_{d'}^{q'} \hookrightarrow d^{1/p'} S_{d}^{p} \hookrightarrow S_1^d$. These give rise to completely contractive inclusions

\[ (1.2) \quad A^\infty(G) \subseteq A^q(G) \subseteq A^p(G) \subseteq A(G). \]

Hence each space is a space of continuous functions on $G$.

Let us see that each $A^p(G)$ is a completely contractive Banach algebra. Hence we are justified in calling it the $p$-Fourier algebra of $G$. We first observe that the dual space is the direct product space

\[ (1.3) \quad A^p(G)^* \cong \ell^\infty \bigoplus_{\pi \in \hat{G}} d_\pi^{-\frac{1}{p'}} S_{d_\pi}^{p'}. \]

Also, since the operator projective tensor product commutes with operator space direct sums we have that

\[ (1.4) \quad A^p(G) \hat{\otimes} A^p(G) \cong \ell^1 \bigoplus_{\pi, \pi' \in \hat{G} \times \hat{G}} (d_{\pi} d_{\pi'})^{1 + \frac{1}{p'}} S_{d_{\pi}}^p \hat{\otimes} S_{d_{\pi'}}^p. \]

and hence obtain

\[ (1.5) \quad (A^p(G) \hat{\otimes} A^p(G))^* \cong \ell^\infty \bigoplus_{\pi, \pi' \in \hat{G} \times \hat{G}} (d_{\pi} d_{\pi'})^{-1/p'} S_{d_{\pi}}^{p'} \hat{\otimes} S_{d_{\pi'}}^{p'}. \]

**Theorem 1.1.** The space $A^p(G)$ is a completely contractive Banach algebra under pointwise multiplication.

**Proof.** It suffices to show that the coproduct $M$ of \([0,2] \) takes $A(G)^*$ into $(A^p(G) \hat{\otimes} A^p(G))^*$, completely contractively. Now if $[W_{ij}] \in M_n(A^p(G)^*)$ then we wish to estimate

\[ (1.6) \quad \|[MW_{ij}]\| = \sup_{\pi, \pi' \in \hat{G} \times \hat{G}} (d_\pi d_{\pi'})^{-1/p'} \left\| \bigoplus_{\sigma \in \pi \hat{\otimes} \pi'} U_{\sigma, \pi \hat{\otimes} \pi'}^* W_{ij, \sigma} U_{\sigma, \pi \hat{\otimes} \pi'} \right\|_{M_n(S_{d_{\pi}}^{p'} \hat{\otimes} S_{d_{\pi'}}^{p'})}. \]

Let us make three general observations.
First, if \(d\) and \(d'\) be two positive integers, the formal identity \(S^p_{dd'} \hookrightarrow S^p_d \otimes S^p_{d'}\) is a complete contraction. Indeed, the desired map is the adjoint of the map \(S^p_d \otimes S^p_{d'} \hookrightarrow S^p_{dd'}, \) which is completely contractive since we may recognize it as

\[
\begin{align*}
S^p_d \otimes S^p_{d'} \cong & \ (C^p_d \otimes h R^p_d) \otimes (C^p_{d'} \otimes h R^p_{d'}) \\
\hookrightarrow & \ (C^p_d \otimes C^p_{d'}) \otimes h (R^p_d \otimes R^p_{d'}) \\
\hookrightarrow & \ (C^p_d \otimes h C^p_{d'}) \otimes h (R^p_d \otimes h R^p_{d'}) \\
\cong & \ C^p_{dd'} \otimes h R^p_{dd'} \cong S^p_{dd'}
\end{align*}
\]

where the complete contraction \(c_1 \otimes r_1 \otimes c_2 \otimes r_2 \mapsto c_1 \otimes c_2 \otimes r_1 \otimes r_2\) at (\(\dagger\)) is provided by [13 Thm. 6.1].

Second, if \(d_1, \ldots, d_m\) are positive integers and \(d = d_1 + \cdots + d_m,\) then the block-diagonal embedding of the operator space \(\ell^p \cdot \bigoplus_{j=1}^m S^p_{d_j}\) into \(S^p_{dd'}\) is a complete isometry. Indeed when \(p' = \infty,\) this is a completely contractively complemented subspace, whence, by duality, the same holds when \(p' = 1.\) The case for general \(p\) then follows from the generalized Riesz-Thorin Theorem, using the facts that \(\ell^p \cdot \bigoplus_{j=1}^m S^p_{d_j} = [\ell^\infty \cdot \bigoplus_{j=1}^m S^p_{d_j}, \ell^1 \cdot \bigoplus_{j=1}^m S^p_{d_j}]_{1/p'}.\)

Third, if \(E\) and \(F\) are operator spaces then the formal identity \(M_n(E) \oplus^p M_n(F) \hookrightarrow M_n(E \oplus^p F)\) is a contraction. Indeed, this map is an isometry if \(p' = \infty,\) and, thanks to the universal property of direct sums, is a contraction when \(p' = 1.\) The case for general \(p'\) follows from the generalized Riesz-Thorin Theorem, using the facts that \(M_n(E) \oplus^p M_n(F) = [M_n(E) \oplus^p M_n(F), M_n(E) \oplus^1 M_n(F)]_{1/p'}\) and \(M_n(E \oplus^p F) = [M_n(E \oplus^\infty F), M_n(E \oplus^1 F)]_{1/p'}\).

Using the three observations above, in order, and then a rudimentary Hölder estimate we obtain

\[
\left\| \left[ \bigoplus_{\sigma \subset \pi \otimes \pi'} U^*_{\sigma, \pi \otimes \pi'} W_{\sigma, \pi \otimes \pi'} \right] \right\|_{M_n(S^p_{d_{\pi', d_{\pi}}})} \\
\leq \left\| \left[ \bigoplus_{\sigma \subset \pi \otimes \pi'} U^*_{\sigma, \pi \otimes \pi'} W_{ij, \sigma} U_{\sigma, \pi \otimes \pi'} \right] \right\|_{M_n(S^p_{d_{\pi', d_{\pi}}})} \\
= \left\| \bigoplus_{\sigma \subset \pi \otimes \pi'} [W_{ij, \sigma}] \right\|_{M_n(\ell^p_{\pi'} \cdot \bigoplus_{\sigma \subset \pi \otimes \pi'} S^p_{d_{\pi'}})} \\
\leq \left( \sum_{\sigma \subset \pi \otimes \pi'} \| [W_{ij, \sigma}] \|_{M_n(S^p_{d_{\pi'}})} \right)^{1/p'} \\
\leq \left( \sum_{\sigma \subset \pi \otimes \pi'} d_{\sigma} \cdot \sup_{\tau \subset \pi \otimes \pi'} \frac{1}{d_{\tau}} \| [W_{ij, \tau}] \|_{M_n(S^p_{d_{\pi'}})} \right)^{1/p'} \\
= \left( d_{\pi} d_{\pi'} \right)^{1/p'} \sup_{\tau \subset \pi \otimes \pi'} d_{\tau}^{-1/p'} \| [W_{ij, \tau}] \|_{M_n(S^p_{d_{\pi'}})}.
\]

It follows that the quantity of (1.6) is no greater than

\[
(1.7) \quad \sup_{\tau \in G} d_{\tau}^{-1/p'} \| [W_{ij, \tau}] \|_{M_n(S^p_{d_{\pi'}})} = \| [W_{ij}] \|_{M_n(A^p(G)^*)}.
\]
Hence $M$ satisfies the desired complete contractivity property.  □

We shall also make use of the $p$-Beurling-Fourier algebras which we define below. As defined in [35, 36], a weight is a function $\omega : \hat{G} \to \mathbb{R}^+$ which satisfies

$$\omega(\sigma) \leq \omega(\pi) \omega(\pi')$$

whenever $\sigma \subset \pi \otimes \pi'$. We will always assume that $\omega$ is bounded away from zero:

$$\inf_{\pi \in \hat{G}} \omega(\pi) > 0.$$  Notice that this is automatic if $\omega$ is symmetric, i.e. $\omega(\bar{\pi}) = \omega(\pi)$; indeed $\pi \otimes \bar{\pi} \supset \mathbb{1}$ so $\omega(\pi) \geq \omega(\mathbb{1})^{1/2}$ in this case. We let

$$(1.8) A^p(G, \omega) = \ell^1 - \bigoplus_{\pi \in \hat{G}} \omega(\pi) d_\pi 1+1/p S^p_{d_\pi}.$$  As before we give this the weighted direct sum operator space structure, with usual interpolated structure on each $S^p_{d_\pi}$. Boundedness away from zero of $\omega$ ensures that $A^p(G, \omega) \hookrightarrow A^p(G)$, completely boundedly – completely contractively provided

$$\inf_{\pi \in \hat{G}} \omega(\pi) \geq 1.$$  

**Corollary 1.2.** For any weight $\omega$, the space $A^p(G, \omega)$ is a completely contractive Banach algebra under pointwise multiplication.

**Proof.** We make the obvious changes to (1.5) and hence to (1.6). Then the computation follows exactly as in the proof of the last theorem. In place of (1.7) we obtain

$$\sup_{\pi, \pi' \in \hat{G} \times \hat{G}} 1 \omega(\pi) \omega(\pi') \sup_{\tau \subset \pi \otimes \pi'} \| [W_{ij, \tau}] \|_{S^p_{d_\tau}} = \sup_{\tau \in \hat{G}} 1 \omega(\tau) \| [W_{ij, \tau}] \|_{S^p_{d_\tau}} = \| [W_{ij}] \|_{M_p(A^p(G, \omega)^*)}.$$  □

Let us close this section by noting that the algebras $A(G)$ are an interpolation scale, $A^p(G) = [A^\infty(G), A(G)]_{1/p}$. Let us explain this fact, briefly, and generalize it. Let $\omega$ and $\bar{\omega}$ each be weights on $\hat{G}$. We remark that complex interpolation is isometrically stable for completely contractively complemented subspaces. See, for example, [44, 2.7.6]. Hence, using (1.8) we see that

$$(1.9) [A^\infty(G, \omega), A(G, \bar{\omega})]_{1/p} = \ell^1 - \bigoplus_{\pi \in \hat{G}} d_\pi 1+1/p' \omega(\pi)\bar{\omega}(\pi)d_\pi.$$  

It is evident that positive powers of single weights, and products of multiple weights, remain weights.
1.2. Spectrum of $\mathcal{A}^\alpha(G)$. We first find it desirable to compute the spectra of a certain class of Beurling-Fourier algebras. Let $\alpha > 0$ and $d^\alpha : \hat{G} \to \mathbb{C}$ be the $\alpha$-power of the dimension weight: $d^\alpha(\pi) = d^\alpha_\pi$.

We shall also make use of the basic polynomial weights for a Lie group $G$. In this case $\hat{G}$ is finitely generated, i.e. there is a finite $S \subset \hat{G}$ for which $\bigoplus_{\pi \in S} \pi$ is faithful. We may and shall suppose that $S$ is symmetric: $\pi \in S$ implies $\bar{\pi} \in S$. Let $S^{\otimes n} = \{ \sigma \in \hat{G} : \sigma \subset \pi_1 \otimes \cdots \otimes \pi_n : \pi_1, \ldots, \pi_n \in S \}$ and $S^{\otimes 0} = \{1\}$. Then $S$ generates $\hat{G}$ in the sense that $\hat{G} = \bigcup_{n=1}^\infty S^{\otimes n}$. See [36] §4.2 for details. It is easy to check that $\tau_S(\sigma) = \min\{n : \sigma \in S^{\otimes n}\}$ is subadditive. We let $\omega_S^\alpha(\pi) = (1 + \tau_S(\pi))^\alpha$, for $\alpha \geq 0$, and call these the polynomial weights. Given another symmetric generating set $S'$, it is each to see that for some constants $c, C$ that $c\omega_S \leq \omega_{S'} \leq C\omega_S$, so all polynomial weights are equivalent.

Suppose now that $G$ is a general compact group. For any finite symmetric set $S \subset G$ we may consider $\tau_S : \langle S \rangle \to \mathbb{R}^{\leq 0}$ to be defined as above, and hence define a weight $\omega_S^\alpha : \langle S \rangle \to \mathbb{R}^{>0}$, as above. Notice that $\omega_S^\alpha$ is really a weight on $G/\mathcal{N}_S \circ q$ where $\mathcal{N}_S = \bigcup_{\pi \in S} \ker \pi$ and $q : G \to G/\mathcal{N}_S$ is the quotient map. A weight $\omega$ on a general compact group $G$ is called weakly polynomial if for any set $S$ as above, there is a constant $C_S$ and $\alpha_S \geq 0$ for which

$$\omega_{\langle S \rangle} \leq C_S \omega_S^{\alpha_S}.$$

(For a connected group, this was termed a “polynomial weight” in [36] Def. 5.1). Compare the results [36] (5.5) & Thm. 5.4,[.] Note that if $G$ is totally disconnected, then any weight is weakly polynomial. Indeed, any finite subset $S$ of $\hat{G}$ has that $\mathcal{N}_S$ is open, so $\langle S \rangle$ is finite.

**Proposition 1.3.** If $\omega$ is a symmetric weakly polynomial weight on $\hat{G}$, then $\mathcal{A}(G, \omega)$ has spectrum $G$.

**Proof.** In [36] Prop. 5.5] this is shown for connected groups. Let us adapt the proof for general $G$. Fix $\pi$ in $\hat{G}$, and let $S = \{\pi, \bar{\pi}\}$. Then for any $\sigma \subset \pi^{\otimes n}$, the definition of $\tau_S$ provides that $\tau_S(\sigma) \leq n$, hence $\omega_S(\sigma) \leq 1 + n$. Hence using our assumption that $\omega$ is weakly polynomial we have

$$\left( \sup_{\sigma \subset \pi^{\otimes n}} \omega(\sigma) \right)^{1/n} \leq \left( \sup_{\sigma \subset \pi^{\otimes n}} C_S \omega_S(\sigma)^{\alpha_S} \right)^{1/n} \leq C_S^{1/n} (1 + n)^{\alpha_S/n^{1/n}} 1.$$

The result now follows from [36] Prop. 4.19].

If $\omega$ is a weight on $\hat{G}$ and $H$ is a closed subgroup, we follow [36] §4.1 or [[35] Prop. 3.5] and define the restricted weight $\omega_{G|H}$ on $\hat{H}$ by

$$(1.10) \quad \omega_{G|H}(\sigma) = \inf\{\omega(\pi) : \pi \in \hat{G}, \sigma \subset \pi|_H \}$$

where $\pi|_H$ refers to the restricted representation.

**Remark 1.4.** For a connected Lie group $G$, and a weakly polynomial weight, $\mathcal{A}(G, \omega_S^\alpha)$ is shown to be regular in [36] Thm. 5.11]. We do not know how to extend this result to non-connected groups. For us to do this, it would be sufficient to see that for a Lie group $G$, with symmetric generating set $S$ for $\hat{G}$, that $\omega_S|_{C\{\sigma\}}$ is weakly polynomial on $\hat{G}_e$. We observe, however, that the easy estimate to show is in the wrong direction.
Let $S_\nu = \{ \sigma \in \hat{G}_e : \sigma \subset \pi|_{G_e} \text{ for some } \pi \text{ in } S \}$. If $\sigma \subset \pi|_{G_e}$, where $\tau_\pi(\sigma) = n$, then there are $\pi_1, \ldots, \pi_n$ in $S$ for which $\sigma \subset \pi_1 \otimes \cdots \otimes \pi_n|_{G_e} = \pi_1|_{G_e} \otimes \cdots \otimes \pi_n|_{G_e}$. It follows that $\tau_{S_\nu}(\sigma) \leq n = \tau_\pi(\sigma)$. Hence

$$\omega_{S_\nu}(\sigma) \leq (\omega_\pi)|_{G_e}(\sigma). \tag{1.11}$$

We shift our attention to dimension weights. We can obtain regularity.

**Proposition 1.5.** (i) The Gelfand spectrum of $A(G, d^\alpha)$ is $G$.

(ii) The algebra $A(G, d^\alpha)$ is regular on $G$.

*Proof.* (i) For $\alpha = 1$, this result is stated as [36 Cor. 5.6] and erroneously attributed to [12]. Regrettably, the proof of [36 Cor. 5.6] only deals with the case of connected groups. It is sufficient to see that that the dimension weight $d$ on $G$ is a weakly polynomial weight, and then appeal to Proposition [1.3].

First, suppose that $G$ is a connected Lie group. Then [36 Ex. 5.2] shows that $d$ is a weakly polynomial weight. (This uses ideas we shall use in proving Theorem 4.11.)

Now suppose that $G$ is a Lie group, so the connected component of the identity $G_e$ is open, hence the index $[G : G_e]$ is finite. Then for $\pi$ in $\hat{G}$ and $\sigma$ in $\hat{G}_e$, the Frobenius reciprocity formula of [37 Thm. 8.2] (see also [33 2.61]) yields equality of multiplicities

$$m(\sigma : \pi|_{G_e}) = m(\pi : \sigma \uparrow^G)$$

where $\sigma \uparrow^G$ denotes the induced representation. Thus if $\sigma \subset \pi|_{G_e}$, then $\pi \subset \sigma \uparrow^G$, so

$$d_\pi \leq d_{\pi \uparrow^G} = [G : G_e]d_\sigma.$$

Fix any symmetric generating set $S$ of $\hat{G}$. Then for any $\pi$ in $\hat{G}$ and $\sigma$ in $\hat{G}_e$ with $\sigma \subset \pi|_{G_e}$, we have

$$d_\pi \leq [G : G_e]d_\sigma \leq C\omega_{S_\nu}^{\alpha'}(\sigma) \leq C(\omega_{S_\nu}^\alpha)|_{G_e}(\sigma) \leq C\omega_{S_\nu}^\alpha(\pi)$$

for some constant $C$ and $\alpha' \geq 0$, where the second inequality follows from the fact that the dimension weight on $G_e$ is weakly polynomial, as noted in the prior paragraph, and the fact that any two polynomial weights are equivalent; and the third inequality is provided by (1.11).

We finally consider the case of a general compact $G$. For any finite symmetric set $S$ of $\hat{G}$, with $N_S = \bigcap_{\pi \in S} \ker \pi$, we see that $G/N_S$, being isomorphic to a subgroup of $\bigoplus_{\pi \in S} \pi(G)$ is a Lie group, with $\langle S \rangle = G/N_S \circ q$, where $q : G \to G/N_S$ is the quotient map. Hence the result of the last paragraph shows that $d|_{\langle S \rangle} \leq C\omega_{S_\nu}^{\alpha'}$ on $\langle S \rangle$, for some $C_S$ and $\alpha_S$, i.e. $d$ is weakly polynomial.

(ii) Let us now show the regularity. First, let us fix $\alpha = 1$. We see from [20 Thm. 4.1] that the map $\hat{\Gamma} : A(G \times G) \to A(G, d)$ given by $\hat{\Gamma}(u) = \int_G u(st, t^{-1}) \, dt$ is a surjection. If $E$ and $F$ are non-empty disjoint closed subsets of $G$ then $E$ and $F$ are non-empty disjoint closed subsets of $G \times G$, where $\hat{S} = \{(s, t) : s \in S \}$. Then [14 (3.2)] provides $u$ in $A(G \times G)$ such that $u|_E = 1$ and $u|_F = 0$. Then $\hat{\Gamma}(u)|_E = 1$ and $\hat{\Gamma}(u)|_F = 0$.

It is now straightforward to verify the (completely) isometric identification

$$A(G, d^\alpha) \hat{\otimes} A(G, d^\alpha) \cong A(G \times G, (d \otimes d)^\alpha)$$

\[\text{p-FOURIER ALGEBRAS 9}\]
where \( d \otimes d(\pi, \sigma) = d_\pi d_\sigma \). Hence the proof of [46] Prop. 2.6 can be followed to show that
\[
\tilde{\Gamma}(A(G \times G, (d \otimes d)^\alpha)) = A(G, d^{2\alpha+1}).
\]
The recursion \( \alpha_0 = 0, \alpha_{n+1} = 2\alpha_n + 1 \) admits solution \( \alpha_n = 2^n - 1 \). See, also, [35, p. 189]. Hence, applying induction to the paragraph above yields that each algebra \( A(G, d^{2^n-1}) \) is regular. The contractive embedding \( A(G, d^{2^{(\log_2(n+1))}-1}) \hookrightarrow A(G, d^n) \) yields the regularity of the latter algebra.
\[\square\]

We move from \( p = 1 \) to all \( 1 \leq p \leq \infty \).

**Proposition 1.6.** The Gelfand spectrum of \( A^p(G, d^\alpha) \) is \( G \), and \( A^p(G, d^\alpha) \) is regular on \( G \).

**Proof.** For any positive integer \( n \) the formal identity map \( S^1_d \to S^p_d \) is a contraction, hence so too is \( dS^1_d \to dS^p_d \to d^{1/p} S^p_d \). Thus the inclusion map \( A(G, d^{\alpha+1}) \hookrightarrow A(G, d^\alpha) \) is a contraction. The desired results are immediate from Proposition 1.5 above.
\[\square\]

We observe that for \( s \) in \( G \), the unitary \( \pi(s) \) in \( S^p_{d^s} \) necessarily has norm \( d^s_\alpha \). Hence by by (1.3) and the result above, each element of the spectrum has norm 1. Thus the choice of exponent \( 1 + \frac{1}{p} \) in (1.1) is minimal for allowing the space \( A^p(G) \) to be a Banach function algebra on \( G \). Indeed, characters need necessarily be contractive.

Let \( \theta : \mathbb{R}^\geq_0 \to \mathbb{R}^>0 \) be a non-decreasing weight (i.e. \( \theta(s + t) \leq \theta(s)\theta(t) \)) and let \( \omega_\theta(\pi) = \theta(\log d_\pi) \). Such weights are symmetric.

**Example 1.7.** The weight \( \theta^{\alpha}(t) = e^{\alpha t} \), where \( \alpha > 0 \), gives the dimension weight \( \omega^{\theta^{\alpha}}(\pi) = d_\pi^\alpha \). The weight \( w^{\alpha\theta}(t) = (1 + t)^\alpha \), on \( \mathbb{R}^\geq_0 \), leads to \( \omega^{w^{\alpha\theta}}(\pi) = (1 + \log d_\pi)^\alpha \).

We say that a weight \( \omega \) on \( \widehat{G} \) is weakly dimension if there is \( C \) and \( \alpha \geq 0 \) for which \( \omega(\pi) \leq C d_\pi^\alpha \). Notice that for \( \theta \) as above, \( \theta(s) \leq \theta(1)^{1+|s|} \leq \theta(1)^{\log \theta(1)s} \), from which it follows that \( \omega_\theta \) is weakly dimension.

**Corollary 1.8.** Let \( \omega \) be any weight on \( \widehat{G} \) which is weakly dimension. Then the algebra \( A^p(G, \omega) \) has Gelfand spectrum \( G \) and is regular on \( G \). In particular, this holds for \( \omega_\theta \) where \( \theta \) is any non-decreasing weight on \( \mathbb{R}^\geq_0 \).

**Proof.** The bounded inclusions \( A^p(G, d^\alpha) \subseteq A^p(G, \omega) \subseteq A^p(G) \) give the first conclusion. The second conclusion is immediate from the comments above.
\[\square\]

The following is a straightforward adaptation of [20 Cor. 2.4], which we leave to the reader.

**Proposition 1.9.** (i) Given a weight \( \omega \) in \( \widehat{G} \) and \( 1 < p \leq \infty \), we have that \( A^p(G, \omega) = A(G, \omega) \) isomorphically, if and only if \( G \) admits an open abelian subgroup.

(ii) For any weight \( \omega \) which is weakly dimension, \( A(G, \omega) = A(G) \) isomorphically, if and only if \( G \) admits an open abelian subgroup.
1.3. **Isometric isomorphisms.** The main theorem of [38] tells us that any isometric isomorphism $\Phi : A(G) \to A(H)$ is of the form $\Phi u = u(s_0 \varphi (\cdot))$ where $\varphi : H \to G$ is a homeomorphism which is either an isomorphism or anti-isomorphism of the groups. In particular, $A(G) \cong A(H)$ isometrically, only if $G \cong H$ as topological groups.

With compact groups, the addition of certain weights does not change this result. Furthermore, we can obtain this result for most indices $p$. We retain our convention that $G$ and $H$ denote compact groups. The weights $\omega_\theta$ are defined at the end of the last section.

**Theorem 1.10.** Let $1 \leq p \leq \infty$ with $p \neq 2$. Fix a non-decreasing weight $\theta : \mathbb{R}^{\geq 0} \to \mathbb{R}^{>0}$. If $A^p(G, \omega_\theta) \cong A^p(H, \omega_\theta)$ isometrically isomorphically then $G \cong H$ as compact groups.

**Proof.** Given any Banach space $E$, we let $B(E)$ denote the closed unit ball, and $S(E)$ the unit sphere. We identify the spaces $\text{Trig}_n = d_1^{1+\frac{1}{\theta}} \omega_\theta(\pi) S^p_{d_\pi}$, for $\pi$ in $\hat{G}$, as subspaces of $A^p(G, \omega_\theta)$. Then we have the following routine identification of sets of extreme points:

$$\text{ext}(A^p(G, \omega_\theta)) = \text{ext} \left( \ell_1^1 \bigoplus_{\pi \in \hat{G}} d_1^{1+\frac{1}{\theta}} \omega_\theta(\pi) S^p_{d_\pi} \right) = \bigcup_{\pi \in \hat{G}} \text{ext} \left( d_1^{1+\frac{1}{\theta}} \omega_\theta(\pi) S^p_{d_\pi} \right).$$

We remark that we have for any $d$ in $\mathbb{N}$, $1 < p < \infty$

$$\text{ext}(S^1_d) = \{ a \in S(S^1_d) : \text{rank} a = 1 \}, \text{ ext}(S^p_d) = S(S^p_d), \text{ and } \text{ext}(S^\infty_d) = U(d)$$

where $U(d)$ is the unitary group. Indeed, $S^1_d = \ell_1^1 \otimes \ell_2^d$ and the description of the projective tensor product norm shows that $\text{ext}(S^1_d)$ must consist of rank one elements. The fact that any two rank one elements $a$ and $b$ admit unitaries $u, v$ for which $uav = b$ show that all such rank one elements are achieved. For $1 < p < \infty$, it is shown by [39] that $S^p_d$ is uniformly convex, hence strictly convex. The description of $\text{ext}(S^\infty_d)$ may be found in [32] or [16, Chap. 10]. Hence we observe that each set $\text{ext}(S^p_d)$, $1 \leq p \leq \infty$ is connected.

Since $\Phi$ is an isometry, for each $u \in \text{ext} \left( d_1^{1+\frac{1}{\theta}} \omega_\theta(\pi) S^p_{d_\pi} \right)$ we have $\Phi(u) \in \text{ext} \left( d_1^{1+\frac{1}{\theta}} \omega_\theta(\pi') S^p_{d_{\pi'}} \right)$ for some $\pi' \in \hat{H}$. We observe that, given $\pi$ in $\hat{G}$, the sets $X_{\pi, \pi'} = \Phi^{-1}(\text{ext}(S^p_{d_{\pi'}})) \cap \text{ext}(S^p_{d_{\pi}})$, $\pi'$ in $\hat{H}$, comprise a cover of $\text{ext} \Phi(S^p_{d_{\pi}})$ by pairwise disjoint open sets. Hence, by connectedness, we have that there is a unique $\pi'$ for which $X_{\pi, \pi'} \neq \emptyset$. Thus we obtain a bijection $\hat{\Phi} : \hat{G} \to \hat{H}$, for which $\Phi(\text{Trig}_n) = \text{Trig}_{\hat{\Phi}(\pi)}$. Clearly $d_{\hat{\Phi}(\pi)} = d_\pi$ for each $\pi$, so this map induces an isometry $S^p_{d_{\hat{\Phi}(\pi)}} \to S^p_{d_{\pi}}$.

Thanks to [16] 10.2.2 or 10.3.5] (based on results of [32] 38) in the case $p = 1, \infty$, and [2] in the case $1 < p < \infty$ but $p \neq 2$, each isometry $S^p_{d_{\pi}} \to S^p_{d_{\hat{\Phi}(\pi)}}$ is of the form $a \mapsto uav$ or $a \mapsto u a^T v$ where $u$ and $v$ are unitaries and $a^T$ denotes the transpose with respect to some orthonormal basis. Hence we see that $\| \Phi u \| = \| u \|$ for $u$ in $A^p(G, \omega_\theta)$ extends to an isometry $A(G) \to A(H)$ with dense range. The structure of $\Phi$ follows from [38], accordingly. \(\square\)
1.4. Different operator space structures on $A^2(G)$. The construction above gives

$$A^2(G) = \ell^1 \bigoplus_{\pi \in \hat{G}} \mathbb{D}^{3/2} S_{\pi,OH}^2$$

where the subscript $OH$ denotes the operator Hilbert space structure on each space $S_{\pi,OH}^2$. However, we wish to observe that other choices of operator space structure allow $A^2(G)$ to be a completely contractive Banach algebra.

A Hilbertian operator space structure is an operator space structure $\mathcal{H} \mapsto \mathcal{H}_E$ which may be assigned to any Hilbert space. Such a structure is called homogeneous if $\mathcal{B}(\mathcal{H}) = \mathcal{B}(\mathcal{H}_E)$ isometrically for all $\mathcal{H}$. Furthermore, $\mathcal{H} \mapsto \mathcal{H}_E$ is subquadratic if for any projection on $\mathcal{H}$ we have $\|x_{ij}\|_{M_n(\mathcal{H}_E)}^2 \leq \|Px_{ij}\|_{M_n(\mathcal{H}_E)}^2 + \|[(I - P)x_{ij}]\|_{M_n(\mathcal{H}_E)}^2$ for any $n$ and $[x_{ij}]$ in $M_n(\mathcal{H})$. This is equivalent to saying that for (finite dimensional) $\mathcal{H}$ and $\mathcal{K}$, the formal identity

$$M_n(\mathcal{H}_E) \oplus_2 M_n(\mathcal{K}_E) \hookrightarrow M_n((\mathcal{H} \oplus^2 \mathcal{K})_E)$$

is a contraction for every $n$. We note that the homogeneity assumption provides that $(\mathcal{H} \oplus^2 \mathcal{K})_E = \mathcal{H}_E \oplus^2 \mathcal{K}_E$, completely isometrically. Finally, we will say that $\mathcal{H} \mapsto \mathcal{H}_E$ is subcross if the identity map on the algebraic tensor product of any two Hilbert spaces $\mathcal{H} \otimes \mathcal{K}$ extends to a complete contraction $\mathcal{H}_E \otimes \mathcal{K}_E \to (\mathcal{H} \otimes_2 \mathcal{K})_E$. By duality, this is equivalent to having the dual structure $\mathcal{H} \mapsto \mathcal{H}_{E^*}$ satisfy that the identity map on any $\mathcal{H} \otimes \mathcal{K}$ extend to a complete contraction $(\mathcal{H} \otimes_2 \mathcal{K})_{E^*} \to \mathcal{H}_{E^*} \otimes \mathcal{K}_{E^*}$.

We note that the standard homogeneous Hilbertian operator space structures $OH$, $C$ (column), $R$ (row), $R + C$, and max are subcross, and that the dual structures $OH^* = OH$, $R = C^*$, $C = R^*$, $R \cap C = (R + C)^*$ and min = max are subquadratic. The structures max and $R + C$, themselves, however, are not subquadratic. See the discussion in [43, p. 81]. Let us also consider the interpolated structures, $\mathcal{H}_{CP} = [\mathcal{H}_C, \mathcal{H}_R]_{1/p}$ for $1 \leq p \leq \infty$, and likewise for row structure. We have that $C^2 = OH = R^2$. By interpolation these structures are each homogeneous. Moreover, stability of the Haagerup tensor products under interpolation gives us that

$$\mathcal{H}_{CP} \otimes^h \mathcal{K}_{CP} = [\mathcal{H}_C \otimes^h \mathcal{K}_C, \mathcal{H}_R \otimes^h \mathcal{K}_R]_{1/p} = [(\mathcal{H} \otimes^2 \mathcal{K})_C, (\mathcal{H} \otimes^2 \mathcal{K})_R]_{1/p} = (\mathcal{H} \otimes^2 \mathcal{K})_{CP}$$

from which it is immediate that each $CP$ is subcross. We observe the duality $(CP)^* = CP$. Finally, subquadraticity of $CP$ follows from that for $C$, $R$, and interpolation.

**Theorem 1.11.** Let $\mathcal{H} \mapsto \mathcal{H}_E$ be a subcross homogeneous operator space structure whose dual structure is subquadratic. Then the operator space

$$A^2_E(G) = \ell^1 \bigoplus_{\pi \in \hat{G}} \mathbb{D}^{3/2} S_{\pi,OE}^2$$

is a completely contractive Banach algebra under pointwise multiplication.

**Proof.** The proof is essentially the same as that of Theorem 1.1. The subcross, homogeneity and subquadratic conditions of $E$, provide, respectively, the first, second and third observations required in that proof. \qed

Of course $A^2_{\max}(G)$ is simply $A^2(G)$ with its maximal operator space structure, hence it is no surprise based on Theorem 1.1 that it is a completely contractive
Banach algebra. As in Corollary\cite{12} we can see that the 2-Beurling-Fourier algebras $A^2_p(G, \omega)$, for weights $\omega$, are completely contractive Banach algebras.

The completely contractive Banach algebra $A^2_p(G)$ has actually been observed in \cite{21}. Let us review this briefly. Let $\Gamma : A(G \times G) \to A(G)$ be given by

\begin{equation}
\Gamma(u) = \int_G u(st, t) \, dt
\end{equation}

so $\Gamma$ averages elements of $A(G \times G)$ over left cosets of the diagonal subgroup $\Delta = \{(s, s) : s \in G\}$. For an elementary tensor, $u \otimes v \in A(G) \otimes A(G) \subset A(G \times G)$,

$\Gamma(u \otimes v) = u \ast \check{v}$ where $\check{v}(s) = v(s^{-1})$.

We record the following fact from \cite{16} Thm. 2.1, which is essentially generalized by Theorem \cite{2.1} below. See Remark \cite{2.5}

**Proposition 1.12.** Let $A_{\Delta}(G) = \Gamma(A(G \times G))$. If we assign $A_{\Delta}(G)$ the operator space structure which makes $\Gamma$ a complete quotient map, then $A_{\Delta}(G) = A^2_p(G)$, completely isometrically.

2. **Amenability properties**

We shall purposely limit our definitions to a commutative unital Banach algebra $A$, even when they may be more broadly made. After \cite{30}, we say that $A$ is *amenable* if there is a net $(w_i)$ in the projective tensor product $A \otimes^\gamma A$ which is bounded, satisfies that $(m(w_i))$ is an approximate identity on $A$, and for each $u$ in $A$, $(u \otimes 1 - 1 \otimes u)w_i \to 0$ in the norm of $A \otimes^\gamma A$. This is equivalent to having any bounded derivation $D : A \to X^*$, where $X$ is a Banach $A$-bimodule with dual module $X^*$, be inner, i.e. $D(u) = u \cdot f - f \cdot u$ for some $f$ in $X^*$.

We say that $A$ is *weakly amenable*, if for every symmetric $A$-module $X$ we have that the only bounded derivation from $A$ into $X$ is zero. This definition was given in \cite{3}, where it was also noted that it is equivalent to seeing that the only bounded derivation from $A$ into the symmetric dual bimodule $A^\ast$ is inner. We note that weak amenability implies that $A$ admits no bounded point derivations. We recall that if $A$ is a function algebra on a compact Hausdorff space $X$, then a point derivation at $x$ in $X$ is a linear functional $d : A \to \mathbb{C}$ which satisfies $d(uv) = d(u)v(x) + u(x)d(v)$.

Both definitions above admit obvious analogues in the setting of completely contractive Banach algebras, where we substitute operator projective tensor product for projective, and study only completely bounded derivations. See, for example, \cite{17}. It is obvious that (weak) amenability implies operator (weak) amenability.

Let us begin with a synthesis of well-known facts. We adopt the perspective of \cite{20} and let $A(G)$ be a unital (regular) Banach algebra of functions on $G$, contains $\text{Trig}(G)$ as a dense subspace, and which admits an operator space structure with respect to which it is completely contractive, and for which translations are complete isometries and are continuous on $G$. We suppose that $A(G) \hat{\otimes} A(G)$ is a (regular) function algebra on $G \times G$. We let $A_{\Delta}(G)$ denotes the image of $A(G) \hat{\otimes} A(G)$ under the map $\Gamma$ of \cite{12}, and let its operator space structure is given to make $\Gamma$ a complete quotient map.

**Proposition 2.1.** The algebra $A(G)$ is operator weakly amenable if and only if $A_{\Delta}(G)$ admits a bounded point derivation at $e$.

**Proof.** We first note that the unital algebra $A(G)$ is weakly amenable if and only if the ideal $I_{A \hat{\otimes} A}(\Delta) = \{u \in A(G) \hat{\otimes} A(G) : u|_{\Delta} = 0\}$ satisfies that it is essential:
Indeed see [24] Thm. 3.2 (which is shown to hold in the operator space setting in [31]). A more illuminating proof may be found in [48, Thm. 2.2]; being mostly functorial, this proof is straightforward to modify into the operator space setting with help of the infinite matrix techniques of [12, 10.2.1].

By [20, Cor. 1.5] having essentiality of \( I_{A\hat{\otimes} A}(\Delta) \) is equivalent to essentiality of \( I_{A\Delta}(e) = \{ u \in A_{\Delta}(G) : u(e) = 0 \} \). Any bounded linear functional on \( A_{\Delta}(G) \) which vanishes on \( I_{A\Delta}(e)^2 \), but not on \( I_{A\Delta}(e) \), is a bounded point derivation. Thus by the Hahn-Banach theorem, \( I_{A\Delta}(e) \) is essential if and only if \( A_{\Delta}(G) \) admits a bounded point derivation at \( e \).

Let us now consider the nature of point derivations at \( e \) on \( A(G) \). We wish to use the perspective of [7]. We observe that \( \text{Trig}(G)^\dagger \cong \prod_{x \in \hat{G}} M_{d_x} \) is an involutive algebra with the usual conjugate transpose on each \( M_{d_x} \) and the coproduct \( \Delta : \text{Trig}(G)^\dagger \to \text{Trig}(G \times G)^\dagger \) is a *-homomorphism. We further assume that \( A(G)^* \subset \text{Trig}(G)^\dagger \) is closed under this involution. In the case that \( A(G) = A^p(G, \omega) \), this is straightforward to check. A point derivation \( D \) at \( e \) on \( A(G) \) clearly restricts to such on \( \text{Trig}(G) \). Moreover, we have the derivation law for the coproduct is \( MD = 1 \otimes D + D \otimes 1 \). Hence \( D^\star \) is also a derivation. Hence we may write as a linear combination of two skew-hermitian derivations: \( D = \frac{1}{2}(D - D^\star) + \frac{i}{2}(D + D^\star) \). Then [7, Thm. 1] provides us with the following.

**Proposition 2.2.** Let \( G \) be a connected Lie group and \( A(G) \) satisfy all the conditions above. Then each if there exists any bounded point derivation on \( A(G) \), then there is necessarily a bounded skew-symmetric point derivation. Furthermore, each bounded skew-symmetric point derivation \( D \) on \( A(G) \) is a classical Lie derivation, i.e. of the form \( D(u) = \frac{d}{d\theta} \big|_{\theta=0} u(t_\theta) \) where \( \theta \mapsto t_\theta : \mathbb{R} \to G \) is a one-parameter subgroup.

Let recall how \( A_{\Delta}(G) \) witnesses the operator amenability of \( A(G) \). We let \( A(G) \) satisfy all of the assumptions we have so far.

**Proposition 2.3.** A completely contractive Banach algebra \( A(G) \) is operator amenable if and only if \( I_{A\Delta}(e) = \{ u \in A_{\Delta}(G) : u(e) = 0 \} \) admits a bounded approximate identity.

**Proof.** A splitting result of [25] (see [10]) shows that \( A(G) \) is operator amenable exactly when \( I_{A\hat{\otimes} A}(\Delta) = \{ w \in A(G) \otimes A(G) : w(s, s) = 0 \text{ for all } s \in G \} \) admits a bounded approximate identity. While this result is stated in the Banach space category, its proof moves easily to operator spaces. Then [21, Sec. 1.2 & Cor. 1.5] shows that the latter statement is equivalent to \( I_{A\Delta}(e) \) admitting a bounded approximate identity. There is also a beautifully “hands-on” proof of this in [31, Thm. 3.2], which can be easily modified to operator spaces and to this general setting. \( \square \)

2.1. **Operator weak amenability and operator amenability.** Motivated by the considerations above, we may immediately launch into the first major result of this section. As above we let \( A^p_{\Delta}(G, \omega) = \Gamma(A^p(G, \omega) \otimes A^p(G, \omega)) \).
Theorem 2.4. The space $A_p^*(G,\omega)$, qua quotient of $A^p(G,\omega)\hat{\otimes}A^p(G,\omega)$ via $\Gamma$, is given by

$$A_p^*(G,\omega) = A^{p'(p)}(G,d_{\beta(p)}\Omega)$$

where $\frac{1}{r(p)} + \frac{|p-2|}{2p} = 1$, $\beta(p) = \begin{cases} 4 - \frac{1}{p} & \text{if } 1 \leq p < 2 \\ 2 & \text{if } p \geq 2 \end{cases}$ and $\Omega(\pi) = \omega(\pi)\omega(\bar{\pi})$.

We call $\Omega$ the symmetrization of $\omega$.

Remark 2.5. We remark that the identification is not, in general, a complete isometry. Indeed the second identification in (2.2), below, is not generally a complete isometry. However if $p = 1$, then we obtain the $S^2_{d\omega}C$ in (2.2), from which we can deduce Proposition 1.12 above. We leave the details to the reader; or see [46 Thm. 2.1]

Proof. We first note that

$$\Gamma^*(\lambda(s)) = \int_G \lambda(st) \otimes \lambda(t) \, dt = (\lambda(s) \otimes I) \int_G \lambda(t) \otimes \lambda(t) \, dt$$

where the integral is a weak* integral in $(A^p(G)\hat{\otimes}A^p(G))^*$. Since $\text{Trig}(G)$ is dense in $A^p(G,\omega)$, and span $\lambda(G)$ is weak* dense in $A^p(G,\omega)$, we have for $T$ in $\text{Trig}(G)^1$ that

$$(2.1) \quad \Gamma^*(T) = (T \otimes I) \int_G \lambda(t) \otimes \lambda(t) \, dt.$$ 

Using the decomposition $\lambda = \bigoplus_{\pi \in \hat{G}} \pi$, the Schur orthogonality relations tell us that $\int_G \lambda(s) \otimes \lambda(s) \, ds \cong \bigoplus_{\pi,\pi' \in \hat{G} \times \hat{G}} \int_G \pi(s) \otimes \pi'(s) \, ds$, where each integral is zero unless $\pi' = \bar{\pi}$. Thus for $T = (T_{\pi})_{\pi \in \hat{G}}$ we obtain

$$\Gamma^*(T) = \bigoplus_{\pi \in \hat{G}} (T_{\pi} \otimes I) \int_G \pi(t) \otimes \bar{\pi}(t) \, dt.$$ 

Further, select for each $\pi$ a basis $\{e_{ij}^\pi, \ldots, e_{d\pi}^\pi\}$ for $\mathcal{H}_\pi$, and let $e_{ij}^\pi = e_i^\pi \otimes e_j^\pi$ in $S^p_{d\pi} \cong C^p_{d\pi} \hat{\otimes} R^p_{d\pi}$. For each $\pi$, we consider both $\pi$ and $\bar{\pi}$ as acting on one and the same Hilbert space, and we depict their matrices with the same basis. Then a more refined use of the Schur orthogonality relations shows that

$$\int_G \pi(t) \otimes \bar{\pi}(t) \, dt = \frac{1}{d\pi} \sum_{i,j=1}^{d\pi} e_{ij}^\pi \otimes e_{ij}^\pi.$$ 

We write each $T_{\pi} = \sum_{k,l=1}^{d\pi} T_{\pi,kl}e_{kl}^\pi$ to obtain

$$(T \otimes I) \int_G \pi(t) \otimes \bar{\pi}(t) \, dt = \frac{1}{d\pi} \sum_{i,j,k=1}^{d\pi} T_{\pi,kl} e_{kj}^\pi \otimes e_{ij}^\pi \cong \frac{1}{d\pi} \sum_{i,j,k=1}^{d\pi} T_{\pi,kl} e_{kj}^\pi \otimes e_{ij}^\pi \otimes e_i^\pi \otimes e_j^\pi.$$ 

Consider the sequence of maps applied to each of the elements above:
We first observe that we have isometric identifications
\[ (2.2) \quad C^p_d \otimes C^p_d \cong CB(C^p_d, C^p_d) = S^{2p+1}_{d'}, \]
where the first identification is standard, and the second is observed in [59] Lem. 5.9. We further note that \( \frac{2p+1}{4} = \frac{2p}{4} = \frac{2p}{4} \). Since \( (R^p_d)^* \cong C^p_d \), we likewise obtain \( R^p_d \otimes R^p_d \cong S^p_{d'} \), as well. Collecting together the results of the prior three observations we obtain
\[
\frac{1}{d_x} \left\| \sum_{i,j,k=1}^{d_x} T_{\pi,ki}e^\pi_{ij} \otimes e^\pi_{ij} \right\|_{S^p_{d}\otimes S^p_{d'}} = \frac{1}{d_x} \| T_{\pi} \otimes I \|_{S^{d_x}_{d'} \otimes S^{d_x}_{d'}}^{2p} = \frac{1}{d_x} \| T_{\pi} \|_{S^{d_x}_{d'}}^{2p} = \frac{d_x^{1-2p}}{2p^{1-2p}} \| T_{\pi} \|_{S^{d_x}_{d'}}^{2p} .
\]
We then observe, in analogy to [14], that
\[ (A^p(G, d^\pi) \otimes A^p(G, d^\pi))^* \cong T_{\pi,\pi'} \otimes S^p_{d'} \otimes S^p_{d_x} .\]
In summary, for \( T \in \text{Trig}(G) \) we find that
\[ \Gamma^*(T) \in (A^p(G, \omega) \otimes A^p(G, \omega))^* \iff \sup_{\pi \in \hat{G}} d_x^{\frac{1}{2p} + \frac{|p\pi|}{2p} - 1} \frac{2p}{\omega(\pi)\omega(\pi')} S^p_{d'} \otimes S^p_{d_x} .\]
Hence we obtain
\[ (2.3) \quad A^p_d(G, \omega)^* \cong T_{\pi,\pi'} \otimes S^p_{d'} \otimes S^p_{d_x} = \left\| T_{\pi,\pi'} \right\|_{S^{d_x}_{d'}}^{2p} = \frac{d_x^{1-2p}}{2p^{1-2p}} \| T_{\pi} \|_{S^{d_x}_{d'}}^{2p} = \frac{d_x^{1-2p}}{2p^{1-2p}} \| T_{\pi} \|_{S^{d_x}_{d'}}^{2p} .\]
where \( r(p) = \frac{2p}{4} \) and \( \beta(p) = 1 + 2 - \frac{2|\pi|}{p} \). The desired result follows by duality. \( \square \)
In particular, we obtain an isometric identification
\[ A^2(G) = A(G, d^2). \]
This stands in contrast to \([20]\) Thm. 2.6 where the isometric identification
\[ A^2_{\alpha, \Delta}(G) = A^2(G, d) \]
is obtained. Let us compare these two further. In the notation of Section 1.4 we let for \(1 \leq q \leq \infty\), \(A^2_{\alpha, \Delta}(G, \omega) = \Gamma(A^2_{\alpha, \Delta}(G, \omega) \otimes A^2_{\alpha, \Delta}(G, \omega)). \)

**Theorem 2.6.** The space \(A^2_{\alpha, \Delta}(G, \omega), \text{qua quotient of } A^2_{\alpha, \Delta}(G, \omega) \otimes A^2_{\alpha, \Delta}(G, \omega) \text{ via } \Gamma, \text{ is given by} \)
\[ A^2_{\alpha, \Delta}(G, \omega) = A^r(q)(G, d^r(q)\Omega) \]
where \(1 \leq q \leq \infty\), \(\gamma(q) = \begin{cases} \frac{2}{q} - \frac{1}{2} & \text{if } 1 \leq q < 2 \\ 1 + \frac{1}{q} & \text{if } q \geq 2 \end{cases} \) and \(\Omega(\pi) = \omega(\pi)\omega(\bar{\pi})\).

**Remark 2.7.** As before, we do not generally obtain a complete isometry. However, when \(q = \infty\) we will, in fact, get \(A^2_{\alpha, \Delta}(G, \omega) = A^h_{\alpha, \Delta}(G, d\Omega)\) completely isometrically, as we comment in the proof, below. In particular, we generalize and refine \([21, \text{Thm. 2.1}]\): we see that \(A^2_{\alpha, \Delta}(G, d^{2n-1}) = A^2_{\alpha, \Delta}(G, d^n), \text{ completely isometrically.} \)

**Proof.** We use the template of the proof of Theorem 2.4. First recall that we get isometric identifications
\[ S^2_{d, R^q} = R^q_d \otimes h R^q_d \quad \text{and} \quad R^q_d \otimes h R^q_d \equiv CB(R^q_d, R^q_d) = S^2_{\pi, \bar{\pi}} \]
which are both completely isometric if \(q = 1, \infty\) and we let \(S^2_d = S^2_{d, R^q}\). We may then compute, as in the last proof, that for \(T\) in \(\text{Trig}(G)\) and each \(\pi\) in \(\hat{G}\) we have
\[
\|\Gamma^\pi(T)\|_{S^2_{d, R^q} \otimes S^2_{d, R^q}} = \frac{1}{d_{\pi}} \left\| \sum_{i,j,k=1}^d T_{\pi, ki}e_{kj}^\pi e_{ij}^\pi \right\|_{S^2_{d, R^q} \otimes S^2_{d, R^q}} = \frac{1}{d_{\pi}} \left\| \sum_{i,j,k=1}^d T_{\pi, ki}e_{kj}^\pi e_{ij}^\pi \otimes \sum_{j=1}^d e_{ij}^\pi \otimes e_{ij}^\pi \right\|_{(R^q_d \otimes h R^q_d) \otimes (R^q_d \otimes h R^q_d)} = d_{\pi}^{\frac{|q-2|}{2}} \|T\|_{S^2_{d, R^q}}^{-1}.
\]
Hence we see for such \(T\) that
\[ \Gamma^\pi(T) \in (A^2_{\alpha, \Delta}(G, \omega) \otimes A^2_{\alpha, \Delta}(G, \omega))^* \quad \Leftrightarrow \quad \sup_{\pi\in\hat{G}} \frac{d_{\pi}^{1+\frac{|q-2|}{2}}}{\omega(\pi)\omega(\bar{\pi})} \|T\|_{S^2_{d, R^q}}^{-1} < \infty. \]
Hence we obtain
\[ A^2_{\alpha, \Delta}(G, \omega)^* \cong \ell^\infty \bigoplus_{\pi\in\hat{G}} \frac{d_{\pi}^{2+|q-2|/2}}{\omega(\pi)\omega(\bar{\pi})} S^2_{d, R^q} = \ell^\infty \bigoplus_{\pi\in\hat{G}} \frac{d_{\pi}^{-\gamma(p)\frac{1}{\Omega(\pi)}} S^2_{d, R^q}}{\omega(\pi)\omega(\bar{\pi})}, \]
where \(r(q) = \frac{2q}{|q-2|}\) and \(\gamma(q) = 2 - \frac{|q-2|}{q}\). If \(q = 1, \infty\), then \(r(q) = r(q) = 2\) and the description above is completely isometric provided we use structure \(R^q\) on each \(S^2_{d, R^q}\). \(\square\)
Observe that if \( \omega \) is a weakly dimension weight then it follows from Corollary 1.38 and [34] that \( A^p(G, \omega) \otimes A^p(G, \omega) \) has spectrum \( G \times G \), and is regular on its spectrum. Hence the analysis of the beginning of the section applies.

We can now apply our results to the \( 2 \times 2 \) special unitary group \( SU(2) \). Observe that in the case \( p = 1 \), we improve a result of [35, Thm. 4.2 (v)].

**Theorem 2.8.** For \( p \geq 1 \), the completely contractive Banach algebra \( A^p(SU(2), d^\alpha) \) admits a bounded point derivation if and only if \( \alpha \geq 1 \). The algebra \( A^p(SU(2), d^\alpha) \) is operator weakly amenable if and only if

\[
1 \leq p < \frac{4}{3 + 2\alpha}.
\]

In particular, if \( p = 1 \), \( A(SU(2), d^\alpha) \) is operator weakly amenable if and only if \( \alpha < \frac{1}{2} \).

**Proof.** Up to conjugation, the only one-parameter subgroups in \( G = SU(2) \) are \( \theta \mapsto t_\theta = \text{diag}(e^{i\theta}, e^{-i\theta}) \). By Proposition 2.1, \( D(u) = \frac{d}{d\theta} \big|_{\theta=0} u(t_\theta) \) is, up to conjugacy and scalar, the only candidate bounded skew-symmetric point derivation at \( e \) on either of \( A^p(G, d^\alpha) \) or on \( A^p_n(G) \) and hence its boundedness determines the only occasions in which such a derivation may exist.

We recall that \( SU(2) = \{ \pi_n : n = 0, 1, 2, \ldots \} \) and \( d_{\pi_n} = n + 1 \), and \( \pi_n(t_\theta) = \text{diag}(e^{i\theta}, e^{i(n-2)\theta}, \ldots, e^{-i(n-2)\theta}, e^{-i\theta}) \). Thus in the dual pairing (0.1) we have for \( u \) in Trig(SU(2)) that

\[
\langle u, D \rangle = \sum_{n=0}^{\infty} (n+1) \text{Tr}\left( \hat{u}(\pi_n) \frac{d}{d\theta} \big|_{\theta=0} \text{diag}(e^{i\theta}, e^{i(n-2)\theta}, \ldots, e^{-i(n-2)\theta}, e^{-i\theta}) \right)
\]

\[
= \sum_{n=0}^{\infty} (n+1) \text{Tr}\left( \hat{u}(\pi_n)[i\text{diag}(n, n-2, \ldots, -(n-2), -n)] \right)
\]

so \( D_{\pi_n} = i\text{diag}(n, n-2, \ldots, 2-n, -n) \). Hence for any \( s \geq 1 \) we find

\[
\|D_{\pi_n}\|_{S^s_{n+1}} = \left( \sum_{j=0}^{n} |n-2j|^s \right)^{1/s}.
\]

Elementary integral estimates yield constants \( c, C \) (depending only on \( r' \)) for which

\[
c(n+1)^{1+\frac{1}{r'}} \leq \left( \sum_{j=0}^{n} |n-2j|^s \right)^{1/s} \leq C(n+1)^{1+\frac{1}{r'}}.
\]

Thus setting \( s = p' \), we see from the weighted analogue of (1.3) that \( D \in A^p(G, d^\alpha)^* \) if and only if

\[
\sup_{n=0,1,2,\ldots} (n+1)^{-(\alpha+\frac{1}{r'}) + (1+\frac{1}{r'})} < \infty
\]

i.e. \(-\alpha + 1 \leq 0 \), so \( \alpha \geq 1 \). This characterizes when we get a bounded point derivation at \( e \). Since \( A^p(G, d^\alpha) \) is evidently isometrically translation invariant, we get a bounded point derivation at any point if and only if we get one at \( e \).

We now wish to determine operator weak amenability. Hence we need to establish those \( p \) which allow \( D \in (A^p_n(G))^* \). We use (2.3), with \( \Omega(\pi_n) = d^2_{\pi_n} = (n+1)^{2\alpha} \),
respectively, we obtain duality relations
This uses the idea of [35, Thm. 3.10]. Appealing to Theorem 2.4 and 2.6, Proof.
Given the weight
Remark 2.10.
Lemma 2.9. Theorem 2.11.

\[ \delta \] is finite. For an infinite group this means \( \lim_{\pi \to \infty} d_\pi = \infty \). According to [28, Thm. 3.2], a semisimple compact Lie group is tall. However, there exist tall totally disconnected groups [29].

Theorem 2.11. Suppose that \( G \) is infinite and tall. Then \( A^p(G) \) is not operator amenable for any \( p > 1 \), and \( A^2_{R^\infty,\Delta}(G) \) is not operator amenable for any \( 1 \leq q \leq \infty \). Proof. This uses the idea of [35, Thm. 3.10]. Appealing to Theorem 2.4 and 2.6 respectively, we obtain duality relations

\[
A^p_\Delta(G) \cong \left( \bigoplus_{\pi \in \hat{G}} d_\pi^{\frac{1}{\gamma(q)} - \frac{(p - 2)}{\gamma(q)} - \frac{1}{\gamma(q)}} \right)^* \]
for \( \pi \in \hat{G} \), where

\[ \gamma(q) = \frac{1}{2} \left( \frac{q}{p} \right) \left( \frac{q}{p} - 1 \right) \left( \frac{q}{p} - 2 \right) \]
We observe, moreover, that $\beta(p) > 0$ if $p > 1$, and $\gamma(q) \geq 1 > 0$ for $1 \leq q < \infty$. Hence, if $G$ is tall, each $\lambda(s) = (\pi(s))_{s \in G}$ is an element of this predual of $A^p_\Delta(G)$, respectively $A^2_{R^p,\Delta}(G)$.

Now suppose $A^p(G)$ is operator amenable. Then the bounded approximate identity for $I_{A^p_\Delta}(e)$ (respectively for $I_{A^2_{R^p,\Delta}}(e)$) promised by Proposition 2.10 admits the indicator function $1_G\setminus \{e\}$ as a weak*-cluster point, thanks to weak*-continuity of evaluation characters, and to the regularity of $A^p_\Delta(G)$ (respectively of $A^2_{R^p,\Delta}(G)$). This forces $G$ to be discrete, hence finite. 

It is hence obvious that for tall $G$ and any weight $\omega$ on $\hat{G}$, no algebra $A^p(G,\omega)$ is operator amenable for $p > 1$. We suspect that for $p > 1$, $A^p(G)$ is only operator amenable if and only if $G$ admits an open abelian subgroup. We will be able to transport Theorem 2.11 to connected non-abelian groups. See Section 3.1

For the case of $A^1_R(G) = A_\Delta(G)$, we have that this algebra is operator amenable exactly when $G$ is virtually abelian, and operator weakly amenable exactly when the connected component of the identity, $G_e$, is abelian. See [21 Thm. 4.1].

2.2. Weak amenability and amenability. We observe that it is easy to characterize amenability of $A^p(G, d^n)$.

**Proposition 2.12.** For any $1 \leq p \leq \infty$ and weakly dimension weight $\omega$, $A^p(G, \omega)$ is amenable if and only if $G$ admits an open abelian subgroup.

**Proof.** If $A^p(G, \omega)$ — which is dense within $A(G)$ — is amenable, then so too must be $A(G)$. Hence $G$ contains an open abelian subgroup by [18 Thm. 2.3] (or see [49]). The converse is immediate from Proposition 1.9 and the fact that $A(G)$ is amenable in this case (see [31]).

The weak amenability of the Banach algebras $A^p(G, d^n)$ is now straightforward to establish. It is interesting in its own right to observe that our algebras respect quotient subgroups.

Let $\omega_N = \omega|_{G/N \circ q}$, where $q : G \to G/N$ is the quotient map. Notice that $\omega_N$ retains all of our assumptions of being bounded away from zero and weakly dimension.

**Lemma 2.13.** Let $N$ be a closed normal subgroup of $G$. Then the map $u \mapsto T_N(u) = \int_N u(n) dn$ is a completely contractive projection for which we have $T_N(A^p(G, \omega)) \cong A^p(G/N, \omega_N)$ completely isometrically. Moreover, if $(N_i)$ is a decreasing net of subgroups converging to $e$ (i.e. any open neighborhood of the identity contains some $N_i$), then $u = \lim_i T_{N_i} u$ for each $u$ in $A^p(G, \omega_N)$.

**Proof.** The proof of the first statement may be adapted from that of [36] Prop. 4.14 (i), with obvious changes. In particular we see that

$$A^p(G/N, \omega_N) = T_N(A^p(G, \omega)) \cong \ell_1 - \bigoplus_{\pi \in G/N \circ q} d_\pi^{1 + \frac{1}{p}} \omega(\pi) S^p_{d_\pi}.$$  

The second statement is well-known, see for example the proof of [18 Thm. 3.3]. Briefly, given $u$ in $A^p(G, \omega)$, by continuity of translations we can arrange $N_i$ so small that $\|u - u(n)\|_{A^p(G, \omega)}$ is uniformly small for $n$ in $N_i$. Averaging over $N_i$ does not increase this norm. 

□
We shall make repeated use the observation that if a commutative Banach algebra has within itself a dense image of a weakly amenable commutative algebra, then it is weakly amenable; see [3, Def. 1.1 & Thm. 1.5]. The result (ii), below, improves upon [35, Thm. 3.14], where operator weak amenability is established.

**Proposition 2.14.** (i) For any $1 \leq p \leq \infty$ and weight $\omega$ weakly dominated by $d^\alpha$, the algebra $A^p(G, \omega)$ is weakly amenable if and only if $G_e$ is abelian.

(ii) For any $1 \leq p \leq \infty$ and weight $\omega$, if $G$ is totally disconnected, then $A^p(G, \omega)$ is weakly amenable.

**Proof.** (i) If $A^p(G, \omega)$ — which is dense within $A(G)$ — is weakly amenable, then so too must be $A(G)$. Hence $G_e$ is abelian by [20] Thm. 2.1. To see the converse we summarize the proof of [19] Thm. 3.3, with adaptations to our particular setting. Consider a decreasing net of subgroups $(N_i)$ converging to $e$ for which each $G/N_i$ is a Lie group with open abelian connected component of the identity. By Proposition 1.4 we obtain that each $A^p(G/N_i, \omega_{N_i}) = A(G/N_i)$ isomorphically and, as observed above, is amenable. As in Lemma 2.13 $A^p(G, \omega)$ is an inductive limit of the algebras $T_N(A^p(G, \omega)) \cong A^p(G/N, \omega_{N_i})$. Any derivation $D : A^p(G, \omega) \to A(G, \omega)^*$ must vanish on each $T_N(A^p(G, \omega))$, whence $D = 0$.

(ii) For totally disconnected $G$ we can choose $N_i$ open, so $G/N_i$ is finite. □

### 3. Restriction to subgroups

We do not get a general usable restriction theorem, unless the subgroup is a finite group. We will turn our focus to the example of a torus on SU(2), where $p$ to characterize operator amenability of $A^p$. Essentially factor in a direct product. This latter fact gives us enough technology to summarize the proof of [18, Thm. 3.3], with adaptations to our particular setting.

Let us first consider the general situation. We fix a closed subgroup $H$ of $G$ and let $R_H : A(G) \to A(H)$ denote the restriction map. Let us consider this map on $\text{Trig}(G)$. In this context, its adjoint is given by

$$R_H^\dagger(T_\sigma)_{\sigma \in \hat{H}} = \left( \sum_{\sigma \subset \pi|_H} m(\sigma, \pi) \sum_{k=1}^{m(\sigma, \pi)} V_{\pi, \sigma}^{(k)} T_\sigma V_{\pi, \sigma, k}^{(k)*} \right)_{\pi \in \hat{G}}$$

where each $V_{\pi, \sigma} : \mathcal{H}_\sigma \to \mathcal{H}_\pi$ is an isometry, and $m(\sigma, \pi)$ is the multiplicity of $\sigma$ in $\pi|_H$. Indeed, this is straightforward to see if $T = \lambda(s) = (\sigma(s))_{\sigma \in \hat{H}}$, for $s$ in $H$, and follows from the weak density of span $\lambda(G)$ in $\text{Trig}(G)^\dagger$, otherwise. By picking a suitable basis for each $\mathcal{H}_\pi$, we may suppress explicit mention of the isometries $V_{\pi, \sigma}^{(k)}$ and write

$$R_H^\dagger(T_\sigma)_{\sigma \in \hat{H}} = \left( (T_\sigma^{m(\sigma, \pi)})_{\sigma \subset \pi|_H} \right)_{\pi \in \hat{G}}.$$

For a weight $\omega$ we let

$$A^p_{G, \omega}(H) = R_H(A^p(G, \omega))$$

be endowed with the quotient operator space structure which makes $R_H : A^p(G, \omega) \to A^p_{G, \omega}(H)$ a complete quotient map.
Proposition 3.1. The operator space structures on $\mathcal{A}^p_{G,\omega}(H)^*$ is determined by the completely isometric embedding

$$T \mapsto ((T_\sigma)_{\sigma \in \pi|H})_{\pi \in \hat{G}} : \mathcal{A}^p_{G,\omega}(H)^* \to \ell^\infty - \bigoplus_{\pi \in \hat{G}} \frac{d_{\pi}^{-1/\nu'}}{\omega(\pi)} \left( \mathcal{S}_{\nu'}^m(\sigma, \pi) \right).$$

Proof. The embedding result on $\mathcal{A}^p_{G,\omega}(H)^*$ is immediate from (3.1) and the weighted analogue of (1.3).

We have not come up with an illuminating closed-form formula for the norm on $\mathcal{A}^p_{G,\omega}(H)$, for general $p$. For $p = 1$ we obtain

$$\mathcal{A}^p_{G,\omega}(H) = \mathcal{A}(H, \omega|H)$$

completely isometrically, where $\omega|H$ is the restricted weight defined in (1.10). See [35] Prop. 3.5 or [36] Prop. 4.12. We shall see that even with trivial weights, this does not hold generally for $p$-Fourier algebras.

Let us begin by observing the case of restriction to a central subgroup.

Proposition 3.2. Let $Z$ be a closed central subgroup of $G$. Then $\mathcal{A}^p_{G,\omega}(Z) = \mathcal{A}(Z, \omega|Z)$, completely isometrically.

Proof. It is a consequence of Schur’s lemma that for $\pi$ in $\hat{G}$, there is a character $\chi$ in $\hat{Z}$ for which $\pi|Z = \chi(\cdot)I_Z$. In fact $\chi = \frac{1}{d_{\pi}}\text{Tr} \circ \pi|Z$. Furthermore, since $R_Z(\text{Tr}(G)) = \text{Tr}(Z)$, each character on $Z$ is attained thusly. Hence Proposition 3.1 yields completely isometric embedding

$$t \mapsto \left( t \frac{1}{d_{\pi}}\text{Tr} \circ \pi|Z \right)_{\pi \in \hat{G}} : \mathcal{A}^p_{G}(Z) \to \ell^\infty - \bigoplus_{\pi \in \hat{G}} \frac{d_{\pi}^{-1/\nu'}}{\omega(\pi)} \left( d_{\pi}^{1/\nu'} \mathcal{S}_{\nu'}^m \right) \cong \ell^\infty(\hat{G}, 1/\omega).$$

Following through to the range of this map gives us the isometric identification $\mathcal{A}^p_{G,\omega}(Z)^* \cong \ell^\infty(\hat{Z}, (\omega|Z)^{-1})$. \qed

3.1. Direct products. The situation of direct product groups is very nice, in this setting. The only weighted version we shall use in the sequel is with dimension weights which are easier to work with as they enjoy a certain multiplicativity with Kronecker products. In a direct product group $H \times K$, we may identify $H = H \times \{e\}$ and $K = \{e\} \times K$.

Theorem 3.3. Let $G = (H \times K)/Z$ where $Z$ is a central subgroup of $H \times K$ which satisfies $H \cap Z = \{e\} = Z \cap K$. Then $\mathcal{A}^p_{G}(H) = \mathcal{A}^p(H)$, completely isometrically. Furthermore, we have that $\mathcal{A}^p_{G}(H, d^\nu) = \mathcal{A}^p(H, d^\nu)$, completely isometrically if $Z$ is trivial, or $K$ is abelian, and completely isomorphically if $Z$ is finite.

Proof. We first recall that $\hat{H} \times \hat{K} = \hat{H} \times \hat{K}$ via Kronecker products. Then $\hat{G} = \{ \sigma \times \tau : \sigma \in \hat{H}, \tau \in \hat{K} \}$ and $Z \subseteq \ker(\sigma \times \tau)$. Let $\sigma \times \tau \in \hat{G}$. Let $p_J : H \times K \to J$ be the projection map, for $J = H, K$, and note that each $p_J(Z)$ is central in $J$. Hence an application of Schur’s lemma tells us that there are characters $\chi, \chi'$ on $Z$ for which $\sigma \circ p_H|Z = \chi(\cdot)I_{d_{\sigma}}$ and $\tau \circ p_K|Z = \chi'(\cdot)I_{d_{\tau}}$, while

$$I_{d_{\sigma}} \otimes I_{d_{\tau}} = \sigma \times \tau|Z = \sigma \circ p_H|Z \otimes \tau \circ p_K|Z = \chi(\cdot)I_{d_{\sigma}} \otimes I_{d_{\tau}}$$

which means that $\chi' = \bar{\chi}$.
Thus we see for any \( \sigma \) in \( \hat{H} \), that there is \( \tau \) in \( \hat{K} \) for which \( \sigma \times \tau \in \hat{G} \) only if
\[
(3.2) \quad \frac{1}{d_\sigma} \operatorname{Tr} \circ \bar{\sigma} \circ p_H|_Z = \frac{1}{d_\tau} \operatorname{Tr} \circ \tau \circ p_K|_Z.
\]
Furthermore, \( \ker(p_H|_Z) = Z \cap K = \{ e \} = H \cap Z = \ker(p_K|_Z) \), so \( p_H(Z) \cong Z \cong p_K(Z) \). Hence since \( R_{\rho(J)}(\operatorname{Trig}(J)) = \operatorname{Trig}(p_J(Z)) \cong \operatorname{Trig}(Z) \) for \( J = H, K \), we have for any \( \sigma \) in \( \hat{H} \), that there exists \( \tau \) in \( \hat{K} \) for which (3.2) holds. Thus if we let \( \hat{K}_{Z,\sigma} = \{ \tau \in \hat{K} : (3.2) \) holds \} then we have shown that
\[
\hat{G} = \{ \sigma \times \tau : \sigma \in \hat{H} \text{ and } \tau \in \hat{K}_{Z,\sigma} \}.
\]
It is easily checked that the condition above is symmetric in \( H \) and \( K \).

Proposition 3.1 now yields completely isometric embedding
\[
T \mapsto (T_{\sigma,\tau}^{d_\sigma})_{\sigma \times \tau \in \hat{G}} : A_{G,d_\sigma}^p(H)^* \to \ell^{\infty -} \bigoplus_{\sigma \times \tau \in \hat{G}} (d_\sigma d_\tau)^{-\frac{1}{p'}} d_\tau^{-\frac{1}{p'}} S_{d_\sigma}^{p'}.
\]
(3.3)
In the event that \( \sup_{\tau \in \hat{K}_{Z,\sigma}} d_\tau^{-\alpha} = 1 \) (which happens if \( \alpha = 0 \), or if \( Z \) is trivial, or if \( K \) is abelian), we see that the range of the map (3.3) lands in a completely isometric copy of \( \ell^{\infty -} \bigoplus_{\sigma \in \hat{H}} d_\sigma^{-\frac{1}{p'}} S_{d_\sigma}^{p'} \cong A^p(H,d^\alpha)^* \).

Otherwise, letting \( \chi_\sigma = \frac{1}{d_\sigma} \operatorname{Tr} \circ \bar{\sigma} \circ p_H|_Z \), which is in \( \hat{Z} \), a simple examination of the definition of \( \hat{K}_{Z,\sigma} \), shows that
\[
\sup_{\tau \in \hat{K}_{Z,\sigma}} d_\tau^{-\alpha} = \left( \inf \{ d_\tau^\alpha : \tau \in \hat{K} \text{ and } \chi_\sigma \subset \tau \} \right)^{-1} = \frac{1}{d_K^{\operatorname{sup}}(p_K(Z)(\chi_\sigma)}
\]
where we have a slight abuse of notation: since \( p_K(Z) \cong Z \), it would be more logical to write \( \chi_\sigma \circ p_K^{-1}(Z)(\chi_\sigma) \), instead of \( \chi_\sigma \), above. The range of the map (3.3) then lands in a completely isometric copy of
\[
\ell^{\infty -} \bigoplus_{\sigma \in \hat{H}} d_\sigma^{-\frac{1}{p'}} d_K^{\operatorname{sup}}(p_K(Z)(\chi_\sigma))^{-1} S_{d_\sigma}^{p'}.
\]
Observe that \( \omega^\alpha(\sigma) = d_K^{\operatorname{sup}}(p_K(Z)(\chi_\sigma)) \) defines a weight on \( \hat{H} \) and the space above is completely isometrically isomorphic to \( A^p(H,d^\alpha \omega^\alpha)^* \). In the event that \( Z \) is finite, and hence so too is \( \hat{Z} \), there are only finitely many values of \( \omega^\alpha(\sigma) = d_K^{\operatorname{sup}}(p_K(Z)(\chi_\sigma) \), and \( A^p(H,d^\alpha \omega^\alpha) \) is completely isomorphic to \( A^p(H,d^\alpha) \).

**Example 3.4.** Let us consider an example where \( A_{G,d_\sigma}^p(H) = A^p(H,d^\alpha) \) completely isomorphically, but not isometrically. We have that \( U(2) = (\mathbb{T} \times SU(2))/Z \) where \( Z = \{ \pm(1,1) \} \). Then \( \hat{Z} = \{ 1, \text{sgn} \} \). Observe that in the notation above \( \omega^\alpha(\text{sgn}) = d_{SU(2)}^{\operatorname{sup}}(\text{sgn}) = 2^\alpha \), since the standard representation \( \pi_\tau \) is the lowest dimension representation of \( SU(2) \) which “sees” \( \text{sgn} \). Further, letting for \( k \) in \( \mathbb{Z} \), \( \sigma_k(z) = z^k \) on \( \mathbb{T} \), we see, again in the notation above, that
\[
\chi_\sigma_k = \begin{cases} 1 & \text{if } 2 \mid k \\ \text{sgn} & \text{if } 2 \nmid k \end{cases}
\]
and hence \( \omega^\alpha(\sigma_k) = \begin{cases} 1 & \text{if } 2 \mid k \\ 2^\alpha & \text{if } 2 \nmid k \end{cases} \).
Thus $A^p_{\Gamma(T)}(d^\alpha) = A^p(T, d^\alpha \omega^\alpha) = A(T)$, completely isomorphically, though not isometrically.

**Remark 3.5.** Proposition 3.4 admits an obvious analogue when we replace $A^p(G)$ by $A^2_{R}(G, d^\alpha)$; we get a completely isometric embedding

$$A^2_{R}(G, d^\alpha) \hookrightarrow \ell^\infty - \bigoplus_{\pi \in \hat{G}} d^{-\frac{1}{2}-\alpha} \left( \ell^2 - \bigoplus_{\sigma \subseteq \pi | H} m(\sigma, \pi)^{1/2} S_{d, \pi}^2 \right).$$

Thus, as in Theorem 3.3 in any of the situations that $\alpha = 0$, $Z$ is trivial, or $K$ is abelian, we obtain that

$$A^2_{R}(G, d^\alpha)(H) = R_H(A^2_{R}(G, d^\alpha)) = A^2_{R}(H, d^\alpha).$$

With our restriction formula in hand, we can now characterize operator amenability of our algebras for connected Lie groups and of infinite products of finite groups. Let us first obtain a brief quantitative result on finite groups. Any finite-dimensional amenable algebra admits a cluster point of a bounded approximate diagonal, which we simple call a *diagonal*. It is well-known that if the algebra is commutative, then the diagonal is unique; see, for example, [22, Prop. 1.1].

**Proposition 3.6.** If $G$ is finite, then the unique diagonal $w$ for $A^p(G) = A^2_{R(G)}$ has

$$\|w\|_{A^p(G) \hat{\otimes} A^p(G)} = \frac{1}{|G|} \sum_{\pi \in \hat{G}} d^{2+\beta(p)} \quad \text{and} \quad \|w\|_{A^2_{R(G)} \hat{\otimes} A^2_{R(G)}} = \frac{1}{|G|} \sum_{\pi \in \hat{G}} d^{2+\gamma(q)}.$$

**Proof.** Let $A$ be either of $A^p$ or $A^2_{R(G)}$. Let $N : A\Delta(G) \rightarrow A(G) \hat{\otimes} A(G)$ be given by $N[u(s, t) = u(st^{-1})$, which is an isometry by [23] (1.2)]. We let $1_e$ denote the indicator function of $\{e\}$. Then $N1_e$ is the the unique diagonal for $A(G) \otimes A(G)$ and has norm $\|1_e\|_{A\Delta(G)}$. We have that $\hat{1}_e(\pi) = \frac{1}{|G|} I_{d, \pi}$ for each $\pi$, and we note that $\|I_{d, \pi}\|^q_{A\Delta(G)} = d^{1+\gamma(p)}$. Hence we use Theorems 2.4 and 2.6 to finish. \(\square\)

**Theorem 3.7.** (i) Let $G$ be connected and $p > 1$. Then either of $A^p(G)$ or $A^2_{R(G)}$ ($1 \leq q \leq \infty$) is operator amenable if and only if $G$ is abelian.

(ii) If $G$ is connected and non-abelian, then $A^p(G, d^\alpha)$ is not operator weakly amenable for any $p \geq \frac{4}{1+2n}$, and no $A^2_{R(G)}$ is operator weakly amenable.

(iii) Let $(G_n)_{n=1}^\infty$ be a sequence of finite groups, $G = \prod_{n=1}^\infty G_n$ and $p > 1$. Then either of $A^p(G)$ or $A^2_{R(G)}$ is operator amenable if and only if all but finitely $G_n$ are abelian.

**Proof.** (i) If $G$ is abelian, then $A^p(G) = A^2(G)$ is amenable by Proposition 2.12. If $G$ is not abelian then there exists a non-empty collection of simple, connected, compact, Lie groups $\{S_i\}_{i \in I}$, a connected abelian group $T$, and a closed central subgroup $D$ of $T \times S$ where $S = \prod_{i \in I} S_i$, for which $G \cong (T \times S)/D$. This is the Levi-Mal’cev Theorem; see, for example, [27, Thm. 9.24]. The third isomorphism theorem tells us that $G = (T/T \cap D \times S/D \cap S)/(D/(T \cap D \times S \cap D\cap S))$. Thus if we let $H = T/T \cap D$, $K = S/D \cap S$, and $Z = D/(T \cap D \times S \cap D\cap S)$, then $G = (H \times K)/Z$ where $H = \{e\} = Z \cap K$. Furthermore, $K \cong \prod_{i \in I} S_i/Z_i$ where each $Z_i$ is a
central subgroup of $S_i$. Fix $i_0$ in $I$. Then, $K_{i_0} = S_{i_0}/Z_{i_0}$ is a simple Lie group. Also, $A^p(K_{i_0})$ is a complete quotient of $A^p(G)$ by Theorem 3.3, while $A^2_{R_0}(K_{i_0})$ is one of $A^2_{R_0}(G)$, by Remark 3.5. However, neither of $A^p(K_{i_0})$ nor $A^2_{R_0}(K_{i_0})$ is operator amenable by Theorem 2.11 and the fact that $K_{i_0}$ is tall ([28, Thm. 3.2]).

(ii) If $p \geq \frac{4}{3+2\alpha}$, then the complete quotient algebra $A^p(K_{i_0})$, from the proof of (i), above, is not operator weakly amenable, thanks to Theorem 2.9. Likewise for $A^2_{R_0}(K_{i_0})$.

(iii) If all but finitely may $G_n$ are abelian, then $A^p(G)$ is amenable by Proposition 2.12. If $A^p(G)$ is operator amenable, then $A^p(G) \odot A^p(G)$ admits a bounded approximate diagonal $(w_i)$. Let $H_n = \prod_{k=1}^n G_k$. Then by Theorem 3.3 each $(R_{H_n} \otimes R_{H_n}, w_i)$ is a bounded approximate diagonal for $A^p(H_n)$, and hence has limit point the unique diagonal $w_n$ for $A^p(H_n)$. Hence we appeal to Proposition 3.6 to see that

$$\sup_i \|w_i\|_{A^p(G) \odot A^p(G)} \geq \sup_i \|R_{H_n} \otimes R_{H_n}, w_i\|_{A^p(H_n) \odot A^p(H_n)} \geq \frac{1}{|H_n|} \sum_{\pi \in H_n} d_\pi^{2+\beta(p)} = \frac{1}{|G_1 \times \cdots \times G_n|} \sum_{\sigma_1 \times \cdots \times \sigma_n \in G_1 \times \cdots \times G_n} (d_{\sigma_1} \cdots d_{\sigma_n})^{2+\beta(p)} = \prod_{k=1}^n \frac{1}{|G_k|} \sum_{\sigma_k \in G_k} d_{\sigma_k}^{2+\beta(p)}.$$

We note that $\beta(p) > 0$ proved $p > 1$. Since each $|G_k| = \sum_{\sigma_k \in G_k} d_{\sigma_k}^2$, the sequence above diverges as $n \to \infty$, unless the groups $G_n$ are ultimately abelian.

Obvious modifications show the same for $A^2_{R_0}(G)$. Again we note that $\gamma(q) \geq 1 > 0$, for all $1 \geq q \geq \infty$. □

If we could learn the structure of $A^p_{G_i}(G_e)$, say, where $G_e$ is the connected component of the identity, then we may be able to assess conditions of operator amenability more generally. Also, the situation for general totally disconnected groups is unknown to us.

3.2. The torus in SU(2). We now analyze the example of the (unique up to conjugacy) torus $T$ in SU(2). We will not bother with general weights, but will consider dimension weights. We recall again that $SU(2) = \{\pi_n : n = 0, 1, 2, \ldots\}$ with $d_{\pi_n} = n + 1$, and the character theory reveals

$$\pi_n|_T = \text{diag}(\chi_n, \chi_{n-2}, \ldots, \chi_{2-n}, \chi_{-n})$$

where $\chi_n(z) = z^n$. Proposition 3.4 immediately yields the following.

**Proposition 3.8.** The operator space structure on $A^p_{SU(2), d}(|\mathbb{T}|^*) \subset \mathbb{C}^\mathbb{N}$ is given by the completely isometric embedding

$$t \mapsto ((t_{n-2j})_j=0)_{n=0}^\infty : A^p_{SU(2), d}(|\mathbb{T}|^*) \to \ell^\infty \bigoplus_{n=0}^\infty (n+1)^{-\frac{1}{p}-\alpha} p'_{n+1} = \mathcal{M}^\alpha p'$$
Proof.
We simply observe that for an analogue of Theorem 2.4. In preparation we require the following, surely well-

\[ \left| \sum_{j=0}^{n} |t_{n-2j}|^{p'} \right|^{1/p'} \left( n + 1 \right)^{\frac{\alpha}{p} + \frac{1}{p'}}. \]

Remark 3.9. Notice that when \( \alpha = 0 \), \( A_{SU(2)}^{p}(\mathbb{T})^* \) admits the description

\[ \left\{ t \in \mathbb{C}^2 : \sup_{n=0,1,2,...} \left( \frac{1}{n + 1} \sum_{j=0}^{n} |t_{n-2j}|^{p'} \right)^{1/p'} < \infty \right\}. \]

Thus the space is defined in terms of Cesaro summing norm. We suspect such spaces must exist elsewhere in the literature.

Corollary 3.10. The Beurling algebra \( A(T, w^{1/p'+\alpha}) \), where \( w^{1/p'+\alpha}(n) = (1 + |n|)^{\frac{\alpha}{p'} + \alpha} \), embeds completely contractively into \( A_{SU(2),d^\alpha}^{p}(\mathbb{T}) \).

Proof. We simply observe that for \( t \in A_{SU(2),d^\alpha}^{p}(\mathbb{T})^* \), and each \( n \in \mathbb{Z} \), we have

\[ \|t\|_{A(T, w^{1/p'+\alpha})^*} = \sup_{n \in \mathbb{Z}} \frac{|t_n|}{(1 + |n|)^{\frac{\alpha}{p} + \frac{1}{p'}}} \leq \|t\|_{A_{SU(2),d^\alpha}^{p}(\mathbb{T})^*}. \]

From which it follows that the adjoint of the map \( A(T, w^{1/p'+\alpha}) \rightarrow A_{SU(2),d^\alpha}^{p}(\mathbb{T}) \), whence the map itself, is contractive. Moreover, \( A(T, w^{1/p'+\alpha}) \cong \ell^1(\mathbb{Z}, w^{1/p'+\alpha}) \) is a maximal operator space.

Remark 3.11. Techniques of the proof of the corollary show that \( A_{SU(2),d^\alpha}^{p}(\mathbb{T}) = A(T, w^\alpha) \), completely isomorphically. Hence it follows from \([12]\) that for \( p \geq 1 \), \( A_{SU(2),d^\alpha}^{p}(\mathbb{T}) \) embeds completely contractively into \( A(T, w^\alpha) \). In particular, with completely contractive inclusions we have that

\[ A(T, w^{1/p'+\alpha}) \subseteq A_{SU(2),d^\alpha}^{p}(\mathbb{T}) \subseteq A(T, w^\alpha). \]

We wish to study the operator weak amenability of \( A_{SU(2),d^\alpha}^{p}(\mathbb{T}) \). We first require an analogue of Theorem [2,4] In preparation we require the following, surely well-known, estimate.

Lemma 3.12. Let \( T : \mathbb{C}^n \rightarrow \mathbb{C}^m \) be linear. Then

\[ \|T\|_{CB(\ell^n_p, \ell^m_q)} \leq \begin{cases} (nm)^{\frac{1}{p'q' - 1}} \|T\|_{B(\ell^n_p, \ell^m_q)} & \text{if } p \geq 2 \\ \|T\|_{B(\ell^n_p, \ell^m_q)} & \text{if } 1 \leq p < 2 \end{cases} \]

Proof. We recall the well-known equalities, \( \|\text{id}\|_{CB(\ell^n_\infty, \ell^m_{\infty})} = \|\text{id}\|_{CB(\ell^n_p, \ell^m_p)} = n^{1/2} \).

Since \( \ell^n_p = [C_n, R_n]_{1/2} \), we obtain that \( \|\text{id}\|_{CB(\ell^n_\infty, \ell^n_p)} \leq n^{1/2} \). (Of course, equality holds.) Now if \( p \geq 2 \) we have \( \ell^n_p = [\ell^n_\infty, \ell^n_{2/p}] \), so

\[ \|\text{id}\|_{CB(\ell^n_p, \ell^n_{2/p})} \leq n^{\frac{1}{2(p - 1)}} \|\text{id}\|_{CB(\ell^n_{2/p}, \ell^n_{2/p})} \leq n^{\frac{1}{2(p - 1)}} = n^{\frac{1}{2(p - 1)}}. \]

By duality \( \|\text{id}\|_{CB(\ell^n_{2/p}, \ell^n_{2/p})} \leq m^{\frac{1}{2(p - 1)}} - \frac{1}{2(p - 1)} \). Finally we have

\[ \|T\|_{CB(\ell^n_p, \ell^m_q)} \leq \|\text{id}\|_{CB(\ell^n_p, \ell^m_q)} \|T\|_{CB(\ell^n_p, \ell^n_p)} \|\text{id}\|_{CB(\ell^n_p, \ell^n_p)} \leq (nm)^{\frac{1}{p'q' - 1}} \|T\|_{B(\ell^n_p, \ell^m_q)} \]

where the last inequality is facilitated by the homogeneity of the operator Hilbert space structure.
If $p < 2$, then since $\|\text{id}\|_{CB(\ell^1_n, \ell^\infty)} = 1$ by virtue of $\ell^1_n$ being a maximal space, we apply the reasoning above to $\ell^p_n = [\ell^1_n, \ell^\infty]_{2/p'}$, to see that $\|\text{id}\|_{CB(\ell^p_n, \ell^\infty)} \leq 1$, likewise $\|\text{id}\|_{CB(\ell^\infty_n, \ell^p_n)} \leq 1$, and we finish accordingly.

We let $\Gamma$ be as in [1,12] with $G = T$ and then let

$$A^p_{SU(2), d^*, \Delta}(T) = \Gamma \left( A^p_{SU(2), d^*}(T) \hat{\otimes} A^p_{SU(2), d^*}(T) \right).$$

**Proposition 3.13.** For $t \in \mathbb{C}^Z$, we have

$$\|t\|_{A^p_{SU(2), d^*, \Delta}(T)^*} \leq \begin{cases} \sup_{n=0,1,2,...} (n+1)^{-1-2\alpha} \max_{k=0,...,n} |t_{-n+2k}| & \text{if } p \geq 2 \\ \sup_{n=0,1,2,...} (n+1)^{-2\alpha} \max_{k=0,...,n} |t_{-n+2k}| & \text{if } 1 \leq p < 2. \end{cases}$$

**Proof.** We let $M_{\alpha, p'}$ be as in Proposition 3.8. Since $A^p_{SU(2), d^*, \Delta}(T)$ is a complete quotient of the predual $M_{\alpha, p'}$ which respects the dual pairing (6.1), and since

$$M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'} \cong \ell^1_{\infty} \bigoplus_{m,n=0}^{\infty} \left| (m+1)(n+1) \right|^{1/p'} \ell^p \otimes \ell^p \cong M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'}$$

we see that the space

$$(M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'})^* \cong \ell^\infty_{\infty} \bigoplus_{m,n=0}^{\infty} \left| (m+1)(n+1) \right|^{-1/p'-\alpha} \ell^p \otimes \ell^p \cong M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'}$$

will contain $\Gamma(A^p_{SU(2), d^*, \Delta}(T)^*)$ completely isometrically. In particular, $t = (t_k)_{k \in \mathbb{Z}}$ in $\mathbb{C}^Z$, we have $\|t\|_{A^p_{SU(2), d^*, \Delta}(T)^*} = \|\Gamma^*(t)\|_{M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'}} < \infty.$

Since $\lambda(s) = (s^k)_{k \in \mathbb{Z}}$, for $s$ in $T$, (2.1) gives us for $t$ in $A^p_{SU(2), d^*, \Delta}(T)^*$ that

$$\Gamma^*(t) = (t_k E_k \otimes E_{-k})_{k \in \mathbb{Z}} \subset \mathbb{C}^{\mathbb{Z} \times \mathbb{Z}}$$

where $(E_k)_{k \in \mathbb{Z}}$ is the standard “basis” in $\mathbb{C}^Z$. The isometric embedding of Proposition 3.8 gives $E_k \mapsto \left( \sum_{j=0}^{n} \delta_{k,n-2j} e_j \right)_{n=0}^{\infty}$, where $(e_0, \ldots, e_n)$ is the standard basis for $\ell^p_{n+1}$. Hence we find for $t$ in $A^p_{SU(2), d^*, \Delta}(T)^*$ that

$$\Gamma^*(t) \mapsto \begin{pmatrix} t_k \left( \sum_{j=0}^{m} \delta_{k,n-2j} e_j \right) \otimes \left( \sum_{i=0}^{n} \delta_{-k,m-2i} e_i \right) \end{pmatrix}^{n,m=0} \in M_{\alpha, p'} \hat{\otimes} M_{\alpha, p'}$$

where

$$\varepsilon_{n \pm k} = \begin{cases} \frac{e^{i\pi n}}{n} & \text{if } 2 | n \pm k \text{ and } n \geq |k| \\ 0 & \text{otherwise}. \end{cases}$$

We know appeal to the fact that $\ell^p_{n+1} \hat{\otimes} \ell^p_{n+1} \cong CB(\ell^p_{m+1}, \ell^p_{m+1})$ and then to Lemma 3.12 to see that the quantity $\|t\|_{A^p_{SU(2), d^*, \Delta}(T)^*}$ is dominated in the case $p \geq 2$ by

$$\sup_{m,n=0,1,2,...} \left| (m+1)(n+1) \right|^{-1/p'-\alpha} \max_{k=0, \ldots, \min\{m,n\}} |t_{-\min\{m,n\}+2k}|$$
Proposition 3.16. These from one another.

Proof. Let \( \alpha \) and \( n \) be chosen as above. If \( 2 \mid m+n \), then the antidiagonal operator \( \sum_{k \in \mathbb{Z}} t_k \varepsilon_{m-k} \otimes \varepsilon_{n+k} \) is chosen as above. If \( 2 \nmid m+n \), then we are interested in testing the norm of \( \Gamma^* \) in

\[
\left\| (m+1)(n+1) \right\|^{\frac{1}{2}} \alpha \max_{k=0,\ldots,\min\{m,n\}} \left| t_{\min\{m,n\}+2k} \right|.
\]

In either case the supremum is approximated by choices of \( m = n \), giving the desired result. \( \square \)

Our efforts in this section culminate in the following.

Theorem 3.14. The algebra \( A^p_{SU(2),d^\alpha}(T) \) is operator weakly amenable if and only if \( 1 \leq p < \frac{2}{1+2\alpha} \). Furthermore, it is weakly amenable for such \( p \) and \( \alpha \).

Proof. Thanks to Propositions 2.11 and 2.22 we need only to check when \( D(f) = \frac{df}{d\theta} \) defines a bounded element of \( A^p_{SU(2),d^\alpha}(T)^* \). The functional \( D \) corresponds to the sequence \( d = (k)_{k \in \mathbb{Z}} \) in \( \mathcal{C}_n^\alpha \cong \text{Trig}(T) \). If \( p \geq 2 \), it is immediate from Proposition 3.13 that \( \|d\|_{A^p_{SU(2),d^\alpha}(T)^*} < \infty \). If \( p < 2 \), then

\[
\|d\|_{A^p_{SU(2),d^\alpha}(T)^*} < \infty \text{ if } (n+1)^{\frac{1}{p} - 2\alpha} \leq (n+1)^{\frac{1}{p} - 1 - 2\alpha} \text{ is uniformly bounded in } n \geq 0, \text{ i.e. if } \frac{2}{p} - 1 - 2\alpha < 0, \text{ which means that } p < \frac{2}{1+2\alpha}
\]

In these cases \( A_{SU(2)}^p(d^\alpha,T) \) is not operator weakly amenable, hence not weakly amenable.

Thanks to [3], the algebra \( A(T, u^{1/p'}) \cong \ell^1(\mathbb{Z}, u^{1/p'+\alpha}) \) is weakly amenable when \( \frac{1}{p'} + \alpha < \frac{1}{2} \), i.e. when \( p < \frac{2}{1+\alpha} \). Hence it follows from Corollary 3.10 that \( A_{SU(2)}^p(d^\alpha,T) \) weakly amenable in this case, thus also operator weakly amenable. \( \square \)

Let us observe the following trivial consequence of Proposition 3.8, which uses the proof of Theorem 2.3.

Corollary 3.15. The algebra \( A_{SU(2)}^p(T) \) admits a bounded point derivation if and only if \( \alpha \geq 1 \).

Thus far, we have observed only situations in which \( A^p_{SU}(G) \) exhibits the same amenability behaviour for all \( 1 \leq q \leq \infty \). However, the next result will distinguish these from one another.

Proposition 3.16. For \( t \in \mathbb{C}^\alpha \), we have

\[
\|t\|_{A^2_{SU(2),d^\alpha}(T)^*} = \sup_{n=0,1,2,\ldots} (n+1)^{-1-2\alpha} \left( \sum_{k=0}^n |t_{-n+2k}|^{r(q)'} \right)^{1/r(q)'}
\]

Proof. Let \( \mathcal{M}^{\alpha,2}_{q'} = \mathcal{C}_n^\alpha \bigoplus_{n=0}^\infty (n+1)^{-\frac{1}{p'}-\alpha} \mathcal{R}^p_{n+1} \), which completely isometrically hosts \( A^2_{R,SU(2),d^\alpha}(T)^* \), by an obvious modification of Proposition 3.8. Then, as in the proof of Proposition 3.13, we are interested in testing the norm of \( \Gamma^*(t) \) in

\[
\mathcal{C}_n^\alpha \bigoplus_{m,n=0}^{\infty} (m+1)(n+1)^{-\frac{1}{p'}-\alpha} \mathcal{R}^p_{m+1} \otimes \mathcal{R}^p_{n+1} \cong \mathcal{M}^{\alpha,2}_{q'} \otimes \mathcal{M}^{\alpha,2}_{q'}
\]

Appealing to the row version of 2.22 we see that \( \mathcal{R}^p_{m+1} \otimes \mathcal{R}^p_{n+1} \cong S^*_{m+1,n+1} \) where \( r' \) is chosen as above. If \( 2 \mid m+n \), then the anti-diagonal operator \( \sum_{k \in \mathbb{Z}} t_k \varepsilon_{m-k} \otimes \varepsilon_{n+k} \),
with notation as in the proof of Proposition\ref{thm:00} admits norm
\[ \left( \min_{m,n} \sum_{k=0}^{(m,n)} |t_{m,n} + 2k|^{r(q')} \right)^{1/r(q')} \].

The supremum over all \(m\) and \(n\) is approximated by values where \(m = n\).

\begin{thm}
The algebra \(A_{\mathbb{R},SU(2),d_0}(T)\) is operator weakly amenable if and only if \(1 \leq \min\{q, q'\} < \frac{2}{4\alpha + 1}\).
\end{thm}

\begin{rem}
Notice that the Banach algebra \(A_{\mathbb{SU}(2),d_0}(T)\) is never weakly amenable for any \(\alpha \geq 0\). Indeed, this would imply that \(A_{\mathbb{R},SU(2)}(T)\) is operator weakly amenable, violating Theorem\ref{thm:14} Alternatively, by Remark\ref{thm:11} this would imply that \(\mathcal{A}(T, u_{1/2})\) is weakly amenable, violating a result of\[24\].
\end{rem}

\begin{proof}
In Proposition\ref{thm:10} we gained an exact computation. Hence if we examine the derivation \(D\) from the proof of Theorem\ref{thm:14} and its associated sequence \(d = (k)_{k \in \mathbb{Z}}\), we find
\[ \|d\|_{A_{\mathbb{R},SU(2),d_0}(T)^*} = \sup_{n=0,1,2,...} \left( n + 1 \right)^{-1-2\alpha} \left( \sum_{k=0}^{n} \frac{n^2 - 2k}{r(q')} \right)^{1/r(q')} . \]

The estimate \ref{thm:24} shows that \(\left( \sum_{k=0}^{n} \frac{n^2 - 2k}{r(q')} \right)^{1/r(q')} \) grows as \((n+1)^{1+1/r(q')}. Hence \(\|d\|_{A_{\mathbb{R},SU(2),d_0}(T)^*} < \infty\) if and only if \(\frac{1}{r(q')} - 2\alpha \leq 0\). Since \(r(q) = r(q')\), let us suppose that \(1 \leq q \leq 2\). Then we have \(\frac{1}{r(q)} = \frac{2-q}{2q} \leq 2\alpha\) if and only if \(\frac{2q}{2-q} \geq \frac{2}{4\alpha+1}\). This gives the desired result.
\end{proof}

We close this section by addressing operator amenability. We recall, in passing, that \(A_{\mathbb{SU}(2)}(T) = \mathcal{A}(T)\) is (operator) amenable.

\begin{thm}
If \(p > 1\), then \(A_{\mathbb{SU}(2)}(T)\) is not operator amenable. The algebra \(A_{\mathbb{R},SU(2)}(T)\) is never operator amenable for \(1 \leq q \leq \infty\).
\end{thm}

\begin{proof}
Let us begin with \(A_{\mathbb{SU}(2)}(T)\). In the notation above, we let \(M^0 = M^{0,p}\) and consider the predual \(L^p = M^*_p\) which respects the dual pairing \ref{thm:01}. Let \(D = \Gamma^*(A_{\mathbb{SU}(2)}(T)^*) \subset M^p \hat{\otimes} M^{p'}\). We combine the observations \ref{thm:23}, the fact that \(\ell^p_{m+1} \hat{\otimes} \ell^p_{n+1} \cong CB(\ell^p_{m+1}, \ell^p_{n+1})\) and Lemma\ref{thm:12} to see that in the \(m, n\)th component of \(M^p \hat{\otimes} M^{p'}\), each \(\Gamma^*(\lambda(s))\) \((s \in T)\) has norm bounded by
\[ [(m+1)(n+1)]^{-\frac{1}{p} + \left( \frac{1}{p'} - \frac{1}{2} \right)} = [(m+1)(n+1)]^{-1/2} \]
for \(p > 2\) and by \([m+1](n+1)]^{-\frac{1}{p'}} \) for \(1 < p < 2\). In other words \(\Gamma^*(\lambda(s)) \in D_0 = D \cap C_0\) where
\[ C_0 = C_0^{- \infty} \sum_{m,n=0}^{\infty} [(m+1)(n+1)]^{-1/p'} \ell^p_{m+1} \hat{\otimes} \ell^p_{n+1} . \]

Observe that \(C_0^* = \ell^p \hat{\otimes} \ell^p\).

Let \(K = D^\perp\), the pre-annihilator of \(D\) in \(\ell^p \hat{\otimes} \ell^p\). Since \(\Gamma^*(\lambda(G))\) is a weak* spanning set for \(D\), we have that \(K = \bigcap_{s \in T} \ker \Gamma^*(\lambda(s))\). But then \(K = D^\perp\) where
$D_0$ is the closed subspace generated by $\Gamma^*(\lambda(G))$ in $\mathcal{L}_0$. Collecting all of these facts together, we see that $A^p_{SU(2),\Delta}(\mathbb{T}) \cong \mathcal{L}^p \bar{\otimes} \mathcal{L}^p / \mathcal{K}$ is the dual of $D_0$.

Now by Proposition 2.3, if $A^p_{SU(2)}(\mathbb{T})$ were operator amenable, then $I_{A^p_{SU(2),\Delta}}(1)$ would admit a bounded approximate identity. However, since each evaluation functional $\Gamma^*(\lambda(s))$ is weak*-continuous, this bounded would admit the indicator function of $T \setminus \{1\}$ as a weak*-cluster point, which is absurd.

Now we consider $A^2_{Rn, SU(2)}(\mathbb{T})$. Let $\mathcal{M}^2_q = \ell^\infty \oplus_{n=0}^{\infty} (n+1)^{-1/2} R^2_{n+1}$ and $\mathcal{L}^2_q = (\mathcal{M}^2_q)^{\prime}$. The preual which respects the dual pairing (0.1) In $\mathcal{M}^2_q \bar{\otimes} \mathcal{M}^2_q$, the $(m,n)$-th component of $\Gamma^*(\lambda(s))$ ($s \in \mathbb{T}$) is an anti-diagonal matrix, thanks to (3.4), with entries bounded in modulus by 1. Hence it has norm bounded by

$$[(m+1)(n+1)]^{-1/2}[\min\{m,n\} + 1]^{1/r(q')} \leq [(m+1)(n+1)]^{-1/2} + \frac{1}{2r(q')}$$

since we can identify that component with a weighted version of $S^r_{m+1,n+1}$, by virtue of (2.2). However, we always have that $\frac{1}{2r(q')} = \frac{|q-2|}{4q} \leq \frac{1}{4} < \frac{1}{2}$.

Just as above, the subspace $K = \bigcap_{s \in \mathbb{T}} \ker \Gamma^*(\lambda(s)) \subset \mathcal{L}^2_q \bar{\otimes} \mathcal{L}^2_q$ serves to allow $A^2_{Rn, SU(2)}(\mathbb{T})$ to be viewed as the dual of a space containing each $\Gamma^*(\lambda(s))$. We conclude, as above.

4. Arens Regularity and Representability as an Operator Algebra

We say that a (commutative) Banach algebra $A$ is Arens regular if for any $\Phi$, $\Psi$ in $A^*$, and any bounded nets $(u_i)$, $(v_j)$ from $A$ for which $\Phi = \lim_i u_i$ and $\Psi = \lim_j v_j$, we have that both of the weak* iterated limits $\lim_i \lim_j u_i v_j$ and $\lim_j \lim_i u_i v_j$ exist in $A^*$ and coincide. Arens regularity passes to closed subalgebras and isomorphic quotients of $A$. Arens regularity is a sufficient condition to see that $A$ is isomorphic to a closed subalgebra of bounded operators on a reflexive Banach space (see [61]). It is a consequence of the main result of [11] that if $A$ is isomorphic to a closed subalgebra of bounded operators on a superreflexive Banach space, then $A$ is Arens regular.

We say $A$ is representable as an operator algebra, if it is isomorphic to a closed subalgebra of operators on a Hilbert space. This property implies Arens regularity. The main result of [4] tells us that $A$ is representable as an operator algebra provided that it admits an operator space structure with respect to which the multiplication on $A \otimes A$ extends to a completely bounded map on the Haagerup tensor product $A \otimes^h A$. If $A$ is already equipped with an operator space structure, we will say it is completely representable as an operator algebra provided there is a complete isomorphism between $A$ and an operator algebra; equivalently, if multiplication factors through $A \otimes^h A$.

Let us remark that for the weights $w^\alpha(n) = (1 + |n|)^\alpha$ on $\mathbb{Z} \cong \mathbb{T}$, we have that $A(\mathbb{T}, w^\alpha)$ is Arens regular exactly when $\alpha > 0$ thanks to [11, 61], and is representable as a Q-algebra (a certain type of operator algebra) exactly when $\alpha > 1/2$, thanks to [56]. As a maximal operator space, $A(\mathbb{T}, w^\alpha)$ is completely representable an operator algebra exactly when $\alpha > 1/2$, thanks to [23]. A study of Arens regularity of algebras $A(G, \omega)$ is conducted in [35], and of when $A(G, \omega)$ is completely representable an operator algebra is conducted in [23].
4.1. Arens regularity. Let us begin by showing that for an infinite G, the algebras $A^p(G)$ are never Arens regular. We require a supporting result which is of independent interest and was observed in [21 Cor. 2.3] in the case $p = 2$.

**Proposition 4.1.** Let $ZA^p(G) = \{ u \in A^p(G) : u(\tau s^{-1}) = u(s) \text{ for all } s, t \in G \}$. Then $ZA^p(G) = ZA(G)$ completely isometrically for each $p \geq 1$.

**Proof.** We note that for each $u$ in $ZA^p(G)$, we have $\hat{u}(\pi) = \frac{1}{d_\pi} \left( \int_G u(s) \overline{\chi_\pi(s)} \, ds \right) I_{d_\pi}$. Moreover, for each scalar matrix, $\| \alpha I_d \|_{sp} = d^{1/p} |\alpha|$. Hence each space $ZA^p(G)$ is completely isometrically isomorphic to $\ell^1(G)$.

**Theorem 4.2.** The algebra $A^p(G)$ is Arens regular only if $G$ is finite.

**Proof.** If $A^p(G)$ is Arens regular, then so too must be the subalgebra $ZA(G)$ and also its ideal $I_{ZA}(e) = \{ u \in ZA(G) : u(e) = 0 \}$. It is a well-known consequence of the Schur property for $ZA(G) \cong \ell^1(G)$ that it is weakly sequentially complete, hence so too is the $\alpha$-dimension one space $I_{ZA}(e)$. By [17 Prop. 3.7] or [19 Thm. 1.5], $I_{ZA}(e)$ admits a bounded approximate identity $(u_\alpha)$. Let $P : \Lambda(G) \to ZA(G)$ be given by $P u(s) = \int_G u(t \tau^{-1}) \, dt$, which is a surjective contraction with expectation property $P(\sigma v) = P(\sigma) P(v)$ for $u \in \Lambda(G)$ and $v \in ZA(G)$. Then $(P u_\alpha)$ is a bounded approximate identity for $I_{ZA}(e)$, as is straightforward to check. Being weakly sequentially complete and admitting a bounded approximate identity, [55 Cor. 2.4] tells us that $I_{ZA}(e)$ is a reflexive Banach space. Hence $(P u_\alpha)$ admits a weak cluster point, which, by regularity of $ZA(G)$ on its spectrum (the space of conjugacy classes of $G$ see remarks in [1], for example), is necessarily the indicator function of $G \setminus \{ e \}$. This implies that $G$ is discrete, hence finite.

Let us note a condition which implies Arens regularity.

**Theorem 4.3.** Suppose the weight $\omega$ on $\hat{G}$ satisfies

$$\lim_{\pi \to \infty} \limsup_{\pi' \to \infty} \frac{\max_{\sigma \in \pi \otimes \pi'} \omega(\sigma)}{\omega(\pi) \omega(\pi')} = 0 \quad \text{and} \quad \lim_{\pi \to \infty} \limsup_{\pi' \to \infty} \frac{\max_{\sigma \in \pi \otimes \pi'} \omega(\sigma)}{\omega(\pi) \omega(\pi')} = 0.$$ 

Then $A^p(G, \omega)$ is Arens regular for any $p \geq 1$.

**Proof.** This is an easy modification of the proof of [55 Thm. 3.16]. Indeed it is easy to verify that

$$A^p(G, \omega)^{**} \cong A^p(G, \omega) \bigoplus \left( c_0 \bigoplus_{\pi \in \hat{G}} \overline{d^{-1/p'}} \left( S_{d^\alpha}^\pi \right) \right)^\perp.$$ 

All other aspects of the proof are similarly straightforward to modify.

A function $\tau : \hat{G} \to \mathbb{R}^{\geq 0}$ is called subadditive if $\tau(\sigma) \leq \tau(\pi) + \tau(\pi')$ whenever $\sigma \subseteq \pi \otimes \pi'$. Let for $\alpha > 0$, $\omega_\tau^\alpha(\pi) = (1 + \tau(\pi))^\alpha$. It is easy to verify $\omega_\tau^\alpha$ is a weight.

**Corollary 4.4.** Let $\tau : \hat{G} \to \mathbb{R}^{\geq 0}$ be subadditive and satisfy $\lim_{\pi \to \infty} \tau(\pi) = \infty$. Then $A^p(G, \omega_\tau^\alpha)$ is Arens regular for any $p \geq 1$ and $\alpha > 0$.

**Proof.** Note that of $\sigma \subseteq \pi \otimes \pi'$ then

$$\omega_\tau^\alpha(\sigma) \leq (1 + \tau(\pi) + \tau(\pi'))^\alpha \leq (1 + 2\tau(\pi))^\alpha + (1 + 2\tau(\pi'))^\alpha \leq 2^\alpha [\omega_\tau^\alpha(\pi) + \omega_\tau^\alpha(\pi')]$$.
Hence
\[
\frac{\max_{\sigma \subseteq \pi \otimes \pi'} \omega_{\pi}^\sigma(\sigma)}{\omega_{\pi}(\pi) \omega_{\pi'}(\pi')} \leq \frac{2^\alpha}{\omega_{\pi}(\pi)} + \frac{2^\alpha}{\omega_{\pi'}(\pi')}
\]

Our assumption on \( \tau \) assures that either iterated limit of Theorem 4.3 is zero. \( \square \)

**Example 4.5.** (i) Let \( \tau : \hat{G} \to \mathbb{R}^{\geq 0} \) be given by \( \tau(\pi) = \log d_\pi \), which is subadditive. The weight \( \omega^\alpha_{\pi} \), given here, is thus the weight \( \omega_{\pi_{\infty}} \) of Example 1.7. If \( G \) is tall, then \( \lim_{\tau \to \infty} \tau(\pi) = \infty \).

(ii) For an infinite Lie group \( G \), consider the polynomial weights \( \omega^\alpha_{\pi}(\pi) = (1 + \tau_S(\pi))^\alpha \), introduced in Section 1.2. Since each \( S^\otimes n \) is finite, \( \lim_{\tau \to \infty} \tau_S(\pi) = \infty \).

For the special unitary groups, a special feature of the dual allows us to deal with dimension weights.

**Corollary 4.6.** The algebra \( A^p(SU(n), d^\alpha) \) is Arens regular for any \( \alpha > 0 \).

**Proof.** We parameterize \( \hat{SU}(n) \) by dominant weights: each \( \pi = \pi_\lambda \) where \( \lambda = (\lambda_1, \ldots, \lambda_n) \) with \( \lambda_1 \geq \cdots \geq \lambda_n \geq 0 \) in \( \mathbb{Z} \). Then \([8, \text{Cor. 1.2}], \) in whose notation \( \lambda_n = \mu_n = 0 \), shows that
\[
\frac{d^\alpha_{\lambda_n}}{d^\alpha_{\lambda_n} d^\alpha_{\mu_n}} \leq C^\alpha \left( \frac{1}{\lambda_1 + 1} + \frac{1}{\mu_1 + 1} \right)^\alpha \leq (2C)^\alpha \left( \frac{1}{(\lambda_1 + 1)^\alpha} + \frac{1}{(\mu_1 + 1)^\alpha} \right)
\]
for \( \pi_\lambda \subset \pi_\lambda \otimes \pi_\mu \), where the constant \( C \) depends only on \( n \). Either iterated limit of Theorem 4.3 is zero. (We remark that the choice of generators corresponding to dominant weights \( \{(1,0,\ldots,0),(1,1,0,\ldots,0),\ldots,(1,\ldots,1,0)\} \) is such that \( \tau_S(\pi_\lambda) = \lambda_1 \) for \( \lambda \neq (0,\ldots,0) \). See [23, (3.8)]. Hence the present result may also be viewed as following from Corollary 4.4.) \( \square \)

We say a connected group \( G \) is *semisimple* if the commutator subgroup \([G,G]\) equals \( G \). For non-semisimple connected groups, we never have Arens regularity with dimension weights. This generalizes [23, Thm. 4.8].

**Theorem 4.7.** Let \( G \) be a non-semisimple connected group. Then \( A^p(G, d^\alpha) \) is never Arens regular.

**Proof.** Thanks to [27, 9.19 & 9.24], \( G = (T \times S)/D \) where \( T \) is a non-trivial connected abelian group, and \( S = \prod_{i \in I} S_i \) is a product of simple connected Lie groups, and \( D \) is totally disconnected. Then \( N = DS/D \) is a closed normal subgroup of \( G \) and the third isomorphism theorem tells us that \( G/N = ((T \times S)/D)(DS/D) \cong (T \times S)/SD \cong T/T \cap D \). Since \( T \cap D \) is totally disconnected, we see that \( G/N \) is an infinite abelian group. Thus by Lemma 4.8, \( A^p(G/N) = A^p(G/N, d^\alpha) \) is isomorphic to a closed subalgebra of \( A^p(G, d^\alpha) \). Proposition 1.9 shows that \( A^p(G/N) = A(G/N) \cong \ell^1(G/N) \), which is never Arens regular by [60].

Let us observe that we have an interesting alternate proof if \( G \) is Lie. Indeed, in the Levi-Mal’cev decomposition, \( G = (T \times S)/D \) above, we may assume again that \( T \) is a non-trivial abelian connected Lie group, \( S \) is a semisimple Lie group, and \( D = T \cap S \), so \( T \cap D = \{e\} = D \cap S \) and \( D \) is finite. See [27, Thm. 6.15]. But then Theorem 3.3 shows that \( A^p(T, d^\alpha) = A(T) \) is an isomorphic quotient of \( A^p(G, d^\alpha) \). As above, this quotient algebra cannot be Arens regular. \( \square \)
4.2. **Representability as an operator algebra.** Let us look at some situations in which $A^p(G, \omega)$ is representable, in fact completely representable, as an operator algebra. We will focus mainly on the polynomial weights $\omega^\alpha_G$, defined in Section 1.2. We do not know if our estimates are sharp in the ranges of $p$ and $\alpha$.

We will first develop an analogue of the Littlewood multipliers of \cite{23}. We let $(d_\sigma)_{\sigma \in \Sigma}$ be an indexed collection of positive integers. We then define

$$
\mathcal{D}^p = \ell^\infty - \bigoplus_{\sigma \in \Sigma} d_\sigma^{-\frac{1}{p}} S_{d_\sigma}^p, \quad \mathcal{H}^p = \ell^2 - \bigoplus_{\sigma \in \Sigma} d_\sigma^{-\frac{1}{p}} S_{d_\sigma}^2 \quad \text{and} \quad \mathcal{A}^p = \ell_1 - \bigoplus_{\sigma \in \Sigma} d_\sigma^{1 + \frac{1}{p}} S_{d_\sigma}^p.
$$

We observe that $\mathcal{A}^* = \mathcal{D}$ with respect to the dual pairing

$$
\langle (A_\sigma)_{\sigma \in \Sigma}, (D_\sigma)_{\sigma \in \Sigma} \rangle = \sum_{\sigma \in \Sigma} d_\sigma \text{Tr}(A_\sigma D_\sigma).
$$

Furthermore, with respect to this dual pairing we have linear dual

$$
\mathcal{H}^{p*} = \ell^2 - \bigoplus_{\sigma \in \Sigma} d_\sigma^{1 + \frac{1}{p}} S_{d_\sigma}^2.
$$

This being an $\ell^2$-direct sum, we have norm $\|X\|_{\mathcal{H}^{p*}} = \left( \sum_{\sigma \in \Sigma} d_\sigma^{1 + \frac{1}{p}} \|X_\sigma\|^2_{S_{d_\sigma}^2} \right)^{1/2}$.

Of course, each of $\mathcal{H}^p$ and $\mathcal{H}^{p*}$ are also Hilbert spaces with the map $U(H_\sigma)_{\sigma \in \Sigma} = (d_\sigma^{-1} H_\sigma)_{\sigma \in \Sigma}$ serving as a unitary between them. Since $U : \mathcal{H}^p \rightarrow \mathcal{H}^{p*}$ is a complete isometry, we still obtain operator duality $(\mathcal{H}_C)^* \cong \mathcal{H}^{p*}_R$, and the same with row and column structures interchanged.

The spaces $\mathcal{D}^p$ and $\mathcal{A}^p$ will have their usual operator spaces structures. However, we write $\mathcal{D}^2_A$, $\mathcal{A}^2_A$, when the component spaces $S_{d_\sigma}^2$ have column structure; likewise for rows. For any $A = (A_\sigma)_{\sigma \in \Sigma}$ and $B = (B_\sigma)_{\sigma \in \Sigma}$ in $\prod_{\sigma \in \Sigma} M_n$, we let $AB = (A_\sigma B_\sigma)_{\sigma \in \Sigma}$.

**Proposition 4.8.** (i) The formal identities $\mathcal{H}^p_C \hookrightarrow \mathcal{D}^p$ and $\mathcal{H}^{p*}_R \hookrightarrow \mathcal{D}^p$ are normal complete contractions.

(ii) Given $X$ in $\mathcal{H}^{p*}$, the maps $D \mapsto DX$ and $D \mapsto XD$ from $\mathcal{D}^p$ into $\mathcal{H}^p_C$, or equivalently into $\mathcal{H}^{p*}_R$, are normal and completely bounded.

(iii) Given $X$ in $\mathcal{H}^{p*}$, the maps $D \mapsto DX$ and $D \mapsto XD$ from $\mathcal{D}^2_A$ or from $\mathcal{D}^2_R$ into either of $\mathcal{H}^p_C$, or $\mathcal{H}^{p*}_R$, are normal and completely bounded.

**Proof.** (i) It suffices the show that $\mathcal{A}^p \hookrightarrow \mathcal{H}^{p*}_C$ completely contractively, and then the desired inclusion is the adjoint map. The roles of rows and columns may be interchanged naturally in all of our manipulations. We first recall that the identity $d^{1/2} C_d \mapsto R_d$ is a complete contraction. Thus by interpolation we find that $d^{1/2} C_d^p \mapsto C_d$ is a complete contraction. Hence we get a complete contraction

$$
d^{1/2} S_{d_\sigma}^p = d^{1/2} C_d^p \otimes R_d^p = d^{1/2} C_d^p \otimes \sigma d^{1/2} C_d^p \mapsto C_d \otimes \sigma C_d = S_{d_\sigma}^2.
$$

Thus we obtain a complete contraction from each summand $d^{1/2} S_{d_\sigma}^p$ of $\mathcal{A}^p$ into the summand $d^{1/2 + 1/p} S_{d_\sigma}^p S_{d_\sigma}^2$ of $\mathcal{H}^{p*}$. By the universal property of direct sums, we are done.

(ii) Given $X$ in $\mathcal{H}^{p*}$, the map $D \mapsto DX : \mathcal{D}^p \rightarrow \mathcal{H}^p_C$, will be the adjoint of the map $H \mapsto XH : \mathcal{H}^{p*}_R \rightarrow \mathcal{A}^p$, once we establish that the latter is well-defined. To see that this latter map is well-defined, even completely bounded, is sufficient that $X \otimes H \mapsto XH$ extends to a completely bounded map from $\mathcal{H}^{p*}_C \otimes \mathcal{H}^{p*}_R$ to
$A^p$. Let us first observe two facts. First, matrix multiplication $S^2_{d,C} \otimes S^2_{d,R} \to S^1_d$ is completely contractive. Indeed, this is akin to applying trace to the middle factor of $C_d \otimes S^1_d \otimes C_d = C_d \otimes C_d \otimes R_d$. Second, we see by interpolation that $d^{1/p} C_p \hookrightarrow C_p$ is a complete contraction. Hence, similarly as in (i), above, we see that $d^{1/p} S^1_d \hookrightarrow S^p_d$ is completely contractive. Now let us proceed to our multiplication computation. Multiplication may be realized as factoring through the following complete contractions:

$$H^p_C \otimes H^p_R = S^1(H^{p*}) \to \ell^1 - \bigoplus_{\sigma \in \Sigma} S^1(d^{1 + \frac{1}{p}} S^2_{d,\sigma}) = \ell^1 - \bigoplus_{\sigma \in \Sigma} d^{1 + \frac{1}{p}} S^2_{d,\sigma,C} \otimes S^2_{d,\sigma,R}$$

$$\to \ell^1 - \bigoplus_{\sigma \in \Sigma} d^{1 + \frac{1}{p}} S^1_{d,\sigma} \to \ell^1 - \bigoplus_{\sigma \in \Sigma} d^{1 + \frac{1}{p}} S^p_{d,\sigma} = A^p$$

where the map in the first line is block-diagonal compression, and the two maps in the second line are discussed above.

The commutativity of the projective tensor product, and general symmetry of row versus column operations allows us to switch the order of the computations above rather liberally.

(ii') With considerations so far, it is straightforward to see, for example, that $d^{1/2} S^1_d \hookrightarrow S^2_{d,C}$ is completely contractive. We require this fact exactly at the last step of the multiplication computation, above.

Our special Littlewood type multipliers are the content of the next theorem. The extended (or weak*) Haagerup tensor product $\otimes^{eh}$ is defined in [6, 13]. It is desirable for us specifically because of the completely isometric duality formula $(V \otimes^h W)^* \cong V^* \otimes^{eh} W^*$ for any operator spaces $V$ and $W$.

**Theorem 4.9.** Fix $T$ in $H^{p*}$. Then each of the maps given by $A \otimes B \mapsto TA \otimes B$ $A \otimes TB \mapsto A \otimes TB$ extends uniquely to normal linear maps from $D^p \otimes D^p$ to $D^p \otimes^{eh} D^p$. In the case $p = 2$, each of these maps extends uniquely to normal linear maps from $D^2 \otimes D^2$ to $D^2 \otimes^{eh} D^2$, where $E = C$ or $R$.

**Proof.** Let us first observe that $H^p_C \otimes D^p = H^p_C \otimes^{eh} D^p$, completely isometrically. Indeed, each space is the dual of $H^p_R \otimes A^p = H^p_R \otimes^h A^p$. Then Proposition 4.8 (ii) shows that $A \otimes B \mapsto TA \otimes B$ extends uniquely to a normal map from $D^p \otimes D^p$ into $H^p_C \otimes D^p = H^p_C \otimes^{eh} D^p$. Then Proposition 4.8 (i) shows that the formal identity on elementary tensors, extends uniquely to a normal complete contraction $H^p_C \otimes^{eh} D^p \longrightarrow D^p \otimes^{eh} D^p$. The composition of these maps yields the desired result. The right handed case case works similarly.

The proof in the case $p = 2$ is identical. Here we use (ii') in place of (ii), from the prior proposition; and the complete contractivity of the map $A^p_E \hookrightarrow H^p_E$, $E = R$ or $C$, is obvious. At this particular step, however, we may use only rows or columns.

Thus, for elements $T$ of $H^{p*}$, we may think of $T \otimes I$ and $I \otimes T$ in $\prod_{\sigma,\sigma' \in \Sigma \times \Sigma} M_{d, \sigma} \otimes M_{d, \sigma'}$ as elements which multiply $D^p \otimes D^p$ into $D^p \otimes^{eh} D^p$.

With our new Littlewood type multipliers in hand, we are almost in position to determine some occasions for which $A^p(G, \omega)$ is an operator algebra. We will work only with connected Lie groups and polynomial weights, as defined at the end of the previous section.
As in [57, 5.6.5], a connected Lie group $G$ admits a system of fundamental weights $\Lambda_1, \ldots, \Lambda_n(G)$ which are proportional to the simple roots of $G$, and $\lambda_1, \ldots, \lambda_n(G)$ which are related to the characters of the connected component of the centre of $G$. Each $\pi$ in $\widehat{G}$ corresponds to some $\Lambda_\pi = \sum_{j=1}^{n} m_j \Lambda_j + \sum_{i=1}^{n} n_i \lambda_i$ where each $m_j$ is a non-negative integer and each $n_i$ is an integer. In this notation we let

$$\|\pi\|_{p} = \left( \sum_{j=1}^{n} m_j^p + \sum_{i=1}^{n} n_i^p \right)^{1/p}.$$ 

Clearly $\|\pi\|_\infty \leq \|\pi\|_2 \leq \|\pi\|_1 \leq (s(G) + \pi(G)) \|\pi\|_\infty$. The following estimate is a refinement of [57, 5.6.7]. For $r > 2$, it will allow us better estimates by using more refined data about $G$

**Lemma 4.10.** We have for $G$ as above and any positive real number $r$, that

$$\sum_{\pi \in \widehat{G}} \frac{d_{\pi}}{(1 + \|\pi\|_1)^{2\alpha}} \text{ converges if } \alpha > \frac{r}{4} d(G) - \frac{r - 2}{4} (s(G) + \pi(G))\text{ where } d(G) \text{ is the dimension of } G.$$ 

**Proof.** We simply adapt the proof of [57, 5.6.7]. There, it is first established that for some constant $C$ we have $d_{\pi} \leq C \|\pi\|_2^{1/2} (d(G) - (s(G) + \pi(G)))$, where of course we can replace $\|\cdot\|_2$ with $\|\cdot\|_1$ at the cost of a new constant.

Now we let $\widehat{G}_j = \{ \pi \in \widehat{G} : \|\pi\|_\infty = j \}$, for which the cardinality is estimated by

$$|\widehat{G}_j| \leq (s(G) + \pi(G))(2j + 1)^{s(G) + \pi(G) - 1} \leq K(j + 1)^{s(G) + \pi(G) - 1}$$

for some constant $K$. Moreover, for $\pi$ in $\widehat{G}_j$ we use the estimate of the prior paragraph to see that

$$\frac{d_{\pi}}{(1 + \|\pi\|_1)^{2\alpha}} \leq \frac{C}{(1 + j)^{2\alpha - \frac{r}{4} d(G) - \frac{r - 2}{4} (s(G) + \pi(G))}}.$$ 

Thus we see that

$$\sum_{\pi \in \widehat{G}} \frac{d_{\pi}}{(1 + \|\pi\|_1)^{2\alpha}} = \sum_{j=0}^{\infty} \sum_{\pi \in \widehat{G}_j} \frac{d_{\pi}}{(1 + \|\pi\|_1)^{2\alpha}} \leq \sum_{j=0}^{\infty} K(j + 1)^{s(G) + \pi(G) - 1} \frac{C}{(1 + j)^{2\alpha - \frac{r}{4} d(G) - \frac{r - 2}{4} (s(G) + \pi(G))}}$$

which converges provided $2\alpha > \frac{r}{2}(d(G) - \frac{r - 2}{2} (s(G) + \pi(G)))$. \hfill $\square$

Let us recall how to relate the quantity $\|\cdot\|_1$ to our polynomial weight, introduced in Section 1.2. As observed in [36, p. 483 & Thm. 5.4], there are constants $c, C$ for which

$$c \tau_S(\pi) \leq \|\pi\|_1 \leq C \tau_S(\pi).$$

The following generalizes [23, Thm. 4.5], which deals only with the case $p = 1$.

**Theorem 4.11.** Let $G$ be a connected Lie group with polynomial weight $\omega^G_p$. If

$$\alpha > \left( \frac{1}{2} + \frac{1}{2p} \right) d(G) - \frac{1}{2p} (s(G) + \pi(G))$$

then $\Lambda^p(G, \omega^G_p)$ is completely representable as an operator algebra.
Proof. We will summarize those details of the proof of [23, Thm. 4.5] which need checking. We recall that with the coproduct $M$, and $W = (\omega(\pi)I_{d_{\pi}})_{\pi \in \tilde{G}}$, we have that $T = M(W)(W^{-1} \otimes W^{-1})$ in $A^p(G)^* \widehat{\otimes} A^p(G)^*$ satisfies

$$T_{\pi, \pi'} = \left( \frac{1 + \tau_S(\sigma)}{(1 + \tau_S(\pi))(1 + \tau_S(\pi'))} \right)^\alpha I_{d_{\pi}}$$

in the sense of the notation (1.5). Further, just as in the proof of Corollary 4.13, we gain an estimate

$$\left( \frac{1 + \tau_S(\sigma)}{(1 + \tau_S(\pi))(1 + \tau_S(\pi'))} \right)^\alpha \leq 2^\alpha \left( \frac{1}{(1 + \tau_S(\pi))^{\alpha}} + \frac{1}{(1 + \tau_S(\pi'))^{\alpha}} \right).$$

We then let $T_1$ and $T_2$ be given by

$$T_1 = \left( \frac{1}{(1 + \tau_S(\pi))^\alpha} I_{d_{\pi}} \right)_{\pi \in \tilde{G}}, \quad \text{and} \quad T_2 = \left( \frac{1}{(1 + \tau_S(\pi'))^\alpha} I_{d_{\pi'}} \right)_{\pi' \in \tilde{G}}.$$

Then in $\prod_{\pi, \pi' \in \tilde{G} \times G} M_{d_{\pi}} \otimes M_{d_{\pi'}}$, we can write

$$T = S(T_1 \otimes I + I \otimes T_2)$$

where $S$ is diagonal on each block $M_{d_{\pi}} \otimes M_{d_{\pi'}}$, with scalars bounded by $2^\alpha$, i.e. $T \in \ell^\infty \bigoplus_{\pi, \pi' \in \tilde{G} \times G} S_{d_{\pi}} \otimes S_{d_{\pi'}}$. It is easy to check that such $S$ acts as a multiplier of $A^p(G)^* \widehat{\otimes} A^p(G)^*$. Letting $\mathcal{H}^p$ denote the multiplier space from Theorem [19] it now suffices to find conditions for which $\|T_j\|_{\mathcal{H}^p} < \infty$ for $j = 1, 2$. Now we have for $j = 1, 2$ that

$$\|T_j\|_{\mathcal{H}^p}^2 \leq (1 + C)^{2\alpha} \sum_{\pi \in \tilde{G}} d_{\pi}^{-2} \frac{d_{\pi}}{(1 + \|\pi\|_1)^{2\alpha}},$$

thanks to [4, 11]. We then appeal to Lemma [4, 10] with the value $r = 2 + \frac{2}{p}$ to find values $\alpha$ for which the last series converges.

We have seen that $M(W)(W^{-1} \otimes W^{-1})(A^p(G)^* \widehat{\otimes} A^p(G)^*) \subset A^p(G)^* \widehat{\otimes} ch A^p(G)^*$. By duality, this is sufficient to see that multiplication on $A^p(G, \omega^q_S)$ factors completely boundedly through the Haagerup tensor product. Then we appeal to the main result of [4]. □

Corollary 4.12. Let $G$ be a connected Lie group. If $\alpha > \frac{3}{4}d(G) - \frac{1}{4}(s(G) + z(G))$, then for any $1 \leq q \leq \infty$ we have that $A^2_{R^e}(G, \omega^q_S)$ is completely representable as an operator algebra.

Proof. For $q = 1, \infty$, the proof of Theorem [4, 11] can be used to establish that for $\alpha$ as above, $A^2_{R^e}(G, \omega^q_S)$ is an operator algebra for $E = R = R^\infty$ or $C = R^1$. We use a similar formula to (1.9) to obtain that

$$A^2_{R^e}(G, \omega^q_S) = [A^2_{R^e}(G, \omega^q_S), A^2_{C}(G, \omega^q_S)]_{1/q}.$$

By [3, 2.3.7], this interpolated algebra is completely isomorphic to an operator algebra. □

Let us close by returning to dimension weights, although only for special unitary groups.

Corollary 4.13. If $\alpha > (\frac{3}{4} + \frac{2}{mp})(n^2 - 1) - \frac{1}{mp}(n - 1)$, then $A^p(SU(n), d^\alpha)$ is completely representable as an operator algebra.
Proof. We use notation and comments in the proof of Corollary 4.6. We have that \( \lambda_1 = \| \pi_\lambda \|_1 \) in this particular case. The main estimate of that proof hence carries over, whence so too does the proof of Theorem 4.11 and the last corollary. \( \square \)

We remark that \( A(SU(n), d^\alpha) \) is known not to be completely isomorphic to an operator algebra when \( \alpha \leq 1/2 \) ([23, 4.11]). With the difficulty of the restriction result to tori, even for \( n = 2 \), we have no such result for \( p \neq 1 \), at present.

5. Summary of results

5.1. The tables. We summarize our results in tables, below. We require labels for our first table.

\[ \begin{array}{|c|c|c|c|c|c|} \hline \text{A} & \text{WA} & \text{OA} & \text{OWA} & \text{PD} \\ \hline A^p(G, d^\alpha) & \text{always} & \text{always} & \text{always} & \text{always} & \text{never} \\ G \text{ v.a.} & & & & & \\ \hline A^p(G, d^\alpha) & \text{always} & p = 1^{(*)} & \text{always} & \text{never} \\ G_e \text{ abelian} & & & & & \\ \hline A^p(SU(2), d^\alpha) & \text{never} & \text{never} & p = 1 & \alpha = 0 (s) & p < \frac{1}{3+2\alpha} & \alpha \geq 1 (s) \\ & & & & & \\ \hline A^p(G, d^\alpha) & \text{never} & \text{never} & p = 1 & \alpha = 0 (s) & \text{no if } p \geq \frac{4}{1+2\alpha} & \alpha \geq 1 \\ G \text{ c.n.a.} & & & & & \\ \hline A^p_{\mathbb{R}^q}(G, d^\alpha) & \text{never} & \text{never} & \text{never} & \text{never} & \alpha \geq 1 \\ G \text{ c.n.a.} & & & & & \\ \hline A^p_{\mathbb{R}^q}(SU(2), d^\alpha) & p = 1 & \alpha = 0 (s) & p < \frac{2}{1+4\alpha} & p < \frac{2}{1+4\alpha} & \alpha \geq 1 (s) \\ & & & & & \\ \hline A^p_{\mathbb{R}^q}(SU(2), d^\alpha) & \text{never} & \text{never} & \text{never} & q < \frac{2}{1+4\alpha} & \alpha \geq 1 (s) \\ & & & & & \\ \end{array} \]

\((*)\) Sharp for tall groups and those groups with direct product factors which are infinite products of non-abelian finite groups.

\[ \begin{array}{|c|c|c|} \hline \text{A} & \text{WA} & \text{PD} \\ \hline A^p(G) & \text{never} & \text{never} \\ \hline A^p(G, d^\alpha), \text{ connected} & \text{never} & \text{never} \\ \text{non-semisimple} & & \\ \hline A^p(G, \omega^\alpha), \text{ infinite} & \alpha > 0 (s) & \alpha > \left( \frac{1}{2} + \frac{1}{2p'} \right) d(G) - \frac{1}{2p'} (s(G) + z(G)) \\ \text{connected Lie} & & \\ \hline A^p_{\mathbb{R}^q}(G, \omega^\alpha), \text{ infinite} & \alpha > 0 (s) & \alpha > \frac{1}{2} d(G) - \frac{1}{4} (s(G) + z(G)) \\ \text{connected Lie} & & \\ \hline A^p(SU(n), d^\alpha) & \alpha > 0 (s) & \alpha > \left( \frac{1}{2} + \frac{1}{2p'} \right) (n^2 - 1) - \frac{1}{2p'} (n - 1) \\ \end{array} \]
5.2. Questions. The following questions were partially addressed, and arose naturally in the course of this investigation.

(a) If $G$ is a disconnected Lie group and $\omega^S_\alpha$ a polynomial weight, is $A_{G,\omega^S_\alpha}(G_e)$ always regular? [If this is shown to be true, we can conclude that $A(G,\omega^S_\alpha)$ is always regular, and then extend this to $A^p(G,\omega^S_\alpha)$.]  

(b) If $A^2(G) \cong A^2(H)$ isometrically, must we have $G \cong H$, topologically?

(c) Under what general conditions is $A^p(G)$ operator amenable for $p > 1$?

(d) Under what general conditions is $A^p(G, d^\alpha)$ operator weakly amenable?

(e) Given a connected non-abelian Lie group $G$, does $p < \frac{1}{\dim G}$ imply that $A^p(G, d^\alpha)$ is operator weakly amenable? How about the case of $G$ being semi-simple?

(f) If $G$ is a tall infinite group, and $H$ is any closed subgroup which meets every conjugacy class of $G$, is $A^p_G(H)$ ever operator amenable for any $p > 1$.

(g) Is there a good general description of $A^p_{G, d^\alpha}(G_e)$?

(h) What are the sharp bounds for complete representability as an operator algebra of $A^p(G, \omega^S_\alpha)$ for a connected Lie group $G$? How about for $G = SU(n)$? How about sharp bounds for representability as an operator algebra?
